Our study shows that *Spiroplasma* was not only found as long helical filaments, as previously described, but was also found in a Y-shaped form. The use of electron microscopy and immunogold staining of the FtsZ protein unambiguously linked the *S. poulsonii* Y shape to cell division. Observation of the Y shape in another *Spiroplasma*, *S. citri*, and anecdotic observations from the literature suggest that cell division by longitudinal scission might be prevalent in the *Spiroplasma* clade. Our study is the first to report the Y-shape mode of cell division in an endosymbiotic bacterium and adds *Spiroplasma* to the so far limited group of bacteria known to utilize this cell division mode. It also raises the hypothesis that this mode of cell division by longitudinal scission could be linked to the symbiotic mode of life of these bacteria.

SAMPLER SELECTION FOR WHOLE AIRBORNE BIOLOGICAL COMMUNITY ANALYSIS USING SHOTGUN NGS

A. Rastrojo[1], A. Núñez[2], A.M. García[3], D.A. Moreno[2], A. Alcamí[1]
[1]Centro de Biología Molecular Severo Ochoa, Virology, Madrid, Spain
[2]Escuela Técnica Superior de Ingenieros Industriales Universidad Politécnica de Madrid, Departamento de Física Aplicada e Ingeniería de Materiales, Madrid, Spain
[3]Escuela Técnica Superior de Ingenieros Industriales Universidad Politécnica de Madrid, Escuela Técnica Superior de Ingenieros Industriales, Madrid, Spain

Backgrounds

A great effort is being made by the international community to reduce air pollution but very little is known about the biological community (airbiota) present in the outdoor air. The study of the airbiota is relevant due to its potential role in dissemination of plant, animal and human diseases, with important implications in public health, and a huge economic impact on crops and stockbreeding productivity. Our current knowledge about airbiota is almost restricted to pollen and fungal spores, measured through microscopy techniques, and bacterial communities studies using culture-dependent analysis or amplicon-based approaches, while studies on viruses are almost inexistent. Therefore, a global overview of the airborne biological community is crucial to understand the dynamics of the air ecosystem, to identify marker organisms and to establish new air quality indicators. However, there is not a standarized method to capture the whole diversity present in the air. Therefore, the evaluation of different capturing methods is a key step to establish a standard framework.

Objectives

The present work aims to establish a standard method for airborne particles capture.

Methods

We have tested simultaneously different methods for collecting airborne organisms, including impactor samplers, liquid impingers, cyclonic samplers and different filters. Additionally, to avoid the biases of culture-dependent methods or amplicon-based analyses, we have performed a next generation sequencing (NGS) shotgun approach (Illumina) to uncover the whole airborne diversity.

Conclusions

A detailed analysis of the genetic diversity captured using different methodologies and the taxonomic classification of the biota in the air will be presented.

DEVELOPMENT OF A MICROBIAL PROCESS OF METHANE GENERATION FROM COAL AT THERMOPHILIC CONDITIONS

R. Rathi[1], L. Meeta[1], N. Singh[2], P. Sarma[2], P. Kishore[2], B. Lal[1]
[1]The Energy and Resources Institute- New-Delhi, Environmental and Industrial Biotechnology, New-Delhi, India
[2]ONGC ENERGY CENTER, Biotechnology, New-Delhi, India

Backgrounds

There has been a growing interest in coal bed methane (CBM) both for energy production and reduction of greenhouse gases. CBM has been used as an alternative fossil resource. India has CBM generating potential but lacks in technology for *in-situ* biogenic methane generation from its coal reservoirs. most of the unminable coal seams/reserves that have CBM recovery potential are at a higher temperature range.

Objectives

The objective of the current study is to develop a thermophilic methanogenic consortium from samples collected from high temperature coal seams with CBM potential. Also, optimization of parameters that may subsequently influence the *in situ* biogenic CBM production by selected thermophilic methanogenic consortium.

Methods

In this study, a thermophilic methanogenic consortium was enriched from samples collected from Banaskantha coal drilling mines (depth of about 1200m) of western India that had bottom -hole temperature of 60 °C. Microbes were enriched with 1% (w/v) bituminous coal obtained from the same coal mines. Subsequently, effect of reservoir parameters were optimized for enhanced CBM generation for the selected consortium CBM 4.

Conclusions

The methane production from coal was observed by the thermophilic methanogenic consortium CBM 4 at temperature 60 °C, pH 7.5 and salinity 0.1% NaCl. This study suggested that the selected consortium isolated from Banaskantha coal mines is capable of utilizing high rank bituminous coal as a carbon-energy source at thermophilic condition. Thus, indicating a possibility of stimulating or augmenting this consortium in coal seams of similar temperature and to develop a microbial process for enhanced CBM generation.

IMPACT OF BONE ENVIRONMENT ON STAPHYLOCOCCUS AUREUS BIOFILM FORMATION

F. Reffuveille[1], Q. Vallé[1], L.G. Thiery[1], J. Josse[2], S.C. Gangloff[1]
[1]University of Reims Champagne Ardenne, BIOS, Reims, France
[2]University of Lyon 1, INSERM U1111 - CNRS UMR5308, Lyon, France

Backgrounds

As discovered during the last decades, most of the bacteria are able to form “biofilm” representing the bacterial capacity to build a multicellular structure highly resistant to any concentration of antimicrobial compounds. Despite the unbelievable medical progress, the success of all surgical interventions is threatened by the development of biofilm-associated infections. They represent 65 to 80% of nosocomial infections and *Staphylococcus aureus (S. aureus)* is the leading species in this domain.

Objectives

Bacteria can detect any stress (like presence of antibiotics) in order to survive and biofilm could be one of those “resistance” strategies. However, the stress signals that could induce irreversible adhesion and so the bacterial biofilm program, is still unknown. In consequence, there is a real challenge to better understand this phenomenon.

Methods

In this study, regarding more specifically at the context of bone infections, collected supernatants of osteoblast-like cells (Saos-2) were applied on *S. aureus* culture. Bacterial adhesion was evaluated after 24h of contact using two models to apprehend any signal from osteoblasts cell culture that could induce or influence biofilm first step formation. Osteoblast cell culture supernatants increased adhesion capacity by 2-fold ($P<0.001$) compared to medium control in our two models.

Moreover, different molecules as magnesium or iron, present in bone environment, were tested. Among others, high concentration of magnesium and iron increased the biofilm formation.

Conclusions

In conclusion, there is an impact of bone environment on biofilm formation. The perspectives of this work will be to determine the most important compounds that leads to the formation of the biofilms.

[2]University of Granada, Department of Ecology, Granada, Spain
[3]Fundación Medina,
Centro de Excelencia en Investigación de Medicamentos Innovadores en Andalucía, Armilla, Spain
[4]Institute of Biotechnology- Center for Biomedical Research, Armilla, Spain

Backgrounds

Aquaculture is one of the most expanding industries in the world, as reported by the Food and Agriculture Organization of the United Nations (FAO) in its last report in 2016. Nevertheless, it has to face different problems including infections, some of which are caused by microorganisms, which are the main cause of severe economic losses in this sector.

Recently, it has been shown that the expression of virulent genes in some bacterial pathogens is controlled by a population-density-dependent gene-expression mechanism known as quorum sensing (QS). The inhibition of QS systems has been demonstrated to be a potential strategy in the fight against diseases affecting aquaculture. Here, we present a screening of the production of compounds with QS inhibition activity amongst the bacteria isolated from the microbiota of marine invertebrate animals, an underexplored source of bioactive molecules.

Objectives

The aim of this study is the selection of compounds that interfere with QS systems (quorum quenching enzymes, QQ, and quorum sensing inhibitors, QSIs) of bacteria isolated from the microbiota of two sea anemones and two holothurians.

Methods

A high-throughput screening of quorum sensing inhibition activity amongst 856 strains was carried out. The selected QQ strains were then evaluated against a broad range of QS signal molecules, whilst the selected QSI strains were tested against the QS systems of *Chromobacterium violaceum* and *Pseudomonas aeruginosa*.

Conclusions

We have selected 31 symbiotic bacteria from marine invertebrate animals with quorum sensing inhibition mechanisms that are based on enzymatic degradation and interference of the detection of signal molecules.

CHARACTERIZATION OF AHL-DEGRADING ENZYMES FOUND IN STENOTROPHOMONAS MALTOPHILIA STRAINS ISOLATED FROM HOLOTHURIA SPP AND ANEMONIA SULCATA

J.C. Reina[1], J. Martín[2], I. Pérez-Victoria[2], N. Ruiz[1], F. Reyes[2], I. Llamas[1,3]
[1]University of Granada, Department of Microbiology, Granada, Spain
[2]Fundación Medina,
Centro de Excelencia en Investigación de Medicamentos Innovadores en Andalucía, Armilla, Spain
[3]Institute of Biotechnology- Center for Biomedical Research, Armilla, Spain

Backgrounds

The quorum sensing (QS) signal molecules *N*-acylhomoserine lactones (AHLs) control the expression of virulence factors in some Gram-negative pathogenic bacteria. The use of antibiotics in aquaculture is creating an increased resistance and consumers are rejecting their use.

One of the most promising tools for fighting infections that affect aquaculture is based on the disruption of QS through a mechanism known as quorum quenching (QQ). In this work we present the study of four *Stenotrophomonas maltophilia* strains isolated from the microbiota of invertebrate marine animals such as *Holothuria* spp and *Anemonia sulcata* that have the ability to degrade AHLs as mechanism of QQ.

Objectives

Characterization of the AHL degradation activity of four *S. maltophilia* strains.

Methods

The QQ activity of the four *S. maltophilia* strains was tested against a broad range of AHLs and monitored in well-diffusion agar-plate assays by using the indicator strains *Chromobacterium violaceum* CV026, *C. violaceum* VIR07 and *Agrobacterium tumefaciens* NTL4 (pZLR4). The enzymes were expressed in *Escherichia coli* and their AHLs degradation activity was confirmed through a well-diffusion agar-plate and HPLC-HRMS analyses.

Conclusions

We have found that *S. maltophilia* environmental strains isolated from marine invertebrates degrade a wide range of AHLs, including synthetic and natural AHLs produced by different microorganisms through enzymes with homology to penicillin acylases.

[3]Karlsruhe Institute of Technology KIT, Engler-Bunte-
Institut- Bereich Wasserchemie und Wassertechnologie, Karlsruhe, Germany
[4]Heidelberg University Hospital, Clinical Pharmacology and Pharmacoepidemiology, Heidelberg, Germany
[5]Swiss Federal Institute for Aquatic Science and Technology Eawag, Environmental Microbiology, Dübendorf, Switzerland

Backgrounds

Sulfonamides are widespread micropollutants that carry unpredictable risks to diverse ecosystems. Despite being ubiquitous and persistent, these antibiotics are often degraded by diverse microbial communities. Nevertheless, the full metabolic pathway has only been proposed for a few strains and its relevance for wastewater treatment has not been assessed.

Objectives

In this study, we aimed at characterizing the metabolic pathway for sulfamethoxazole (SMX) degradation in *Achromobacter denitrificans* PR1 and at evaluating whether these lab-based findings are valid in the wastewater treatment process.

Methods

LC-MS/MS was used to identify the metabolites produced by strain PR1 and to monitor the concentration of 8 sulfonamides and 13 metabolites in five wastewater treatment plants. Radio-labeling was used for benchmarking assays of activated sludge samples.

Conclusions

Degradation of SMX by strain PR1 resulted in the accumulation of 3-amino-5-methylisoxazole and revealed new dead-end products resulting from the parallel mono-hydroxylation of the aniline moiety at *ipso* and *ortho*/*meta* positions and additional molecular rearrangements. The metabolites found in wastewater samples suggest this to be a prevalent pathway for sulfonamide elimination

Furthermore, culturing PR1 for 14 days revealed a slow growing Gram positive bacterium (GP). Based on the 16S rDNA analysis, this strain showed highest sequence similarity (96.75%) to *Leucobacter luti* RF6T, indicating affiliation to the phylum *Actinobacteria*. Strain GP grows only in co-culture with PR1 and SMX degradation also only occurs in the same conditions, suggesting a possible metabolic cooperation between the strains.

Our results give valuable insights at different levels of microbial ecology of sulfonamide degrading strains.

MICROBIAL DIVERSITY AND FUNCTIONALITY IN AVOCADO RHIZOSPHERE SOILS AMENDED WITH COMMERCIAL BIOFERTILIZERS

R. Prabhaharan[1], S. González[2], M. Astorga-Eló[3], M. Jorquera-Tapía[4]
[1]Laboratory of Applied Microbial Ecology, Universidad de La Frontera, Temuco, Chile
[2]Doctoral Program in Natural Resources Sciences, Universidad de La Frontera, Temuco, Chile
[3]Doctoral Program in Natural Resources Sciences, Universidad de La Frontera, Temuco, Chile
[4]Scientific and Technological Bio-resource Nucleus, Universidad de La Frontera, Temuco, Chile

Backgrounds

The perception of eating healthy, avocado (Persea americana) consumption and demand hits highest growth concentration in different world markets. Chile is one of the largest producer and exporter of avocado in world market. Currently, the production is significantly decreased from 263,476 to 164,720 ton ha^{-1} (2009-2013), which mainly attributed to climatic events in association with global warming. Many studies have revealed the protective mechanisms of plant growth promoting microorganisms used as biofertilizers to promote plant crops against diverse environmental stresses. In Chile,the existing biofertilizers are imported from various countries and sold by local distributers. Studies revealed that the inoculation of foreign microorganisms can disrupt the native soil microorganisms associated with plant crops. Certainly, native strains are disappeared from the microbial community structure, it is highly difficult or even impossible to detect, and, thus, they can possibly affect certain plant physiological functions.

Objectives

To explore the effect of commercial biofertilizers on the diversity and functionality of microbial communities in rhizosphere soils of avocado.

Methods

The effect of commercial biofertilizers on the rhizosphere microbial communities (bacteria, fungi and archaea) of avocado have been studied by denaturing gradient gel electrophoresis (DGGE) analysis using ribosomal genes as target. The functional diversity has been determined by using miniaturized kits Biolog®Ecoplates (Biolog, Inc.; US).

Conclusions

This study has clearly determined which imported commercial biofertilizer had significant effect on microbial communities in rhizosphere soil of avocado. This evidence can be very useful when imported biofertilizer based management practices are being designed, revised and/or established in commercial avocado nursery soils.

VERTICAL TRANSMISSION OF BACTERIA IN THE INTRAUTERINE ENVIRONMENT

A. Rey-Mariño[1], A. Vallés[1], N. Jiménez-Hernández[1], F. Ballester[2], M.J. Gosalbes[1], M.P. Francino[1]
[1]Centro Superior de Investigación en Salud Pública,
Unidad Mixta de Investigación en Genómica y Salud, Valencia, Spain
[2]FISABIO-UJI-University of Valencia, Epidemiology and Environmental Health Unit of Research, Valencia, Spain

Backgrounds

The origin of the bacteria present in the intrauterine medium remains not defined or fully studied. The complexity of the treatment and quantification of DNA from placenta and meconium, due to the low microbial content of these environments, makes research in this field difficult. In addition, possible contamination should be considered for the taxonomic assignment of these samples.

Objectives

The aim of this project is to define maternal microorganisms that are transmitted to offspring through the placenta and are accumulated in meconium during intrauterine life.

Methods

We used massive sequencing of 16S rRNA gene amplicons in paired samples of placenta and meconium microbiota in 23 term newborns from a Spanish birth cohort and performed taxonomic assignment and estimation of diversity for each pair of samples obtained. In order to detect a possible transmission of bacteria from placenta to meconium, we performed clustering analysis based on taxa composition and abundance to determine similarities between samples and searched for 100% identical 16S rRNA sequences in paired meconium/placenta samples.

Conclusions

We detected 100% identical 16S rRNA sequences in placenta and meconium from 21 of the 23 pairs analysed, with *Lactobacillus* as the most abundant genus among the transmitted bacteria. Our findings suggest that the meconium microbiota has an intrauterine origin as a possible vertical transmission of bacteria between mother and child was detected. These bacteria will be further studied as potential candidates for being used as probiotics that promote a successful programming of health at immune and metabolic levels.

LARGE SCALE ANALYSIS OF THE TOPOLOGY AND DYNAMICS OF METABOLIC NETWORKS OF ENDOSYMBIOTIC BACTERIA OF INSECTS

M. Reyes Prieto[1], D.J. Martínez Cano[2], C. Vargas Chávez[1], L. Delaye[2], A. Moya[1,3]
[1]Institute for Integrative Systems Biology I2SysBio - University of Valencia, Evolutionary Genetics, Valencia, Spain
[2]Cinvestav Unidad Irapuato, Genetic Engineering, Irapuato- Guanajuato, Mexico
[3]Valencian Region Foundation for the Promotion of Health and Biomedical Research FISABIO, University of Valencia, Valencia, Spain

Backgrounds

More than 100 genomes of endosymbiotic bacteria of insects have been sequenced. Through their analysis we are aware that they present different degrees of genome degradation, a common feature of bacteria becoming endosymbiotic, dependent on the age of the symbiotic formation and the evolutionary pressures acting upon their genes. In free living organisms, metabolic networks are extremely robust to the deletion of genes. Network modulation can evolve rapidly through horizontal gene transfer thus complementing these gene deletions. In endosymbiotic bacteria, the behavior of metabolic networks is exceptional, since once the bacteria becomes endosymbiotic, not only the loss of genes is important and accelerated, but they are unable to receive new genetic information due to the barriers imposed by the intracellular lifestyle.

Objectives

Analyses on metabolic networks of different organisms have helped understand the principles under which these respond and accommodate to varying conditions. We focus on large-scale topology and dynamics of metabolic networks of endosymbiotic bacteria to understand the evolution of these topologies and the elements involved in the adaptation to endosymbiotic life.

Methods

Using bioinformatic tools, we developed a pipeline for large-scale analysis of metabolic networks which allows us to build complete networks of each endosymbiotic bacterial genome, compare between these endosymbiotic networks and an assembled metabolic network from a theoretical minimal cell, and analyze the topology of each organism.

Conclusions

We found that as the genomes of endosymbiotic bacteria of insects shrink, their metabolic networks lose robustness, showing different topologies dependent on the different stages of genome degradation.

Backgrounds

Environmental pollution is a serious problem for ecosystems and human health. Many pollutants are associated with several diseases and with the deterioration of human health. In addition to this, the increasing consumption of pharmaceuticals is also becoming an environmental problem leading, among other effects, to the emergence of antibiotic resistant microorganisms.

As health problems pose a constant threat to humanity, it is necessary to continuously seek for new therapeutic solutions, one of which is the discovery of new bioactive compounds.

Actinomycetes are a group of Gram-positive and filamentous bacteria well known for their unmatched capacity to produce a vast range of bioactive compounds with high industrial and pharmaceutical interest.

Objectives

The objective of this study was to investigate the diversity of actinomycetes associated with marine costal sediment and to explore their potential to produce bioactive compounds.

Methods

The isolates were obtained from coastal sediment collected in Parque Natural do Litoral Norte, Esposende, Portugal. To improve the isolation efficiency of actinomycetes, three different pre-treatments were applied and three selective culture media were used.

Conclusions

A total of 117 isolates were obtained from the collected marine sediment sample. 16SrRNA gene sequencing results revealed that most isolates belong to the *Micromonospora* genera. Some non-actinomycetes isolates have also been obtained, essentially belonging to the phylum Firmicutes and to the genera *Paenibacillus* and *Bacillus*, which also encompass many bacterial producers of interesting bioactive compounds. These isolates are presently being studied for their capability to produce bioactive compounds.

STUDIES ON THE BIODEGRADATION OF THREE STRUCTURALLY RELATED ALIPHATIC ORGANOFLUORINES WITH ENVIRONMENTAL RELEVANCE

D. A. M. Alexandrino[1], I. Ribeiro[1,2,3], L. M. Pinto[4], R. Cambra[4], R. S. Oliveira[4,5], F. Pereira[6], M. F. Carvalho[1]
[1]Interdisciplinary Centre of Marine and Environmental Research, EcoBioTec, Matosinhos, Portugal
[2]Institute of Biomedical Sciences, University of Porto, Porto, Portugal
[3]Faculty of Sciences, University of Porto, Porto, Portugal
[4]Research Centre on Health and Environment, Department of Environmental Health, Porto, Portugal
[5]Centre for Functional Ecology, Department of Life Sciences, Coimbra, Portugal
[6]Interdisciplinary Centre of Marine and Environmental Research, BBE, Matosinhos, Portugal

Backgrounds

The use of synthetic organofluorines has significantly increased in the last decades, contributing to the emergence of many of these compounds in the environment. Fluoroacetates, mono-, di- and trifluoroacetate are aliphatic organofluorines with various uses in industrial applications. They have been reported to occur in the environment, mainly in aquatic compartments. Current biodegradation data indicate that these compounds are highly recalcitrant, with the exception of the monofluorinated molecule, thus justifying more studies on their biodegradation. Moreover, the wide industrial applications of fluoroacetates may lead to their simultaneous presence in the environment, being also important to understand how mixtures of these compounds influence their biodegradation.

Objectives

This work aimed to investigate the aerobic biodegradation of mono-, di- and trifluoroacetate as sole carbon sources, in mixtures and in cometabolism with acetate.

Methods

Biodegradation of fluoroacetates was studied in batch mode under aerobic conditions, using various environmental samples as microbial inocula. Different conditions were tested: biodegradation of fluoroacetates as sole carbon sources, mixtures of monofluoroacetate with di- or trifluoroacetate and mixtures of di- or trifluoroacetate with acetate as a cometabolite. Cultures were sampled at regular intervals for monitoring fluoride release and biomass growth. Degrading microorganisms were identified through 16S rRNA gene sequencing analysis.

Conclusions

A total of 13 bacterial strains isolated from distinct environmental sources had the capacity to biodegrade monofluoroacetate. Di- and trifluoroacetate were shown to be recalcitrant in all tested conditions. When in mixture, difluoroacetate was found to inhibit the metabolism of monofluoroacetate, which was not verified with trifluoroacetate.

GROWTH IN A MULTISPECIES BIOFILM RESULTS IN REMODELLING OF CENTRAL METABOLISM

S. Rice[1], K.W.K. Lee[1], H.A.S. Nair[1], R.B.H. Williams[2], S. Kjellberg[1]
[1]Nanyang Technological University,
The Singapore Centre for Environmental Life Sciences Engineering, singapore, Singapore
[2]The National University of Singapore,
The Singapore Centre for Environmental Life Sciences Engineering, Singapore, Singapore

Backgrounds

Mixed species biofilms have been shown in several studies to outperform mono-species biofilms. Here, a mixed species biofilm model comprising *Pseudomonas aeruginosa*, *Pseudomonas protegens* and *Klebsiella pneumoniae* was previously shown to display enhanced biofilm development and tolerance to antimicrobials. However, the mechanisms behind these traits are unknown.

Objectives

To define how mixed species communities interact to display emergent biofilm properties

Methods

RNA-sequencing was thus performed for mixed and mono-species biofilms subjected to different treatments (sodium dodecyl sulfate (SDS) treated and untreated), and for biofilms at different developmental stages (4, 5 and 6 days of growth) to identify key genes that account for these emergent traits.

Conclusions

It was found that *K. pneumoniae* and *P. protegens* cooperate through carbon metabolism, where genes associated with the pentose phosphate pathway and citric acid cycle were significantly altered. These results indicate the exchange of metabolites and improved resource utilization within the mixed species biofilms. Subsequently, it was demonstrated that *K. pneumoniae* grew slowly on citrate as a mono-species cultures, but achieved significant biomass when grown in the presence of *P. protegens* and *P. aeruginosa*. Despite having access to identical resources, a communal metabolic pathway that enables increased biomass production relative to mono-species biofilms is proposed. Comparison between SDS treated and untreated biofilms showed that production of SDS hydrolase (SdsA1) by *P. aeruginosa* increased 72 fold. The secretion of SdsA1 could explain the cross protection of SDS sensitive *P. protegens* in the mixed species biofilms. Therefore, these data demonstrate that synergistic interactions occur within mixed species biofilms, whereby the community members can share and redistribute resources to optimise their fitness.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

ECOLOGICAL ASPECTS OF BACTERIAL HCN PRODUCTION

T. Rijavec[1,2], *A. Lapanje*[1,2,3]
[1]*Jozef Stefan Institute, Department of Environmental Sciences, Ljubljana, Slovenia*
[2]*Institute of Metagenomics and Microbial Technologies, -, Ljubljana, Slovenia*
[3]*Saratov State University, Remote Controlled Theranostic Systems Lab, Saratov, Russia*

Backgrounds

HCN producing bacteria (HPB) are commonly isolated from soil and predominantly identified as *Pseudomonas* spp. The ecological role of HCN is not always clear, though we show it is associated with mineral weathering and nutrient availability in the rhizosphere. Particularly interesting here is the oligotrophic alpine environment with its high ecological patchiness, which calls for detailed analysis of the spatial distribution of HPB populations, the biochemical characteristics and the evolutionary aspects of HCN production.

Objectives

We wanted to characterize the association of HPB with the rhizosphere of alpine pioneering plants and further examine for each strain in the population its ability to produce HCN. We wanted to determine how this ability is related to a specific rhizobacterial genotype. We finally wanted to characterize the genomes of few selected HPB, identify the *hcn* genes and assess the characteristics of gene regulatory elements.

Methods

We obtained a large collection of strains to characterize biochemically their ability to produce HCN and to genetically characterize each strain using BOX-PCR. We also characterized the production of HCN for selected strains during different growth phases. Using genome sequencing we characterized the *hcn* genes in few selected HCN producing strains.

Conclusions

The rhizosphere of pioneer plants is rich in HPB, harbouring the most potent HCN producers. Nevertheless, HCN+ phenotype is not associated with one particular genotype and it is still unclear how these genes are spread within the population. HPB genomes, diversity of *hcn* genes and regulation of HCN production will also be discussed.

TYPE OF METABOLISM AND ATTACHMENT OF BACTERIAL CELLS PROMOTE HG ENTRY INTO THE ECOSYSTEM

T. Rijavec[1,2], M. Kovač Viršek[3], A. Lapanje[1,2,4]
[1]Jozef Stefan Institute, Department of Environmental Sciences, Ljubljana, Slovenia
[2]Instititute of Metagenomics and Microbial Technologies, -, Ljubljana, Slovenia
[3]Institute for Water of the Republic of Slovenia, -, Ljubljana, Slovenia
[4]Saratov State University, Remote Controlled Theranostic Systems Lab, Saratov, Russia

Backgrounds

Our understanding of bacterial mobilization of different forms of Hg is currently insufficient. More and more data shows that bacteria can mobilize also the inert mineral forms of Hg. Bacteria can solubilize mineral particles, which contain Hg using organic acids, siderophores, other secondary metabolites, extracellular proteins, etc. How efficiently Hg is released and whether it is transformed into the biologically available form by different bacteria has not been examined to date.

Objectives

In our study we wanted to test how different types of bacterial metabolism can affect the release of Hg from Hg-contaminated sediment. We also wanted to examine how the vicinity of cells and particles, and the attachment of cells to, can affects the increase of biological availability of Hg.

Methods

Using the *in vitro* whole-cell bacterial biosensor and measurements of total Hg, we assessed how different types of bacteria can mobilize Hg from Hg-contaminated sediment. Using bacterial culturing of strains collected from a Hg contaminated site and biochemical characterization, we assessed how the production of secondary metabolites can coincide with Hg mobilization and Hg resistance.

Conclusions

Certain bacteria, i.e. *Bacillus* spp., *Pseudomonas* spp., are more pronounced Hg mobilizers compared to other bacteria tested. Though the vicinity of cells and particles can be an important factor affecting Hg mobilization, certain extracellular secondary metabolites prove to be even more important in increasing the level of bioavailable Hg. Finally, ability to mobilize Hg might promote the spread of Hg resistance (*mer*), resulting in novel selective advantages.

IMPROVEMENT OF MAIZE GROWTH BY ROOT COLONIZING BACTERIA

C.H. Hernández Rodríguez[1], R.I. Arteaga Garibay[2], B. Rios Galicia[1]
[1]Instituto Politécnico Nacional, Microbiology, México city, Mexico
[2]Centro Nacional de Recursos Genéticos INIFAP, Microbiology, Tepatitlán- Jalisco, Mexico

Backgrounds

Microbial interactions with plants involve either endophytic or free living microorganisms able to establish interactions in the environment. Some associative and free-living microorganisms promote plant growth through a variety of mechanisms of biocontrol of pathogens, biofertilization or phytostimulation.

Objectives

The growth promoting plant-microbe interactions are studied for being a handful tool in the search of solutions that reduce crop problems through the biotechnological development of fertilizers.

Methods

A collection of 91 strains was isolated following a strategy of direct isolation and bacterial population enrichment. Plant-growth-promoting capabilities were measured and the most outstanding strains were selected for the assays in plants.

Conclusions

Already reported *Serratia marcescens, Ochrobactum anthropic* and *Gordonia terrae* strains were able to control fungal diseases caused by *Ustilago maydis, Fusarium culmorum* or *Sporisorium reillianum.* Meanwhile *Herbaspirillum seropedicae*, *Pantoea allii*, and *Phytobacter diazotrophicus* displayed plant-growth promotion capabilities such as nitrogen fixation, auxin production and phosphate solubilization. Despite observed effects and previous characterization of strains, it is still unknown the bacterial strategy that produce the effect *in vivo* due to the strains showed more than one growth-promoting strategy.

RHIZOBIUM ZEAE A NOVEL SPECIES WITH POTENTIAL AS PGPB FOR MAIZE CROPS

L. Celador-Lera[1], E. Menéndez[1], M.E. Velázquez[1], P.F. Mateos[1], R. Rivas[1]
[1]Universidad de Salamanca, Microbiología y Genética, Salamanca, Spain

Backgrounds

The members of genus *Rhizobium* are widely known as legume endosymbionts. Nevertheless, they have been also found in roots of non-leguminous plants, including some cereals such as rice or wheat, whose growth is promoted by these bacteria. Some of them have been firstly isolated from roots of cereals, such as *Rhizobium oryzicola,* which was isolated from rice roots. However, there is no evidence that new *Rhizobium* species have been isolated from maize roots.

Objectives

To evaluate the potential of *Rhizobium zeae* strain as a biofertilizer for *Z. mays* crops.

Methods

Here, a new bacterial species, designated *Rhizobium zeae*, was isolated from maize roots, which were collected in NW Spain. This strain produced siderophores and also, is an excellent producer of indole-acetic acid and/or derivatives. In vitro inoculation of *Z. mays* seedlings showed earlier root development than seedlings from the uninoculated treatment in the first stages of development. Fluorescence and confocal microscopy in vitro assays with the GFP-tagged strain showed that this strain interacts efficiently with maize roots, forming complex tridimensional structures and showing a special ability for colonizing maize tissues.Greenhouse assays were performed and the results confirmed the ability of this strain to promote maize growth, observing that the inoculated plants presented a superior number of knots and a significative increase of shoot length. A field trial was carried out, confirming that the inoculation of this strain contribute to an increased maize production.

Conclusions

The strain of *Rhizobium zeae* isolated from *Zea mays* is susceptible to be used as biofertilizer in these crops.

METAGENOMIC ANALYSIS OF BIOREMEDIATION CONSORTIA.

R. Rivilla[1], D. Garrido-Sanz[1], J. Manzano[1], M. Redondo-Nieto[1], M. Martin[1]
[1]Universidad Autónoma de Madrid, Biología, Madrid, Spain

Backgrounds

Bioremediation of organic contaminants is carried out by individual microbia or by microbial consortia. Consortia are specially important when complex contaminants are tackled.

Objectives

To identify genes and pathways implicated in bioremediation of PCBs and diesel within the consortia

Methods

We have generated two microbial consortia by enrichment cultures from rhizospheric soil, using defined mineral medium supplemented with biphenyl or with diesel as the only carbon and energy sources. After several passes, consortia able to degrade either biphenyl (as an analogue of PCBs) or diesel were obtained. Samples of the cultures during exponential growth, were deep-frozen to be used as reference. DNA from these samples were used to analyze biodiversity, by means of sequencing and analysis of 16S libraries and to identify key genes and enzymes implicated in bioremediation by means of sequencing of metagenomics libraries.

Conclusions

Biodiversity analysis showed that the diesel consortium was more diverse than the biphenyl consortium (Shannon index 3.6 versus 3.0), although both of them contained a discrete (below 50) number of OTUS at the genus level. Both consortia were dominated by proteobacteria, especially pseudomonads but contained a significant number of OTUs from other phyla. Genera known by their ability to degrade PCBs such as *Pseudomonas, Rhodococcus, Achromobacter* and *Stenotrophomonas* were predominant in the biphenyl consortium, while *Pseudomonas*, *Azospirillum, Sphingobium* and *Chrysobacterium* dominated the diesel consortium. Metagenomic analysis is being used to identify genes and pathways relevant for bioremediation and to assign them to specific OTUs.

DGS was granted by FPU (FPU14/03965) from MECD, Spain. Funded by BIO2015-64480-R(MINECO/FEDER EU).

COMBINING DNA STABLE ISOTOPE PROBING AND METAGENOMICS TO EXPLORE THE PHYLOGENETIC AND METABOLIC MICROBIAL DIVERSITY IN ARSENIC CONTAMINATED SEDIMENTS

A. Rizoulis[1], *M. Héry*[2], *J.R. Lloyd*[3]
[1]*University of Central Lancashire, School of Forensic and Applied Sciences, Preston, United Kingdom*
[2]*Université Montpellier, Laboratoire HydroSciences Montpellier- HSM- UMR 5569 IRD- CNRS, Montpellier, France*
[3]*The University of Manchester,*
Williamson Research Centre for Molecular Environmental Science- School of Earth and Environmenta l Sciences, Manchester, United Kingdom

Backgrounds

The consumption of arsenic contaminated groundwater is causing a humanitarian disaster in Southeast Asia, threatening the health of tens of millions. The factors controlling arsenic release from sediments into groundwater have been the subject of numerous studies, which have shown that various geological, mineralogical and geochemical characteristics and processes can contribute to increased As(III) mobilisation. In addition, microbial reduction of As(V) sorbed to mineral surfaces is widely accepted as being an important mechanism of As(III) release in shallow anoxic aquifers.

Objectives

To date, molecular studies in arsenic contaminated environments have mainly described the phylogenetic diversity of the indigenous microbial communities. In this study, we combined DNA stable isotope probing and metagenomics in order to investigate the phylogenetic and metabolic microbial diversity in arsenic contaminated Cambodian sediments.

Methods

Following incubation with ^{13}C-lactate, the ^{13}C-labelled fraction of the DNA was isolated and after 454 pyrosequencing, more than 124,000 reads were obtained.

Conclusions

The results indicated the presence of a phylogenetically and metabolically diverse microbial community, which was dominated by members of the *Geobacter* genus. Metagenomic sequences related to respiratory arsenic reduction and lactate utilisation were also identified, as well as an increased number of sequences affiliated to motility, chemotaxis and *c*-type cytochromes. In addition, the identification of Archaeal sequences indicated the presence of metabolic interactions within the complex microbial community. The results from this study and the publicly accessible metagenome will allow comparisons to be made by future metagenomic studies in arsenic contaminated environments.

STUDYING BACTERIAL CELL SURFACE PROPERTIES THROUGHOUT BIOFILM FORMATION ON DIFFERENT SURFACES

C.J. C. Rodrigues[1], *C.C. C. R. de Carvalho*[1]
[1]*Instituto Superior Técnico,*
Department of Bioengineering- Institute for Bioengineering and Biosciences IBB, Lisboa, Portugal

Backgrounds

Microorganisms colonize most of the surfaces in the World. They grow preferentially attached to surfaces, in a community that confers protection to individuals termed biofilm. The interaction between a bacterial cell and a surface is the first step to the establishment of a biofilm. The process is complex and influenced by the properties of both the surface material and the bacterial cell surface [1]. The local environmental conditions are also quite influential for cell adhesion. Establishment of biofilms in industrial and medical settings cause heat and mass transfer problems and are a source of infections.

Objectives

To understand how surface properties of *Rhodococcus erythropolis* cells change during adhesion and biofilm formation

Methods

Cells response to surface type and environmental conditions was studied by promoting biofilm growth both on metallic and non-metallic surfaces and by using a recirculation system with different types of tubes. Flow cells allowed the access to the different layers of cells in a biofilm.

Conclusions

A poor nutrient medium promoted more biofilm formation than a rich medium, while causing changes in biofilm architecture. The recirculation system showed that the biofilm biomass correlated with the oxygen permeability of the tubes but not to the hydrophobicity of the materials. The cells strongly attached to the surface of the flow cells have less negative net surface charge and a higher saturation degree of their membrane lipids than cells lightly attached. These studies could contribute to new insights into the complex process of cell adhesion and biofilm formation.

CHARACTERIZATION AND COMPARATIVE GENOMICS OF A NEW HYDROCARBON-DEGRADING PSEUDOMONAS SP. FROM GULF OF MEXICO

J.L. Rodríguez Mejía[1], L.F. Muriel-Millán[1], E.E. Godoy Lozano[1], S.R. Sánchez Catalán[1], D.X. Sahonero Canavesi[1], W.I. Escobedo Hinojosa[1], L.P. Segovia Forcella[1], R.M. Gutiérrez Ríos[1], M.D.R. Trejo Hernández[2], F.A. Sánchez Flores[1], L. Pardo López[1]
[1]Biotechnology Institute - UNAM, Gulf of México Research Consortium CIGoM, Cuernavaca- Morelos, Mexico
[2]Centro de Investigación en Biotecnología, Gulf of México Research Consortium CIGoM, Cuernavaca- Morelos, Mexico

Backgrounds

In last few years the characterization of new bio-tools for biotechnology applications is increased, the principal activity for this is the seeking of novel microorganisms, these discoveries are couple with the description of new ecosystems. The fusion of these strategies represents a new interdisciplinary approach that improves the way to obtain a specific tool for a specific application.

Objectives

Our aim is discovery bio-tools that have a natural evolve in the degradation of hydrocarbons, principally, bacteria with a wild adaptation for different abiotic conditions and the pollution by xenobiotic compounds.

Methods

The natural hydrocarbon emanation in the Gulf of Mexico and the oil industry activity produce a potential ecosystem for the development of microorganisms with skills to use oil as a unique carbon source. A microbiology approach let us isolated a new *Pseudomonas sp.* from 1000 meters of depth in a water column, able to growth in a mineral media with crude oil as a unique source of carbon.

Conclusions

The complete sequencing of its genome let us to know that this organism is a new specie with close relatives as *Pseudomonas alcaligenes*, and in add a wide comparative bioinformatics analysis describes a conserved set of tools for alkane oxidation and also aromatics hydrocarbons. The genes of this cluster were previously described in other members of Pseudomonas exposing a level of adaptation to the presence of aliphatic hydrocarbons. Growth experiments with specific aliphatic compounds show a taste for short chain alkanes. The results obtained allow us to have a potential hydrocarbon degrading bio-tool.

DETECTION OF BLAKPC CARBAPENEMASE GENE IN GRAM-NEGATIVE BACTERIA ISOLATED FROM WASTEWATER TREATMENT PLANT (WWTP) IN MEDELLIN, COLOMBIA

E.A. Rodríguez[1], A. Aristizábal[2], L. Arias[3], A. Yamilet[3], J.N. Jiménez[2]
[1]Bacterial Molecular Epidemiology Line. Molecular Microbiology Research Group and Applied & Basic Microbiology Research Group MICROBA, Universidad de Antioquia, Medellin, Colombia
[2]Bacterial Molecular Epidemiology Line. Applied & Basic Microbiology Research Group MICROBA, Universidad de Antioquia, Medellín, Colombia
[3]Microbial Bioprocesses Research group-BIOMICRO, Universidad de Antioquia, Medellín, Colombia

Backgrounds

In Colombia, the problem of resistant to carbapenems Gram-negative bacteria has been evidenced in hospitals but knowledge in wastewater treatment plant (WWTP) is limited.

Objectives

The aim of this study was to determine the presence of Carbapenem-resistant gram-negative bacteria in one WWTP of Medellín, Colombia

Methods

A cross-sectional study was conducted in one WWTP. Four samples of water of affluent and effluent were collected in September 2016. Isolation of bacteria was performed on chromID® CARBA medium. Identification and susceptibility testing were performed using the VITEK®-2 system. Molecular analyzes included PCR for detection of *bla*KPC, *bla*NDM, and *bla*OXA-48 genes.

Conclusions

A total of 44 bacteria were isolated (18 affluent and 26 effluent). Of these, 14 (32%) isolates were resistant to carbapenem and their resistance pattern showed resistances to three or more of the tested antibiotics. *Klebsiella pneumoniae* was high prevalence among carbapenem-resistant isolated species (35.7%, n=5) followed by *Escherichia coli* (14.3%, n=2), *Enterobacter cloacae* (14.3%, n=2), *Citrobacter freundi* (14.3%, n=2) and less frequently (7.1% n=1) *Klebsiella oxytoca, Pseudomonas aeruginosa y Enterobacter aerogenes.* The carbapenemese KPC was detected in all isolates resistant to carbapenem, 9 in the affluent and 5 in the effluent, no other carbapenemases were detected.

This study describes the first detection of KPC-producing Gram negative bacteria in the affluent and effluent of WWTP in Colombia. These results have serious implications for public health because to shows the capacity of this resistance mechanism to persist in the effluent of WWTP and the possibility of dissemination and transferred from the aquatic environment to the human.

Departamento de Microbiologia- Imunologia e Parasitologia, Florianópolis, Brazil
[3]*ITACyL, BY products Unit, Valladolid, Spain*
[4]*EMBRAPA, Suínos e Aves, Concórdia, Brazil*
[5]*ITACyL, Laboratory of Molecular Biology and Microbiology, Valladolid, Spain*

Backgrounds

Swine digestate can contain high levels of enteric pathogens that may contaminate soil, water and foods.

Objectives

We aimed to evaluate the survival and percolation of several major enteric micoroganisms and to (select the most suitable enteric microorganisms to serve as biomarkers of percolation and leaching after biofertilization with swine digestate.

Methods

We evaluated the survival, percolation and leaching of model enteric pathogens in clay and sandy soils after biofertilization with swine digestate: PhiX-174, mengovirus (vMC_0), *S*. Typhimurium and *Escherichia coli* O157:H7 were used as biomarkers.

Conclusions

The survival of viruses in clay soil was significantly lower than in sandy soil ($i T_{90}$ values of 10.520 ± 0.600 *vs* 21.270 ±1.100 and 12.040 ± 0.010 *vs* 43.470 ± 1.300, respectively) and PhiX-174 showed faster percolation and leaching in sandy soil than clay soil ($i T_{90}$ values of 0.46 and 2.43, respectively). *S*. Typhimurium was percolated and inactivated more slowly than *E. coli* O157:H7 ($i T_{90}$ values of 9.340 ± 0.200 *vs* 6.620 ± 0.500 and 11.900 ± 0.900 *vs* 10.750 ± 0.900 in clay and sandy soils, respectively), such that *E. coli* O157:H7 was transferred more quickly to the deeper layers of both soils evaluated (percolation). Consequently, *E. coli* O157:H7 may serve as a useful microbial biomarker of depth contamination and leaching in clay and sandy soil and that bacteriophage could be used as an indicator of enteric pathogen persistence. Our study contributes to development of predictive models for enteric pathogen behaviour in soils, and for potential water and food contamination associated with biofertilization.

CHARACTERISING THE CULTURABLE BACTERIA FROM MINKE WHALE (BALAENOPTERA ACUTOROSTRATA) GUT BY 16S RRNA AMPLICON SEQUENCING

I.S. Roiha[1], C.S. Svanevik[1], B.T. Lunestad[1]
[1]National Institute of Nutrition and Seafood Research, Seafood safety and health, Bergen, Norway

Backgrounds

Whales are homeothermic animals in an environment dominated by heterothermic ones, and as such represent an exclusive reservoir of microbes. Investigating the cultured portion of bacteria from the gut microflora gives new insight to the diversity and functional aspects of the gut microbial communities, including nutritional functions, biogeochemical cycling, and of possible antibiotic resistance.

Objectives

In this study, we explored the gut microbiomes of jejunum, ileum, and colon samples from four minke whale (*Balaenoptera acutorostrata*) individuals, by traditional microbiological methods and molecular analyses. For increased understanding of the taxonomic and functional diversity of the whale gut microbiome, 16S rRNA amplicon metagenomic sequencing were applied to investigate the culturable portion of bacteria from the gut.

Methods

Gut samples from whales, caught in the Barents Sea, were obtained from a commercial Norwegian whaling vessel. Aerobic and anaerobic plate counts were set up, parameters included total plate count (TPC), Enterobacteriaceae, Enteroocci, *Listeria monocytogenes*, *Salmonella*, pathogenic vibrios, *Lactobacillus* sp., and *Pseudomonas* sp. Bacterial colonies were harvested from the agar plates in bulks for future DNA analysis. Glycerol stocks were made for future microbiological investigations.

Conclusions

Parameters included analyses of *Listeria*, *Salmonella,* and pathogenic vibrios, neither of which were detected in the gut content. Higher bacterial counts were found in the jejunum and ileum samples compared to colon samples. Results from the 16S rRNA amplicon sequencing will be presented.

CHARACTERISING THE GUT MICROBIOTA OF MINKE WHALE (BALAENOPTERA ACUTOROSTRATA) – MEMBERS AND FUNCTIONS

I.S. Roiha[1], B. Wilson[2], P. Whatmore[3], B.T. Lunestad[1]
[1]National Institute of Nutrition and Seafood Research, Seafood safety and health, Bergen, Norway
[2]University of Bergen, Department of Biology, Bergen, Norway
[3]National Institute of Nutrition and Seafood Research, Fish Nutrition, Bergen, Norway

Backgrounds

Whales are homeothermic animals in an environment dominated by heterothermic ones, and as such represent an exclusive reservoir of microbes.

Objectives

In this study, we explored the taxonomic and functional diversity of gut microbiomes from four minke whale (*Balaenoptera acutorostrata*) individuals, by shotgun metagenomic sequencing of jejunum, ileum, and colon samples.

Methods

Gut samples from whales, caught in the Barents Sea, were obtained from a commercial Norwegian whaling vessel, and DNA extracted and sequenced by the Illumina HiSeq 2500 platform.

Conclusions

All of the three domains Archaea, Bacteria, and Eukaryota were well represented in the jejunum and ileum samples; however, the Archaea were noticeably absent from the colon. Whilst gut microbiomes were dominated by the Bacteria (comprising 32-97 % relative abundance), ileum samples from two of the whales were dominated (61-63 % relative abundance) by the Eukaryota. The highest relative proportions of Bacteria (96-97 %) were found in the colon. In the Bacterial fractions, higher diversities were seen in the jejunum and ileum samples compared with those of the colon.

Investigations into the taxonomic diversity continue, to compare the gut microbiome of the four different whale individuals (consisting of three females [one young and two mature] and one mature male). Microbial genomes have been assembled from the metagenomic data and the functional role of these uncultured organisms in the whale gut is being investigated. These data will be presented.

MICROBIAL SELECTION AND STOICHIOMETRY OF GLUCOSE AND XYLOSE FERMENTATION IN MIXED CULTURE ECOSYSTEMS OF ANAEROBIC SEQUENCING BATCH REACTORS

J.L. Rombouts[1], D.G. Weissbrodt[1], R. Kleerebezem[1], M.C.M. van Loosdrecht[1]
[1]Delft University of Technology, Biotechnology, Delft, The Netherlands

Backgrounds

Enrichment culture experiments can elucidate mechanisms behind microbial selection and diversity in mixed-culture fermentation systems. Here, microbial selection and conversion stoichiometries were studied during the fermentation of glucose and xylose, which are two monomers abundant in agro-waste streams. Anaerobic sequencing batch reactors (ASBRs) were used for enrichment of the strain with highest growth rate on the respective substrate. Do both enrichments result in one dominant organism? And do xylose or glucose lead to a similar product spectrum in chemical steady state?

Objectives

1. Compare the metabolic stoichiometry for glucose and xylose fermentation at steady state
2. Analyze the community structure to evaluate the hypothesis

Methods

Two 2-L ASBRs were operated in 6h cycles at 30±0.5 °C and pH 8.0±0.1, with a short hydraulic residence time of 8h, after inoculation with bovine rumen fluid. A medium composed of inorganic salts (Temudo *et al.* 2007) was fed with either glucose or xylose as sole carbon sources at 4 g/L. Main products were quantified by HPLC and off-gas analysis. The stoichiometries of the metabolisms were verified with COD balancing. Community compositions of the suspensions were analyzed by light microscopy, PCR–DGGE and band sequencing on the V3-16S rRNA gene pool, and 16S rRNA-targeted FISH.

Conclusions

1. A similar product spectrum dominated by coupled acetate/ethanol formation was obtained for both substrates, reported earlier (Temudo *et al.* 2007).
2. For glucose, one *Enterobacter* population dominated.
3. For xylose, one *Citrobacter* population dominated, additional to a *Clostridium* population
4. FISH confirmed dominance of Gammaproteobacteria for both enrichments

Following up, we will characterize a mixed substrate ASBR, hypothesizing two organisms will dominate.

RIVER BIOFILM RESPONSES TO MULTIPLE STRESSORS: EFFECTS OF A CONCENTRATION GRADIENT OF WASTEWATER EFFLUENTS ARE MODULATED BY DESICCATION

F. Romero[1], *S. Sabater*[1], *V. Acuña*[1]
[1]*Catalan Institute for Water Research, Recursos i Ecosistemes, Girona, Spain*

Backgrounds

Wastewater treatment plants (WWTPs) release large amounts of chemical compounds such as inorganic micropollutants and nutrients to river and stream ecosystems. Discharge from WWTPs results in high concentrations of chemicals immediately after the discharge point, whereas downstream sites usually show smaller concentrations due to natural dilution and attenuation of chemicals. Microorganisms in biofilms exposed to these chemicals play a major role on ecosystem maintenance and functioning. Further, climate change-related stressors also affect the biological communities. In particular, flow interruption and desiccation affect systems under water scarcity, and exert formidable effects on microbial communities.

Objectives

Here we aim at evaluating the response of river biofilms across a concentration gradient of a complex chemical stressor (i.e. WWTP effluent) within the context of a climate-change-related stressor (i.e. desiccation).

Methods

To that purpose, we used a mesocosms approach to expose river biofilms affected or not by desiccation to a concentration gradient of WWTP effluents using a regressional design. The response of the biofilm community was studied at two levels: (i) bacterial diversity and composition was assessed by means of high-throughput sequencing of 16S rRNA genes, and (ii) community functioning was assessed by quantitative PCR to determine the prevalence of genes involved in major ecosystem functions such as nitrogen metabolism and photosynthesis.

Conclusions

We hypothesize that desiccation will significantly modify the community responses to the pollution gradient and this will be reflected in the biofilm functioning.

FEMS7-3221
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

BIOGEOCHEMICAL CHARACTERIZATION OF THE SEDIMENT OF THE SEINE RIVER ESTUARY

C. Roose-Amsaleg[1], *A. Laverman*[2], *A. Thibault*[1], *A. Huguet*[1]
[1]*Metis, University Pierre and Marie Curie, Paris, France*
[2]*Ecobio, University Rennes 1, Rennes, France*

Backgrounds

At the land – sea interface, estuaries receive dissolved and suspended matter from both terrestrial and ocean environments. The transport and fate of this matter (organic carbon, nutrients and pollutants) depends on biogeochemical cycling within the water column and sediment. The Seine river estuary (France), under high anthropogenic influence, presents important nitrogen and organic carbon loads.

Objectives

Our **objective** was to determine benthic nitrate reduction and carbon oxidation rates, enumerate nitrogen transforming bacteria in relation to carbon quantity and quality in the Seine Estuary, France.

Methods

To this end, surface sedimentary nitrate reduction and ammonium production rates from 4 sites along the Seine estuary were determined. The microbial presence was estimated by qPCR of functional genes. Furthermore the organic matter was quantified and qualified (total C and N, sugar and protein concentrations, solid state ^{13}C NMR).

Conclusions

Sedimentary OM characterization showed the variation of OM sources (allochthonous vs. autochthonous) along the estuary. Denitrifiers represented the most abundant nitrogen cycle microorganisms (14-22% of the total microbial community) in April 2016. In addition, a small fraction of the bacteria able to mediate Dissimilative Nitrate Reduction to Ammonium was detected (0.4-0.79%). These proportions were consistent with potential nitrate reduction and ammonium production rates.

FEMS7-2049
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

MINING FOR DETOXIFICATION GENES IN THE GUT MICROBIOTA OF A MONOPHAGOUS INSECT

T. Rosas Pérez[1], *F. González Serrano*[1], *J. Marín Miret*[1], *A. Moya*[1]
[1]*Institute for Integrative Systems Biology, Evolutionary Genetics, Valencia, Spain*

Backgrounds

Brithys crini (Lepidoptera:Noctuidae) is a monophagous insect which feeds exclusively on leaves of *Pancratium maritimum,* a plant that grows on coastal sand dunes of the Mediterranean region. Several Pancratium species contain different alkaloids in large amounts that have toxic effects and have a role in protecting the plant against natural enemies.
Specialist insects like *B. crini* must have a gut microbiota capable of surviving to the toxicity of its diet or/and of catabolizing or transforming the toxic compounds.

Objectives

To investigate the capabilities of the *B. crini* gut microbiota to cope with the alkaloids on its diet, midgut and hindgut of 20 larvae were dissected and the purified DNA from the sections was sequenced.

Methods

The metagenome of the gut microbiota was sequenced using the Illumina MySeq technology. Reads and contigs were annotated and genes related to detoxification, aromatic compounds catabolism, metabolism of secondary metabolites and defense mechanisms where mined. Taxonomic and functional classifications were compared between midgut and hindgut datasets.

Conclusions

The classified sequences derived from bacteria belong to 27 different phyla. The most abundant genera were Bacteroides, Clostridium, Parabacteroides, Desulfovibrio, Enterococcus, Enterobacter, Klebsiella, Escherichia and Mycobacterium, but their proportions varied between midgut and hindgut. Also a higher bacerial diversity was found in the hindgut section.
We found that while some genera have many genes related to catabolism of secondary metabolites, most of the bacterial groups may relay on a variaty of efflux pumps and transporters to cope with the toxic compounds in the gut.

FEMS7-0636
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

POULTRY-RELATED MICROBIOME CHANGES FROM EMBRYONIC DEVELOPMENT TO FINAL PRODUCT: A SINGLE PASTURED-RAISED FLOCK FARM-TO-FORK ANALYSIS

M.J. Rothrock - Jr.[1], *A. Locatelli*[1], *K. Hiett*[1], *A. Caudill*[2]
[1]*USDA-ARS, US National Poultry Research Center, Athens, USA*
[2]*University of Georgia, Department of Public Health, Athens, USA*

Backgrounds

While conventionally grown poultry continues to dominate the U.S. poultry industry, there is an increasing demand for locally-grown, “all natural” alternatives. Unfortunately, limited research has been done on this type of poultry management practice, and thus many of these management effects on the environment, poultry products, and human health is unknown.

Objectives

The use of next generation sequencing allows for not only the gross (e.g. community structure) but also fine-scale (e.g. genera abundances) examination of complex microbial communities. Utilizing these technologies can provide a better understanding of the poultry microbiome and how it changes throughout a flock’s life cycle to better elucidate not only the overall microbial ecology of these communities, but specifically the ecology of the foodborne pathogens inherent within poultry production.

Methods

Broiler samples were taken during the entire flock life cycle, including Hatchery, Brood, Pasture, Processing, and Final Product, as well as samples from other farm animals in close contact with the broilers. Genomic DNA was extracted, 16S microbiomic profiles were generated (Illumina MiSeq), and microbiomes were analyzed and compared using QIIME 1.91 to determine how microbiomes shifted throughout production continuum, as well as what environmental or management factors may be influencing these shifts.

Conclusions

Significant microbiome shifts occurred during the life cycle of this broiler flock, with microbiomes clustering based on sample type and stage of production continuum. Additionally, while this flock was considered “free-range” with access to and contact with other farm animals, the poultry fecal microbiomes remained distinct from the non-poultry animals throughout their lives.

METAGENOME AND ACTIVE MICROBIOME PROFILING IN AMMONIA-RICH ANAEROBIC DIGESTION

J. Ruiz Sánchez[1], S. Campanaro[2], M. Guivernau[1], B. Fernandez[1], F.X. Prenafeta-Boldú[1]
[1]IRTA, GIRO, Caldes de Montbui, Spain
[2]Universita di Padova, Biology, Padova, Italy

Backgrounds

Ammonia released during the anaerobic digestion (AD) of N-rich organic wastes is a well-known inhibitor of methanogens and, particularly, the acetoclastic archaea. Recently, an alternative pathway known as syntrophic acetate oxidation (SAO) has been identified as possible strategy to overcome this inhibition.

Objectives

This study is aimed at gaining a better understanding of the microbial community interactions in industrial AD reactors operated at different total nitrogen ammonia (TAN) levels.

Methods

A shotgun metagenomics sequencing and binning of scaffolds into population genomes has been performed with the biomass from four full-scale digesters (R1, R2, R3 and R4) operated under 6, 5, 2 and 2 g_{TAN} L^{-1}.Total DNA and RNA from the biomass of each digester was extracted. Genomic DNA was prepared for paired-end sequencing using Nextera Kit and cDNA obtained obtainedwasas used for high throughput sequencing purposes, utilizing equipment.

Conclusions

The combination of DNA and RNA-based taxonomic analysis and functional genetic studies allowed the reconstruction of Wood–Ljungdahl (W-L) pathway in *Bacteroidetes* and *Chloroflexi* genomes bin. This fact evidenced that both phyla might harbour SAOB potential and were in agreement with high abundance and metabolic activity in digesters exposed to high TAN levels. W-L pathway is fundamental for acetate conversion to H_2 and CO_2, which are the principal substrate for hydrogenotrophic methanogens that were found out the most active archaeal community in TAN-rich digesters. Consequently, the obtained results point to the occurrence of novel, to our knowledge not yet described, syntrophic associations between SAOB-HM.

FEMS7-3095
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

MICROBIAL COMMUNITY DYNAMICS IN NITROGEN RICH DIGESTERS: IMPACT OF EFFLUENT RECIRCULATION

J. Ruiz Sánchez[1], M. Romero[1], S. Astals-Garcia[2], B. Fernandez[1], F.X. Prenafeta-Boldú[1]
[1]IRTA, GIRO, Caldes de Montbui, Spain
[2]University of Queensland, Advanced Water Management Centre - AMWC, Queensland, Australia

Backgrounds

Anaerobic digestion (AD) is a widely consolidated biotechnology for the valorization of organic wastes.

Objectives

The AD microbiome response towards increasing ammonia concentrations, up to inhibitory levels (<6 $gN\text{-}NH_4^+\ L^{-1}$) was studied in two lab-scale mesophilic AD bioreactors operated with (AD1) and without (AD2) recirculation.

Methods

The active microbial community from the biomass of each digester was characterized by triplicate and at different operational stages by extracting the total RNA and generating cDNA, libraries. Total transcripts of ribosomal 16S rRNA and mcrA genes were determined by qPCR. Meanwhile, the same cDNA was used for high throughput sequencing purposes.

Conclusions

No significant differences were observed between the two digesters, concerning physic-chemical and efficiency parameters, but a drastic microbial community shift was observed between both reactors, as evidenced by biodiversity indexes and multivariate analysis on the species abundance matrix. Active biomass in AD1 was dominated by *Pseudomonas* spp., possibly due to their degradation capability against polymeric materials (lingocelullose) that accumulated due to recirculation. Meanwhile, the phyla *Bacteroidetes* and *Firmicutes* were the predominant population in AD2. Putative acetogenic bacteria within these groups have recently been described as syntrophic acetate oxidation bacteria (SAOB). Despite differences in the bacterial communities, hydrogenotrophic methanogens (HM) belonging to the genera *Methanobacterium* and *Methanoculleus* were the prevalent archaeal counterparts in both bioreactors. This finding highlights the enrichment of HM, which tend to be relatively tolerant towards ammonia, and the establishment of potential syntrophic interactions with exoelectrogenic *Pseudomonas* spp., which might in fact be able to carry out the SAO pathway.

Departamento de Nutrición- Bromatología y Tecnología de los Alimentos, Madrid, Spain
[3]Universidad Complutense de Madrid,
Departamento de Nutrición- Bromatología y Tecnología de los Alimentos, Madrid, Spain
[4]Centro de Salud Arrabal, Centro de Salud Arrabal, Zaragoza, Spain
[5]Universad Complutense de Madrid,
Departamento de Nutrición- Bromatología y Tecnología de los Alimentos, Madrid, Spain

Backgrounds

The infant oral microbiome exerts an important role in the establishment of the infant gut microbiome since it contains the first commensals that will reach and stably colonize the infant gut, but it also influences the dental health of the adult. In this context, human milk represents a source of bacteria for the initial establishment of the oral (and gut) microbiomes in the breastfed infant although little is known on the specific mechanisms that condition the early establishment and development of the infant oral microbiomes.

Objectives

To investigate the maternal colostrum and infant oral microbiomes to identify bacterial species (strains) shared in the maternal-infant dyad.

Methods

Maternal pre-colostrum and infant saliva were collected from 19 mother-infant pairs and their microbiomes were analyzed through 16S rRNA metagenomics sequencing. Bacteria were also cultured, isolated and identified by MALDI-TOF. RAPD-PCR was performed on those isolates that, belonging to the same species, were shared in the maternal and infant samples of the same pair.

Conclusions

Maternal pre-colostrum and infant salivary microbiomes were significantly different from each other, although certain groups were consistently shared between both sample types. *Streptococcus* and *Staphylococcus* spp were the most abundant groups in all samples. In 13 pairs, at least one isolate from the same species was recovered from the colostrum and the salivary sample. From those, the isolates obtained from colostrum and infant saliva in 8 of the pairs could not be distinguished by RAPD-PCR profiling, thus suggesting the sharing of bacteria at strain level between milk and infant oral microbiomes.

CLOSTRIDIUM DIFFICILE COLONIZATION AND GUT MICROBIOTA IN HOSPITALIZED IBD PATIENTS

A. Mahnic[1], S. Pintar[2], A. Kocuvan[2], P. Skok[3], M. Rupnik[4]
[1]National Laboratory of Health Environment and Food, Department for microbiological research, Maribor, Slovenia
[2]University of Maribor- Faculty of Medicine, Department for Microbiology, Maribor, Slovenia
[3]University Medical Centre Maribor, Department of gastroenterology, Maribor, Slovenia
[4]National Laboratory of Health Environment and Food and University of Maribor faculty of Medicine, Department for microbiological research, Maribor, Slovenia

Backgrounds

Gut microbiota performs numerous essential metabolic, developmental and immune functions and defends against invading pathogens and resident opportunists. Imbalance in gut microbiota can destabilize homeostatic relationship and lead to various health issues. Studies show strong association between dysbiotic gut microbiota and several gastrointestinal diseases such as inflammatory bowel disease (IBD), irritable bowel syndrome and *Clostridium difficile* infection (CDI).

Objectives

Aim of this study was to analyze *C. difficile* colonization and gut microbiota of patients hospitalized in the Department of gastroenterology (UMC Maribor, Slovenia) including IBD and non IBD patients compared to a group of healthy individuals.

Methods

Study includes a group of 94 hospitalized patients and a control group of 55 healthy volunteers. *Clostridium difficile* colonization was examined with specific real-time PCR. 16S metagenomes were acquired by paired-end sequencing on Illumina MiSeq platform targeting V3-V4 hypervariable region of the bacterial 16S rRNA gene.

Conclusions

Rate of *C. difficile* colonization is similar between IBD and non IBD patients (20.4 % and 25.0 %, respectively) while significantly lower among healthy volunteers (1.8 %).

Microbiome data can differentiate hospitalized patients from healthy controls. Dissimilarities are evident as lower alpha diversity (Shannon $p<0.001$) as well as differences in community structure (AMOVA $p<0.001$). Focusing solely on hospitalized patients we were able to show that IBD patients have a lower alpha diversity (Shannon $p=0.008$) and distinguish from other patients based on bacterial community (AMOVA $p=0.014$) with the most prominent being decreased abundance of genus *Akkermansia.* No significant differences were found between *C. difficile* colonized versus non-colonized patients.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

THE CHARACTERISTICS OF CANDIDA ALBICANS "GROWTH FITNESS" UNDER THE NEW SYNTHETIC PORPHYRIN INFLUENCE

M. Rusakova[1], *O. Ruschak*[2], *S. Vodzinskiy*[1], *Y. Ishkov*[1]
[1]*Odessa I. I. Mechnikov National University, Biotechnological Scientific Education Center, Odessa, Ukraine*
[2]*Odessa I. I. Mechnikov National University, Microbiology- Virology and Biotechnology Department, Odessa, Ukraine*

Backgrounds

In vivo Candida albicans is polymorphic microorganism. It is detected that *C. albicans* hyphae have greater invasive potential than the yeast forms. In this existence form *C. albicans* is more resistant to antifungal substances.

There have been several reports on the use of porphyrins to kill *C. albicans*. However, there has been much less study on the types of physicochemical properties necessary in a molecule in order to make it effective in microbial killing.

Objectives

The aim was to determine the sensitivity of different *Candida albicans* morphological forms to a number of synthetic porphyrins.

Methods

During microorganism cultivation in the Sabouraud and Spider media there were determined differences between *C. albicans* forms. In the first medium the most cells had an oval shape, were actively dividing and eventually generated a continuous biofilm. In the case of *C. albicans* growth in Spider medium cells elongated, were not practically separating from each other during the division that resulted to the formation of pseudohyphae.

Conclusions

Results of experimental investigations have demonstrated that different *C. albicans* forms can be effectively killed by the porphyrins. *C. albicans* biofilm cells are more resistant to low concentrations of the compounds however the significant inhibition of the microbial community is in the presence of 1 μM. Modification of porphyrin molecules by N-methyl-6-quinolinyl increases the fungicidal effect on the yeast cells, in contrast to N-methyl-7-quinolinyl derivatives that are effective against hyphal structures.

So, therapy with porphyrins has the potential to evolve into a useful treatment for difficult to eradicate *C. albicans* infections.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

BIODEGRADATION OF ORGANOPOLLUTANTS BY SOIL MICROORGANISMS ISOLATED FROM POLLUTED SITES IN CHINA

Z. Rybková[1], K. Malachová[1], J. Červeň[1], R. Ji[2]
[1]University of Ostrava, Department of Biology and Ecology- Faculty of Science, Ostrava, Czech Republic
[2]Nanjing University,
State Key Laboratory of Pollution Control and Resource Reuse- School of the Environment, Nanjing, China

Backgrounds

Soil samples were collected from five agriculturally and industrially contaminated locations in China. These sites included a pesticide production plant, fields heavily treated with pesticides, and soil polluted with different organic pollutants and heavy metals.

Objectives

Aim of this work was to isolate bacterial and fungal strains with a potential for biodegradation of recalcitrant organopollutants.

Methods

Bacterial and fungal strains were isolated using low-nutrient-concentration media with Bisphenol A (BPA), Tetra-Bromo Bisphenol A (TBBPA), Sulfamethoxazole (SMX) and Diclofenac (DF) as single carbon sources. Experiments were conducted with selected isolates using ^{14}C labeled BPA and TBBPA. The biodegradation efficiency was evaluated using HPLC-LSC and the degradation products were identified. Biodegradation potential of four isolated strains of microorganisms was also checked by degradation of recalcitrant synthetic dyes.

Conclusions

A total of 151 bacterial and 41 fungal strains were isolated from the soil samples using diclofenac, sulfamethoxazole, BPA, and TBBPA as single carbon sources. Experiments with ^{14}C labelled BPA showed that the fungal isolate ST19 had a higher ability to mineralize BPA than the bacterial strain 12B4. In the study, the ability of the above strains to degrade synthetic dyes was also documented.

Acknowledgements: The study was supported by the projects: Podpora bilaterální spolupráce v oblasti VŠ vzdělávání, vědy a výzkumu mezi univerzitami Moravskoslezského kraje a čínskými univerzitami a výzkumnými organizacemi (reg. no. 00955/2015/RRC) and TEWEP LO1208 of the National Feasibility Programme I of the Czech Republic.

EVALUATION OF THE ANTIBACTERIAL POTENTIAL OF SOME ESSENTIAL OILS IN BIOLOGICAL CONTROL AGAINST PHYTOPATHOGENIC AGENT PSEUDOMONAS SYRINGAE PV. TOMATO DC3000 RESPONSIBLE FOR THE TOMATOES SPECK

A. SABIR[1], B. El Khalfi[1], F. Errachidi[1], A. Serrano Delgado[2], A. Soukri[1]
[1]Faculty of Sciences, Biology, Casablanca, Morocco
[2]Instituto de Bioquímica Vegetal y Fotosíntesis CSIC-
Universidad de Sevilla- Centro de Investigaciones Científicas Isla de la Cartuja- Américo Vespucio 49 - 41092-Sevilla- Spain, Biology, Sevilla, Spain

Backgrounds

The essential oils are exploited in various fields due to their many therapeutic virtues. In phytotherapy, they can present a serious candidate to replace the various chemical pesticides commonly used against infectious diseases of fungal and bacterial origin.

Objectives

The aim of this study is to determine the chemical composition and the antimicrobial activity of six essential oils against the strain *Pseudomonas syringae pv.tomato DC3000* that is responsible for bacterial speck and resistant to rifampicin, in order to develop a biological control means.

Methods

Essential oil from the plant collected in north centre region of Morocco obtained by hydro-distillation were analyzed by gas chromatography equipped with flame ionisation detector (GC-FID).The antimicrobial activity of the oils was determined using well diffusion, micro atmosphere, and determination of MIC/CMB methods. An acp analysis was also done.

Conclusions

The GC analysis showed that the major constituents of the oils were monoterpene hydrocarbons and phenolic monoterpenes, but the concentration of these compounds varied greatly among the oils examined. The results of the antimicrobial assay showed that four essential oils inhibited the growth of *Pseudomonas syringae pv.tomato DC3000* namely *Thymus vulgaris*, *Citrus limonum*, *Mintha puligium* and *Eucalyptus globulus.* The best bacteriostatic and bactericidal effect remains that of *Eucalyptus globulus*. The results of this study confirmed the possibility of using these oils or some of their components in agriculture to prevent the growth of this phytopathogen bacterium and extend the shelf-life of tomatoes.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

ACTINOBACTERIA RESPIRATION AT SITES DIFFERING IN HEAVY METAL CONTAMINATION WAS ALTERED BY SUPPLEMENTATION WITH ORGANIC SUBSTRATE.

M. Sagova-Mareckova[1], *P. Madrova*[1], *J. Kopecky*[1]
[1]*Crop Research Institute, Epidemiology and ecology of microorganisms, Prague 6, Czech Republic*

Backgrounds

At sites contaminated with heavy metals, the composition and activity of microbial communities are influenced by stress factors one of which is the content and character of organic matter. *Actinobacteria* contribute to breakdown of organic matter and survive in heavy metal contaminated conditions because they possess efflux resistances enabling cell detoxification.

Objectives

The aim of the study was to show how organic matter decomposition is affected by heavy metal contamination in *Actinobacteria*.

Methods

We selected two sites differing in long-term contamination by cadmium (L low, H high contamination). We assessed the changes in respiration after addition of cadmium and two organic substrates, cellobiose and straw using OxiTop system. We assessed quantity of actinobacteria by qPCR, diversity of cellobiohydrolase by specific primers, and bacterial diversity by Illumina sequencing.

Conclusions

The addition of cadmium did not have any effect on respiration but in the cellobiose-cadmium treatment. The addition of organic substrate did not influence the quantity of actinobacteria but in the cadmium-cellobiose treatment at H site. Sequences of cbh gene (coding for cellobiohydrolase) differed significantly (Libshuff) between the sites H and L, both untreated and in the straw-cadmium threatment. The two sites differed in actinobacteria community composition after addition of straw, *Micrococcaceae* increased at both sites, *Nocardiaceae* and *Cellulomonadaceae* increased at H site, and *Thermomonosporaceae* increased at L site. In conclusion, the microbial communities at site with low contamination seemed to be more resilient being less affected after additions of organic substrates.

FEMS7-3231
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

BUTYRATE PRODUCTION IN FUSOBACTERIUM NUCLEATUM IS ENHANCED BY CROSS-FEEDING WITH STREPTOCOCCUS GORDONII

A. Sakanaka[1], M. Kuboniwa[1], A. Amano[1]
[1]Osaka University Graduate School of Dentistry, Preventive Dentistry, Suita- Osaka, Japan

Backgrounds

Streptococcus gordonii, an oral commensal, has been considered to be an accessory pathogen that is able to enhance the colonization of periodontal pathogens. We previously showed that excretion of ornithine by *S. gordonii* helped bolster biofilm formation by a periodontitis-associated bacterium, *Fusobacterium nucleatum*.

Objectives

The objective of this study is to further dessect the metabolic interactions between two organisms.

Methods

Co-culture experiments were conducted using transwell setup, where *F. nucleatum* and *S. gordonii* were placed in the lower and upper chambers, respectively. After 6 h of incubation, metabolic profiles of *F. nucleatum* cells and culture supernatants were determined using CE-TOF-MS.

Conclusions

Metabolomics analysis showed significant increases in the extracellular level of ornithine and the intracellular levels of acetylornithine and putrescine in *F. nucleatum* when in co-culture, providing evidence for our previous finding; ornithine cross-feeding. In addition, the presence of *S. gordonii* elevated the intra- and extracellular levels of other amino acids, including alanine and glutamate in *F. nucleatum*, suggesting multiple amino acids cross-feeding. Furthermore, pathway analysis suggested major changes in fatty acid metabolism in *F. nucleatum* co-cultured with *S. gordonii*. Indeed, drastic increase in butyrate level was observed in the supernatants of co-cultures as compared to the respective mono-cultures, indicating enhanced formation of butyrate by *F. nucleatum*, possibly due to activated amino acid fermentation. Considering that enhanced butyrate production involves pathogenesis of periodontitis, our findings highlight the pathogenic potential of *S. gordonii* via cross-feeding with *F. nucleatum*, providing further evidence for the properties of *S. gordonii* as an accessory pathogen.

EVALUATION OF THE BACTERIAL COMMUNITY TO ASSESS THE TRACEABILITY OF BOTTLED WATER OF DIFFERENT MINERAL WATER BRANDS DURING THE SHELF LIFE

L. Sala-Comorera[1], A. Casanovas-Massana[2], C. García-Aljaro[1], A.R. Blanch[1]
[1]University of Barcelona, Department of Genetics- Microbiology and Statistics, Barcelona, Spain
[2]School of Public Health- Yale University-,
current address: Department of Epidemiology of Microbial Diseases, New Haven, USA

Backgrounds

Natural mineral waters are complex environments containing a high microbial diversity, which is characteristic of each spring. Once bottled, these communities may change over time until the water is consumed. The bottling material is believed to play a major role in the succession of these populations.

Objectives

The microbial community structure and diversity of three natural mineral water brands were investigated over 3 months after bottling in glass and PET bottles for their traceability.

Methods

Each mineral water was bottled on the same day from the same spring in glass and PET. Samples were processed on days 1, 7, 15, 21, 30, 60 and 90 after bottling. Culture-dependent: (heterotrophic plate count) and culture-independent methods: fluorescent microscopy with vital dyes), PCR-DGGE (polymerase chain reaction -denaturing gradient gel electrophoresis) and bacterial 16S rRNA gene amplicon 2x300 bp paired-end sequencing on the MiSeq Illumina platform were used.

Conclusions

Shifts in bacterial composition at different times during the 3 months were observed, however the cluster analysis of the DGGE fingerprints and Illumina sequencing revealed that the samples clustered mainly according to the brand and the bottle material. No difference in the number of total, viable and culturable bacteria counts were observed among mineral water bottled with PET and glass during long term storage. Some of the water brands and/or material had a distinct microbial community structure clearly distinguishable from the others, which suggests the possibility of defining a molecular marker for traceability.

FEMS7-0572
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

EFFECTS OF CRUDE OIL ON MICROBIAL DENITRIFICATION AND N2O PRODUCTION IN SALT MARSH SEDIMENTS

H. Ribeiro[1], P. Salgado[1], C.M.R. Almeida[1], A.P. Mucha[1], C. Magalhães[1]
[1]Interdisciplinary Centre of Marine and Environmental Research CIIMAR/CIMAR, EcoBioTec Laboratory, Matosinhos, Portugal

Backgrounds

Denitrification is a key process for the reduction of external N loads and alleviation of eutrophication in coastal waters. Also, denitrification is an important process on the production of nitrous oxide (N_2O), a potent greenhouse gas. Additionally, estuaries receive and tend to accumulate pollutants, such as petroleum hydrocarbons (PHC). Therefore, the evaluation of the impact of PHC on denitrification process and N_2O production is of crucial importance.

Objectives

We assessed the impact of PHC contamination on microbial denitrification, in a five months greenhouse experiment. In addition, the role of *Juncus maritimus*, an estuarine plant, comparatively to non-vegetated sediments was also evaluated.

Methods

Both sediments (vegetated and non-vegetated) were mixed manually with Arabian Light crude oil (supplied by an oil refinery) to a concentration of 5 ml L^{-1} wet sediment. Similar triplicate vegetated and non-vegetated vessels were prepared without crude oil contamination as control. Denitrification and N_2O potential rates were measured, along time, using the acetylene method.

Conclusions

Results revealed that, in both sediments, denitrification rates did not seem to be affected by the addition of crude oil. On the other hand, crude oil clearly enhanced N_2O production in vegetated sediments, but not in non-vegetated sediments. This study provides insights into the potential effects of crude oil on denitrification and N_2O production in estuarine environments, with profound implications for the management of aquatic ecosystems regarding eutrophication and global warming.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

GENE EXPRESSION ANALYSIS OF SECRETION SYSTEM DURING INTERACTION OF METHYLOBACTERIUM MESOPHILICUM SR 1.6/6 WITH THE HOST PLANT

J.K. Salguero Londoño[1], W.L. Araujo[1], M. Nobrega Dourado[1], D. Souza Santos[1], A. Camargo Neves[1]
[1]Institute of Biomedical Sciences - University of Sao Paulo, Microbiologia, São Paulo, Brazil

Backgrounds

Methylobacterium genus is composed by pink-pigmented facultative methylotrophic bacteria that are able to promote plant growth, increase photosynthetic activity of the host plant and reduce the incidence of pathogens. The *M. mesophilicum* strain SR1.6/6 is a bacterium isolated from citrus and due the interaction with the host plant has been the focus of several studies.

Objectives

This project, evaluated the identification and the expression of some genes related to codification of protein secretion system that could be involved in *M. mesophilicum*-citrus (*Citrus* sinensis) interaction during colonization of this bacterium through the recognition of root exudates compounds released by the host plant. We evaluated the bacterial cells adhered to the roots forming biofilm and bacterial cells in suspension compared to control (bacterial cells without plant).

Methods

For expression analysis, genes that encode protein from secretion system and multidrug efflux pumps were evaluated by qPCR. Then, the *M. mesophilicum* SR1.6/6 genome was reevaluated and genes related to transport systems were reannotated employing bioinformatics tools (BLASTp, BLASTx and JGI), comparing to previously described secretion systems genes. The exudates released by citrus roots, were identified by gas chromatography mass spectrometry (GC-MS)

Conclusions

It was found in the genome of *M. mesophilicum* SR1.6/6 type I, II and V secretion system, multidrug efflux pumps and related ABC transporters. Citrus root exudates released are composed mainly by sugars, organic acids, organic compounds, aminoacids and lipids. Gene expression analysis suggests a differential activation of secretory machinery for translocation of protein during the interaction between *M. mesophilicum* SR1.6/6 and the host plant.

GENOME SEQUENCING AND COMPARATIVE GENOME ANALYSIS OF PSEUDOMONAS BALEARICA STRAINS ISOLATED FROM HIGHLY POLLUTED ENVIRONMENTS

F. Salvà-Serra[1], H. E. Jakobsson[1], D. Jaén-Luchoro[1], C. Seguí[2], F. Aliaga[3], A. Busquets[2], M. Gomila[2], J. Lalucat[2], E. R. B. Moore[4], A. Bennasar-Figueras[2]
[1]University of Gothenburg, Department of Infectious Diseases, Gothenburg, Sweden
[2]University of the Balearic Islands, Department of Biology, Palma de Mallorca, Spain
[3]Clínica Rotger, Microbiology, Palma de Mallorca, Spain
[4]University of Gothenburg, Culture Collection University of Gothenburg, Gothenburg, Sweden

Backgrounds

Pseudomonas balearica (former genomovar 6 of *P. stutzeri*) is a marine denitrifying species that has been isolated several times all over the world. In most cases, it was isolated from highly polluted environments, such as oil spills or waste waters. Strains of *P. balearica* have been shown to degrade compounds such as naphthalene, phenanthrene or organophosphorus pesticides.

Objectives

1- To complete the whole-genome sequence of *P. balearica* DSM 6083^T.

2- To obtain the genome sequence of additional strains of *P. balearica*.

3- To compare the genomes of *P. balearica* and strains of related species.

Methods

Genomic DNA of *P. balearica* DSM 6083^T was sequenced with 454 and Illumina technology. The genome was closed combining several bioinformatic methods and Sanger sequencing. Two additional strains of *P. balearica* were sequenced using Illumina and assembled combining *de novo* and reference assemblies. Comparative analysis of four genomes of *P. balearica* and further strains of *P. stutzeri* was done, using UHGene, an *in-house* pipeline that combines different algorithms to determine orthologous gene clusters, that are individually aligned and concatenated to estimate the core- and pan-genome of the species.

Conclusions

The genome of the type strain of *P. balearica* was closed and the genomes of two other strains of the species were obtained as draft. The analysis of the genomes has revealed numerous metabolic pathways and genes that explain the degradative capabilities of the strains and their life-style. Analysis with UHGene has determined the core- and pan-genome of *P. balearica* and supports the current phylogenetic status of the species.

MICROORGANISMS AS BIOINDICATORS OF NITROGEN REMOVAL IN ACTIVATED SLUDGE FROM DIFFERENT WASTEWATER TREATMENT PLANTS

E. Ciriero[1], J.A. Parada-Albarracín[2], J. Méndez[3], A.M. Huguet[1], H. Salvadó[2]
[1]Empresa Mixta d'Aigües de la Costa Brava S.A, Operation and maintenance, Roses, Spain
[2]University of Barcelona, Evolutive Biology- Ecology and Environmental Sciences, Barcelona, Spain
[3]University of Barcelona, Fermentation Unit, Barcelona, Spain

Backgrounds

Biological processes in wastewater treatment plants (WWTP) is possible due to a diverse activated sludge biocenosis. Monitoring of certain microorganisms as indicators may offer several advantage in WWTP. Thus, the potential use of microorganisms as bioindicators in the wastewater treatment continues to develop to achieve an understanding of the microbial ecology of activated sludge.

Objectives

Microorganisms potential as indicators of nitrifying performance in different configuration of activated sludge processes were studied.

Methods

Three full-scale WWTP in north west of Catalonia working with different configurations: anaerobic/anoxic/aerobic (A2O), anoxic/aerobic (AO), and oxidation ditch (OD) were used in this study. Sludge samples for microscopic examination in each system were collected from the aeration tanks. Multivariate analysis was performed to correlate the operational and environmental parameters with respect to the microfauna found.

Conclusions

Multivariate analysis showed a cluster involved in ammonia removal efficiency, cluster formed by *Arcella* sp. (0.667), *Calyptotricha lanuginosa* (0.596), *Metacystis* sp. (0.490), *Chaetospira* sp. (0427), *Euglypha* sp. (0.370), and *Pyxidicula* sp. (0.350) showed significant Spearman's correlations coefficients with ammonia removal. Comparative study suggests that high efficiency in nitrogen removal tend to have some protists abundance than others when the efficiency nitrogen removal decreases. Indicating the positive role of *Arcella* sp., *Calyptotricha lanuginosa*, *Metacystis* sp., *Chaetospira* sp., *Euglypha* sp. and *Pyxidicula* sp. have been selected as performance bioindicators based on ammonium removal in this study, highest density of these protozoa was achieved when nitrogen removal was high. We suggest calling this cluster ARI (Ammonium Removal Indicator) as good bioindicators of high nitrogen removal efficiency in WWTP.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

PHARMACEUTICAL AND ENVIRONMENTAL APPLICATION OF A PRODUCT OF BIOLOGICAL ORIGIN AND OTHER SYNTHETICS

F. Samira[1], A. Redha[1], B. Abdelmalek[2]
[1]Yahia FARES University, MEDEA, MEDEA, Algeria
[2]Saad DAHLEB University, BLIDA, BLIDA, Algeria

Backgrounds

The objective of this study was to evaluate firstly, the power of surfactants to remove heavy metals present in the soil, using an extraction method by solvent such as a depollution technique, secondly, to study the stability of pharmaceutical creams using these surfactants. This work has two parts, first, we evaluated the effectiveness of surfactants that are natural (biosurfactant) or synthetic (SDS and Tween 80) on desorption of heavy metals (Ni, Cu).The results were shown that the biosurfactant gave higher recovery yield for Cu, when its concentration is lower than the critical micelle concentration (CMC). In the second part, we studied the stability of an anti-burn cream by these surfactants where it was more stable with Tween 80.

Objectives

1. The study of the effectiveness and the power of surfactant (chemical or biological) in the depollution of the soils rich in heavy metals.
2. The study of the stability of a pharmaceutical cream by various surfactants

Methods

- The analysis technique used throughout this work is: UV-Visible spectrophotometry. It was used to monitor the absorbance of an aqueous solution loaded with heavy metals. The principle of this method is governed by the Beer-Lambert la.
- The pharmaceutical emulsion prepared was subjected to a series of physico-chemical analysis, namely macroscopic appearance, pH, microscopic appearance, emulsion direction and stability. These analyzes are necessary to evaluate the effect of each surfactant on the stability of the surfactant

Conclusions

1. As a result, it was concluded that the best depollutant was the biosurfactant because the natural surfactants are biodegradable and non-toxic to synthetic surfactants
2. The surfactants having a liquid form are easier to use and play an emulsifying role in the dispersed systems and it is subsequently concluded that Tween 80 promotes a uniform distribution of The cream

ROLE OF CHEMOTAXIS IN THE COLONIZATION OF SALICORNIA PLANTS WITH HALOPHILIC BACTERIA

I. Sampedro[1,2], *L. Toral*[1,2,3], *I. Llamas*[1,2]
[1]*Pharmacy Faculty, Microbiology, GRANADA, Spain*
[2]*Biomedical Research Center CIBM- Biotechnology Institute, Microbiology, GRANADA, Spain*
[3]*Xtrem Biotech S.L.- European Business Innovation Center, Microbiology, GRANADA, Spain*

Backgrounds

Based on FAO statistics, 800 million hectares of land are degraded through drought in the world. Climate change will affect the sea level increasing the area of wetland ecosystems and threaten the agriculture production by the increase of soil salinity.Therefore, the halophiles plants growth promotion in saline soils is an important strategy to consider. The halophilic plant *Salicornia* is one of the most promising biotic resources for the economic development of semiarid regions. Regarding to the chemotaxis, it has been extensively described in bacteria such as *Escherichia coli*, however, it is essentially unknown for halophilic bacteria.

Objectives

The main objective of this study is the characterization of the bacteria associated with *Salicornia* and their chemotaxis.

Methods

Bacteria isolated from *Salicornia* plants were identified by sequencing their 16S rRNA gene. Chemotaxis was quantified using the Adler capillary assay.

Conclusions

The bacteria associated with *Salicornia* belong mainly to the *Halomonas* genus. We have found that *Salicornia* exudates are chemoattractants for *H. anticariensis*. HPLC analysis shows the presence in *Salicornia* exudates of macrolides like Calenduloside E and it derivate oleanolic acid, a triterpenoid widely distributed in plants. We also showed that oleanolic acid is a chemoattractant for the halophilic bacteria used in this study. Inoculation of *Salicornia* seeds with *H. anticariensis* resulted in significant increases of germination percentage and vigour index compared with the results obtained in seeds inoculated with the chemotaxis mutant. These studies suggest the positive influence of chemotaxis in the colonization of *Salicornia* plants with halophilic bacteria.

ANTIFUNGAL ACTIVITY OF LIPOPEPTIDES FROM BACILLUS SP. AGAINST BOTRYTIS CINEREA

L. Toral[1,2,3], V. Béjar[1,2], I. Sampedro[1,2]
[1]Pharmacy Faculty, Microbiology, GRANADA, Spain
[2]Biomedical Research Center CIBM- Biotechnology Institute, Microbiology, GRANADA, Spain
[3]Xtrem Biotech S.L.- European Business Innovation Center, Microbiology, GRANADA, Spain

Backgrounds

Botrytis cinerea is a filamentous fungus classified as the second most important phytopathogen worldwide. Due to the low efficiency of control strategies against this fungus it causes important economic and agricultural losses in vineyards, and in tomato and strawberry crops.

Objectives

The main objectives of this study are to characterize the antifungal activity of strain Bacillus sp., against B. cinerea and to identify the compounds that are responsible for its activity.

Methods

In vitro techniques antibiosis, microscopy studies, determination of minimum inhibitory concentration (MIC) and minimum bacterial concentration (MBC), identification and characterization of lipopeptides using PCR and electrospray Q-TOF mass spectrometry.

Conclusions

The Bacillus sp. strain exhibited antifungal activity against B. cinerea in solid and liquid medium (inhibition rates of 60% and 100%, respectively). Microscopy studies revealed a morphological alteration of phytopathogen in interaction with Bacillus sp. strain. Molecular and mass spectrometry analyzes confirmed that Bacillus sp. secretes various forms of surfactin, iturin/mycosubtilin and fengycin. We demonstrate that these are the main compounds that have a bio-control ability.

INSIDE OUT: ARE GUT BACTERIA INVOLVED IN WHITEFLIES' PLANT ADAPTATION?

D. Santos-Garcia[1], N. Mestre-Rincon[1], E. Zchori-Fein[2], S. Morin[1]
[1]The Hebrew University of Jerusalem - The Faculty of Agriculture, Entomology, Rehovot, Israel
[2]Newe Ya'ar Research Center- The Agricultural Research Organization, Entomology, Ramat Yishay, Israel

Backgrounds

Polyphagous insects require an ability to overcome different sets of host plant defense compounds. Usually, during host-plant switch, their performance decline and only rebound few generations later. In contrast to natural selection, phenotypic plasticity and new gut bacteria acquisition are fast processes that could be involved in the host switching process.
The whitefly *Bemisia tabaci*, a tiny phloem-feeder, is considered an important and polyphagous pest species. Reported microbiomes of *B. tabaci* are dominated by obligatory bacterial endosymbionts. However, because insects' gut microbiota can play a major role in host-plant adaptation and are mainly acquired from the diet/environment, we hypothesized that *B. tabaci* might acquire environmental bacteria that can provide different benefits/costs related to host adaptation.

Objectives

Our goal was to explore the putative role of gut bacteria in the plant-adaptation process of *B. tabaci* under field conditions.

Methods

Field-like assays were conducted by following the adaptation process of a *B. tabaci* population switching from watermelon (suitable host) to pepper (unsuitable) along four generations. Each generation, samples were collected for gut dissections (cDNA 16S rRNA amplicons) and performance assays (offspring survival). Amplicons were amplified using endosymbionts' dual priming blockers and analyzed using USEARCH and phyloseq.

Conclusions

B. tabaci adaptation to pepper took 2-3 generations. Microbiome differences between *B. tabaci* watermelon/pepper populations were significant. Genera significantly associated with watermelon or pepper diets were identified. Also, a generational effect was detected, being more noticeable in the pepper samples. These data suggest that gut bacteria might help *B. tabaci* to adapt to new host plants.

USING PORTIERA TO ANSWER OPEN QUESTIONS IN WHITEFLIES TAXONOMY

D. Santos-Garcia[1], N. Mestre-Rincon[1], N. Netanel[2], D. Ouvrard[3], E. Zchori-Fein[2], S. Morin[1]
[1]The Hebrew University of Jerusalem - The Faculty of Agriculture, Entomology, Rehovot, Israel
[2]Newe Ya'ar Research Center- The Agricultural Research Organization, Entomology, Ramat Yishay, Israel
[3]Natural History Museum, Department of Life Sciences, London, United Kingdom

Backgrounds

Whiteflies (Hemiptera: Sternorrhyncha: Aleyrodidae) are small phloem feeding insects that include several agricultural pests. In contrast to other insects, whiteflies taxonomy is based on nymphal stages morphology. However, this stage shows phenotypic plasticity, which produces several inconsistencies at the genus level.
Whiteflies harbor specialized cells that host an obligatory/primary bacteria endosymbiont named *Candidatus* Portiera aleyrodidarum which complements the insect's diet. *Portiera* has been vertically transmitted since the divergence of whiteflies from their Psyllinea ancestor (*circa* 160 Mya), and therefore can reflect its host phylogeny. Also, *Portiera* from *Bemisia tabaci* lineage has lost the polymerase proofreading sub-unit (*dnaQ*) and presents an uncommon genome instability.

Objectives

Our main goal was to establish a phylogenetic framework based on several *Portiera*'s genes. This framework will be used to improve whiteflies classification and to trace the *dnaQ* loss and the rise of genomic instability.

Methods

A PCR screening with specific primers targeting five *Portiera* genes (*16S* and *23S* rRNA, *groEL*, *dnaK, rpoD* and *dnaQ*), plus some *Portiera* rearrangements, was performed on 22 whiteflies species (including *exsiccata* museum specimens). Phylogenetic methods were used for tree inference, divergence dating, species delimitation and ancestral node reconstruction of *dnaQ/*rearrangements (RaxML, BEAST2, bPTP and ape).

Conclusions

The use of *Portiera* sequences outperform the universal mitochondrial cytochrome oxidase subunit I (mtCOI) region as they show low signal saturation, avoid common misclassification of similar insects and can be used on parasitized samples. Therefore, it solves some problems/inconsistencies in current whiteflies phylogeny. The loss of *dnaQ* and the associated rearrangements are unique to the *Bemisia* genus.

MICROBIOME OF THE MAIZE RHIZOSPHERE CULTIVATED WITH ROCK PHOSPHATE BY CULTURE-DEPENDENT AND INDEPENDENT APPROACHES

V. Santos[1], U. Silva[1], D.R.C.D. Silva[1], L.F. Freitas Jr.[1], A.C. Fernandes[1], J.D. Medeiros[2], S.C. Orellana[2], C.A. Oliveira[3]
[1]Biological Sciences Institute, Microbiology, Belo Horizonte, Brazil
[2]Research Center René Rachou/FIOCRUZ, Group of Genomics and Computational Biology, Belo Horizonte, Brazil
[3]Embrapa Milho e Sorgo, Microbiology, Sete Lagoas, Brazil

Backgrounds

Maize (Zea mays L.) is a crop used worldwide. For its productivity is necessary use of high quantity of fertilizers. For greater agricultural sustainability, has been investigated use of rock phosphate (RP) of low reactivity together with microbial inoculants capable phosphorus (P) providing of these rocks. However, little is known about community of RP solubilizing microorganisms, specially, by culture-independent techniques.

Objectives

To access the microbial diversity on the maize rhizosphere cultivated in soil fertilized with RP, Triple superphosphate (TSP) or no P using new generation sequencing.

Methods

Amplicons of ribosomal markers (16S rRNA V3-V4 and ITS regions) were sequenced on Miseq Illumina platform and mapped against the Greengenes and Unite databases. For isolation of the PSB, it was used enrichment cultures using NBRIP broth supplemented with RP and added of rizhospheric soil from area fertilized with RP or no P fertilized as inoculum, followed selection on the NBRIP agar added calcium triphosphate.

Conclusions

Taxa related to P solubilization (PSB) were enriched in the soil RP added, including *Burkholderia* sp. and *Bacillus* sp., while *Klebsiella s*p. was enriched in the soil without P addition. For fungal community, mycorrhizal fungi predominated in the soil RP added, such as *Scutellospora* sp., *Racocetra* sp., *Acaulospora* sp. 32 strains of PSB were obtained in the enrichment culture, with predominance of *Klebsiella* in the RP soil. The strains 20 and 21 of this genus showed high RP and iron phosphate solubilization potential correlating with lower pH values. Some bacteria also showed capacity to produce siderophore and to antagonize phytopathogens.

TAXONOMIC AND FUNCTIONAL DIVERSITY OF THE BACTERIAL COMMUNITY ASSOCIATED TO THE LIQUID FRACTIONS OF AQUIFER CONTAMINATED WITH CREOSOTE THROUGH METATAXONOMIC ANALYZES.

V. Santos[1], A.D.L. Júlio[1], F.S. Castanon[1], U.D.C. Silva[1], J.M. Dutra[2], D.K. Morais[2], S.C. Orellana[2]
[1]Biological Sciences Institute, Microbiology, Belo Horizonte, Brazil
[2]Research Center René Rachou/FIOCRUZ-, Group of Genomics and Computational Biology, Belo Horizonte, Brazil

Backgrounds

Bioremediation has been considered a cost-effective and environmentally friendly method to remediate contaminated areas, as by creosote, which consists predominantly of Polycyclic Aromatic Hydrocarbons. However the efficiency of technique is dependent of knowledge of taxonomic and functional diversity of the microbiota on these sites.

Objectives

In this study, we used metataxonomic analyzes to characterize the bacterial community from samples of aquifer liquid fraction contaminated with creosote and to predict its catabolic potential.

Methods

Samples were collected from eight points with different levels of contamination in Espírito Santo State-Brazil. The DNA of the samples was extracted using the PowerWatter DNA Isolation Kit, and the 16S rRNA amplicons of bacterial ribosomal markers (16S rRNA V3-V4 regions) were sequenced on the IlluminaMiseq platform.

Conclusions

A negative correlation was observed between the alpha diversity of the samples and the concentration of the contaminants. At the phylum level, it was observed a predominance of Proteobacteria in all the samples, but others taxonomical levels varied widely. The most enriched taxa in the contaminated samples were the genera *Treponema, Geobacter, Bdellovibrio, Hydrocarboniphaga, Anaerolinea, Paulidibacter, Comamonas* and *Desulfomonille.* Regarding beta diversity, a group consisting of non-contaminated samples and a group formed by the majority of the highly-contaminated samples was formed, and a greater proportion of xenobiotic degradation pathways were observed in the contaminated samples. The data indicate the presence of microorganisms with catabolic potential in the area, which can be biostimulated *in situ* to accelerate the degradation of contaminants.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

DIVERSITY OF CULTURED BACTERIA FROM THE DEEP OCEAN

I. Sanz Sáez[1], *S. G. Acinas*[1], *O. Sánchez Martínez*[2]
[1]*Institut de Ciències del Mar - CSIC, Biologia Marina i Oceanografia, BARCELONA, Spain*
[2]*Universitat Autònoma de Barcelona. Facultat de Biociències,*
Departament de Genètica i Microbiologia, Barcelona, Spain

Backgrounds

Isolation of marine microorganisms is fundamental to infer their physiology, ecology and genome content. However, little effort has been invested to isolate microorganisms from the deep sea, and previous works have focused on the use of molecular methodologies or have been carried out at a local scale.

Objectives

To fill the existing gap concerning the research of microorganisms from the deep ocean using culture dependent techniques two main objectives were addressed: (i) to describe the identity and diversity of 1317 isolates retrieved from bathypelagic sea samples, and (ii) to compare the phylogenetic relationship of these deep ocean isolates with cultures obtained from photic waters of the same oceanographic locations.

Methods

We isolated 1259 bathypelagic isolates from the Mediterranean Sea (2000 m depth), and North and South Atlantic Ocean (4000 m depth) using different culture media to maximize the diversity retrieval. Additionally, a total of 1097 isolates were also isolated from photic waters from the same samples (NW Mediterranean, North and South Atlantic Ocean), as well as from Indian and Arctic Oceans for comparative analyses. The 16S rRNA gene was partially sequenced for a total of 1317 isolates (surface and deep) to infer their phylogenetic relationship.

Conclusions

The isolates retrieved from the deep ocean were mainly affiliated to the phylum Proteobacteria, (classes Alphaproteobacteria and Gammaproteobacteria), and Bacteroidetes. A large proportion (54.6%) of the deep isolates sequences were 100% identical to sequences of previous identified photic isolates, highlighting the cosmopolitan nature of these bacteria in the whole water column. In addition, two isolates, related to the genera *Teredinibacter* sp. and *Mesonia* sp. may represent new potential genera.

MICROBIAL DIVERSITY IN HEAVY METAL POLLUTED SOILS ASSESED VIA CULTURE-DEPENDENT APPROACH

G. Satchanska[1], A. Doicheva[1], V. Groudeva[2], E. Golovinsky[3]
[1]New Bulgarian University, Natural Sciences, Sofia, Bulgaria
[2]Sofia University, Faculty of Biology, Sofia, Bulgaria
[3]Institute of Molecular Biology-Bulgarian Academy of Sciences, Biochemical pharmacology and molecular design, Sofia, Bulgaria

Backgrounds

Heavy metal polluted soils represent one of the most severe environmental problems. Metal ions as Hg^{2+}, Cd^{2+}, Ag^{+}, Cu+, Zn^{2+} and Pb^{2+} form strong toxic complexes in the biological cells, bind to enzymes and erythrocytes, disrupt the cell membrane and are responsible for genotoxic effects. Bacteria are highly sensitive and adaptive to pollutants organisms and could serve as reliable biomarker for environmental contamination.

Objectives

Shifting of the microbial community structure was detected in three metal-polluted soils collected near the Pb-Zn smelter KCM and pesticide enterprise AGRIA, Bulgaria. Due to new waste water treatment plant functioning the environmental pollution was significantly decreased.

Methods

CFU of heterotrophic aerobs, heterophic anaerobs, sporeforming bacteria, denitrifying bacteria, amonifying bacteria, nitrifying bacteria, Fe(II)-oxidizing bacteria, Mn(II)-oxidizing bacteria, Fe(III)-redicing bacteria, Mn(IV)-reducing bacteria, colourless sulphur bacteria, cellulose degradating bacteria, oligocarbophiles, actinomicetes and fungi were assessed *via* culturing on selective media. Presence of metal-leaching bacteria as *A. thiooxidans*, *A. ferrooxidans*, *A. denitrificans*, A. *thioparus* was analyzed as well. Twenty novel indigenous soil bacterial isolates were cultured. Most of them showed metal resistance.

Conclusions

Microbial community structure in two of investigated soil samples was affected due to heavy metal and pesticide pollution. Our results demonstrated the nitrifying and denitrifying bacteria as well as actinomycetes and fungi were not detected in two out of three samples. Absence of above mentioned bacterial groups resulted in abundance of other groups as heterotrophic and sporeforming bacteria. Microbial community responded to long-term heavy metal- and pesticide contamination through changes in its structure and selection of metal resistant bacteria.

SACA LA LENGUA: A STUDY OF THE HUMAN MOUTH MICROBIOME

L. Cozzuto[1,2], J. Willis[1,2], M. Alloza[1,2], N. Andreu Somavilla[1,2], C. Company[1,2], A. Hermoso Pulido[1,2], A. Pittis[1,2], E. Ksiezopolska[1,2], S. Iraola[1,2], E. Saus[1,2], H. Onywera[1,3], C. Carolis[1,2], J. Hecht[1,2], J. Ponomarenko[1,2], T. Gabaldón[1,2]
[1]Centre for Genomic Regulation CRG, Bioinformatics and Genomics, Barcelona, Spain
[2]Universitat Pompeu Fabra, UPF, Barcelona, Spain
[3]Institute of Infectious Disease and Molecular Medicine IDM, University of Cape Town UCT, Cape Town, South Africa

Backgrounds

High-throughput DNA sequencing continues to offer comprehensive insights into microbial ecosystems and we utilize this technology here to explore human oral microbiome of about 1500 teenagers throughout Spain in the citizen's science project "Saca La Lengua". Several bioinformatics tools have been inconclusively benchmarked, yet variations in algorithms are known to impact the microbiome results.

Objectives

First, we aimed to validate 16S rRNA sequencing and four bioinformatics tools for microbiome analyses. Then, we applied this technology to explore the oral microbiome of Spanish students around age 15 and analyze it alongside survey data regarding daily habits, hygiene, diet, location and others.

Methods

Genomic DNA from two microbial mock communities was sequenced by shotgun and V3-V4 16S rRNA sequencing. Four bioinformatics tools for 16S rRNA analysis – mothur, QIIME, QUPARSE and riboPicker – were set up and tested. 1582 "Saca La Lengua" samples were collected, and data obtained by 16S sequencing was processed with the mothur pipeline. Collected survey data provided by each individual and metadata associated with each sample was used to perform correlative analyses with the sample counts.

Conclusions

Species abundances were significantly different between 16S and WGS approaches, although genera distributions by most tools were similar to the 16S mapping data. Overall, mothur performed better than the other three bioinformatics tools tested. In "Saca La Lengua" samples, *Streptococcus* was generally the most abundant genus, while several correlations were found between samples and survey, as well as within samples, indicating numerous factors influencing the growth of many genera.

METAGENOMIC ANALYSIS OF HOT SPRINGS IN CENTRAL INDIA REVEALS HYDROCARBON DEGRADING THERMOPHILES

R. Saxena[1], D.B. Dhakan[1], P. Mittal[1], P. Waiker[1], A. Chowdhury[2], A. Ghatak[2], V.K. Sharma[1]
[1]Indian Institute of Science Education and Research, Department of Biological Sciences, Bhopal, India
[2]Indian Institute of Science Education and Research,
Department of Earth and Environmental Sciences, Bhopal, India

Backgrounds

Extreme ecosystems such as hot springs are of great interest as a source of novel extremophilic species, enzymes and biotechnological products. India harbors hundreds of hot springs, the majority of which are not yet explored and require comprehensive studies to unravel their unknown phylogenetic and functional diversity.

Objectives

The aim of this study was to perform a large-scale metagenomic analysis of three major hot springs located in central India namely, Badi Anhoni, Chhoti Anhoni and Tattapani, to uncover their resident microbial community and functional traits.

Methods

Water samples were collected from seven distinct sites of the three hot spring locations with temperature ranging from 43.5-98°C. 16S rRNA gene amplicon sequencing of V3 hypervariable region and shotgun metagenome sequencing was carried out.

Conclusions

Taxonomic and functional analysis revealed hydrocarbon degradation and methane metabolism pathways to be abundant in the Anhoni hot springs (43.5-55 °C), dominated by *Methylococcus capsulatus*, *Pseudomonas stutzeri* and *Acidovorax* sp., suggesting the presence of a chemoorganotrophic thermophilic community at Anhoni. The Tattapani hot spring with a high-temperature range (61.5-98 °C) displayed a lower microbial diversity, and was primarily dominated by a nitrate-reducing archaeal species *Pyrobaculum aerophilum*. A higher abundance of cell metabolism pathways essential for the microbial survival in extreme conditions was observed at Tattapani. A novel consortium of microbes, genes and pathways associated with the prominent hot springs of India having potential applications in biotechnology and bioremediation were revealed. The main results of this study will be presented.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

IDENTIFICATION OF THOUSANDS OF CONSERVED SMALL PROTEINS WIDESPREAD IN MICROBIAL METAGENOMES

H. Sberro Livnat[1], *A. Bhatt*[1]
[1]*Stanford University, Genetics and Medicine, Palo Alto, USA*

Backgrounds

Small bacterial proteins (<=50 aa) have traditionally been overlooked due to the difficulty of distinguishing proteins encoding open reading frames (ORFs) from those occurring by chance. However, the few examples that have been characterized, indicate that small proteins play important roles in bacterial physiology, including morphogenesis, cell division, transport, enzymatic activities and more.

Objectives

Here, we took advantage of the growing wealth of metagenomic data to systematically detect small ORF (sORFs) within hundreds of metagenomic samples originating from diverse metazoan hosts as well as environmental samples.

Methods

For each metagenome, sORFs were recovered using *ab initio* gene finding algorithms with adjusted parameters. Clustering of these sORFs based on sequence similarity revealed families that are conserved and widespread in microbial metagenomes.

Conclusions

Our analyses, while retrieving some of the well-characterized small proteins including lineage specific proteins such as SpoVM, SgrT, AcrZ, CydX, PmrR, Blr, MntS, KdpF and others that are found in diverse lineages, such as small ribosomal proteins, have also exposed **thousands of yet unknown conserved sORFs**. Within this set, we could identify ~100 putative secreted protein families and ~2000 putative transmembrane families, possibly representing novel mediators between bacteria and their environment. Furthermore, we discriminate between sORF families that are enriched in host-associated metagenomes and those that are also found in environmental microbes. Whereas proteins in the first group may be important for adaptation of bacteria to life within a metazoan host, short proteins that are found in diverse ecological niches are more likely to display ‘house-keeping’ roles.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

EFFECT OF MULTIPLICITY OF INFECTION, TEMPERATURE AND PH ON THE ACTIVITY OF ISOLATED PSEUDOMONAS AERUGINOSA BACTERIOPHAGES

G. Scarascia[1], S. Yap[1], P. Hong[1]
[1]King Abdullah University of Science & Technology KAUST,
Biological and Environmental Science and Engineering, Thuwal Jeddah, Saudi Arabia

Backgrounds

Pseudomonas aeruginosa is a thiosulfate-reducing bacteria ubiquitous in the marine environment. Their presence is often associated with membrane biofouling and biocorrosion in desalination process. Chlorine is commonly used as biocide against *P. aeruginosa* but would require sodium metabisulfite to neutralize residual content. High sulfate content in seawater, coupled with the addition of metabisulfite can further select for *P. aeruginosa* and/or other sulfate-reducers. Bacteriophage treatment can be used to complement current biocidal strategies.

Objectives

This study aims to assess the optimal conditions (i.e., multiplicity of infection (MOI), temperature, pH) for phage treatment against *P. aeruginosa*.

Methods

Optical density of the *P. aeruginosa* cultures was monitored over 24 h in presence of isolated bacteriophages. UF membranes were retrofitted into drip flow reactors, and seawater biofilm was allowed to develop on the membranes prior to phage application.

Conclusions

In co-culture with phages, *P. aeruginosa* growth was characterized by an initial lag phase followed by growth. Non-infected cultures were characterized by a lag-phase of between 0 and 2h; the lag-phase in presence of phage at MOI of 10 and 1 was 10h and 7h, respectively. A MOI of 0.1 achieved lag phase of 3h but the growth rate was significantly lower than that observed at MOI 10 and 1 (p<0.0001).
The growth rates of non-infected cultures were very similar over the range of temperature (25-45°C). However, the presence of phage resulted in a reduced growth rate at 25°C compared to 30°C and 37 °C (p<0.0001), suggesting that *P. aeruginosa* is more sensitive to low temperature upon bacteriophages exposure. Similarly, phage treatment of biofilm at 25°C showed stronger reduction of CFU compared to the control and to the other temperatures (p<0.0001).
All bacteriophages exhibited similar lytic effect over pH 5.0-8.0, revealing that their application can be coupled with conventional biocides or cleaning strategies.

DETECTING TOXIC CYANOBACTERIA IN BRAZILIAN FRESHWATER RESERVOIRS USING NEW PIGMENT/CHLOROPHYLL A RATIOS

L. Schlüter[1], G.S. David[2], N.O.G. Jørgensen[3], R. Podduturi[3]
[1]DHI, Environment & Toxicology, Hørsholm, Denmark
[2]São Paulo State Agribusiness Agency, APTA, Jau, Brazil
[3]University of Copenhagen,
Section of Microbial Ecology and Biotechnology- Department of Plant and Environmental Sciences, Copenhagen, Denmark

Backgrounds

Intensified use of water bodies and reservoirs for e.g., aquaculture increases the need for monitoring and early warning of toxins from cyanobacteria, and simple analytical monitoring methods, which can determine this risk, are crucial.

Objectives

The content of pigments and the toxic microcystins of different strains of cyanobacteria at three different light intensities and at stationary growth was investigated to determine if pigment analyses can be used for determining presence of toxic cyanobacteria in reservoirs.

Methods

The pigments and microcystins were analysed by HPLC. The pigment/chlorophyll (Chl) *a* ratios were tested using the CHEMTAX software to calculate the biomass of phytoplankton groups in samples from four sampling periods in five Brazilian reservoirs.

Conclusions

Various different carotenoids characteristic for cyanobacteria were detected in the cultures: two different myxoxanthophylls (myxol glucosides), echinenone, canthaxanthin, β-cryptoxanthin, oscillaxanthin, aphanizophyll, nostoxanthin, caloxanthin, as well as zeaxanthin and β-carotene. The diagnostic pigments, echinenone and myxoxanthophyll, were commonly present in the cultured cyanobacteria and in the reservoirs. The presence of two types of cyanobacteria in the reservoirs were determined from the pigment concentrations and ratios between the pigments: filamentous/colony forming cyanobacteria with echinenone and myxoxanthophyll, and coccoid/pico-sized cyanobacteria with zeaxanthin only. New pigment/Chl *a* ratios were used to calculate the biomass of toxic cyanobacteria as well as other phytoplankton groups. The concentrations of microcystins were significantly correlated to the Chl *a* concentrations of cyanobacteria, and indicated that pigment analysis by HPLC can be used as early warning for detecting microcystin-producing cyanobacteria in the Brazilian reservoirs investigated.

THE CRISPR-CAS GENE CLUSTER IN BURKHOLDERIA GLUMAE STRAIN PG1 IS IN PART CONTROLLED BY ITS THREE N-ACYL-HOMOSERINE-LACTONE QUORUM-SENSING SIGNALS

C. Schmeisser[1], *G. Stiebelehner*[1], *W.R. Streit*[1]
[1]*Biocenter Klein Flottbek, Microbiology and Biotechnology, Hamburg, Germany*

Backgrounds

Burkholderia glumae PG1 (BG1) is a soil-associated motile plant pathogenic bacterium. Recently we have established the genome sequence of this organism. BG1 encodes a CRISPR-cas gene cluster of the F-I (Yersinia pestis) subytpe. Using RNA-seq we observed that the expression of the cas/csy genes is regulated in a quorum sensing-dependent manner. Thereby it is notably that BG1 codes for three autoinducer (AI) synthases (bgal1-bgal3), which are all involved in the synthesis of N-acyl-homoserine-lactones (AHLs) with varying chain length. This is an unusual feature within the species *B. glumae*, since the genomes of all other currently sequenced strains contain only a single AHL synthase gene. Mutations in each of the three loci resulted in the up to 10-fold reduced expressions of the respective cas/csy genes on a population wide level.

Objectives

Our aim is to identify the role of CRISPR-cas in BG1 besides its obvious role for immunity. Further we are interested in identifying the key regulators involved in this QS-dependent response and the level of AI dependence. Finally, we are searching for a possible link between the CRISPR-cas gene expression and the interaction with the host plant.

Methods

To reach our aims we used RNA seq, qRT-PCR and promoter fusion approaches.

Conclusions

The work demonstrated that quorum sensing in BG1 affects CRISPR-cas gene regulation. It also provides evidence that the cas gene expression depends on the presence of oxo-C_8 AHL and is less effected by oxo-C_{10} and oxo-C_{12} AHL. This indicates a complex mode of regulation.

[2]The University of Queensland,
Australian Centre for Ecogenomics- School of Chemistry and Molecular Biosciences, St Lucia, Australia
[3]The University of Queensland, School of Veterinary Science, Gatton, Australia
[4]Queensland Government, Agriscience Queensland- Department of Agriculture and Fisheries, Dutton Park, Australia
[5]The University of Queensland, School of Agriculture and Foods Sciences, Gatton, Australia

Backgrounds

The probiotic *Bacillus amyloliquefaciens* strain H57 increased weight gain, feed intake and nitrogen retention when fed to pregnant Dorper ewes.

Objectives

We undertook a metagenomic and metatranscriptomic analysis of the rumen microbiome to elucidate possible mechanisms for the probiotic response.

Methods

The relative dominance of particular population genomes, assembled from the rumen metagenome, differed between the Control sheep and those fed H57. For the Control sheep, a *Prevotella sp.* (SR_c51) and a *Succinivibrionaceae sp.* (SR_c46) were dominant, while in the H57 fed sheep it was two *Prevotella* spp. (SR_t35 and SR_t60) that dominated. A gene-centric analysis of the transcripts that mapped to population genomes in both Control and H57 fed sheep showed the population genomes clustered into functional guilds that were based on taxonomy. A number of gene families involved with the degradation of hemicellulose were significantly more abundant in the metatranscriptomes of H57 fed sheep. Mapping the reads associated with these gene families to the population genomes showed that *Lachnobacterium sp.* (SR_t49), *Prevotella sp.* (SR_t35) and *Prevotella sp.* (SR_t60) were the populations most responsible for expression of genes associated with hemicellulose degradation in the H57-fed rumen microbiome.

Conclusions

B. amyloliquefaciens H57 fed to sheep elicited a shift in the dominant rumen microbiome towards populations expressing a greater abundance of genes associated with hemicellulose degradation. Such an increased ability to digest plant cell wall components may support the increased weight gain observed in the H57 fed sheep. Supported by ARC Linkage Grant with Ridley AgriProducts.

ROLE OF TYPE II SECRETION/TYPE IV PILUS ASSEMBLY COMPLEXES IN SELF-SUPPRESSION OF CYANOBACTERIAL BIOFILM DEVELOPMENT

R. Schwarz[1], E. Nagar[1], R. Parnasa[1], Y. Yegorov[1], Z. Reich[2], S. Zaidman[3], R. Simkovsky[4], S. Golden[4], E. Sendersky[1]
[1]Bar-Ilan University, Faculty of Life Sciences, Ramat Gan, Israel
[2]Weizmann institute of Science, Department of Biological Chemistry, Rehovot, Israel
[3]Weizmann institute of Science, Electron Microscopy Unit, Rehovot, Israel
[4]University of California, Division of Biological Sciences, San Diego, USA

Backgrounds

Information on the molecular mechanisms underlying biofilm formation in cyanobacteria is scarce in spite of their environmental prevalence and the economic loss associated with these microbial assemblages. We revealed a self-suppression mechanism that prevents biofilm development in the cyanobacterium *Synechococcus elongatus*.

Objectives

Characterization of the role of type II/type IV secretion systems in the self-suppression mechanism of cyanobacterial biofilm development.

Methods

Genetic, mutational, electron microscopy and physiological approaches.

Conclusions

We demonstrated that the planktonic nature of the cyanobacterium *Synechococcus elongatus* is a result of a self-inhibition mechanism, which depends on the deposition of factor(s) to the extracellular milieu. These extracellular inhibitory substances govern expression of small secreted proteins that enable biofilm development. Inactivation of a gene encoding a homolog of the ATPase subunit of type II protein secretion or type IV pilus assembly systems impairs the inhibitory process and results in biofilm formation (1-3). Additionally, the RNA-chaperone homolog, Hfq, and a highly conserved cyanobacterial protein, thus far annotated as hypothetical, are essential for the biofilm inhibitory mechanism. Furthermore, inactivation of either one of the genes encoding these proteins, results in aberrant protein secretion and absence of pili, suggesting involvement of the Hfq-homolog and the "hypothetical protein" in modulation of type II/type IV complexes. Localization of these modulators to the photosynthetic membranes implies a new mode of regulation of type II/Type IV systems in cyanobacterial cells.

MICROBIAL COMMUNITIES OF HEAVY OIL RESERVOIRS

E. Semenova[1], D. Sokolova[1], T. Babich[1], I. Borzenkov[1], A. Ershov[1], T. Tourova[1], A. Poltaraus[2], T. Nazina[1]
[1]Winogradsky Institute of Microbiology- Research Center of Biotechnology RAS, Laboratory of Petroleum Microbiology, Moscow, Russia
[2]Engelhardt Institute of Molecular Biology- RAS, Laboratory of structural and functional genomics, Moscow, Russia

Backgrounds

In many oil-producing countries, deposits of light conditional oil have already exhausted, so it is important to develop technology of heavy oil (with a density greater than 0.92 g/cm^3) recovery. Geological reserves of heavy and high-viscosity oil in Russia reached 6–7 billion tons, but their extraction requires expensive technologies. Biological effect on heavy oil is selective for specific reactions, improving its characteristics, and may represent an alternative approach for additional oil recovery. Currently, information on the microorganisms inhabiting of heavy oil reservoirs remains fragmented.

Objectives

The goal of the work is determination of functional and phylogenetic diversity of microorganisms in heavy oil reservoirs and their biotechnological potential for enhancement of heavy oil recovery.

Methods

Microbial community composition of formation water samples from heavy oil reservoirs (Russian Federation) was studied by radioisotope and culture-based techniques, by high-throughput sequencing of the 16S rRNA genes and DGGE analyses of *mcrA* genes of methanogens.

Conclusions

It was revealed that in oilfields exploited without water-flooding microbial populations were scarce, while microbial numbers in water-flooded oilfields were as high as 10^6 cells/mL. The rates of sulfate reduction and methanogenesis were low. The library of 16S rRNA genes included sequences of bacteria *Acinetobacter*, *Pseudomonas, Dechloromonas* and *Rhodococcus* genera and of methanogenic archaea. Members of genera *Acinetobacter*, *Pseudomonas*, *Bacillus* and *Gordonia*, capable of biosurfactant production, were isolated from formation waters. Aerobic organotrophic and anaerobic fermentative bacteria, revealed in oil reservoir, produce biomass and metabolites (volatile acids and alcohols) having the oil-displacing properties.

This work was supported by Russian Science Foundation, grant no. 16-14-00028.

SMALL SECRETED PROTEINS ENABLE BIOFILM DEVELOPMENT IN THE CYANOBACTERIUM SYNECHOCOCCUS ELONGATUS

E. Sendersky[1], R. Parnasa[1], E. Nagar[1], Z. Reich[2], R. Simkovsky[3], S. Golden[3], R. Schwarz[1]
[1]Bar-Ilan University, Faculty of Life Sciences, Ramat Gan, Israel
[2]Weizmann Institute of Science, Department of biomolecular sciences, Rehovot, Israel
[3]University of California, Division of Biological Sciences, San Diego, USA

Backgrounds

Small proteins characterized by a double-glycine (GG) secretion motif, typical of secreted bacterial antibiotics, are encoded by the genomes of diverse cyanobacteria, but their functions have not been investigated to date.

Objectives

Using a biofilm-forming mutant of *Synechococcus elongatus* PCC 7942 and a mutational approach, we demonstrate the involvement of four small secreted proteins and their GG-secretion motifs in biofilm development. These proteins are denoted EbfG1-4 (enable biofilm formation with a GG-motif). Furthermore, the conserved cysteine of the peptidase domain of the Synpcc7942_1133 gene product (dubbed PteB for peptidase transporter essential for biofilm) is crucial for biofilm development and is required for efficient secretion of the GG-motif containing proteins. Transcriptional profiling of *ebfG*1-4 indicated elevated transcript levels in the biofilm-forming mutant compared to wild type (WT). However, these transcripts decreased, acutely but transiently, when the mutant was cultured in extracellular fluids from a WT culture, and biofilm formation was inhibited.

Methods

mutational approach

Conclusions

We propose that WT cells secrete inhibitor(s) that suppress transcription of *ebfG*1-4, whereas secretion of the inhibitor(s) is impaired in the biofilm-forming mutant, leading to synthesis and secretion of EbfG1-4 and supporting the formation of biofilms.

APPLICATION OF NANOSTRING NCOUNTER TECHNOLOGY FOR MEASURING BACTERIAL POPULATION DIVERSITY

Z.J. Seng[1], Y.Y. Cheng[1], J.K.H. Yam[1], L. Yang[1]
[1]Singapore Centre for Environmental Life Sciences Engineering SCELSE,
Singapore Centre for Environmental Life Sciences Engineering SCELSE, Singapore, Singapore

Backgrounds

Rapid measurement of microbial population diversity and dynamics remains to be a challenge for microbial ecology investigations. Classic approaches such as the cultivation-based assays and Fluorescence In Situ Hybridization (FISH) were generally low throughput. 16S rRNA gene amplicon sequencing is widely used for studying microbial population diversity, while it is known for the generation of PCR bias. The nCounter technology has been developed by NanoString to detect unique signal from complex hybridized samples at single molecular level without the need of PCR amplification.

Objectives

To customized nCounter array to measure the 16S rRNA genes of artificial microbial community.

Methods

Total RNAs of different bacterial species has been mixed together by different proportions in three different groups before nCounter analysis. Our results showed that the 16S rRNA read detected from each bacterial species by nCounter analysis correlates well with each species' actual total RNA added to the pool during grouping. The variation in the percentage analysis might due to the fact the total RNA from each bacterial species contains different amounts of 16S rRNA after extraction.

Conclusions

In summary, we conclude that the nCounter technology will be a useful tool for rapid and sensitive analysis of microbial diversity and dynamics based on the 16S rRNA gene.

PSEUDOMONAS AERUGINOSA PSL EXOPOLYSACCHARIDE INTERACTS WITH THE ANTIMICROBIAL PEPTIDE LG21 AND ATTENUATES ITS EFFECT

S.F. Chin[1], S. Sinha[2], S. Bhattacharjya[2], L. Yang[1]
[1]Nanyang Technological University,
Singapore Centre for Environmental Life Sciences Engineering SCELSE, Singapore, Singapore
[2]Nanyang Technological University, School of Biological Science SBS, Singapore, Singapore

Backgrounds

Biofilm formation by opportunistic pathogens serves as one of the major causes of chronic and persist infections. Bacterial cells in the biofilms are embedded in their self-generated protective extracellular polymeric substances (EPS), which include exopolysaccharides, large adhesin proteins and extracellular DNA.

Objectives

In this study, we identified an antimicrobial peptide (AMPs), LG21 that is able to interact specifically with the Psl exopolysaccharide of *Pseudomonas aeruginosa*. Psl reduces the antimicrobial efficacy of LG21 against *P. aeruginosa*. Psl also attenuates the pyoverdine synthesis inhibitory effects of LG21 on the Psl-overproducing *P. aeruginosa* variants.

Methods

Confocal laser scanning microscope was used to screen for the binding of rhodamine-tagged LG21. Rhodamine-tagged LG21 that were able to bind to *PAO1* biofilms but not *ΔpslBCD* biofilms were identified and used for further characterization.

The target binding of the LG21 was further confirmed by NMR studies, via performing a series of one-dimensional H NMR experiments on crude extracted psl and pel with the AMPs.

A dose dependent study of LG21 on the pyoverdine synthesis of psl-over producing strain (Δ*wspF)* and psl knock-out *(ΔwspFΔpslBCD)* strain were performed. Δ*wspF*Δ*pslBCD* lost the capacity to counter interact with LG21 and addition of LG21 to its cultures reduced significantly more pyoverdine synthesis compared to the *ΔwspF* cultures.

Conclusions

Our study suggests that biofilm EPS components might be able to modulate the host innate immune response via interacting with the AMPs.

CO-CULTURING OF FUNGAL STRAINS WITH THE PHYTOPATHOGEN BOTRYTIS CINEREA INDUCES THE PRODUCTION OF CHEMICAL DIVERSITY, WITH APPLICATION AS AGROCHEMICAL AND THERAPEUTIC AGENTS

R. Serrano[1], V. González-Menéndez[1], L. Rodríguez[2], J. Martin[3], J.R. Tormo[3], O. Genilloud[1]
[1]Fundacion MEDINA, Microbiology, Granada, Spain
[2]Fundacion MEDINA, Screening, Granada, Spain
[3]Fundacion MEDINA, Chemistry, Granada, Spain

Backgrounds

Microorganisms are a potential source of secondary metabolites (SMs), but frequently they are not expressed under standard laboratory conditions. Co-culturing of fungi has proved to be an efficient tool to simulate interactions between different microorganisms that may occur in their natural environment and can induce new bioactive molecules.

Objectives

Co-culturing study on the induction of new SMs in fungal strains related to ecological niches of the phytopathogen fungus *B. cinerea*, and evaluation of the activities against a panel of pathogens and their cytotoxicity profile.

Methods

We selected *Botrytis cinerea* as a model to be confronted to a large set of fungal strains (762) by using a co-culturing methodology on agar media. A collection of extracts was obtained from the antagonistic fungal interactions zones with potential of containing new bioactive molecules. The antifungal active extracts, obtained from the fungal interaction with *B. cinerea*, was also screened against a panel of three additional important phytopathogens (*Colletotrichum acutatum*, *Fusarium proliferatum* and *Magnaporthe grisea*) and two relevant human pathogens (*Candida albicans* and *Aspergillus fumigatus*). Their cytotoxicity was also evaluated against the human hepatocellular carcinoma cell line (HepG2) and the parasitic cell line (SF9). We compared by LC-HRMS the chemical profiles of 93 relevant co-culture antifungal extracts with their corresponding axenic control extracts and identified a wide variety of induced molecules including both, known and novel compounds.

Conclusions

Fungal co-culturing has permitted to induce different microbial interactions that generated new chemical diversity, setting up a methodology with wide potential both in drug discovery and crop protection.

QUORUM QUENCHING BACTERIA ISOLATED FROM MBR PLANTS TREATING LEACHATE FROM SOLID RESIDUES IN SPAIN

S. Serrano[1], A. Soler[1], L. Arregui[1], D. Marquina[1], C. Álvarez-Requena[2], F. Muñagorri[2], C. García-Vera[2], A. Santos[1]
[1]Universidad Complutense de Madrid, Microbiología III, Madrid, Spain
[2]URBASER S.A., Área de Proyectos I+D+i, Madrid, Spain

Backgrounds

Quorum sensing (QS) is a mechanism dependent on bacterial density. This coordinated process is mediated by the synthesis and secretion of signal molecules called autoinducers (AIs). *N*-acyl-homoserine lactones (AHLs) are the most common AIs used by Gram-negative bacteria and are involved in biofilm formation. Quorum quenching (QQ) is the interference of QS by producing hydrolyzing enzymes, among others strategies.

Objectives

The main objective of the present study is to identify QS and QQ strains from MBR Wastewater Treatment Plants.

Methods

Plausible biofouling strains have been determined by their adhesion capability (Crystal Violet method) using AHL biosensor strains (*Chromobacterium violaceum* CV026 and *Agrobacterium tumefaciens* NT1). A total of 91 strains had been isolated from two MBR plants treating solid residues. Twenty isolates of Gram-negative strains were tested, four of them were classified as strongly adherent and one as moderately adherent. The QQ potential of 71 isolates of Gram-positive strains has been studied, showing that 15 of them could reduce at least one AHL activity. The analysis of 16S rRNA gene sequence showed the relevance of the genus *Bacillus* in the disruption of QS mechanism and the relevance of the *Pseudomonas* and *Aeromonas* genera in the production of biofilms.

Conclusions

The studies about the ability of QQ-bacteria in MBR systems intended to treat leachate from municipal solid waste are scarce, so this study could contribute to solve biofouling problems, in order to increase the useful lifespan of the membranes, minimizing operational costs.

MULTI-DRUG RESISTANT ACINETOBACTER BAUMANNII FROM HOSPITAL WASTEWATER OF ZAGREB, CROATIA

M. Seruga Music[1], J. Hrenovic[1], D. Skoric[1], I. Goic-Barisic[2], B. Hunjak[3], S. Kazazic[4], T. Ivankovic[1]
[1]University of Zagreb, Department of Biology, Zagreb, Croatia
[2]University Hospital Centre Split and University of Split School of Medicine, Department of Clinical Microbiology, Split, Croatia
[3]Croatian Institute of Public Health, Croatian Institute of Public Health, Zagreb, Croatia
[4]Ruđer Boskovic Institute, Division of Physical Chemistry, Zagreb, Croatia

Backgrounds

Acinetobacter baumannii is well known emerging hospital pathogen of the 21st century. Multi-drug resistant (MDR) *A. baumannii* are found in untreated as well as in chemically treated hospital wastewaters. However, there is no clear evidence about their origin.

Objectives

The aim of this study was to screen the hospital wastewater for the presence of viable *A. baumannii* and to find the correlation between recovered wastewater and clinical isolates.

Methods

The sampling of the hospital wastewater was done at the central manhole of the Special Hospital for Pulmonary Diseases in Zagreb, Croatia. The clinical isolate was recovered on the exact date from bronchial aspirate of patient hospital. The isolation of *A. baumannii* was performed on CHROMagar Acinetobacter supplemented after incubation at 42°C/48h.

One clinical and six isolates from hospital wastewater gave reliable MALDI-TOF MS score values ranging from 2.021-2.271 confirming the identity of *A. baumannii* colonies. All isolates were MDR and shared the resistance to carbapenems and fluoroquinolones, but sensitivity to colistin. MLST analysis following Oxford scheme revealed that all isolates belong to the ST-195 clustering into the CC92 within the IC2.

Conclusions

This study confirmed the occurrence of viable MDR *A. baumannii* in hospital wastewater in Zagreb. Close relatedness of isolates from hospital wastewater with the clinical isolates from the same hospital in the period of monitoring suggests the possible origin of recovered wastewater *A. baumannii.* This finding confirms the need for proper treatment and disposal of untreated hospital wastewaters in order to prevent the spread of MDR *A. baumannii* in nature.

MICROBIAL DIVERSITY OF TWO HOT SPRINGS IN PORTUGAL

A. Polónia[1], R. Severino[1], L. Albuquerque[2], H. Froufe[1], C. Egas[1], M. da Costa[2]
[1]Biocant- Biotechnology Innovation Center, Next Generation Sequencing Unit, Cantanhede, Portugal
[2]University of Coimbra, Center for Neuroscience and Cell Biology, Coimbra, Portugal

Backgrounds

The microbial diversity of hydrothermal areas has been constrained by the lack of extensive studies of the combined examination of the culture-dependent and culture-independent methods.

Objectives

In this respect we have begun an extensive study of the biodiversity of hydrothermal areas in Portugal, which reach vent temperatures of nearly 80ºC.

Methods

The biodiversity of two hot springs at S. Pedro do Sul and Chaves were examined using culture-independent methods – metagenome sequencing and analysis; and culture-dependent methods – cultivation and 16S rRNA gene sequence analysis.

Conclusions

Metagenome analysis at S. Pedro do Sul, with water temperature of 63ºC and pH 8.9, revealed the presence of primarily *Hydrogenothermaceae*, *Nitrospirales*, *Anaerolineae*. Eighty-seven isolates were recovered at random and identified by 16S rRNA gene sequence analysis as belonging to the genus *Thermus*, *Meiothermus*, *Rubrobacter*, *Geobacillus* and *Anoxybacillus*. The hot spring at Chaves comprises two boreholes with water temperatures of 65ºC and 76ºC. Metagenome analysis of the combined boreholes had a large predominance of bacteria of the genus *Thermus*, *Thermodesulfovibrionaceae*, *Aquificaceae* and *Thermodesulfobacteriaceae*. The archaea detected were primarily *Crenarchaeota*, unassigned Archaea and a few *Euryarchaeta*. The preliminary identification of the isolates indicates that they belong to the genus *Geobacillus*, *Thermus* and *Meiothermus*. The diversity both in terms of cultivation and in situ examination of the 16S rRNA gene sequence analysis indicates large difference in the prokaryotic communities. The reason for these differences is unknown, but may be related to the levels of reduced sulfur compounds, namely hydrogen sulfide, in the water vented at Chaves.

ASSESSMENT OF BIO-FERTILIZER POTENTIAL OF PSEUDOMONAS AURANTIACA ISOLATES AND ANALYSIS OF THEIR ANTI-MICROBIAL METABOLITES

I. Shahid[1], M. Rizwan[2], D. Noreen Baig[1], K. Abdulla Malik[1], S. Mehnaz[1]
[1]Forman Christian College a Chartered University, Biological Science Department, Lahore, Pakistan
[2]Applied Chemistry Research Centre- Pakistan Council of Scientific and Industrial Research PCSIR- L ahore 54600- Pakistan, Applied Chemistry Research Centre, Lahore, Pakistan

Backgrounds

Green revolution introduced heavy use of chemical fertilizers and pesticides which are threatening environmental and public health. These threats and increased antibiotic resistance of pathogens pushed microbiologists to explore new microbial sources as potential antagonists.

Objectives

In this study, eight strains of *Pseudomonas aurantiaca* were evaluated *in vitro* as potential antifungals against phyto-pathogens of rice, chickpea and sugarcane.

Methods

P. aurantiaca strains were isolated from cotton, cactus and para grass and compared with reference *P. aurantiaca* PB-St2 (sugarcane) strain. Antifungal activity of these strains was determined by agar diffusion method based on inhibition of mycelial growth. On average, all strains exhibited 0.8 cm inhibition zones against the causal agents of root rot, seedling blight, red and stem rot. All secondary metabolites were isolated by the use of solvent partitioning and subjected to LC/ESI/MS for confirmation of compounds.

Conclusions

The ESI-mass spectra obtained were used to characterize the surfactants ionization behavior and $[M + H]^+$ and $[M + Na]^+$ ions were monitored for phenazines, lahorenoic acids and cyclic lipopeptide (WLIP). This study demonstrated the production of WLIP and Lahorenoic acid A for the first time from *Pseudomonas chlororaphis.* Production of extracellular enzymes such as cellulase, protease, phosphatase, and lipase were also detected. In addition, these strains were screened for indole-3-acetic acid, HCN, siderophore production and for zinc solubilization. Plant experiments were conducted on wheat and showed considerable increase in shoots and root weight. Our results support that based on their antifungal metabolites and plant growth promoting traits, these strains can be helpful as biofertilizer.

ARE THE EFFECTS OF BIOINOCULANTS RELATED TO THEIR PERSISTENCE IN RHIZOSPHERE?- A CASE STUDY WITH CAJANUS CAJAN

R. Sharma[1], J.S. Paliwal[1], D. Dogra[1], V.S. Bisaria[1], S. Sharma[1]
[1]Indian Institute of Technology Delhi, Department of Biochemical Engineering and Biotechnology, New Delhi, India

Backgrounds

Agricultural amendments interact with resident microbial community to exert cumulative effect on plants. It is therefore essential to assess their survivability in plant's rhizosphere before their widespread release into the field. Several methods have been attempted to track the bioinoculants, still tracking at strain level is considered tedious. One of the methods is to develop antibiotic resistant strains. These strains when monitored, must have a selective characteristic without interfering with their inherent ability to survive or colonize.

Objectives

Current study aimed to (a) determine the survivability of *Bacillus megaterium, Pseudomonas fluorescens* and *Azotobacter chroococcum* (both individually and in combination) in the rhizosphere of *Cajanus cajan* by generating rif mutants, and (b) find correlation, if any, between the inoculants' persistence in the rhizosphere and their impact on plant parameters.

Methods

Spontaneous rifampicin-resistant mutants of the bioinoculant strains were introduced in Pot experiment set in completely randomized design, with 'No inoculation' and 'Bulk soil' as controls. Five samplings points were chosen during the plant's growth.

In terms of the effects of rif mutants on root length, shoot length and dry weight, the treatments exerted positive impact when compared with control. Within different treatments, dual inoculations surpassed the result of mono-inoculations. With time the population of bioinoculants showed a gradual reduction while they could be detected until approximately two months after sowing. After 59 days of sowing no mutants were detected.

Conclusions

There was a sharp reduction in the abundance of applied bioinoculants with time. However, these bioinoculants exerted their positive impact on the plant growth parameters even at the harvest stage showing their long-term effects irrespective of their persistence.

DIFFERENTIAL STRESS RESPONSE OF COAL MINE ISOLATES BACILLUS SUBTILIS MNU16, ALCALIGENES FAECALIS MNU13 AND LEUCOBACTER ARIDICOLLIS MNU27 AND ITS IMPACT ON BIOREMEDIATION POTENTIAL

S. Sharma[1], *N. Upadhyay*[1], *R. Rani*[1], *D.K. Tripathi*[2]
[1]*Motilal Nehru National Institute of Technology Allahabad, Department of Biotechnology, Allahabad, India*
[2]*Motilal Nehru National Institute of Technology Allahabad, Centre for Medical Diagnostic and Research, Allahabad, India*

Backgrounds

Coal mining results in the destruction of land ecosystem by removing the aboveground vegetation and causes an increases heavy metal contaminants in soils which influences microbial activity and plant growth. The utilization of the synergistic effect of microorganisms and plants is an effective approach of bioremediation that ensures a more efficient clean-up of heavy metal contaminated soils.

Objectives

To study the adaptive changes of bacteria in response to different Cr(VI) concentrations and their potential to remediate chromium contaminated soils.

Methods

Floral diversity of the site was analyzed by quadrat analysis technique. Bacteria were screened for stress tolerance and plant growth promoting (PGP) potential. The adaptation of potential isolates at various Cr(VI) concentrations were studied by analyzing the growth kinetics and changes in surface elemental composition and morphology was studied by using SEM–EDX and TEM analysis. The toxicity of Cr(VI) at various concentrations was further studied by flow cytometry and % Cr(VI) reduction potential was evaluated.

Conclusions

The study confirms that due to the deterioration of soil quality there is decrease in plant and microbial diversity in dump soils as compared to native soils. Three potential isolates identified as *Bacillus subtilis* MNU16, *Alcaligenes faecalis* MNU13 and *Leucobacter aridicollis* MNU27 were found to be positive for multifarious PGP activity and demonstrated Cr(VI) reduction and resistance against multi-metals, high temperature, drought and various pH ranges. The stress tolerance and chromium reduction potential of the selected PGPR strains make them suitable for the efficient microbial assisted phytoremediation of contaminated soils.

A NEW INSIGHT TO PLANT GROWTH PROMOTING RHIZOBACTERIA FOR BIOREMEDIATION/ BIORECLAMATION OF COAL MINE SOILS OF SONBHADRA (U.P.) INDIA

S. Sharma[1], N. Upadhyay[1], R. Rani[1], D.K. Tripathi[2]
[1]Motilal Nehru National Institute of Technology Allahabad, Department of Biotechnology, Allahabad, India
[2]Motilal Nehru National Institute of Technology Allahabad,
Centre for Medical Diagnostic and Research, Allahabad, India

Backgrounds

Heavy metals cause environmental pollution as a result of anthropogenic activities and results into a global environmental problem as it affected an extensive area of arable land worldwide. Microorganisms native to the contaminated site were found to be resistance to various stresses and possess different mechanism for remediation of polluted soils. The significance of the current study is to explore the ability of the selected plant growth promoting rhizobacteria for tolerance and reduction of hexavalent chromium.

Objectives

To screen potential chromium resistant-PGPR isolates and to evaluate its impact on hexavalent chromium reduction.

Methods

Bacterial isolate was isolated by serial dilution technique from soil samples collected from coal mining regions. They were screened for plant growth promoting (PGP) potential viz., IAA production, phosphate solubilization, siderophore production and ACC deaminase activity as per standard method. The multi-metal resistance and chromium reduction percentage of the isolates was evaluated and potential isolates were identified by 16s rRNA sequencing.

Conclusions

The study presented here leads to the delivery of potential isolates identified as *Alcaligenes faecalis* MNU13 and *Leucobacter aridicollis* MNU27 which shows significant plant growth promotion characteristics highlighting resistance to high concentration of chromium and ability to decrease the toxicity of Cr(VI) by reducing it to Cr(III) a less toxic form. These strains will be utilized for their implication of bioremediation of chromium contaminated soils. The strains along with native plant species have potential to establish a successful bioremediation strategy for maintaining a healthy ecosystem.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

STUDY OF BIODIVERSITY OF ENDOPHYTIC BACTERIA INHABITING THE CONIFERS AND GRAPE AS PERSPECTIVE BASE FOR MICROBIOLOGICAL PREPARATIONS

A. Shcherbakov[1], E. Shcherbakova[1], S. Mulina[1], P. Rots[1], L. Yahina[1], V. Chebotar[1]
[1]All-Russia Research Institute for Agricultural Microbiology, Laboratory of microbial technology, Saint-Petersburg- Pushkin, Russia

Backgrounds

The study of biodiversity of endophytic bacteria inhabiting seeds and seed material of woody plants (hardwood and softwood) from various ecology and geographical origin was the first explored in Russia. The study of the spatial localization of endophytic bacteria in the seeds and seed material of woody plants and the selection of cultivated forms will build a collection of strains of endophytic bacteria, study their beneficial to plants properties and select promising strains to develop microbiological preparations for agriculture.

Objectives

Cones from *Pinus sylvestris L.* and *Picea abies L.*were collected in summer 2014 at the 2 native sites in the Middle Volga: forestry Serunskoe and forestry Zelenodolsk. Cones from *Pinus sibirica L.*were collected in autumn 2014 at the 3 native sites on the Baikal Lake coast. We isolated bacterial endophytes from plants of grapevine (*Vitis vinifera* L.) of four cultivars (Fetyaska, Rkatsiteli, Black Muskat and Muskat) sampled in Astrakhan region and Krasnodar region (Russia).

Methods

Seeds were surface sterilized with 70% ethanol and sodium hypochlorite. Endophytic bacteria were isolated from plants using an original method of surface sterilization of plant samples. Surface-sterilized cuttings were cut under sterile conditions, pieces of xylem and core were plated onto R2A medium.

Conclusions

Biodiversity of endophytic bacteria inhabiting seed and plant material of woody plants from different ecological and geographical origin has been studied. Isolated and studied 79 strains of cultivated forms of endophytic bacteria. For further research selected three most promising strains of endophytic bacteria *Bacillus megaterium*, *Bacillus thuringiensis* and *Pseudomonas sp*. Microbiome of seeds and vegetative parts of conifers plants has been studied. It was studied the spatial localization of endophytic microorganisms in plants using fluorescence *in situ* hybridization (FISH). Technological parameters for cultivation of most promising strains of endophytic bacteria have been developed and developed a laboratory protocol for production of microbial preparation.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

EFFECTS OF FUNGICIDES ON THE YEAST-LIKE SYMBIOTES AND THEIR HOST, NILAPARVATA LUGENS STAL (HEMIPTERA: DELPHACIDAE)

X. Shentu[1], *L. Danting*[1], *Y. Xiaoping*[1]
[1]*China Jiliang University, College of Life Sciences, Hangzhou, China*

Backgrounds

Yeast-like symbiotes (YLS) are endosymbionts that are closely related to the growth, development and reproduction of their host, the brown planthopper (BPH), *Nilaparvata lugens* Stål (Hemiptera: Delphacidae).

Objectives

In order to understand the relationship between the population of YLS in BPH cells and the survival rate of BPH.

Methods

Eight different fungicides were applied to rice plants infested by BPH, and the number of YLS and mortality of BPH were determined. Three of the fungicides, 27% toyocamycin & tetramycin P & tetrin B & tetramycin A, 0.01% trichodermin, and 75% trifloxystrobin & tebuconazole WG, were found to significantly reduce the number of YLS in BPH, subsequently causing a high mortality of BPH. The three fungicides were each mixed with a commonly used insecticide-imidacloprid, and the fungicide/insecticide mixtures could cause a marked reduction in YLS number in BPH, resulting in a significantly higher mortality of BPH than did the imidacloprid alone. The mixture of 27% toyocamycin & tetramycin P & tetrin B & tetramycin A with imidacloprid showed the best inhibitory effect on BPH population.

Conclusions

Our study demonstrated a high dependence of the BPH survival rate on the number of YLS harbored in BPH fat-body cells. It implies that using specific fungicides as an additive to imidacloprid for controlling BPH could be a novel way to enhance the efficacy of insecticide, minimizing the use of imidacloprid in paddy fields.

GUT MICROBIAL MODULATION BY ANTIBIOTICS IMPROVES GLUCOSE HOMEOSTASIS OF DIET-INDUCED OBESE MICE

N.R. Shin[1], J.W. Bae[1]
[1]Kyung Hee University, Department of Biology, Seoul, Republic of Korea

Backgrounds

An excessive energy intake promotes metabolic disorders such as obesity and type 2 diabetes. Increasing evidence indicates that alterations in the gut microbiota composition play a role in the development of obesity-induced diabetes. Recently, we have demonstrated that treatment of oral antibiotic regimen in diet-induced obese (DIO) mice improved glucose homeostasis.

Objectives

We hypothesized that antibiotic treatment can affect gut microbial community composition and subsequently glucose metabolism in DIO mice.

Methods

C57BL/6 mice on either a normal-chow diet or a high-fat diet were treated with carbenicillin, metronidazole, neomycin, vancomycin or all mixture. We examined the response of gut microbiota and glucose homeostasis after 8 weeks of diet intervention and antibiotic treatment for 5 weeks. The fecal microbiota composition was assessed by analysis of 16S rRNA gene sequences using 454 pyrosequencing.

Conclusions

Although an administration of oral antibiotic altered the overall gut microbial composition of both lean and obese mice, DIO mice showed more profound shift in their microbial community profiles of gut microbiota. There were differences in the changes of gut microbial community in response to each antibiotic; however, glucose homeostasis of antibiotic-treated DIO mice was significantly improved regardless of type of antibiotics. These results suggest that oral antibiotic treatment ameliorate impaired glucose metabolism of DIO mice by modulation of the gut microbiota, indicating that this modified gut microbiota may alleviate dysbiosis induced by high-fat diet. As a follow-up study, it would be precise to tracking the specific gut microbial group or single bacteria that modify glucose and energy metabolism of the host.

EXPRESSION OF AN ALCOHOL DEHYDROGENASE GENE IN A HETEROTROPHIC BACTERIUM INDUCES THE OLIGOTROPHIC GROWTH WITH CARBON DIOXIDE FIXATION

S. Inaba[1], *H. Kato*[1], *Y. Ohtsubo*[1], *M. Tsuda*[1], *Y. Nagata*[1]
[1]*Tohoku University Graduate School, Environmental Life Sciences, Sendai, Japan*

Backgrounds

The gamma-hexachlorocyclohexane-degrading *Sphingobium japonicum* strain UT26 is a heterotrophic bacterium that needs organic carbon source for its growth. Although UT26 cannot grow on minimal salt agar medium prepared without adding any organic carbon sources, its transposon-inserted mutants able to grow on such medium were isolated. This phenotype was designated oligotrophic growth (OG).

Objectives

The aim of this study is to investigate the details and mechanism of OG in the UT26 mutants.

Methods

These mutants also grew on the organic carbon source-free minimal salt medium that was solidified by gellan gum, and subsequent analysis indicated no assimilation of agar or gellan gum by the mutants. It was revealed that OG was accompanied with carbon dioxide fixation although UT26 does not have the genes for key enzymes of known autotrophic carbon dioxide fixation mechanisms. The transposon in the OG mutants was inserted just upstream of the putative Zn-dependent alcohol dehydrogenase (ADH) gene (*adhX*) so that the *adhX* gene was constitutively expressed by the transposon-derived promoter. The *adhX* deletion mutant did not exhibit OG phenotype, and this phenotype was observed when the deletant had a plasmid carrying the *adhX* gene under the control of constitutive promoter. The purified His-tagged AdhX protein expressed in *Escherichia coli* showed ADH activity towards methanol and other alcohols, and site-directed mutagenesis of *adhX* indicated correlation between the ADH activity and OG.

Conclusions

These results clearly showed that the constitutive expression of the AdhX protein with ADH activity in UT26 leads to OG with carbon dioxide fixation.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

GUT PHAGEOMICS: YET ANOTHER VIEW OF HUMAN GUT MICROBIOME

A. Shkoporov[1], A. Forde[1], K. Daly[1], S. McDonnell[1], J. Nolan[1], O. O'Regan[1], L. Draper[1], S. Stockdale[1], M. Dalmasso[1], F. Ryan[1], A. McCann[1], P. Ross[1], C. Hill[1]
[1]APC Microbiome Institute, Gut Phageomics Lab, Cork, Ireland

Backgrounds

A healthy human gut is populated by an enormously diverse and dense consortium of microorganisms. While the bacterial component of this consortium has received significant attention in the last decade, relatively little is known about viral (and in particular, the phage) component. While metagenomic sequencing provides a powerful tool for studying phage populations, little has been done to standardise or validate sequencing and bioinformatic analysis strategies, or to analyse the impact of potentially confounding factors such as storage or handling conditions.

Objectives

1) To develop and validate a protocol for metagenomic analysis of viral/bacteriophage populations in human faeces 2) To compare reproducibility and resolution of this protocol with the more traditionally used 16S rDNA amplicon sequencing methodology. 3) To analyse operator-to-operator reproducibility of the protocol, the impact of sample storage at various temperatures, the effect of repeated freeze/thaw cycles, and the addition of exogenous viral standards for absolute quantification of VLPs.

Methods

Faecal samples collected from healthy and patient cohorts were enriched for virus like particles. Viral/bacteriophage DNA was extracted and sequenced using the Illumina HiSeq platform.

Conclusions

The gut phageome sequencing method developed in this study provides an essential complementary tool to 16S amplicon sequencing for studying (and quantifying) organisms in the gut microbiome. The accuracy and reproducibility of results compare favourably between the methods and phageomics provides a valuable additional view of human gut microbiota structure and composition. Rapid storage and limited freeze-thaw cycling of faecal samples is recommended for optimum results.

RAPID DEGRADATION OF LIGNOCELLULOSIC RESIDUES GENERATED AT COLDER REGIONS USING SYNTROPHIC INTERACTIONS BETWEEN PSYCHROPHILES AND MESOPHILES

L. Shukla[1], A. Senapati[1], A. Suman[1]
[1]Indian Agricultural Research Institute, Division of Microbiology, New Delhi, India

Backgrounds

Sustainable management of lignocellulose residues for improving soil fertility by biodegradation into compost has been widely practised in agricultural regions across temperate regions. In extreme cold climates, degradation rate of lignocellulose to compost is lower due to the fact that at low temperature < 10°C the activity of mesophilic microorganisms slows down, resulting in delayed onset of composting.

Objectives

This study focuses on accelerating lignocellulose transformation processes by exploiting the biological aspect of composting at cold climates through syntrophic interactions between lignocellulolytic psychrophiles and mesophiles.

Methods

Lignocellulolytic microorganisms with plant beneficial activities were screened for rapid decomposition of lignocellulose using rice straw as substrate. This included psychrophilic microorganisms *Eupenicillium crustaceum*, *Paciliomycis* sp., *Bacillus atropheus, Bacillus* sp. and mesophilic microorganisms *Aspergillus awamori, Trichoderma viride, Aspergillus nidulans* and *Phanerochaete chrysosporium* respectively. Following optimization of inoculum dose and nitrogen amendments, field trials were conducted across arable regions of the Himalayan range during extreme cold environments. Post harvest residues from rice, wheat and maize crops were used as substrates. Composting was assessed through evaluating the physicochemical parameters (colour, texture, moisture level, pH, electrical conductivity, total carbon, total nitrogen, humus content and structural analysis of lignin), biochemical parameters (dehydrogenase activity, xylanase and alkaline phosphatase), microbiological parameters (viable cell count, microbial biomass carbon and N-acetyl glucosamine level) and assessing phytotoxicity through germination tests.

Conclusions

Application of farm and poultry manure as nitrogen source restricted the use of chemical nitrogen source used for adjusting C/N ratio. Composting duration of lignocellulosic residues was 60 days only.

TREATMENT OF VINASSE WITH A MIXTURE OF WILD YEAST STRAINS TO REDUCE SOIL AND FRESH WATER POLLUTION

C. Silva[1], J. Pires[1], G. Ferreira[2], K. Reis[2], R. Schwan[2]
[1]Federal University of Lavras, Biology/ Microbiology, Lavras, Brazil
[2]Federal University of Lavras, Biology/Microbiology, Lavras, Brazil

Backgrounds

The vinasse is a waterwaste from cachaça, tequila or biofuel production. Vinasse show high content pollution and needs a treatment before to be launched in the environment.

Objectives

This study evaluated the use of vinasse as a substrate for microbial biomass production and its disposal impact on the environment. .

Methods

Two *Saccharomyces cerevisiae* strains, CCMA 0137 and CCMA 0188, were grown in fresh and treated vinasse. Biomass productivity, physicochemical properties, nutritional composition, and anti-nutritional factors were evaluated. Spent vinasse was analysed and evaluated in terms of phytotoxicity and toxicity on soil microbiota in the short (5 days) and medium (60 days) term.

Conclusions

The microbial biomass showed high levels of essential amino acids (3.78%), varying levels of chemical elements, and low nucleic acid content (2.38%). Following biological treatment, vinasse biochemical oxygen demand (BOD) and chemical oxygen demand (COD) decreased to 51.56 and 29.29%, respectively. Cultivation with *S. cerevisiae* significantly reduced short term phytotoxicity and toxicity of spent vinasse. Prokaryotic microorganisms were the most sensitive to vinasse application, suggesting their possible use as biomarkers for monitoring the impact of this effluent on soil.

THE GENOME OF THE BACTERIAL ENDOSYMBIONT OF THE HETEROPTERAN HENESTARIS HALOPHILUS REVEALS THE REASONS OF THIS SYMBIOSIS AND SERVES TO DISCUSS TAXONOMIC AFFILIATIONS IN SYMBIONTS

F.J. Silva[1], D. Santos-Garcia[2], S. Morin[2], S.M. Kuechler[3]
[1]Universitat de València,
Institute for Integrative Systems Biology and Institut Cavanilles de Biodiversitat i Biol. Evolutiva, Paterna, Spain
[2]The Hebrew University of Jerusalem, Department of Entomology, Rehovot, Israel
[3]University of Bayreuth, Department of Animal Ecology II, Bayreuth, Germany

Backgrounds

The advances of genomics have allowed the characterization of many unculturable species such as the bacterial endosymbionts of insects. Most of these associations started many million years ago and helped to the diversification of many host lineages. The characterization of the endosymbiont gene repertoire has allowed, in many cases, determining the reasons for such successful associations. However, the taxonomic affiliations given to many of these symbionts follow heterogeneous criteria. The use of phylogenomics and genomic similarity indices may help to arrive to consensus criteria for the assignment of new species and genus names.

Objectives

The aim of this work was the characterization of the genome of the gamma-proteobacterial endosymbiont of the lygaeoid bug *Henestaris halophilus* and the determination of the reasons for the start and persistence of this symbiotic relationship.

Methods

DNA from purified bacteriomes was sequenced with Illumina HiSeq paired-ends. Several computational methods were used to produce the assembly, annotation and analysis of the genome. Phylogenomics, average nucleotide (ANI) and amino acid (AAI) identity were used for taxonomic assignment.

Conclusions

The insect-bacterial association was not recent since its genome shows several characteristics of intermediate to long reductive evolution (1.62 Mb genome, 713 CDS, no mobile elements, etc.). The main reason for the persistence of this relationship has been the ability of the symbiont to complement the deficient insect diet composed by seeds/vascular tissue of some halophytes. We propose for this new symbiont the name *Sodalis baculum* and suggest that other *Sodalis* allied species should be assigned to the genus *Sodalis* as well.

THE ORAL MICROBIOME IN LUNG TRANSPLANT RECIPIENTS

A. Simon-Soro[1], A. Bailey[2], M. Brown[1], I. Imai[1], V.R. Knecht[1], K. Bittinger[2], E. Clarke[2], E. Cantu[1], J.M. Diamond[1], J.D. Christie[1], F.D. Bushman[2], R.G. Collman[1]
[1]University of Pennsylvania, Department of Medicine. Perelman School of Medicine, Philadelphia, USA
[2]University of Pennsylvania, Department of Microbiology. Perelman School of Medicine, Philadelphia, USA

Backgrounds

The oral microbiota is associated with oral health, and can also influence pulmonary infections, which are an important problem in lung transplant subjects.

Objectives

The goal is to understand the bacterial and fungal communities in the oral microbiome of lung transplant patients in comparison to healthy and pre-transplant populations, and the impact of immunosuppression and other treatment and disease-related factors.

Methods

We studied 34 patients longitudinally who underwent lung transplantation. We characterized changes in oral microbiome from 6 weeks through 6 months after transplant surgery by high-throughput sequencing of bacterial 16S and fungal ITS rRNA genes in oropharyngeal samples. We included 12 healthy subjects and 23 subjects with end stage lung disease awaiting transplant as controls. Clinical data were analyzed to understand whether specific clinical parameters are related to a particular structure of the oral microbiome.

Conclusions

Our results showed that the oral microbiota of lung transplant patients have lower diversity than healthy individuals in both fungal and bacterial populations. We found that diversity decreased though time post-transplant. Those on more immunosuppressive agents showed had higher proportion of genera *Haemophilus*, *Lactobacillus*, *Rothia*, *Veillonella*, *Staphylococcus* and *Neisseria*. *Candida* spp. was enriched post-transplant. In conclusion, lung transplant patients have a distinctive oral microbiome during the 6 week to 6 month period after transplant in comparison to healthy subjects. This suggests a specific environment could be conditioned by the medication favoring the dominance of some species, displacing the wide normal oral microbiota.

NEW THERMOPHILIC CHEMOLITHOAUTOTROPHIC SULFITE-REDUCING BACTERIA

G. Slobodkina[1], *E. Bonch-Osmolovskaya*[1], *A. Slobodkin*[1]
[1]*Winogradsky Institute of Microbiology,*
Research Center of Biotechnology of the Russian Academy of Sciences, Moscow, Russia

Backgrounds

The dissimilatory metabolism of sulfur compounds is likely to have been among the earliest energy-yielding processes to sustain life. Prokaryotes capable of dissimilatory sulfite reduction are involved in global cycling of sulfur and carbon in modern anaerobic environments.

Objectives

We have isolated two strains of thermophilic anaerobic sulfite-reducing bacteria from a shallow submarine (SH388^T) and a terrestrial (SF97^T) hydrothermal vents located at Kuril Islands, Russia.

Methods

The very few simple inorganic compounds of direct volcanic origin could sustain development of these microorganisms. Both strains grew chemolithoautotrophically with molecular hydrogen as an electron donor, sodium sulfite or SO_2 gas as an electron acceptor and bicarbonate/CO_2 as a carbon source. Strain SH388^T was also able to grow by disproportionation of sulfite, SO_2 gas and elemental sulfur. Cells of the strain SH388^T were Gram-negative motile short rods. They grew optimally at 50^{o}C, pH 6.0-6.5 and NaCl concentrations 2.0-2.5% (w/v). The strain represents a novel species of a new genus within the class *Deltaproteobacteria*, for which we proposed the name *Dissulfurirhabdus thermomarina* gen. nov., sp. nov. Cells of strain SF97^T were Gram-positive motile rods. The optimal growth conditions for the novel isolate were 65^{o}C and pH 6.0-6.5. Strain SF97^T represents a novel species of a new genus in the family *Thermoanaerobacteraceae*, for which the name *Thermodesulfitimonas autotrophica* gen. nov., sp. nov. is proposed.

Conclusions

Dissulfurirhabdus thermomarina SH388^T is a first thermophilic disproportionator of sulfur compounds isolated from a shallow sea environment. *Thermodesulfitimonas autotrophica* SF97^T is a first obligate sulfite-reducer.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

USE OF BDELLOVIBRIO AND LIKE ORGANISMS (BALOS) IN PATHOGEN CONTROL AND BIOREMEDIATION: QUANTIFICATION OF ITS PREDATORY CAPACITY UNDER DIFFERENT ENVIRONMENTAL CONDITIONS

R. Solana-Guillén[1], *F. Torrella*[1]
[1]*University of Murcia, Genetics and Microbiology, Murcia, Spain*

Backgrounds

The frequent occurrence of antibiotic multi-resistant pathogenic Gram-negative bacteria causing human and animal infections has aroused interest in the predatory capacity of BALOs as control agents. The BALOs' growth dynamics under "classical in vitro cultivation" is well known, but the real micro-environments where the predatory activity of these organisms takes place are quite different and diverse.

Objectives

The purpose of this study has been to know more about the predatory capacity of various strains of BALOs in laboratory microcosms with different suspension media ("natural water" *vs* NB-10 medium), while preying on either single species or on mixed prey bacterial suspensions.

Methods

Wild type BALOs were isolated from urban wastewaters (lysis plaques, double layer NB-10-agar). Primary isolations were made using *K.pneumoniae, E.coli*, *S. typhimurium* and other Gram-negatives as prey. Each BALO was purified, maintained and cultured in the prey strain in which was first obtained until used to check its predatory capacity on other taxa.

Conclusions

Quantitative predatory tests ("quantified host range") showed differences in the predatory dynamics and final yield of BALOs, particularly a strain isolated on *K. pneumoniae* did best in their isolation host than when preying on other susceptible enterobacteriaceae. That behavior was observed both in "natural water medium" and also in NB-10. In mixed suspensions of different susceptible preys, a specific BALO lysed preferentially cells of the species in which it was isolated originally from wastewater. These results show that in order to use BALOs as bacterial control agents, a careful strain selection is necessary.

FEMS7-0033
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

ROLE OF TEMPERATURE INCREASE ON BACTERIAL CARBON FLUX TOWARDS HIGHER TROPHIC LEVELS IN THE ADRIATIC SEA

M. Solic[1], *D. Santic*[1], *S. Sestanovic*[1]
[1]*Institute of Oceanography and Fisheries, Laboratory of Microbiology, Split, Croatia*

Backgrounds

Mediterranean Sea (including Adriatic Sea) has been identified as a 'hotspot' for climate change, with prediction of the increase in water temperature of 2-4^{o}C over next few decades. Being mainly oligotrophic, and strongly phosphorus limited, Adriatic Sea is characterised by important role of microbial food web in production and transfer of biomass and energy towards higher trophic levels.

Objectives

We hypothesized that predicted rise in temperature of 3^{o}C in the near future may be resulted with increase of bacterial production and bacterial losses to grazers which could significantly enlarged trophic base for metazoans.

Methods

This empirical study is based on combined 'space-for-time-substitution' analysis and experimental approach (*in situ* grazing experiments performed). 'Space-for-time-substitution' analysis includes 3583 data sets of seawater temperature, salinity, inorganic nutrients (P, N, Si), bacterial abundance, HNF abundance and bacterial production, collected at 75 sampling sites located all over the central and south Adriatic Sea during the 2014-2016 period. Grazing on bacteria and bacterial carbon flux towards higher trophic levels were studied by 36 *in situ* experiments, which were performed on the monthly bases at three sites in the central Adriatic, covering temperature range from 10.26^{o}C to 25.07^{o}C.

Conclusions

Results showed that predicted temperature increase of 3^{o}C in the near future, as a result of global warming, could cause a significant increase in bacterial growth at temperatures lower than 16^{o} C (during the colder winter-spring period, as well as in the deeper layers). Furthermore, temperature increase of 3^{o}C, could double the grazing on bacteria by their predators, and could increase the proportion of bacterial production transferred to metazoan food web by 42%. Therefore, it is expected that global warming may further strengthen the role of microbial food web in a carbon cycle in the Adriatic Sea.

ISOLATION OF SOIL BACTERIA WITH ANTIMICROBIAL ACTIVITIES AGAINST SEVERAL HUMAN SKIN PATHOGENS

H.G. Song[1], D.S. Lee[1]
[1]Kangwon National University, Dept. of Biological Sciences, Chuncheon, Republic of Korea

Backgrounds

At present chemical preservatives have been widely used in food and cosmetic industries, but due to their toxicity and other side-effects they should be replace to safe ones. Recently there have been many studies on development of effective and unharmful antiseptics from natural substances of plants and microorganisms.

Objectives

This study was carried out to evaluate effects of antimicrobial substances produced by isolated bacteria from various soils of South Korea, which can inhibit some skin pathogens.

Methods

Methods: Among several hundreds of bacterial strains isolated, *Paenibacillus elgii* DS381, *Bacillus subtilis* DS660 and *Paenibacillus peoriae* DS842 showed high antimicrobial activities against human skin pathogens such as *Staphylococcus aureus*, *Bacillus subtilis, Escherichia coli, Pseudomonas aeruginosa, Candida albicans* and *Aspergillus niger*. Isolated strains inhibited growth of all six pathogens tested. DS381, DS660 and DS842 showed 400, 800 and 200 AU/ml of maximum antimicrobial activity. When antimicrobial mechanisms were examined, strains DS660 and DS842 produced 0.056 and 0.17 mmol/ml of siderophore, respectively, and strain DS381 showed 1.56 U/ml of chitinase activity. Strains DS660 and DS842 also exhibited 167.29 and 357.28 nmol/min/mg of β-1,3 glucanase activity, respectively. In addition, oil spreading test and TLC of ethyl acetate extract of strains DS381, DS660 and DS842 culture supernatant suggested production of biosurfactants such as lipopeptide and glycolipid. Culture supernatants of strains DS381, DS660 and DS842 could reduce surface tension to 41, 33.5 and 33.5 mN/m. Antimicrobial substance of all 3 strains were stable at broad range of temperature (-22~121℃), pH (3~12) and chemical compounds (urea, Triton X-100, Tween 20 and 80).

Conclusions

These results suggest that *Paenibacillus elgii* DS381, *P. peoriae* DS842 and *Bacillus subtilis* DS660 may be utilized as an environment-friendly biocontrol agent against some human skin pathogens for commercial products such as cosmetics.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

ISOLATION OF SOME BACTERIA WITH CAPABILITIES OF DEGRADATION AND PRODUCTION INHIBITION OF AFLATOXIN B1

H.G. Song[1], *H.E. Lee*[1]
[1]*Kangwon National University, Dept. of Biological Sciences, Chuncheon, Republic of Korea*

Backgrounds

Various mycotoxins are produced by many fungi and aflatoxin B_1 (AFB_1) produced mainly by *Aspergillus flavus* is the most well-known and can be found from contaminated cereals. It is extremely toxic and carcinogenic, and poses a severe threat to animal health and brings about huge economic losses. Therefore, production of AFB_1 by *A. flavus* has to be inhibited and AFB_1 already produced should be removed to prevent economic losses from contamination of crops.

Objectives

This study investigated AFB_1 biodegradation ability of some isolated bacteria. We also tested growth inhibition and AFB_1 produced of *A. flavus* (KACC 44986).

Methods

Over 100 bacterial strains were isolated from various sources including animal feces on coumarin medium. Among them, AF34 strain degraded 72.7 and 88.44% of 0.1 and 1.25 mg/L of AFB_1, respectively in liquid culture in 72 h at 30℃. At 37℃, AF34 strain reduced 98.03 and 90.89% of 0.1 and 1.25 mg/L of AFB_1, respectively. At same conditions, strains AF38 and AF40 showed 98.08 and 83.57% of AFB_1 degradation, respectively. Then, inhibition of AFB_1 production by *A. flavus* was examined in yeast extract sucrose medium with simultaneous inoculation of isolated strains or addition of culture supernatant. The control fungal culture showed 11.91 mg/L of AFB_1 production, but the fungal culture with the addition of culture supernatant of AF34, AF38 and AF40 formed 9.76, 10.42 and 7.37 mg/L of AFB1, respectively after 120 h. Even co-inoculation of isolated bacteria reduced them to 6.32, 7.59 and 0.39 mg/L, respectively.

Conclusions

These results suggest these bacteria can be utilized to inhibit and remove of AFB_1 production from valuable resources including various crops.

EVOLUTION OF THE MARSUPIAL GUT MICROBIOME AND ADAPTATION TO PLANT TOXINS

R. Soo[1], M. Shiffman[1], D. Wood[1], P. Dennis[2], V. Mazumdar[1], M. Morrison[3], G. Tyson[1], P. Hugenholtz[1]
[1]Australian Centre for Ecogenomics, School of Chemistry and Molecular Biosciences, Brisbane, Australia
[2]School of Agriculture and Food Sciences, The University of Queensland, Brisbane, Australia
[3]The University of Queensland Diamantina Institute, The University of Queensland, Brisbane, Australia

Backgrounds

Culture-independent methods have been applied extensively to the gut microbiomes of mammals (in particular humans and mice). Given their evolutionary and geographic novelty, surprisingly little culture-independent work has been done with iconic Australian fauna, including the diprotodont (two lower incisors) marsupials (order *Diprotodontia*). Members of this order are particularly interesting, as several are capable of anaerobically digesting eucalyptus leaves which are nutrient poor, high in lignified fibre, and enriched in natural toxins. Gut microbiota are thought to be an integral component of the toxic folivores' ability to digest eucalyptus leaves together with anatomical adaptations.

Objectives

Our objectives were 1) to survey diprotodont marsupial faecal microbiomes using 16S amplicon community profiling and shallow metagenomes and 2) recover population genomes using coverage binning of metagenomic datasets.

Methods

We collected faecal pellets from a range of marsupials that were eucalyptus eaters (possums, suborder *Phalangeriformes* and koalas, family *Phascolarctidae*) and non-eucalyptus eaters (kangaroos, family *Macropodidae* and wombats, family *Vombatidae*) from six different zoos and from the wild. We performed both amplicon and whole metagenome shotgun sequencing on 95 samples and conducted gene- and genome-centric analyses.

Conclusions

We found that faecal communities correlated with both host phylogeny and diet and identified indicator species of eucalyptus digestion.

FEMS7-1293
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

IN VITRO ACTIVITY OF ENTEROCIN AP-CECT7121 AGAINST MULTI-RESISTANT STAPHYLOCOCCUS AUREUS BIOFILMS

G. Delpech[1], M. Sparo[1], M. Bistoletti[1], S. Lissarrague[1], M. Cherjovsky[1], B. Baldaccini[1], L. García Allende[1]
[1]School of Medicine, Universidad Nacional del Centro de la Provincia de Buenos Aires, Olavarría, Argentina

Backgrounds

The pathogen *Staphylococcus aureus* is able to persist on biotic and abiotic surfaces through biofilm formation. Enterocin AP-CECT7121 has shown homogenous bactericidal activity *in vitro* against *Staph. aureus* of food and clinical origin.

Objectives

Assess the eradication of biofilm-associated cells of multi-resistant clinical *Staph. aureus*.

Methods

7 multi-resistant *Staph. aureus* (HSSA32-HSSA38) isolated from blood cultures of inpatients, from Hospital Ramón Santamarina (Tandil City, Argentina) during the period January-November 2016 were studied. All included patients had hip prosthesis infections. Purified AP-CECT7121 was used. MICs determinations were done by the micro-liquid dilution method. For bactericidal activity against planktonic cells, AP-CECT7121 was added to staphylococcal cultures (10^8 CFU/mL), in a 96-well plate, to final concentrations of 1xMIC and 4xMIC, and incubated at 37°C. CFU counts were performed at 0, 4, 8, and 24 h. For assessing bactericidal activity against *Staph. aureus* biofilm cells, staphylococcal suspensions in Brain Heart Infusion broth-1% glucose were added to the wells and incubated for 24 h at 37°C. Formed biofilms were incubated with the enterocin (1XMIC and 4XMIC) for 1 and 24 h. After, CFU counts of the biofilms were done.

Conclusions

Bactericidal activity of AP-CECT7121 against planktonic cell was detected between 1- 4 h of incubation. A dose-dependent effect of AP-CECT7121 against staphylococcal biofilms was observed. AP-CECT7121 (4XMIC) showed bactericidal activity against biofilm cells, but complete killing was not achieved. AP-CECT7121 showed a significant efficacy against staphylococcal biofilms and constitutes a candidate for future applications in the prevention and treatment of biofilm-associated infections.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

CHEMICAL AND MOLECULAR BIOLOGY FINGERPRINTING OF A COMPLEX CONTAMINATED INDUSTRIAL AREA

T. Stella[1], A. Franzetti[1], I. Pietrini[2], F. de Ferra[3], G. Carpani[3], M. Marchesi[2], L. Alberti[2], D. Antonelli[4]
[1]University of Milano-Bicocca, Department of Earth and Environmental Sciences DISAT, Milan, Italy
[2]Politecnico di Milano, Department of Civil and Environmental Engineering, Milano, Italy
[3]Research Center for Non-Conventional Energy, Istituto Eni Donegani Environmental Technologies, San Donato Milanese, Italy
[4]Eni, Syndial servizi ambientali S.p.A., San Donato Milanese, Italy

Backgrounds

The management and the remediation of large contaminated areas with multiple pollutant sources and different environmental conditions represent a big challenge to site owners. Therefore, a detailed chemical and microbiological site characterization (fingerprinting) is crucial to evaluate, at first, the intrinsic remediation of the contaminated area (natural attenuation) and, then the potential of enhancing specific biodegradation processes (biostimulation).

Objectives

This study aimed at gathering chemical and molecular biology data over multiple campaigns at a contaminated industrial area to quantify the complex mixtures of contaminants, to assess the presence of potential degraders and, thus to enhance the on-going biodegradation processes.

Methods

Contaminated groundwater was collected from 30 piezometers in a restricted area of the site. Chemical analyses of chlorinated ethenes, 1,2-dichloroethane, benzene, toluene, xylene isomers, ethylbenzene and chlorinated benzenes were performed following the standard protocols. The structure of the microbial community was determined by Illumina High Throughput Sequencing, whereas its functional profile was assessed by quantitative PCR of key genes encoding for enzymes involved in specific metabolisms.

Conclusions

Vinyl chloride (VC) and 1,2-dichloroethane (1,2-DCA) were found in most of the water samples at high concentration as well as tetra- and tri-chlorinated ethenes. Illumina sequencing data showed a great bacterial diversity probably due to contamination heterogeneity. However, species belonging to *Burkholderiales* and *Rhodocyclales* orders were predominant in 1,2-DCA and VC-contaminated groundwater, respectively. The functional characterization based on the quantification of catabolic genes enconding for reductive dehalogenases (*PceA*, *TceA, VcrA, BvcA*) and oxidative enzymes (*etnC*, *etnE*) will be accomplished (on-going analysis).

FEMS7-1824
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

RATES AND MECHANISMS OF ORGANOPHOSPHORUS PESTICIDE BIODEGRADATION ON GLACIERS

T. Stella[1], C. Ferrario[1], F. Pittino[1], I. Tagliaferri[1], I. Gandolfi[1], G. Bestetti[1], R.S. Azzoni[2], G. Diolaiuti[2], A. Franzetti[1], R. Ambrosini[1], S. Villa[1]
[1]University of Milano-Bicocca, Department of Earth and Environmental Sciences DISAT, Milan, Italy
[2]University of Milan, Department of Earth Sciences, Milano, Italy

Backgrounds

Organophosphorus pesticides (OPs) deposited on glacier snow and ice can undergo different partition and degradation processes, which determine their environmental fate and accumulation into ice bodies. Because of the global warming, their release in the glacial stream is growing and it contributes to their input in downstream waters. Microorganisms inhabiting the supraglacial sediments can play a pivotal role in the removal of OPs. However, the biodegradation has been neglected so far.

Objectives

This study aimed at assessing the relevance of OP biodegradative processes in cryoconite holes, a deposit of fine-grained material of atmospheric derivation laid on the bottom of small depressions of the glacier surface. In particular, our attention focused on the degradation of chlorpyrifos, an OP that can undergo both abiotic and biotic degradation.

Methods

In situ microcosm experiments were set up to simulate the cryoconite hole environment and kept under both light and dark conditions in order to estimate light influence in both biotic and abiotic degradation. GC-MS analyses were performed to evaluate the degradation of chlorpyrifos. The structure and the functions of the microbial community were determined by High Throughput Sequencing of 16S rRNA gene and of Whole Metagenomes of cryoconite.

Conclusions

Results showed that biodegradation is the most efficient process contributing to the removal of chlorpyrifos on glacier surface. Bacterial communities of cryoconitic holes involved in this process act as “biofilters” accumulating and promoting the biodegradation of chlorpyrifos. Sequencing results suggested that photoheterotrophic bacteria belonging to *Burkholderiales* might be responsible of chlorpyrifos biodegradation in cryoconite.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

IMPACT OF LONG-TERM FERTILIZATION ON SOIL MICROBIOM

H. Stiborova[1], *M. Kracmarova*[1], *K. Demnerova*[1]
[1]*University of Chemistry and Technology, Biochemistry and Microbiology, Prague, Czech Republic*

Backgrounds

Arable soils are usually fertilized by organic or mineral fertilizers to enhance the nutrient contend desired for crop productivity. Organic fertilizers (sewage sludge, farmyard manure) are mainly used due to their high contend of organic matter and others nutrients. Compared to them, mineral fertilizers are popular for their exact composition of nutrients that could be changed as needed. The knowledge about the long-term effect of organic or mineral fertilizers on soil microbial community structure is limited.

Objectives

The changes in soil microbiome were detected in four experimental sites established in 1996. On each site is simulated common agricultural practise: potatoes, winter wheat and spring barley in three-year rotation. Simultaneously, the fields are divided into 5 individual plots and treated as follows: i) NPK mineral fertilization (doses of N-P-K nutrients were 330-90-330 kg/ha); ii) sewage sludge (330 kg N/ha); iii) sewage sludge (990 kg N/ha); iv) farmyard manure (330 kg N/ha) and v) untreated control.

Methods

From soils amended by different fertilizers was isolated DNA followed by *16S rRNA* gene amplification (V4 and V5 region) and sequencing with Illumina Miseq method. The diversity of bacterial community structure in fields was evaluated by traditional diversity indices and multivariate statistical analyses was used to link the community structure with different environmental variables.

Conclusions

Agricultural soils ammended by organic and inorganic fertilizers harbour distinct microbiomes. The response of microbial diversity mainly depends on the type and amount of organic fertilizer.

EXPLORING MICROBIAL DIVERSITY BY PARALLEL CULTIVATION: INFLUENCE OF TEMPERATURE ON THE ENRICHMENT OF BIOPOLYMER PRODUCING MIXED MICROBIAL CULTURES

G. Stouten[1], C. Hogendoorn[1], S. Douwenga[1], E. Kilias[2], G. Muijzer[2], M. van Loosdrecht[1], R. Kleerebezem[1]
[1]Delft University of Technology, Environmental Biotechnology, Delft, The Netherlands
[2]University of Amsterdam, Aquatic Microbiology, Amsterdam, The Netherlands

Backgrounds

Microbial enrichments are elemental to studying ecology from both a microbial and functional point of view. Limitations in our understanding of microbial competition and coexistence can be overcome by more rigorous efforts to align functional and microbial development upon exposure of a microbial community to specific selective conditions.

Objectives

In this work we have used pulse-fed sequencing batch reactors to enrich for microbes with the highest substrate uptake rate. Two distinct ecological strategies contribute to the substrate uptake rate. Growers directly produce catalytic biomass from the substrate. Hoarders store the substrate as an internal storage compound. Stored compounds are later metabolized to catalytic biomass. This work aims for identifying the environmental conditions that favor hoarders over growers.

Methods

To this end, we have used a parallel bioreactor setup to compare functional and microbial development of a microbial community exposed to a pulse-feeding regime at different temperatures (20 to 40°C), in duplicate. High-resolution online measurements are used to identify and characterize shifts in functional process performance of the microbial community. This data is correlated with microbial dynamics, assessed by means of Illumina paired-end sequencing.

Conclusions

Within the temperature range of 25 to 35^{o}C microbes exhibiting the storing characteristic (hoarders) are enriched. At these temperatures biological duplicates show comparable enrichment patterns, however, the combined effect of differences in kinetic properties and initial numbers of microbes is inadequate to explain the succesion of events observed. The duplicates at 20^{o}C diverted into two distinct functional and microbial steady states. Generally, identified functional shifts precede the moment where microbial shifts can be derived from sequencing data. On the other hand, shifts in microbial composition did not always result in pronounced differences in observed functionality. Therefore a strong forward relation exists between observed shifts in functionality and shifts in microbial community structure.

BIOTIC ASPECTS INVOLVED IN THE CONTROL OF SOILBORNE FUNGI DURING COMPOSTING OF VEGETABLE WASTE

F. Suárez-Estrella[1], M.J. López[1], N. Sánchez San Fulgencio[1], M.M. Jurado[1], J.A. López-González[1], J. Moreno[1]
[1]University of Almería- ceiA3, Biology and Geology. Area of Microbiology. CITE IIB., Almería, Spain

Backgrounds

High temperatures generated inside a compost pile greatly influence the eradication of plant pathogens (Ryckeboer *et al*., 2003). However, others factors should not be ruled out. In this sense, during the composting of plant wastes, an important community of thermotolerant bacteria is globally involved in the control of other phytopathogenic organisms that could be present in the plant material. The mechanisms that those bacteria use are very varied and range from substrate competition through the production of siderophores, salicylic acid, chitinase-like enzymes, to the solubilization of phosphates, as well as the release of antifungal substances such as cyanide (Mehta *et al.,* 2014).

Objectives

The main goal of this work was to confirm the hypothesis that in addition to the high temperatures reached during the composting process, the microbial community of a composting pile actively collaborates in the control of *damping-off* producing agents.

Methods

Antagonistic effect of approximately 600 bacterial isolates was assayed by dual cultures against *Pythium ultimun, Fusarium oxysporum* f.sp. *melonis, Rhizoctonia solani* and *Phytophthora capsici*. Production of siderophores, salicylic acid, cyanide, or chitinase-like enzymes was qualitatively tested.

Conclusions

Only 3% of the initial collection of isolates proved to have a multipotential character with respect to its spectrum of action against *damping-off* producing agents, as well as in relation to its capacity to produce substances of agronomic interest. Among the selected strains, the isolates belonging to the genera *Bacillus* and *Pseudomonas* were the most represented.

ACTIVE COMMUNITY IN A PARTIAL NITRITATION ANAMMOX BIOREACTOR

C. Suarez[1], F. Persson[2], M. Hermansson[1]
[1]University of Gothenburg, Department of Chemistry & Molecular Biology, Gothenburg, Sweden
[2]Chalmers University of Technology,
Division of Water Environment Technology- Department of Civil and Environmental Engineering, Gothenburg, Sweden

Backgrounds

Partial nitritation anammox (PNA) is an established technology for nitrogen removal from wastewater. Anammox bacteria and Ammonia oxidizing bacteria (AOB) are necessary for the PNA process, but are only part of a complex community in which the metabolic activity is largely unknown.

Objectives

We studied the total and active community of a mainstream PNA reactor.

Methods

The microbial community of a pilot moving bed biofilm reactor fed with real main stream wastewater was investigated. DNA and RNA were co-extracted from 3 biofilm carriers. Relative abundance of ribosomal DNA (rDNA) and ribosomal RNA (rRNA) was studied using high throughput amplicon sequencing. Active taxa are defined as those with an rRNA:rDNA ratio higher than 1.

Conclusions

Some variation was observed between different carriers in both rDNA and rRNA relative abundance of taxa. Nevertheless, for all 3 biofilms carriers, a large number of active but rare taxa were observed as well as several abundant taxa with a very low rRNA:rDNA. The anammox bacteria *Brocadia* were highly abundant in all carriers, with rRNA:rDNA close to 1. The AOB *Nitrosomonas* had an rDNA relative abundance below 1%, but were active in all carriers (rRNA:rDNA between 1.3 and 20.5). However, also other bacteria showed high activity; for instance glycogen accumulating and putatively denitrifying *Competibacter*, and non-anammox bacteria within *Planctomycetes* (*Planctomyces*) had high rRNA:rDNA. Hence, a more complex picture of the PNA communities can be obtained by comparing rDNA and rRNA relative abundance.

PREVALENCE OF ANTIBIOTIC RESISTANCE GENES AND POTENTIAL PATHOGENS IN STREAMBED BIOFILMS. DOES THE POLLUTION SOURCE MATTER?

J. Subirats[1], X. Triadó-Margarit[2], J.L. Balcázar[1], S. Sabater[3], C. M. Borrego[1]
[1]Catalan Institute for Water Research, Water Quality, Girona, Spain
[2]Centre d'Estudis Avançats de Blanes- CEAB-CSIC, Integrative Freshwater Ecology Group, Girona, Spain
[3]Catalan Institute for Water Research, Resources and ecosytems, Girona, Spain

Backgrounds

Wastewater discharges into surface waters impair their quality by altering not only their overall chemistry and nutrient dynamics but also by introducing antibiotic residues and antibiotic-resistant bacteria (ARB) that directly affect the streambed resistome.

Objectives

The study was aimed to assess the impact of raw and treated wastewater on streambed biofilms at three levels: *i)* on the composition of bacterial communities; *ii)* on the abundance of antibiotic resistance genes (ARGs); and *iii)* on the occurrence of wastewater-derived putative pathogens and their linkage to ARGs.

Methods

The study was carried out in two tributaries of the Ebre River that receive discharges of either treated wastewater or raw sewage. In both streams, epilithic and epipsammic biofilms were collected upstream (control) and downstream (impact) the effluent discharge. The concentration of eleven ARGs, class 1 Integron integrase (*intI1*) and 16S rRNA genes and the composition of streambed biofilms communities were determined by qPCR and high-throughput sequencing, respectively. The occurrence of potential pathogens was assessed by comparing representative OTUs against an in-house database of 283 human and animal pathogens.

Conclusions

Raw sewage discharges had a larger effect than treated wastewater on the composition of bacterial communities and their associated resistome. This effect was especially noticeable in epilithic biofilms, which showed communities more enriched in ARB and potential pathogens than epipsammic biofilms. Our study provides evidences that epilithic biofilms act as source and sink of ARGs and ARB and corroborate that they are sensitive indicators of antibiotic pollution in riverine ecosystems receiving wastewater discharges.

INSIGHT INTO GENOMIC PLASTICITY OF PSEUDOMONAS PUTIDA KF715 WHICH HAS UNIQUE PROPERTIES IN BIPHENYL-UTILIZING ACTIVITY AND GENOME INSTABILITY

H. Suenaga[1], H. Fujihara[2], N. Kimura[3], J. Hirose[4], T. Watanabe[5], T. Futagami[6], M. Goto[7], K. Furukawa[2]
[1]National Institute of Advanced Industrial Science and Technology AIST, Biotechnology Research Institute for Drug Discovery, Tokyo, Japan
[2]Beppu University, Department of Food and Nutrition, Beppu, Japan
[3]National Institute of Advanced Industrial Science and Technology AIST, Bioproduction Research Institute, Tsukuba, Japan
[4]University of Miyazaki, Department of Applied Chemistry- Faculty of Engineering, Miyazaki-, Japan
[5]Kyoto University, Research Institute for Sustainable Humanosphere, Uji, Japan
[6]Kagoshima University, Education and Research Center for Fermentation Studies- Faculty of Agriculture, Kagoshima, Japan
[7]Saga University, Faculty of Agriculture, Saga, Japan

Backgrounds

Biphenyl-utilizing *Pseudomonas putida* KF715 has the unique properties in both catabolic activity and genome instability. We have revealed that DNA region encoding the biphenyl metabolisms (*bph*), was frequently deleted and transferred by conjugation to closely related *P. putida* strains.

Objectives

We reveal the genome plasticity of KF715 which is comprehensive model strain for better understanding of its potential versatile catabolic properties and genome rearrangements for the environmental adaptation.

Methods

We first determined the complete nucleotide sequence of the KF715 wild type genome. Secondly, KF715 genome was compared with those of one KF715 defective mutant (KF715M2) and two transconjugants (AC30Bph+ and KT2440 Bph+) together with several *P. putida* strains available in public database.

Conclusions

The gapless KF715 genome sequence revealed large number of plasmids (pKF715A, pKF715B, pKF715C and pKF715D). Southern blot analyses indicated the majority of KF715 cell population carry the *bph* genes on chromosome and fewer carry it on plasmid pKF715A, and the pKF715A transfer by conjugation to recipient strains. These results suggested that pKF715A behave as Integrative and Conjugative Element (ICE). However, unlike to typical ICE, pKF715A carrying *bph* genes transfer by conjugation to recipient strains and did not integrate into chromosome in its recipient. Furthermore, by comparative genome analysis, a number and variety of putative genetic elements which play a significant role in genome rearrangements were found in KF715. These genome data of KF715 provide insight into the genetic plasticity and adaptability of microorganisms in various ecological niches.

RUMEN FERMENTATION CHARACTERISTICS AND MICROBIAL QUANTITIES OF DAIRY COWS DURING ADAPTATION PERIOD OF CHANGING DIET

L. Mamuad[1,2], S.H. Kim[2,3], Y.J. Choi[2], M. Lee[2], S.S. Lee[2]
[1]The Ohio State University, Animal Sciences, Columbus, USA
[2]Sunchon National University, Animal Science and Technology, Suncheon, Republic of Korea
[3]The Ohio State University, Animal Sciences, Wooster, USA

Backgrounds

Animals become acclimated to the treatments before data are collected during adaptation period where rumen microbiota also undergoes populational and metabolic changes.

Objectives

This study evaluated the effects of changing diet during adaptation on the rumen microbiota and its fermentation characteristics.

Methods

Three Holstein-Friesian cows were initially fed with Italian ryegrass *ad libitum* and 2 kg concentrate diet per day and for 30 days. Then, 8 kg/day of concentrate diets were given for 14 days and then changed to 2 kg/day for another 14 days. Rumen fluids were collected 2 h after morning feeding through stomach tubing at the start of the experiment, at day 7 and 14 of the diets. pH, VFA, and microbial quantities were determined.

Conclusions

The highest pH (7.02) was observed at the start of the experiment while the lowest pH (6.80) at the end of the feeding trial. Concentrations of acetate (56.76 mM), propionate (13.28 mM), and butyrate (6.60 mM) peaked ($P<0.01$) at day 14 day of consuming 8 kg concentrate. The total bacteria quantity was comparable throughout the feeding trials. *Ruminococcus flavefaciens* (4.64 and 5.08) and protozoa (1.94 and 2.00) log copies were highest at day 7 of feeding 8 kg and 2 kg concentrate diets. The lowest methanogen quantity was observed at the start of the experiment (2.96 log copies) with increasing copies until the end of the feeding trial, which was the highest (3.63 log copies). The rumen fermentation characteristics and microbial quantities changed with changing diet during adaptation period.

THE DIFFERENTIATION OF BACTERIA INSIDE PEA SYMBIOTIC NODULES IS REGULATED BY THE PLANT GENE SYM31

A. Sulima[1], A. Afonin[1], A. Zhernakov[1], V. Zhukov[1], I. Tikhonovich[1]
[1]All-Russia Research Institute for Agricultural Microbiology ARRIAM, Laboratory for Genetics of Plant-Microbe Interaction, Saint-Petersburg, Russia

Backgrounds

The development of symbiotic nitrogen-fixing nodules in the leguminous plants (family Fabaceae) is controlled by a complex system of plant genes. Mutation analysis is a powerful tool for the study of this system. The pea (*Pisum sativum* L.) mutant Sprint-2Fix$^-$ carrying a mutation in the gene *Sym31* is characterized by a unique phenotype not described for other model legumes: halting of nodule development coupled with the block of the bacteria differentiation into a specialized symbiotic form called bacteroids.

Objectives

The aim of this study was to compare the coordinated gene expression of both symbionts in nodules of mutant and wild type plants.

Methods

To this end, the combined bacterial and plant transcriptomes of wild-type and mutant nodules, as well as that of free-living bacteria, were sequenced using the novel 5'MACE approach. This method increases the accuracy of differential gene expression analysis by sequencing only a small fragment of each mRNA directly adjacent to the 5' end.

Conclusions

Only in bacteria in wild-type nodules the increased expression of several genes related to the TCA cycle, nitrogen assimilation and transportation of nitrate was observed, while the expression of genes related to quorum sensing, chemotaxis and antibiotic synthesis was decreased. The genes responsible for metabolism of sulfite anion were active in bacteria from the wild-type nodules, while in mutant nodules their expression was significantly lower than even in free-living bacteria, which correlates with decreased expression of plant genes controlling the sulfur compounds transport.

This work was supported by Russian Science Foundation [grant 14-24-00135].

CHARACTERIZATION AND PURIFICATION OF ANTIFUNGAL METABOLITES FROM PAENIBACILLUS SP 16A AGAINST PHYTOPATHOGENS

A. Sundararaman[1], *S.S. Lee*[1]
[1]*Kyonggi University, Life Science, Suwon, Republic of Korea*

Backgrounds

Phytophathogen *Cylindrocarpon*s sp. is detrimental to various agronomic crops, especially *Panax ginseng*. Ginseng is the most widely cultivated as medicinal herb in Korea. Ginseng field are most susceptible for plant pathogenic fungi such as *Cylindrocarpons*, *Alternaria* and *Botrytis*. After the harvest of ginseng from the farm, pathogenic fungi were latent for 3 or 4 years in the rhizosphere and they had influenced in re-cultivation of the ginseng.

Objectives

This study is to identify the potential antifungal bacteria and develop the strain as a biocontrol agent against the phytopathogen *Cylindrocarpon destructans.*

Methods

The potent candidate strain was identified as *Paenibacillus* sp. by 16S rRNA sequencing. Crude metabolite was obtained from cell free supernatant of *Paenibacillus* sp. 16a by ethyl-acetate extraction and it was dissolved in methanol for further purification by column chromatography. The fractions were obtained through the sephadex column were checked for purity by HPLC. The HPLC detections confirmed the presence of single metabolite and purified fraction was observed for antagonistic activity against all the fungal test pathogens. The radial plate assay confirmed the rate of inhibition up to 60.0% against 8 phytopathogens and the metabolite responsible for antifungal activity was identified by LC-MS to be belonging to the class of peptides.

Conclusions

The results demonstrated that *Paenibacillus* sp. 16a *in vitro* study has wide spectrum of antifungal activity to be used as a potential biocontrol agent against fungal phytopathogens. Further studies focus on the *in vivo* efficacy of strain 16a in inhibiting fungal pathogens.

ISOLATION AND CHARACTERIZATION OF THE NOVEL SPECIES CANDIDATES FROM THE GUT OF THE SPOONBILL AND VULTURE

H. Sung[1], H.S. Kim[1], J.Y. Lee[1], W. Kang[1], P.S. Kim[1], D.W. Hyun[1], E.J. Tak[1], M.J. Jung[1], J.H. Yun[1], M.S. Kim[1], N.R. Shin[1], T.W. Whon[1], J.W. Bae[1]
[1]Kyung Hee University, Department of Biology, Seoul, Republic of Korea

Backgrounds

To investigate the bacterial community in the gut of a black-faced spoonbill (Platalea minor) and cinereous vulture (Aegypius monachus), we performed bacterial isolation from fecal samples of two birds protected by Seoul Grand Park Zoo, Korea.

Objectives

We wanted to find out the bacterial community in the gut of the birds, and discover what putative novel microbes can be recovered in a laboratory environment.

Methods

We innoculated the serially diluted fecal samples onto 5 following agars; Marine agar(MA, DifcoTM), Lactobacilli MRS agar(MRSA, DifcoTM), Tryptic soy agar(TSA, BactoTM), R2A agar(R2A, DifcoTM), MacConkey agar(Mac, BBLTM). Using this culture-dependent method, we obtained 126 isolates and 187 isolates from the fecal samples of cinereous vulture and black-faced spoonbill, respectively. Then, we conducted the phylogenetic analysis on the basis of the 16S rRNA.

Conclusions

Consequently, 29 isolates were putative novel species candidate, according to the phylogenetic analysis based on the 16S rRNA gene sequences.
At phylum level, 23, 12, and 2 strains were comprised of Firmicutes, Actinobacteria and Proteobacteria, respectively. In genus level, we found out bacteria which share high sequence similarity with the genus Tumebacillus (3), Virgibacillus (1), Sporosarcina (3), Bacillus (2), Vagococcus (2), Jeotgalibaca (1), Paenibacillus(1), Erysipelothrix(2), Actinomyces (2), Brachybacterium (3), Ornithinimicrobium (1), Kocuria (2), Herbiconiux (1), Micrococcus (1), Brevibaterium (1), Microbacterium(1), Psychrobacter (1), and Oceanisphaera (1 strain).
To identify and characterize these bacterial species, genotypic, phylogenetic, biochemical, phenotypic and chemotaxonomic analyses are in progress.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

MONITORING BACTERIAL DEPOSITION IN POROUS MEDIA BY PREDATORY BACTERIA

R. Sungthong[1], *W. T. Sloan*[1], *A. J. Pinto*[2]
[1]*University of Glasgow, School of Engineering, Glasgow, United Kingdom*
[2]*Northeastern University, Department of Civil and Environmental Engineering, Boston- MA, USA*

Backgrounds

Bacterial deposition in porous media is an important microbial property affecting range of environmental technologies, e.g., prevention of pathogen dispersion towards groundwater, optimization of subsurface bioremediation, and development of biofiltration in water treatments.

Objectives

In order to optimize the biofiltration by exploiting predatory bacteria, we assessed how these bacteria behave through porous media of sand-packed columns and how they influence the transport and deposition of a coliform bacterium, *Escherichia coli* through the columns.

Methods

Bdellovibrio bacteriovorus HD100 and its saprophytic mutant (HI100) were utilized as predatory bacteria.

Conclusions

Our findings revealed that only ~20% of HD100 cells could deposit in the columns, and such amount of deposited HD100 cells could diminish the deposition rate of *E*. *coli* cells in the same columns by up to 35%. However, up to 55% of *E*. *coli* cells pre-deposited in the columns was removed after dosing with HD100 cell suspension. Although pre-saturated cell-free culture (CFC) broth of strain HI100 in the columns did not show significant effect on the deposition rate of *E*. *coli* cells, it could remove up to 50% of *E*. *coli* cells pre-deposited in the columns. The viability of *E*. *coli* in the column effluents did not change after dosing with HD100 cell suspension or CFC broth of strain HI100, suggesting that either deposition or detachment of *E*. *coli* cells was a result of the interfacial interactions with predatory bacteria and/or their extracellular metabolites. This study provides new insights into an attempt for implementing microbial management in the optimization of biofiltration design and performance.

PHYTOCHEMICAL PROPERTIES SHAPE COMMUNITY STRUCTURES OF CULTIVABLE ACTINOBACTERIA INHABITING PLANT INTERIORS OF DIFFERENT THAI PIGMENTED RICE CULTIVARS

N. Nakaew[1], R. Sungthong[2]
[1]Naresuan University, Department of Microbiology and Parasitology, Phitsanulok, Thailand
[2]University of Glasgow, School of Engineering, Glasgow, United Kingdom

Backgrounds

Microbes that live at plant interiors are known as endophytes, which are one among the best-known plant-microbe interactions. Hitherto, it is conceivable that plant interiors are a promising source of numerous bioactive actinobacteria for novel drug discovery. However, little is known about the diversity and ecological functions of cultivable actinobacteria that inhabit the plant interiors of Thai pigmented rice.

Objectives

This study aims of investigating the abundance and plant growth-promoting (PGP) potentials (e.g., antimicrobial activities and productions of ammonia, indole acetic acid, siderophores, etc.) of cultivable actinobacteria isolated from the plant interiors of different Thai pigmented rice cultivars, i.e., Hom Nin (HN) rice and Luem Pua (LP) glutinous rice.

Methods

Surface sterilized plant materials (roots, stems, and leaves) derived from 15-day-old seedlings of both rice cultivars grown in the same soil were used as the sources for isolation of actinobacteria. The water used for the final wash of the plant materials served as the controls of the surface sterilization.

Conclusions

A total number of 66 actinobacterial isolates was obtained, while both rice cultivars housed an equal isolate number (33), and more than 50% of these actinobacteria exhibited at least one PGP potential. *Streptomyces* (55%), *Microbispora* (36%), and unclassified actinobacteria (9%) were derived from HN rice, while only *Microbispora* (97%) and unclassified actinobacteria (3%) were derived from LP glutinous rice. Our findings revealed that the difference in seedling phytochemical properties of both rice cultivars would be a key factor, affecting the community structures of cultivable actinobacteria that live at the interiors of rice plants.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

RE-APPEARANCE OF BACTERIA IN ANTIBIOTIC TREATED MICE AFTER EXPOSURE TO METHYL-MERCURY

C.S. Svanevik[1], L.S. Myrmel[2], E. Fjære[2], A. Maage[1], L. Madsen[2], B.T. Lunestad[1]
[1]National Institute of Nutrition and Seafood Research, Contaminants and Biohazards, Bergen, Norway
[2]National Institute of Nutrition and Seafood Research, Seafood in model systems, Bergen, Norway

Backgrounds

The demonstrated co-selection of resistance to antibiotics and mercury (Hg) may suggest that mercury could act as a driving force for the development of antibacterial resistance.

Objectives

This study examined the different taxa of culturable bacteria in faeces from mice treated with antibiotics and subsequently exposed to methyl mercury (MeHg).

Methods

Mice were treated with an antibiotic cocktail (AB-C) (ampicillin, vancomycin, ciprofloxacin, imipenem, and metronidazole) through the drinking water one week prior exposure of MeHg. Control groups included mice that were given no treatment, only antibiotics or only MeHg exposure. Faecal samples were examined for cultivable bacteria on selective agar plates. Heterotrophic plate counts (HPC) on Mueller-Hinton agar were examined the last week, including MH agars added three concentrations of: the AB-C, the combination of AB-C and MeHg, and only MeHg.

Conclusions

A re-appearance of Bacteroides, Enterobacteriaceae, Enterococci, and in particular Clostridiales were seen in mice treated with AB-C and exposed to MeHg.

HPC showed that faeces from mice treated with AB-C and exposed to MeHg held log 5.4 cfu/g compared to log 8.6 cfu/g in the control, and absence in mice treated with AB-C only.

These bacteria grew in all MH plates with low concentrations, and one sample grew on MH with medium concentrations of AB-C and MeHg, where the control samples did not grow.

We cannot exclude that MeHg could have triggered mechanisms in dormant bacteria to better tolerate the antibacterial treatment, and thus be the reason why the bacteria of some taxa re-appear in the mouse faeces.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

EVALUATION OF CULTURABLE BIFIDOBACTERIAL POPULATION INHABITING THE DIGESTIVE TRACT OF WILD PIGS BASED ON FOUR MOLECULAR GENETICS METHODS

R. Pechar[1], J. Killer[1], V. Rada[1], R. Švejstil[1]
[1]Czech University of Life Sciences Prague, Department of Microbiology- Nutrition and Dietetics, Prague 6, Czech Republic

Backgrounds

One hundred forty-six fructose-6-phosphate phosphoketolase positive bacterial strains were isolated from ileal and rectal contents of twenty-one individuals of wild and feral pigs and based on PCR-DGGE technique targeting the hypervariable V3 region of the 16S rRNA genes, strains were initially differentiated into four groups: i) including probably a new *Bifidobacterium* species (86 strains), ii) including *B. boum/B. thermophilum/B. thermacidophilum* subsp. *porcinum/B. thermacidophilum* subsp. *thermacidophilum* (sub)species (49 strains), iii) represented by *Pseudoscardovia suis* (7 strains) and iv) including *B. pseudolongum* subsp. *globosum/ B. pseudolongum* subsp. *pseudolongum* (4 strains), respectively.

Objectives

The objective was to identify and differentiate intestinal bifidobacterial population of wild pig.

Methods

Strains were further identified by the 16S rRNA gene sequences, and newly using the *dnaK* (encoding the chaperone protein DnaK) and *thrS* (encoding the threonyl-tRNA synthase) gene fragments.

Conclusions

Phylogenetic study allowed to classify members of the first group into five subgroups in a separated cluster of thermophilic bifidobacteria.

Comparative and phylogenetic study based on *thrS* sequences revealed 11 STs (sequence types) classified into 5 different phylotypes, (*Bifidobacterium* sp., *B. boum*, *B. thermophilum/B. thermacidophilum* subsp. *porcinum*/*B. thermacidophilum* subsp. *thermacidophilum*, *P. suis* and *B. pseudolongum* subsp. *globosum/ B. pseudolongum* subsp. *pseudolongum*). Analyses using *dnaK* gene determined 12 STs belonging to 4 phylotypes.

Overall, above molecular genetic techniques allow to identify a probably new *Bifidobacterium* species which is predominant in the digestive tract of examined wild and feral pigs. The second largest group of culturable bifidobacteria is represented by the *B. thermophilum/B. thermacidophilum* subsp. *porcinum*/ *B. thermacidophilum* subsp. *thermacidophilum* phylotype.

INFERENCE OF MICROBIAL INTERACTION NETWORKS FROM MASSIVE DATA SETS THROUGH CAUSAL KNOWLEDGE DISCOVERY

J. Tackmann[1], *J.F.M. Rodrigues*[1], *C. von Mering*[1]
[1]*Universität Zürich, Institute of Molecular Life Sciences, Zürich, Switzerland*

Backgrounds

The recent explosion of metagenomic sequencing data makes tools for rapid computational analysis essential. While such software is becoming increasingly available for OTU mapping and clustering, prediction of microbial interactions based on co-occurrence is still lagging behind.

Objectives

While simple correlation-based tools scaling to large numbers of OTUs and samples exist, these do not distinguish between direct and indirect interactions, resulting in unacceptably high numbers of false positives. Approaches with better resolution, on the other hand, are so far highly limited in the size of data sets they can process. Furthermore, environmental factors, while being important modulators of microbial interactions, are usually not considered by available software. Finally, we observe traditional approaches to produce large numbers of false positives due to double-zero inflation caused by environmental niches in composite datasets.

Methods

We adopt a machine learning framework based on Probabilistic Graphical Models and inspired by causal theory to infer highly resolved microbial interactions from large data sets, with seamless integration of environmental variables and optional adjustment for sub-niches.

Conclusions

The method is highly optimised for speed, scaling to thousands of OTUs and samples and surpassing methods with comparable accuracy by more than an order of magnitude. In benchmarks on several synthetic data sets, it provides accuracy comparable to or surpassing state-of-the-art methods. We apply this approach to a massive meta-dataset of publicly available human feces samples (>37.000 samples), resulting in the largest and most diverse survey of microbial interactions in the human gut to date.

VAGOCOCCUS CREMEUS SP. NOV., ISOLATED FROM THE SMALL INTESTINE OF A MARTEN, MARTES FLAVIGULA

E. Tak[1], H.S. Kim[1], J.Y. Lee[1], W. Kang[1], J.W. Bae[1]
[1]Kyung hee univrsity, Biology, seoul, Republic of Korea

Backgrounds

Martens live in wild forest and they are predator eating other wild animals like badgers, squirrels, birds, boars and elks (PARR[1] & Duckworth, 2007). It is important to investigate gut microbiota of wild animal because the gut microbiota have a lot of influence on their host (Tremaroli & Bäckhed, 2012).

Objectives

Because most wild animals including martens are protected at the state level, it is difficult to investigate their gut microbiota while they are alive. So we used a small intestinal tract sample of the marten, which was killed on the road in Pocheon-si, Gyeonggi-do, Republic of Korea and obtained from the National Institute of Biological Resources (NIBR), for investigating gut microbiota.

Methods

Homogenized intestinal tissue and fluid were diluted with filtered PBS into 10^{-5}, 10^{-6} and 10^{-7}, which were spread onto TSA, R2A, MA and, MRSA plates, respectively. After aerobic incubation at 20 ˚C and 37 ˚C, 53 isolates were obtained as a result of culture-dependent manner. Of that, strain D7T301^{T} was collected from a TSA medium at 37 ˚C.

Conclusions

Strain D7T301^{T} was isolated from the small intestinal tract sample of a *Martes flavigula*, which is Korean endemic species. The isolate is Gram-stain-positive streptococci, non-motile, facultative aerobic, catalase-negative and oxidase-negative. *Vagococcus cremeus* is proposed as a novel species within the genus *Vagococcus* on the basis of the phenotypic, phylogenetic, biochemical, chemotaxonomic and genotypic analyses, with strain D7T301^{T} as the type strain.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

FUNCTIONAL METAGENOMICS OF LOW LATITUDE AREAS OF THE PACIFIC OCEAN

H. Takami[1], K. Takemoto[2], W. Arai[1], Y. Ogura[3], T. Hayashi[3], K. Hamasaki[4]
[1]Japan Agency for Marine-Earth Science and Technology, Yokohama Institute, Yokohama, Japan
[2]Kyushu Insitute of Technology, Bioscience and Bioinformatics, Iizuka, Japan
[3]Kyushu University, Faculty of Medical Sciences, Fukuoka, Japan
[4]The University of Tokyo, Atmosphere and Ocean Research Institute, Kashiwa, Japan

Backgrounds

Although many metagenomic analyses of environmental samples were reported so far, functional information of microbial community is very poor.

Objectives

We performed functional metagenomics of surface sea water samples collected at 9 sites of low latitude areas in the Pacific Ocean from 2011 to 2012 to highlight difference in functional traits of ocean microbial community.

Methods

The collected samples were divided into two fractions (free-living and particle-associated ones) by different pore size filters (0.2-3.0µm and >3.0µm) and metagenomic DNAs were isolated from each sample. One to two million sequences with continuous 300 bp (paired-end) were produced by MiSeq from each sample. Amino acid sequences of the genes predicted by MetaGeneAnnotator were applied to MAPLE system for evaluation of metabolic potential in each sample.

Conclusions

According to community structure analysis based on ribosomal proteins detected by MAPLE, all free-living fractions from 9 sites were mostly composed of bacteria (>99%) although all particulate associate fractions contained achara of 3~6.5% and eukaryote of 2.4~5%. We calculated completion ratio (%) to the KEGG functional modules and the abundance of complete modules in each metagenome samples. We performed canonical correlation analysis based on the module abundance to highlight difference in functional traits between free-living and particle-associated fractions. As a result, we found that free-living fraction correlates to the modules for amino acid biosynthesis and transporters such as amino acid and metal ion. On the other hand, particulate associate fraction was found to correlate to the module of C1 unit inter conversion related to eukaryotic folate metabolism.

COMPARISON OF THE MICROBIOTA OF ANTERIOR AND POSTERIOR INTESTINE OF FARMED SENEGALESE SOLE (SOLEA SENEGALENSIS)

S.T. Tapia-paniagua[1], M. Domínguez Maqueda[2], I. García de la Banda[3], X. Moreno-Ventas[5], M.D.C. Balebona[2], M.A. Moriñigo[4]
[1]Universidad De Malaga, Microbiologia, Malaga, Spain
[2]Universidad De Malaga, Microbiology, Malaga, Spain
[3]Spanish Institute Of Oceanography, Estacion De Cultivos El Bocal-, Santander, Spain
[4]Universidad De Malaga, Microbiologia, Malaga, Spain
[5]Universidad de Cantabria, Santander, Spain

Backgrounds

The intestinal microbiota plays important functions in the host. In this context, previous studies have analyzed the intestinal microbiota of *Solea senegalensis*, one farmed fish with high economic interest, using conventional approaches such as DGGE. However, the use of innovative technologies, such as NGS is driving understanding of the interactions between the microbiota and the host.

Objectives

For this reason, the objective of this study was to apply NGS technology to determine and to compare the intestinal microbiota of *S. senegalensis* considering the structural and morphologic differences between anterior and posterior intestine.

Methods

Samples were collected from anterior and posterior intestine. DNA was extracted from intestinal samples and was sent to ChunLab (Seoul, Korea) to determine the microbial DNA sequences of the 16S rRNA gene by Illumina technology. Sequences were analyzed using CLcommunity™ software (ChunLab). Sequences of a length less than 200 nt were excluded from the analysis. The data were filtered for noisy sequences, checked for the presence of chimeras, and binned into OTUs at the 97% sequence similarity level. A representative sequence of each OTU was taxonomically classified. The relative abundance of microbial clades at different taxonomic levels was calculated as the average value from two independent analyses and was used to perform the comparative distribution analysis.

Conclusions

Microbial diversity in anterior intestine was higher than in posterior intestine.

Proteobacteria and *Actinobacteria* were the most predominant phyla in anterior intestine, whereas *Spirocchaetes* and *Brevinema* were the most frequent genus detected in posterior intestine.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

DETECTION, ISOLATION AND CHARACTERIZATION OF PLASMID DNA FROM FISH PATHOGENIC AND PROBIOTIC SHEWANELLA PUTREFACIENS STRAINS

M. Maqueda Dominguez[2], S.T. Tapia-paniagua[1], E. Alcaide[3], C. Esteve[3], M.D.C. Balebona[4], M.Á. Moriñigo[4]
[1]Universidad De Malaga, Microbiologia, Malaga, Spain
[2]Universidad De Malaga, Microbiology, Malaga, Spain
[3]University Of Valencia, Departament Of Microbiology And Ecology, Valencia, Spain
[4]University Of Malaga, Microbiology, Malaga, Spain

Backgrounds

Plasmids are important vehicles for rapid adaptation of bacteria to changing environments, providing beneficial accessory traits, such as degradative pathways and pathogenicity determinants. *Shewanella putrefaciens* Pdp11 (SpPdp11) is proposed as probiotic for farmed fish and for this reason, the evaluation of the plasmid content in this bacteria is important for its future applications in aquaculture.

Objectives

The objective of this study was the detection of plasmids in SpPdp11 cells to carry out the comparison to those detected in *S. putrefaciens* pathogenic strains.

Methods

SpPdp11 was isolated from healthy gilthead seabream, whereas pathogenic *S. putrefaciens* strains (SH2, SH4, SH6, SH16 and SH19) were isolated from diseased eels. For isolation of plasmid DNA from *S. putrefaciens* the strains were grown in trypticase soy broth, supplemented with 15% sodium chloride. Plasmids DNA from bacterial cells were isolated using Plasmid DNA miniprep kit (Thermo Scientific, Germany). An agarose gel electrophoresis (1% agarose, 0.5% TAE) was performed for the separation of the plasmid DNA at 50 V for 1 h. The molecular weight was calculated using the equivalence 1.0 µM = 2.07 x 10^6 Daltons. Restriction enzymes Sau3AI and SauII were used to digest the plasmids with the same molecular weight and the fragments were separated by agarose gel electrophoresis.

Conclusions

Two different plasmids were detected in SpPdp11 strain whereas only two pathogenic strains contained plasmids, with a different one each of them.

None of these plasmids corresponded to those detected in SpPdp11.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

COMPOSITION OF THE MICROBIOTA PRESENT IN SKIN MUCUS FROM ULCERATED AREAS OF SPARUS AURATA AND COMPARISON WITH HEALTHY SKIN.

S.T. Tapia-Paniagua[1], M. Fumanal[1], H. Cordero[2], M.C. Balebona[3], X. Moreno Ventas[3], M.Á. Esteban[4], M.Á. Moriñigo[5], D. Ceballos-Francisco[4]
[1]Universidad De Malaga, Microbiologia, Malaga, Spain
[2]Faculty Of Biology- University Of Murcia-, Department Of Cellular Biology And Histology., Murcia, Spain
[3]University Of Malaga, Microbiology, Malaga, Spain
[4]University Of Murcia, Department Of Cell Biology And Histology, Murcia, Spain
[5]University Of Malaga, Microbiology, Malaga, Spain

Backgrounds

Skin is the first line of defense, but alike to mammals, fish skin can be considered a mucosal tissue. Teleost fish skin has shown to contain associated lymphoid tissue similar to that of the gut-associated lymphoid tissue, and including antimicrobial peptides, lectins, assorted pathogen recognition receptors (PRR), lysozymes, immune respondents and similarly to the fish gut it harbors a microbiota. The interest in understanding components of the mucosal immune system of fish is growing but it is still limited.

Objectives

The objective of this study has been to evaluate the composition of the microbiota detected in ulcers of skin of gilthead seabream (*Sparus aurata*) and to compare it with the skin microbiota of healthy seabream.

Methods

Skin were collected from experimental chronic ulcers and non-injury areas of healthy specimens of gilthead seabream (*Sparus aurata* L.). DNA was extracted from samples and was sent to ChunLab (Seoul, Korea) to determine the microbial DNA sequences of the 16S rRNA gene by Illumina technology. Sequences were analyzed using CLcommunity™ software (ChunLab). The relative abundance of microbial clades at different taxonomic levels was calculated and used to perform the comparative distribution analysis.

Conclusions

Significant differences were detected in the microbiota from ulcerated skin in comparison with health skin: (1) increases of γ–Proteobacteria such as Vibrionales and Alteromonadales; (2) levels of members of Bacteroidetes and Firmicutes such as Bacteroidaceae and Lactobacillaceae decreased, while Prevotallaceae and Streptococcaceae were increased.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

RHEOLOGICAL CHARACTERIZATION OF IN SITU YEAST BIOFILMS

M.C. Tarifa[1], *L.I. Brugnoni*[2], *J.E. Lozano*[1], *D. Genovese*[1]
[1]*Planta Piloto de Ingeniería Química CONICET-UNS, Ingeniería de Alimentos, Bahía Blanca, Argentina*
[2]*Instituto de Ciencias Biológicas y Biomédicas del Sur CONICET-UNS, Microbiología Industrial y de los Alimentos, Bahía Blanca, Argentina*

Backgrounds

In industrial processes biofilms are grown under a wide distribution of local hydrodynamic strengths; consequently biofilms are characterized by their thickness, architecture, and rheological properties.

Objectives

To study the response in the mechanical properties of yeast biofilms to variations in flow conditions and food matrix.

Methods

A suspension of *Candida tropicalis, C.krusei, C.kefyr* and *Rhodotorula mucilaginosa* isolated from juice ultrafiltration membranes, was done in apple and pear juice (≈10^6 cells/ml of each strain). Biofilms were done on stainless steel surfaces for a period of one month under static and turbulent flow, and two juice concentrations (6 and 12 °Brix). Samples were taken off the system for rheological measurements, counts and SEM processing. Viscoelastic properties were determined by small deformation dynamic oscillatory measurements in a Paar Physica rheometer MCR301, using parallel plates, whereas CHROM agar *Candida* was used for counting.

Conclusions

The results showed that yeast biofilms had a predominately solid-like behaviour indicating gel-type structures, being G' higher than G" at all frequencies studied. Average loss tangent (tan δ) values were low (< 0.25) and approximately independent of frequency. Under turbulent flow biofilms were structurally stronger than under static conditions and presented higher counts (at least 0.5 Log units). The only specie not recovered was *R. mucilaginosa*; the biofilms formed presented tighter structures when subjected to a flow. Rheology determines the mechanical stability of biofilms, its knowledge is crucial to fully interpret their behavior. From our results the type of flow was de parameter that most influenced the development and strength of the biofilms.

FEMS7-0483
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

IMPACT OF FLOW CONDITIONS AND SURFACE TYPE ON THE RESISTANCE OF CANDIDA TROPICALIS BIOFILMS TO DISINFECTION

M.C. Tarifa[1], *B. Pitts*[2], *P. Stewart*[2]
[1]*Planta Piloto de Ingeniería Química CONICET-UNS, Ingeniería de Alimentos, Bahía Blanca, Argentina*
[2]*Center for Biofilm Engineering, Chemical & Biological Engineering, Bozeman, USA*

Backgrounds

While biofilm formation is a general characteristic of microbes, features such as architecture, matrix composition, and resistance to antimicrobials are species and substrate dependent.

Objectives

The aim was to delve into the response in thickness, architecture, and mechanical resistance of *Candida tropicalis* biofilms.

Methods

The strain used was *Candida tropicalis* ATCC 13803, which was cultivated in SDB for 48 and 72 h on stainless steel (SS) and polycarbonate coupons (4.05 cm^2). Two flow conditions were tested: turbulent flow with a CDC reactor (Biosurface Technologies, USA) (flow rate of 4 ml/min, speed of 200 rpm); and for static flow 12 wells plates were used. Coupons were subjected to the analysis of: mechanical resistance in a flow cell, counting, CLSM imaging and cryosectioning. For disinfection, coupons were treated with solutions of 200 ppm of NaClO for 15 minutes, and then neutralized in sodium thiosulfate 0.2%.

Conclusions

Biofilms were observed on SS and polycarbonate at 48 and 72 h after cell staining with LIVE/DEAD® Kit, increasing with Re and time. Flow conditions impacted biofilm architecture and thickness, under turbulent flow biofilms presented mushroom shapes with hyphae and the largest increase in thickness (> 90 µm), whereas static flow presented homogeneous layers of rounded cells (up to 30 µm). The results underline that the biofilm resistance to NaClO depended on the growth time, the surface type and the type of flow. At 48 h log reductions ranged between 0.2-0.58 and 1.2-1.36 for turbulent and static flow, respectively whereas at 72 h were of 0.32-1.7 and 2.65-2.82.

GUT MICROBIOTA DINAMICS IN CARNIVOUROUS FISH FED PLANT-BASED DIETS

C. Serra[1], P. Enes[1], A. Oliva-Teles[1,2], F. Tavares[2,3]
[1]CIIMAR- Centro Interdisciplinar de Investigação Marinha e Ambiental, Universidade do Porto, Matosinhos, Portugal
[2]FCUP – Faculdade de Ciências- Universidade do Porto, Departamento de Biologia, Porto, Portugal
[3]CIBIO - Centro de Investigação em Biodiversidade e Recursos Genéticos, InBIO- Laboratório Associado- Universidade do Porto, Vairão, Portugal

Backgrounds

A major challenge in carnivorous fish aquaculture production is the substitution of fish meal (FM), an unsustainable commodity and a source of organic pollutants, by plant feedstuffs (PF). PF have a limited nutritive value due to the presence of non-starch polysaccharides (NSP) which are not metabolized by fish. Thus, a selective pressure of NSP-enriched diets towards gut microbes with NSP-hydrolytic potential is expected to occur, helping the fish host to obtain energy from otherwise indigestible dietary constituents.

Objectives

Comprehensively assess the microbiota dynamics of carnivorous fish species in response to the dietary incorporation of plant feedstuffs.

Methods

Triplicate groups of European sea bass juveniles were fed a FM-based diet (control) or 3 PF-based diets (SBM, soybean meal; RSM, rapeseed meal; SFM, sunflower meal) during 6 weeks, before recovering intestinal samples for microbiota composition analysis using the Illumina´s MiSeq platform. QUIME software was used for taxonomy assignment and diversity analysis, and one-way ANOVA statistical analysis was carried out with IBM SPSS Statistics 24 and STAMP v2.1.3 software.

Conclusions

A significant (p=0.020) decrease in the *Chao1* species richness estimator index was observed in the gut samples of SBM and RSM experimental fish. The reduction on microbiota richness was accompanied by a decline on the relative abundance of *Acidobacteria* (p=0.030), *Elusimicrobia* (p=0.028) and *Nitrospirae* (p=0.010) phyla. On contrary, SBM and RSM PF-based diets seem to favor the *Firmicutes* (p=0.01), in particular the Bacillaceae (p=0.017) and Clostridiaceae (p=0.007), two bacterial families known to harbor carbohydrate active enzymes and thus putatively more prone to grow in high NSP environments.

STRAIN-LEVEL MICROBIAL POPULATION STRUCTURES FROM SHOTGUN METAGENOMICS USING STRAINPHLAN

A. Tett[1], D.T. Truong[1], E. Pasolli[1], C. Huttenhower[2], N. Segata[1]
[1]University of Trento, CIBIO, Trento, Italy
[2]Harvard School of Public Health, Biostatistics Department, Boston, USA

Backgrounds

It is becoming increasingly evident that crucial microbiome factors associated with human health and disease occurs at the level of microbial strains. Metagenomics offers the opportunity to characterise the communities at a strain-level resolution but appropriate computational methods are required.

Objectives

To fully exploit the potential of metagenomic sequencing we developed StrainPhlAn, a novel metagenomics strain identification approach, based on per-sample dominant sequence variant reconstruction within species-specific marker genes. It provides a strain-level phylogenetic overview of the microbial diversity within and between metagenomic samples.

Methods

We applied StrainPhlAn on lung metagenomes of cystic fibrosis patients and thousands of publically available gut metagenomes. Across metagenomes StrainPhlAn identified subject-specific strain variants (<5% inter-subject strain sharing), that are remarkably stable, with the dominant strain for each species being retained over time (for >70% of species). Applied to gut metagenomes, we found strong evidence of biogeographically correlated population structures suggesting intriguing hypotheses about their population biology. For instance, two common but poorly characterised gut species, *Eubacterium rectale* and *Prevotella copri,* display a discrete subspecies population structure compared to others such as *Faecalibacterium prausnitzii* which has a more continuous genetic variation across and within human populations. We further estimated the genetic variability of different gut inhabitants, with *Bacteroides* species showing relatively low species divergence compared to *P. corpi*, one of the most plastic gut colonisers.

Conclusions

StrainPhlAn has enabled the population structures of previously poorly characterised or inaccessible microbes to be studied providing a comprehensive strain level overview of lung and gut associated microbes.

DETERMINIG THE INFLUENCE OF SOIL PH ON THE ABUNDANCE, DIVERSITY AND ACTIVITY OF COMAMMOX AND CLASSICAL NITRITE-OXIDISING BACTERIA

C. Thion[1], Y. Meng[2], P. Pjevac[3], J.I. Prosser[2], H. Daims[3], G.W. Nicol[1]
[1]Ecole Centrale de Lyon, Laboratoire Ampère, ECULLY cedex, France
[2]Institute of Biological and Environmental Sciences, University of Aberdeen, Aberdeen, United Kingdom
[3]Department of Microbiology and Ecosystem Science, Division of Microbial Ecology, Vienna, Austria

Backgrounds

For over 100 years, aerobic nitrification was thought to be a separated two-step process, with ammonia oxidised to nitrite by ammonia oxidisers (AO), which was subsequently oxidised to nitrate by nitrite oxidising bacteria (NOB), including members of the *Nitrospira* and *Nitrobacter* genera in soil. This dogma was recently challenged by the discovery of *Nitrospira* performing both steps, or 'complete ammonia oxidation' (comammox), with representatives placed within two clades (A and B). Soil pH is a major factor controlling the distribution/activity of AO, however the role of pH influencing the distribution of NOB and comammox *Nitrospira* is unclear.

Objectives

Our objective was to determine how soil pH influences the distribution and activity of soil NOB, testing the hypothesis that *Nitrobacter* and *Nitrospira* (including comammox) communities in soils have contrasting pH preferences.

Methods

Using a long-term soil pH gradient, the community structure, abundance and activity of NOB were determined. qPCR and high-throughput sequencing of functional genes (nxrA, *nxrB*, *amoA*) demonstrated both *Nitrospira* and *Nitrobacter* were found in all soils, with distinct, pH-adapted populations within each genus. Only commamox clade B group was prevalent in soil, with their distribution congruent with that of all *Nitrospira*, i.e. low abundance (or not detected) in acidic soils and more abundant at neutral pH.

Conclusions

Nitrospira populations increased in both diversity and abundance with increasing soil pH, indicating that comammox *Nitrospira* are not likely to be major contributors to nitrification in low pH soils, but may make a major contribution to this process in neutral or alkaline soils.

EVOLUTION AND FUNCTION OF EUKARYOTIC-LIKE PROTEINS IN MICROBIAL SPONGE SYMBIONTS

T. Thomas[1], M. Nguyen[1], D. Reynolds[1], C. Diez-Vives[1], L. Moitinho e Silva[1], S. Nielsen[1], R. Thangamani[1]
[1]University of New South Wales, Centre for Marine Bio-Innovation, Sydney, Australia

Backgrounds

Sponges form ancient and complex symbiotic interactions with microorganisms. How these interactions are mediated on a molecular level is however poorly understood. Our recent (meta-) genomic analyses have uncovered the surprising presence and abundance of genes encoding for eukaryotic-like proteins (ELPs) in microbial symbionts of sponges.

Objectives

Here we hypothesise that these ELPs have an important function in mediating molecular interactions between sponges and their microbial symbionts.

Methods

We applied a range of phylogenetic, –omics and molecular techniques to describe the evolution and function of ELPs.

Conclusions

Phylogenetic analyses indicate that these ELPs have been horizontally transferred from sponges and other eukaryotes into symbiont lineages. Meta-transciptomic analyses showed that a large array of different ELPs is expressed under natural settings, indicating their functional role in symbiosis. Through recombinant approaches it was shown that ELPs can inhibit eukaryotic phagocytosis, which is a relevant phenotype for a symbiont to avoid being consumed by sponge amoebocytes. In fact, *Escherichia coli* cells, which recombinantly express ELPs from sponge symbionts, were able to persist inside sponges, while *E. coli* without ELPs were rapidly consumed. For some symbiont ELPs it was also shown that they specifically bind to sponge proteins involved bacterial recognition and degradation.

Overall these results support a model whereby microbial symbionts have acquired eukaryotic host genes that have subsequently evolved to function as molecular mediators of symbiotic interactions.

ANAEROBIC OXIDATION OF METHANE ASSOCIATED WITH SULFATE REDUCTION IN A NATURAL FRESHWATER GAS SOURCE

P. Timmers[1], D. Suarez-Zuluaga[2], M. van Rossem[1], M. Diender[1], A. Stams[1], C. Plugge[1]
[1]Wageningen University, Laboratory of Microbiology, Wageningen, The Netherlands
[2]Wageningen University, Environmental Technology, Wageningen, The Netherlands

Backgrounds

Anaerobic oxidation of methane (AOM) coupled to sulfate reduction (SR) occurs in marine sediments and is catalysed by anaerobic methane oxidizing archaea (ANME) and sulfate-reducing bacteria (SRB) of the SEEP-SRB1 clade of the Deltaproteobacteria. AOM can also be coupled to other electron acceptors, such as nitrate and metal-oxides (ferrihydrite, birnessite).

Objectives

In freshwater, AOM coupled to SR is thought to be limited by low sulfate concentrations, and has therefore not been extensively studied. Moreover, it is not known if different organisms are involved in freshwater AOM compared to marine environments. We therefore investigated the occurrence of AOM coupled to SR and the organisms involved in a freshwater natural gas source.

Methods

Freshwater samples were used in long-term incubations with and without $^{13}CH_4$ and with and without added electron acceptors (nitrate, sulfate, ferrihydrite, humic acids). After 323 days, archaeal and bacterial 16S rRNA gene profiling and qPCR analysis with specific primers for ANME archaea were performed.

Conclusions

Only with sulfate as electron acceptor, net AOM occurred and sulfide increased simultaneously with $^{13}CO_2$ production. Archaeal 16S rRNA gene analysis showed more ANME-2a/b sequences in incubations with methane and sulfate as compared with only methane addition. Higher abundance of ANME-2a/b in incubations with methane and sulfate as compared with only sulfate addition was shown by qPCR analysis. Bacterial 16S rRNA gene analysis showed presence of SRB belonging to SEEP-SRB1. This is the first report of an enrichment culture of ANME-2a/b and SEEP-SRB1 from a freshwater environment where AOM is associated with SR.

BACTERIAL COMMUNITY SHOWS HIGHLY ADAPTED GROUPS AND VARIOUS LIFE STRATEGIES DURING THE PROCESS OF DEADWOOD DECOMPOSITION

V. Tláskal[1], L. Štercová[1], T. Vrška[2], P. Baldrian[1]
[1]Institute of Microbiology - Academy of Sciences of the Czech Republic, Laboratory of Environmental Microbiology, Prague, Czech Republic
[2]The Silva Tarouca Research Institute for Landscape and Ornamental Gardening, Department of Forest Ecology, Brno, Czech Republic

Backgrounds

Nutrients fixed by photosynthesis in tree biomass are in significant amounts released after death of a tree in the process of deadwood decomposition. This process is driven by fungi and bacteria - microorganisms with several tools for degradation of recalcitrant plant polymers and compounds of microbial origin. However, the contribution of bacteria is far less understood than that of fungi.

Objectives

The aim of this work was to explore bacterial communities in logs of Abies alba and Fagus sylvatica from different phases of decomposition in the natural temperate forest in the Czech Republic and to identify drivers of community assembly.

Methods

Amplicon sequencing of 16S rRNA was used for characterization of community composition while deadwood censuses were the source of log characteristics and their history. Bacterial biomass and fungal/bacterial ratios were followed as well as wood chemistry.

Conclusions

Bacterial taxa typical for fresh deadwood showed the ability to decompose cellulose (*Cellulomonas*) and to fix nitrogen (*Methylocapsa*). Strategies for utilization of fungal biomass as a nutrient source (*Chitinophaga*) and association with mycosphere and rhizosphere (*Steroidobacter*) occurred in taxa present in older deadwood. Co-occurrence pattern analysis showed links between the occurrence of bacterial and fungal taxa either due to mycophagy or due to specialization for degradation of fungal metabolites by bacteria. Bacterial community appears to be driven more by fungal community and deadwood age rather than by tree species or spatial proximity of logs. Nitrogen fixation and mycophagy may represent bacterial strategies to overcome nitrogen limitation. Both strategies may have significant impact on ecosystem functioning.

BIOREMEDIATION POTENTIAL OF ENDOPHYTIC FUNGI MUCOR SP. ISOLATED FROM EICHHORNIA CRASSIPES (MART.) (PONTEDERIACEAE)

T. Tognolli de Almeida[1], J.L. de Azevedo[1], M.C. Quecine[2]
[1]University of São Paulo, Center of Nuclear Energy in Agriculture CENA/USP, Piracicaba, Brazil
[2]University of São Paulo, Department of Genetics- Luiz de Queiroz College of Agriculture, Piracicaba, Brazil

Backgrounds

Endophytic fungi live in the interior of plant tissues or organs, without causing harm to their hosts. The several interesting characteristics of these microorganisms include their bioremediation potential.

Objectives

This study aimed to examine the bioremediation potential of endophytic fungi *Mucor* sp. isolated from *Eichhornia crassipes*, through the absorption ability and fungal tolerance to the heavy metal cadmium.

Methods

For the evaluation of tolerance to the heavy metal cadmium, 6-mm plugs of endophyte were inoculated onto Potato dextrose Agar (PDA) Petri dishes supplemented with 250, 500, 1000 and 2000 mg/L of heavy metal Cadmium sulfate, incubated under B.O.D. at 28 ºC for 7 days. The metal tolerance index (Ti) was estimated by measuring the radial colony extension. For evaluating absorption ability of cadmium, Potato dextrose broth (PDB) containing 200, 400, 600, 800 and 1000 mg/L of cadmium sulfate was dispensed in 100 mL in conical flasks and inoculated with 6-mm plugs of endophyte and incubated at 28 ºC for 3, 9 and 15 days. The fungal growth was harvested through filtration. Then dried at 80 ºC for 18 h, the heavy metal concentration was estimated by Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES).

Conclusions

The metal tolerance index was highest (Ti >0.4) at 1000 mg/L. Regarding an increased cadmium biosorption, the highest absorption was 956 mg/g after 15 days of incubation.Therefore the results indicated that endophytic isolate *Mucor* sp. demonstrated the ability to retain the cadmium indicating its potential to be utilized for remediation of cadmium.

A NOVEL QUORUM-QUENCHING ENZYME IDENTIFIED IN A HYPERSALINE SOIL

M. Torres[1,2], S. Uroz[3], R. Salto[4], L. Fauchery[3], I. Llamas[1,2]
[1]University of Granada, Microbiology, Granada, Spain
[2]Institute of Biotechnology, Biomedical Research Center, Granada, Spain
[3]French National Institute for Agricultural Research INRA, Interactions Arbres-Microorganismes, Nancy, France
[4]University of Granada, Biochemistry and Molecular Biology, Granada, Spain

Backgrounds

Quorum sensing (QS) is an intercellular communication system mediated by signal molecules which is used by many bacteria to coordinate their behaviour. In order to interfere with QS, many of the competing organisms have developed different strategies, such as the enzymatic inactivation of the signal molecules, known as quorum quenching (QQ).

In recent years, the QS and QQ mechanisms have been described in numerous bacterial species. Nevertheless, there is very little data concerning these systems of regulation in hypersaline environments.

Objectives

The aim of this study is the identification and characterization of new QQ enzymes in a hypersaline soil of Spain by using a cultivation-independent approach.

Methods

In this communication we present the construction of a metagenomic library of 250,000 clones and the screening of its QQ activity. One clone was selected that allowed the degradation of a wide range of AHL-type signal molecules. The sequencing of the fosmid in the positive clone revealed a 42,318 bp environmental insert characterized by 46 ORFs. The sub-cloning of these ORFs demonstrated that a single gene (*hqiA*) allowed AHL degradation. Bio-informatic analyses highlighted that HqiA showed no sequence homology with the known prototypic AHL enzymes, expanding the AHL-lactonase family.

Conclusions

This study represents the first fosmid-based screening of a hypersaline soil metagenome to search for genes involved in QQ. A novel type of AHL-degrading enzyme has been identified, not previously related to the known prototypes. It has been tested *in vivo* and it is a very promising tool with biotechnological applications.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

GENOME ANALYSIS OF TWO ALTEROMONAS STELLIPOLARIS STRAINS WITH QUORUM QUENCHING ACTIVITY

M. Torres Bejar[1,2], T.M. Chong[3], K.W. Hong[3], K.G. Chan[3], Y. Dessaux[4], I. Llamas[1,2]
[1]University of Granada, Microbiology, Granada, Spain
[2]Institute of Biotechnology, Center for Biomedical Research, Granada, Spain
[3]University of Kuala Lumpur, Medicine, Kuala Lumpur, Malaysia
[4]National Center of Scientific Research CNRS, Microbiology, Gif-sur-Yvette- Paris, France

Backgrounds

The massive use of antibiotics has resulted in the development of resistant bacterial strains and ineffective antibiotic treatments. Therefore, new strategies to control bacterial infections are urgently needed and sought after. Nowadays, research is focused on finding alternatives to fight bacterial infections. One of them relies upon enzymatic degradation (quorum quenching, QQ) to target the intercellular communication systems (quorum sensing, QS) that regulate the production of virulence factors in pathogenic bacteria.

Since marine environments have been demonstrated to be an enormously rich source of new secondary metabolites to fight diseases, a bivalve hatchery in Granada (Spain) was analyzed, which allowed the selection of two *Alteromonas stellipolaris* strains showing QQ activity *in vivo*.

Objectives

The aim of this study is the sequencing and analysis of the genomes of two marine *A. stellipolaris* strains that have been reported to present QQ activity.

Methods

The genomes of the two marine strains were sequenced by single molecule real-time sequencing approach. In both genomes, genes encoding a QQ enzyme (acylase PvdQ) were identified. Additionally, in one of the strains a non-ribosomal peptide synthase (Nrps) cluster with very low homology compared to previously known Nrps clusters was identified. This cluster could be involved in the synthesis of a natural product of biotechnological interest.

Conclusions

The genome analysis of the two QQ strains has confirmed the presence of an acylase that degrades signal molecules and has provided information related with the production of compounds with a wide perspective of applications.

FUNCTIONAL MICROBIAL FEATURES DRIVING COMMUNITY ASSEMBLY DURING SEED GERMINATION AND EMERGENCE

G. Torres-Cortés[1], S. Bonneau[1], O. Bouchez[2], C. Genthon[2], M. Briand[1], M.A. Jacques[1], M. Barret[1]
[1]Institut de Recherche en Horticulture et Semences INRA, Equipe EmerSys, BEAUCOUZE cedex, France
[2]GeT-PlaGe INRA, Genotoul, Castanet-Tolosan, France

Backgrounds

Plant-associated microorganisms have a decisive role in host adaptation and affect plant productivity. Due to this important role, numerous studies have been focusing on the microbes associated with the rhizosphere or phyllosphere. However, little is known about the role of microbes associated with other plant habitats such as the seed. Microbial interactions occurring on and around the seed are especially important for plant fitness since seed-borne microorganisms are the primary source of inoculum for the plant.

Objectives

The aim of this study is to uncover functional microbial traits implicated in the assembly of the seed microbiota during seed germination and emergence.

Methods

With this purpose, we performed shotgun sequencing of microbial DNA from seeds, germinating seeds and seedlings.

Conclusions

Metagenomic read composition-based classification showed significant changes in microbial community during emergence. Moreover, by predicting the functional profile of these communities, we observed a link between taxonomic changes and functional traits that could lead into niche-specific adaptations. In particular, we found a cluster of microbial functions enriched at emergence (secretion systems, secondary metabolism…) that may be important for microbial colonization and subsequent resilience on seedlings. In addition, we used the generated data for the reconstruction of population genomes drafts of the most significant seed-colonizer taxa. Altogether, these data can be used as molecular markers to select microbial inoculants possessing full genetic potential to colonize and persist in these plant habitats.

MATERNAL INFLUENCE ON THE GUT MICROBIOME EXCEEDS GENETIC CONTRIBUTION DURING EARLY MOUSE DEVELOPMENT

N.S. Treichel[1], A. Schöler[1], Z. Prevoršek[2], B. Stres[2], M. Schloter[1]
[1]Helmholtz Zentrum München GmbH, Comparative Microbiome Analyses, Muenchen, Germany
[2]University of Ljubljana, Department of Animal Science, Ljubljana, Slovenia

Backgrounds

The microbiota of the gut is strongly linked to the phenotype of the host. It is acquired after birth and involves both maternal and environmental contributions. Also the genetic structure of the host was shown to influence the gut microbiome.

Objectives

This study aimed to investigate to what extent the genetics of an individual and the microbiota inherited from the mother have an impact on the gut microbiome composition of the offspring.

Methods

Therefore a cross-fostering experiment involving two genetically different mouse lines was conducted. The mice were sacrificed at three weeks of age and their colonic microbiome was analyzed by paired-end next generation sequencing. The sequences were taxonomically affiliated and analyzed at 97% sequence identity with QIIME using the Greengenes database.

Conclusions

The abundance of several bacterial families was influenced by the genotype of the host or by the kind of inherited microbiome. Beta-diversity analysis showed a higher impact of the maternal microbiome on the gut microbiome composition, than the host's genetic background. The analysis of co-presence networks further revealed a contribution of the genotype to the OTU structure of the networks, while the inherited microbiome determined the connectivity of the network.

This study reveals that at an early stage of development the bacteria derived from the mother have a higher impact on the gut microbiome composition of an individual, than the genetic structure of the individual.

INTER-ANNUAL PREDICTABILITY OF ATMOSPHERIC MICROORGANISMS DYNAMICS AND OCCURRENCE OF AIRBORNE POTENTIAL PATHOGENS

X. Triadó-Margarit[1], J. Caliz[1], L. Camarero[1], E.O. Casamayor[1]
[1]Center for Advanced Studies of Blanes CSIC, Integrative Freshwater Ecology Group, Blanes, Spain

Backgrounds

Microbes represent an important component of atmospheric aerosols with the potential to impact human health. However, our current knowledge on the temporal dynamics of airborne microbial populations remains poorly explored, and no studies have consistently addressed these questions under the long-term.

Objectives

We aimed to (i) describe in detail changes of the airborne microbial diversity and community composition over time, (ii) determine whether or not temporal variability in atmospheric microbial communities is predictable, (iii) estimate the temporal dynamics of the potentially pathogenic airborne microbes.

Methods

We applied high-throughput sequencing techniques (16S rRNA and 18S rRNA genes amplicons) to characterize microorganisms from wet depositions collected at a high elevation site (Central Pyrenees, NE Spain) over a period of seven years. We assessed the presence of potentially pathogenic microbes after comparison against in-house databases of previously reported obligate and opportunistic pathogens. The origin of aerosols was estimated by chemical analyses of rain and snow.

Conclusions

Airborne microbial communities from the same season were more similar each other along the inter-annual study period. Low overlapping was observed between summer and winter communities. Indicative taxa, including a set of potentially pathogenic microbes, were identified for these two seasons. Phytopathogenic fungi and opportunistic bacteria were the most abundant potential pathogens. Overall, the long-term analysis unveiled regularities on the microbial community structure over time and seasonal recurrence of specific airborne microbes.

VARIATIONS IN ECOLOGICAL PROCESSES INFLUENCING THE ASSEMBLY OF BACTERIAL COMMUNITIES IN SUCCESSIONAL ENVIRONMENTS

B. Tripathi[1], J. Stegen[2], M. Kim[1], D. Ke[3], J. Adams[3], Y.K. Lee[1]
[1]Korea Polar Research Institute, Polar Life Sciences, Incheon, Republic of Korea
[2]Pacific Northwest National Laboratory, Biological Sciences, Washington, USA
[3]Seoul National University, Biological Sciences, Seoul, Republic of Korea

Backgrounds

Understanding the fundamental ecological processes that shape the assembly of microbial communities is a major challenge in microbial ecology. Successional soil environments offer a model setting for understanding the ecological processes governing the assembly of microbial communities

Objectives

As pH often changes during succession, this could be the main cause of the observed trends in bacterial community assembly and also influence the relative importance of stochastic and deterministic processes during succession. We tested this hypothesis by carrying out a meta-analysis of a range of different ecological successional environments, not all of which show the same trend in soil pH over time.

Methods

We applied an ecological null modeling approach to analyze the phylogenetic bacterial community assembly and processes.

Conclusions

We found that soil pH was the best predictor of bacterial community assembly and the relative importance of stochastic and deterministic processes along successional environmental gradients. This was irrespective of successional stage (early or late) and time scale (short or long-term). Extreme acidic or alkaline pH conditions lead to assembly of a more phylogenetically clustered bacterial community through deterministic processes, whereas pH conditions close to neutral lead to a less phylogenetically clustered bacterial community with more stochasticity. We suggest that the influence of pH, rather than successional age, is the main driving force in producing trends in phylogenetic assembly of bacteria, and that this also influences the relative balance of stochastic and deterministic processes along successional gradients.

ANTIMICROBIAL AND ANTI-INFLAMMATORY ACTIVITY OF PLANT EXTRACTS AGAINST PATHOGENS CAUSING SKIN INFECTIONS

M. Mishra[1], S. Sharma[1], D. Tripathi[1]
[1]Motilal Nehru National Institute of Technology Allahabad,
Centre for Medical Diagnostic and Research & Department of Biotechnology, Allahabad, India

Backgrounds

Availability of plant derived compounds having medicinal importance is gaining much importance since past few decades. In lieu of importance of plant extract's role in curing skin infections, present work is focused on antimicrobial and anti-inflammatory efficacy of extracts of *Citrica medica, Datura metel, Juniperus communis* against panel of microbes implicated in skin diseases.

Objectives

To evaluate antimicrobial and anti-inflammatory activity of plant extracts for the treatment of skin infections.

Methods

Different plant parts of *Citrica medica, Datura metel, Juniperus communis* in solvents chloroform, ethanol, methanol and water are used for extraction purpose through soxhlet method and obtained extract was filtered and evaporated in hot air oven. The phytochemical analysis for active constituents of these extracts was implicated through thin layer chromatography. MICs, MBC and MFC were determined for antimicrobial and antifungal activities of extract against *P. aeruginosa, S. aureus* and *C. albicans* respectively. Anti-inflammatory activity was determined by Bovine serum albumin denaturation technique.

Conclusions

The extract of these herbal plants has showed potent anti-inflammatory & antimicrobial activity against *P. aeruginosa, S. aureus* and *C. albicans. In silico* analysis for the interactions of phytoconstituents with microbial proteins and their molecular dynamics simulation, prediction of biological activities will be accomplished using computational studies. After the computational studies the extracts will be analyzed for their effectiveness against skin infections followed by development of bioformulations that can be used commercially for skin disease treatment. The effectiveness of the bioformulations after their characterization and toxicity analysis will be accomplished both *in vitro* and *in vivo.*

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

INVESTIGATION OF THE BIOLOGICAL ACTIVITY INDICATORS FOR MILITARY CONTAMINATED SOIL

A. Nurzhanova[1], V. Pidlisnyuk[2], K. Abit[3], R. Aligulova[1], J. Trögl[2]
[1]Institute of Plant Biology and Biotechnology, IPBB, Almaty, Kazakhstan
[2]Jan Evangelista Purkyně University in Ústí nad Labem - Faculty of the Environmen, Department of Technical Sciences, Ústí nad Labem, Czech Republic
[3]Al-Farabi Kazakh National University, afknu, Almaty, Kazakhstan

Backgrounds

Military pollution affects soil microbial communities.

Objectives

Evaluate the level of pollution on the biological activity of military contaminated soil in Kazakhstan (Maili village, Almaty region).

Methods

Determination of heavy metals in the research soils was conducted at inductively coupled plasma mass spectrometry ICP-MS Agilent 7500. Investigation of soil biological motions: urease and cellulolytic activities was done by Aristovkaya express method.

Conclusions

Research soil was polluted by heavy metals: concentrations of As exceed maximum permission level in 5 times, Cu – 13 times, Sr – 22 times, Pb – 29 times, Zn – 11 times. Index of total geochemical contamination varied from 37.1 to 71.7 mg/kg and indicated hazardous state of the research soil. Heavy metals determined in the soil had a depressing effect to the reaction of urease and cellulolytic activities. Cellulolytic activity was reduced to 14% compared to 30% for the control soil. The weak increasing of urease activity determined by pH changing within 24 hours was observed for the military soil (pH 9) in comparison with control one (pH 12).
Soil at the military site is dangerous for the environment and human. Heavy metals inhibited the biochemical activity and reduced fertility and self-purification of the soil.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

NEGATIVE CHEMOTAXIS RESPONSE TOWARD MALEATE IN BACTERIAL WILT PATHOGEN, RALSTONIA SOLANACEARUM

M. Tunchai[1], *A. Hida*[1], *T. Tajima*[1], *J. Kato*[1]
[1]*Hiroshima University, Molecular Biotechnology, Higashi-Hiroshima, Japan*

Backgrounds

Ralstonia solonacearum, the causal agent of bacterial wilt disease, is regarded as one of the world's most destructive plant pathogenic bacteria.

Objectives

Previous studies found that chemotaxis is an essential trait for the early stage of host invasion and pathogenic fitness in *R. solanacearum*, so we have attempted to functionally characterize chemoreceptors, so called methyl-accepting chemotaxis proteins (MCPs), in this pathogen.

Methods

R. solanacearum strain Ps29 exhibited strong negative chemotactic response to a nonmetabolizable maleate. Like most of reported repellents, maleate is harmful to *R. solanacearum* by reducing its growth rate. Result of quantitative chemotaxis assay of *R. solanacearum* Ps29 with various concentration of maleate showed that repellant strength increased as concentration increasing. To identify MCP potentially sensing maleate, single *mcp* gene-deletion mutant library of strain Ps29 was screened. Among 22 mutants, only Δ*mcp16* mutant strain failed to exhibit chemotactic response to maleate, whereas the other mutants showed no significant difference in responses comparing with that of wild-type strain. The Δ*mcp16* mutant harboring the *mcp16* gene on plasmid exhibited wild-type chemotaxis response toward maleate.

Conclusions

These results indicated that *mcp16* encodes chemotactic transducer mediating negative response to maleate. Protein Blast analysis using the putative ligand binding domain (LBD) of Mcp16 as a query sequence revealed that *R. solanacearum* species have Mcp16 orthologs of which LBDs are highly similar to that of strain Ps29 (more than 75% identity). This work contributes to expand the range of characterized chemotactic transducers and their ligands in bacterial wilt pathogen *R. solanacearum*.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

THE ECOLOGICAL ROLE OF VOLATILE AND SOLUBLE SECONDARY METABOLITES PRODUCED BY SOIL BACTERIA

O. Tyc[1], *P. Garbeva*[1]
[1]*Netherlands Institute of Ecology NIOO-KNAW, Microbial Ecology, Wageningen, The Netherlands*

Backgrounds

In soil ecosystems, bacteria live in proximity with many different species and form complex, species rich communities. Within those communities, bacteria produce and release a vast number of secondary metabolites from diverse chemical classes into their environment. However, we are still only at the beginning to understand the factors that affect the production and the ecological role of these metabolites.

Objectives

Bacterial interspecific interactions are one of the main biotic factors influencing the production of bacterial secondary metabolites (Tyc et al., 2015, 2016). Interestingly many bacteria produce both volatile and soluble secondary metabolites. As compared to soluble compounds, that accumulate around the producing strain rather than diffuse into the environment, volatile compounds are able to diffuse through air- and gas- filled pores and can play an important role in long distance microbial interactions.

Methods

Here we present several examples on the role of soluble and volatile secondary metabolites in microbial interactions as well the importance of inter-specific interactions on bacterial volatile and secondary metabolite production and their antimicrobial activities. Furthermore, we will reveal the importance to study both volatile and soluble metabolites simultaneously and their synergistic effects.

Conclusions

Our studies highlights the importance of interspecific bacterial interactions for triggering secondary metabolites production and the perspectives thereof for extending the range of bioactive compounds to be used for control of plant- and human pathogens.

EXPRESSION OF DENITRIFICATION GENES IN RESPONSE TO A WATERLOGGING EVENT IN FLUVISOL AND ITS RELATIONSHIP WITH LARGE NITROUS OXIDE PULSES AT DNA AND RNA LEVELS

Y. Uchida[1], Y. Wang[2], H. Akiyama[3], Y. Nakajima[2], M. Hayatsu[2]
[1]Hokkaido University, Research Faculty of Agriculture, Sapporo, Japan
[2]Institute for Agro-Environmental Sciences- National Agriculture and Food Research Organization, Division of Biogeochemical Cycles, Tsukuba, Japan
[3]Institute for Agro-Environmental Sciences- National Agriculture and Food Research Organization, Division of Climate Change, Tsukuba, Japan

Backgrounds

The contributions of large N_2O pulses following waterlogging to the annual cumulative N_2O productions were significant in a Fluvisol. Soil microbial responses to a dry-wet change might be related to the pulse of N_2O gas emissions.

Objectives

To understand the microbial mechanisms underlying these large N_2O pulses in a poorly drained Fluvisol.

To study the effect of soil depth and structure on the large N_2O pulses.

Methods

N_2O emissions were monitored both in intact soil cores and from sieved soils to investigate the importance of soil properties. Quantitative PCR and quantitative RT-PCR analyses were performed to show the correlation among denitrification genes (*nirS*, *nirK*, and *nosZ*) and N_2O emissions at the mRNA level and at the DNA level.

Conclusions

The major pathway for N_2O production was denitrification and larger emissions were observed from the intact soil cores. The change in denitrification gene mRNA levels was more prominent in the 0- to 1-cm soil compared with the 1- to 3-cm soil, in the intact soil cores. Quantitative PCR and quantitative RT-PCR analyses indicated the correlation among denitrification genes (*nirS*, *nirK*, and *nosZ*) and N_2O emissions at the mRNA level but not at the DNA level, particularly at the 0- to 1-cm soil. These indicate that there was a strong variation in soil microbial properties over very small changes in soil depth, and this variation is important in determining the magnitude of N_2O emissions.

SULFAMETHOXIZOLE/TRIMETHOPRIM-INDUCED ESCHERICHIA COLI O157:H7 TRANSCRIPTIONAL CHANGES FAVOR PROPHAGE-ENCODED VIRULENCE GENES

G. Uhlich[1], E. Andreozzi[1], G. Paoli[1]
[1]Eastern Regional Research Center, USDA/ARS, Wyndmoor, USA

Backgrounds

E. coli serotype O157:H7 genomes contain an abundance of foreign DNA. In the Sakai reference strain, prophage and prophage-like elements comprise nearly 20% of the genome where they control bacteriophage functions, affect host physiology, and regulate virulence. Prophage can also inhibit biofilm formation by inserting in *mlrA*, resulting in truncation of the transcription factor. However, prophage induction can restore *mlrA*, expression of *csgD*, and biofilm formation.

Objectives

We compared RNA-seq profiles of an *E. coli* O157:H7 strain exposed to prophage-inducing concentrations of Sulfamethoxizole/Trimethoprim (SM/T) to investigate biofilm and virulence gene expression.

Methods

RNA collected from O157:H7 strain PA20 grown for either 5 or 12 h on 1% tryptone agar at 30°C ± SM/T at low (20/4 ug/L) and high (540/108 ug/L) concentrations was converted to cDNA and sequenced using Ilumina HiSeq2500.

Conclusions

Results

1. High concentrations of SM/T following 12 h exposure induced ≥4-fold differential expression in >750 genes compared to untreated control

2. Differential expression occurred with higher frequency in prophage, prophage-like, and plasmid genes

3. stx_1, stx_2, and 65% of the genes in the LEE virulence operon were up-regulated

4. High SM/T induced the expression of active truncated forms of *mlrA* by 8-fold; but *csgD* expression showed little changed

Summary

1. At near therapeutic tissue concentrations, SM/T had major effects on O157:H7 gene expression

2. Gene expression changes were common in prophage and plasmid elements

3. Virulence and regulatory genes dominated induced gene populations

4. Truncated *mlrA* products were highly expressed at high SM/T concentrations

PREVALENCE OF ANTIMICROBIAL RESISTANT MARKER GENES (ARMG) IN A GMO-PRISTINE NORWEGIAN ENVIRONMENT

I. Ullmann[1], H. Tunsjø[2], K.M. Nielsen[3], C. Charnock[1]
[1]Oslo and Akershus University College of Applied Sciences, Life sciences and health- Pharmacy, Oslo, Norway
[2]Oslo and Akershus University College of Applied Sciences, Life sciences and health- Biomedical Sciences, Oslo, Norway
[3]Oslo and Akershus University College of Applied Sciences, Life sciences and health, Oslo, Norway

Backgrounds

Neomycin phosphotransferase II (*nptII)* is one of the most frequently used marker genes in the production of genetically modified organisms (GMO). Its sole function is to aid the production procedure, after which it has no further biological function for the GMO. However, the gene may enter the environment along with plant debris, and potentially transfer to the bacterial soil populations. Coding for an aminoglycoside phosphotransferase enzyme, the *nptII* gene inactivates a range of aminoglycoside antibiotics. Some of these agents, such as neomycin and kanamycin, are critically important antimicrobials in medical and veterinary science (WHO, 2014). If horizontal transfer of intact *nptII* from GM plants to bacteria occurs in the environment, this might interfere with animal and human health by the establishment of resistance to essential antimicrobial agents.

Objectives

The primary objective of this study is to determine the baseline prevalence of *nptII* in the naturally occurring bacterial populations in GMO-pristine agricultural locations in Norway.

Methods

By analyzing sludge samples from water treatment plants (WTP) using an *nptII* specific TaqMan qPCR assay, we will map the copy number of *nptII* from 50 different geographical locations in Norway. The sludge samples will contain bacteria draining from the soils and freshwater areas surrounding each individual WTP.

Conclusions

This will provide a reference, at present lacking, for assessing the effects of aminoglycoside phosphotransferase genes introduced artificially into the environment via GM plants, and the effect this may have on the naturally occurring concentrations of antibiotic resistance determinants in soil and freshwater.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

EFFECT OF LIQUID ORGANIC AMENDMENTS ON SOIL MICROBIAL COMMUNITIES

J. Urra[1], I. Mijangos[1], L. Epelde[1], A. Lanzén[1], F. Blanco[1], C. Garbisu[1]
[1]NEIKER-Tecnalia, Conservation of Natural Resources, Derio, Spain

Backgrounds

The implementation of sustainable agricultural practices is a matter of much interest and investigation. In this respect, fertilization with organic amendments is being used to provide a wide range of nutrients while simultaneously improving the physical, chemical and biological properties of the agricultural soil.

Objectives

Here, we studied the effect of liquid organic amendments (locally called “bioles”), prepared by farmers themselves from organic residues, on soil microbial communities as biological indicators of soil health.

Methods

To this aim, a two-year field experiment was carried out using a randomised block design (n=3) and different doses and forms of application of the abovementioned amendment. After two years, soil samples (0-30 cm depth) were taken to the laboratory where the following physicochemical properties were determined: pH, organic matter, and macro- and micronutrients. Several parameters that provide information on the biomass (microbial biomass C, total bacteria and fungi by qPCR), activity (respiration, enzyme activities, nitrogen mineralization) and diversity (16S amplicon sequencing) of microbial communities were also determined.

Conclusions

Values of corn yield were somewhat lower than those obtained in control plots with inorganic (NPK) fertilizer. However, at a high dose, the application of the organic amendment led to significantly higher values of microbial activity (arylsulphatase and phosphatase activities, nitrogen mineralization) and biomass (total fungi and microbial biomass C). Prokaryotic genetic diversity and soil physicochemical parameters were, in general, not statistically affected by the organic fertilization. It was concluded that these home-made liquid organic amendments have potential for agricultural fertilization and soil health improvement.

FEMS7-1841
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

MICROBIAL COMPOSITION OF TECHNOSOLS MADE FROM RECYCLED BENTONITE AND SEWAGE SLUDGE FOR THE REHABILITATION OF A MINING AREA

L. Epelde[1], I. Martín-Sanchez[1], S. Virgel[2], J. Urra[1], A. Lanzén[1], G. Besga[2], C. Garbisu[1]
[1]NEIKER-Tecnalia, Conservation of Natural Resources, Derio, Spain
[2]NEIKER-Tecnalia, Plant Production, Derio, Spain

Backgrounds

Technosols are artificial soils, tailor-made mixtures of wastes that are used to restore degraded areas. However, natural soils contain a myriad of microorganisms that are responsible for many of its vital functions, such as recycling of nutrients, nitrogen fixation, soil structure maintenance, etc. Ideally, one of the objectives of the Technosols should be to correctly fulfill the functions performed by natural soils.

Objectives

To study the microbial composition of Technosols, and compare them to a nearby natural soil.

Methods

The Technosols were established in autumn 2011 at Esther mine (northern Spain) using soil from a waste recovery facility, sewage sludge and recycled bentonite, mixed using three different compositions. The organic matter of each was stabilized in piles for two months before being applied in the field. Triplicate samples from each composition weres then studied and compared to a nearby forest soil as a natural reference. Amplicon sequencing of 16S and 18S rRNA genes was performed for (i) individual ingredients, (ii) the Technosols after stabilization, (iii) the Technosols three years after establishment, and (iv) the reference forest soil.

Conclusions

Out of the ingredients, sewage sludge showed the lowest prokaryotic and eukaryotic diversity. Interestingly, microbial diversity increased significantly in all the Technosols between 2011 and 2014, and its microbial composition was very similar to the reference forest soil in 2014. Therefore, it was concluded that, over time, the microbial communities of the Technosols show signs of resembling the reference soil of the area.

IDENTIFICATION OF LECTINS THAT BIND AND DIFFERENTIATE COMMON COLIFORMS FOUND IN WATER - APPLICATIONS IN NEXT GENERATION ANALYTICAL PLATFORMS FOR ENVIRONMENTAL SENSING OF BIOLOGICAL CONTAMINATION

S. Deegan[1], M. Utratna[1], N. Islam[1], M. Buscaglia[2], S. Biffi[2], G. Tagliabue[2], A. Bendali[3], I. Pereiro[3], S. Descroix[3], L. Joshi[4]
[1]Aquila Bioscience, Research and Innovation Building, Galway, Ireland
[2]Università degli Studi di Milano, Department of Medical Biotechnology and Translational Medicine, Milan, Italy
[3]Institut Curie, Laboratoire Physico Chimie Curie, Paris, France
[4]Glycoscience Group, National University of Ireland Galway, Galway, Ireland

Backgrounds

Biological contamination of lake water is a serious health risk to the surrounding population of people. If undetected pathogenic bacteria, such as *E. coli* O157:H7, can enter the food chain, wiping out entire animal stocks and ultimately enter our drinking water systems resulting in severe illnesses and potential fatalities.

Objectives

In order to control lake water contamination, routine testing of lake water is conducted; however, currently employed *E. coli* detection procedures often require advanced sample processing involving multiple stages (cell sorting, cell lysing, DNA/RNA extraction and analysis, or petri dish growth methods). These methods are both complex and time consuming and are not suitable for onsite analysis. The next generation analytical platform for environmental sensing (NAPES) will revolutionize onsite water sampling, integrating high speed bacteria detection platforms with state of the art technologies.

Methods

Aquila Bioscience has identified a library of lectins that can capture and detect common water borne bacteria such an *E.coli* O1, *E. cloacae* and *E. coli* O157:H7. The lectin molecules are integrated into a label free RPI detection platform developed by the team at the University of Milano, coupled to the innovative cell sorting method based on immobilized magnetic beads, developed by the team of the Institut Curie (Paris)

Conclusions

The integration of the lectin molecules into the highly sophisticated RPI detection platform and magnetic bead pre-concentration module will allow for a highly specific, highly sensitive and exceptionally fast method for detection of bacteria.

[6]Centro de Investigaciones de Ecosistemas Costeros, Biogeochemistry, Cayo Coco, Cuba
[7]Instituto de Ecología- UNAM, Lab. Ecología bacteriana, Mexico City, Mexico
[8]Lawrence Berkeley National Laboratory, BSISB, Berkeley, USA

Backgrounds

Microbialites, rock- forming microbial assemblages whose existence extends from the Archaean (~3,500 mya) until present days are useful study models to explore the diversity and the mechanisms involved in carbonates and other minerals precipitation.

Objectives

The role of microbes in the precipitation of minerals needs clarification, the use of emergent strategies of biological and chemical analysis contribute to address questions such as the participation of microbes in mineral formation as well as the chemical and biogeochemical interactions at micro-scale.

Methods

High throughput sequencing, XRD, XRF, SEM-EDS and S-FTIRS Spectromicroscopy were used to asses biological and chemical diversity in a cross-system analysis (5 sampling locations).

Conclusions

Here, we present preliminary results from our studies of the elemental composition of the biomass and the microbialite mineral matrix, and its possible relationships with the microbial community structure in extant microbialites. Regardless their origin (sampling location), microbial groups such as Cyanobacteria, Alpha, Beta and Gammaproteobacteria exhibited the strongest correlations (positive) with organic carbon (Corg), N and particularly with C:S ratio. A diversity of bacterial taxa showed significant (positive and negative) relationships with trace elements (accumulated in microbialite precipitations relatively to their water environments) such as Cd, Co, Cu, Fe, Se and Ni. OTUs exhibiting significant correlations with chemical signatures are shown for biogeochemical parameters, mineral - major ions and trace elements.

[6]Centro de Investigación y de Estudios Avanzados del IPN, Departamento de Biotecnología y Bioquímica- Unidad Irapuato, Irapuato, Mexico

Backgrounds

Anaerobic methane oxidation (AOM) avoids the release of huge amounts of this greenhouse gas produced at anoxic zones of water bodies, thus representing a microbial process with great impact on Earth's temperature regulation. Methane is manly emitted naturally by wetlands, despite this, microbial processes involved on its anaerobic consumption on these ecosystems are still poorly understood.

Objectives

The purpose of this study, was to assess the potential of the biota of sediment sampled at a tropical wetland to perform AOM linked to the microbial reduction of its intrinsic electron acceptors, including the electron accepting fraction of natural organic matter (*humus*).

Methods

$^{13}CO_2$ production was documented in microcosms inoculated with wetland sediment supplemented with $^{13}CH_4$ and/or humus. Reduction of sulfate, ferric iron and natural organic matter (NOM)/humus, was followed by capillary electrophoresis and spectrometric methods. Presence and reduction of NOM was qualitatively assessed Micro-ATR-FTIR imaging, UV-Vis-NIR spectroscopy, and XPS. Microbial community composition was investigated by Illumina's 16s Metagenomic Sequencing.

Conclusions

Obtained results showing that NOM partially drives anaerobic methanotrophy, constitutes evidence of a novel process that may largely contribute to supress methane emissions from tropical wetlands. Presence of archaea unrelated to the methane cycle, and absence of well-known methane oxidizers, suggests an unknown role of uncultured archaeal lineages outside the Euryarchaeota phylum involved in AOM.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

DECIPHERING THE FUNCTIONAL CAPACITY OF THE SORGHUM RHIZOSPHERE MICROBIOME

T. Oberholster[1], D. Cowan[1], A. Valverde[1]
[1]University of Pretoria, Genetics, Pretoria, South Africa

Backgrounds

Plant roots interact intimately with rhizospheric microbial communities, which affect both biogeochemical cycling and plant growth. For decades, rhizosphere research has focused on knowing the “who” of microbial communities. As a consequence, very little is known about what these microbes are actually doing. To fill this gap, we investigated the functional potential of the rhizosphere microbiome of an economically important crop in South Africa (i.e., sorghum) grown under field conditions.

Objectives

To elucidate the functional capability of the bacterial communities in the sorghum rhizosphere
To relate the function back to the associated bacterial taxa

Methods

Shotgun metagenomics of 12 samples (6 control + 6 rhizosphere) obtained from 2 soils planted with *Sorghum bicolor*

Conclusions

Our results have shown that sorghum rhizosphere bacterial communities are functionally diverse and different from those of the bulk soil. 425 of the 2552 genes evaluated were more abundant in the rhizosphere than in the bulk soil, whereas 202 genes showed the opposite trend. The rhizosphere soil contained differentially abundant genes involved in the metabolism of carbohydrates, nucleotides, xenobiotics, vitamins and cofactors. In contrast, most of the genes overrepresented in the bulk soil were involved in energy, lipid and amino acid metabolism, as well as in the biosynthesis of glycans, polyketides and terpenoids pathways. These results indicate a difference in the trophic requirements of the rhizosphere microbiome and its response to environmental stressors. We anticipate, that coupling metagenomics of the rhizosphere microbiome with culture-dependent functional analyses will allow us to identify potentially important plant-growth promoting rhizobacteria for sorghum production.

IMPACT OF FOOD HABITS ON MICROBIOTA PROFILE OF HEALTHY ROMANIAN WOMEN

E. Vamanu[1], *I. Sarbu*[2], *R. Nita*[1], *A. Mircea*[1]
[1]*University of Agronomic Science and Veterinary Medicine, Faculty of Biotechnology, Bucharest, Romania*
[2]*University of Bucharest, Faculty of Biology, Bucharest, Romania*

Backgrounds

Microbial fingerprint of the gut represents a significant aspect in the process of organism adaptation to the environmental changes. Although there is a characteristic microbial fingerprint for each age group or target group with certain food habits, microbiota reacts, by changing its structure, to various bioactive compounds. The capacity to react and to keep favourable strains in a sufficient number will depend on the type and quality of food.

Objectives

The aim of the study was the identification of microbiota fingerprint changes correlated to the presence or absence of meat in the ingested foods.

Methods

Microbiota of minimum three women, for every group, was analysed, because its structure will influence general health. Samples were sterile and kept in glycerol. The women have not received any antibiotic in the last six months. The microbiota reconstitution process was carried out in the GIS1 simulator (www.gissystems.ro) by *in vitro* studies. There were conducted *in vitro* studies and a molecular analysis based on rep-PCR profiles.

Conclusions

With the presence of meat in food habits, it was determined a normal level of favourable strains. These results were correlated with an increase of the ammonium amount in descending colon. Absence of animal protein was correlated with the low level of bifidobacterium strains. The presence of ammonium was similar in all microbiotas. This study allows a better understanding of the role that food nutrients have on the general health of female population. The results can be used to determine a correlation between food habits and organism resistance to infectious diseases.

ASSESSING THE MICROBIOLOGICAL DIVERSITY IN AQUEOUS ENVIRONMENTS OF A NUCLEAR RESEARCH REACTOR

V. Van Eesbeeck[1], M. Ahmed[1], R. Props[1], R. Van Houdt[1], P. Petit[2], N. Leys[1], J. Armengaud[3], C. Rivasseau[2], J. Mahillon[4], P. Monsieurs[1]
[1]SCK•CEN, Microbiology, Mol, Belgium
[2]CEA, Plant cellular physiology, Grenoble, France
[3]CEA, Biochemistry and Nuclear Toxicology Biochemistry of Perturbed Systems, Bagnols-sur-Cèze, France
[4]UCL, Food microbiology, Louvain-la-Neuve, Belgium

Backgrounds

After being used as energy source inside power plants, spent nuclear fuel must be stored underwater in so-called “spent nuclear fuel pools” (SNFPs) in order to cool down before being safely disposed. Interestingly, despite the highly oligotrophic and radioactive nature of the water, microbial growth is not fully prevented. Microorganisms identified in such environments thus provide a unique opportunity to acquire new insights into survival strategies and radiation-resistance mechanisms.

Objectives

The objective of this work is to inventory the bacterial communities present in SNFPs and other aqueous environments of a nuclear research reactor. In parallel, this research also focuses on following up these communities over time during reactor operation to monitor the long-term effect of ionizing radiation. Finally, this project also aims at a phenotypical characterization of the prevailing species.

Methods

For the inventory and the follow-up of the bacterial communities, a 16S rRNA amplicon sequencing approach was adopted. For the phenotypical characterization, isolates were cultured and their radiation resistance was subsequently tested using a gamma irradiation facility.

Conclusions

Results from the 16S rRNA amplicon sequencing highlighted the presence of bacteria mainly belonging to the Alpha- and Betaproteobacteria. The long-term follow-up of the bacterial communities is still ongoing. The phenotypic characterization showed that all 12 strains tolerated a dose of 300 Gy, but only 8% of the strains was able to cope with a dose of 2100 Gy, indicating large variability in radiation resistance between different strains, and as such not necessarily a high radiation tolerance to survive in these environments.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

ENRICHMENT AND ISOLATION OF NOVEL POLYSACCHARIDE-DEGRADING ANAEROBES FROM ABYSSAL BLACK SEA SEDIMENT

D.M. van Vliet[1,2], *A.J.M. Stams*[1,2,3], *I. Sánchez-Andrea*[1,2]
[1]*Wageningen University, Laboratory of Microbiology, Wageningen, The Netherlands*
[2]*Soehngen Institute of Anaerobic Microbiology, SIAM, Nijmegen, The Netherlands*
[3]*University of Minho, Centre of Biological Engineering, Braga, Portugal*

Backgrounds

Anoxic marine sediments form an important global carbon sink. However, we know little about the ecophysiology of the dominant organic matter-degrading anaerobes from this habitat, due to the lack of ecologically relevant anaerobic isolates. In contrast, important marine aerobes such as SAR11 bacteria were isolated succesfully with oligotrophic, low-nutrient media. Young anoxic sediments are not poor in nutrients, but important anaerobes could nevertheless be oligotrophs, because of the recalcitrance of available biopolymer substrates such as polysaccharides.

Objectives

We aim to enrich and isolate ecologically relevant marine anaerobes from the Black Sea under environmentally representative conditions with polysaccharides as substrates.

Methods

As inoculum, we used anoxic Black Sea sediment from the abyssal plain at 2100 m depth. We set up enrichment cultures with mineral marine medium and with several polysaccharides as separate substrates. The cultures were incubated at 15 °C. From these enrichments, physiologically novel strains of *Psychromonas* and *Marinifilum* were isolated. A previous stable isotope probing experiment with ^{13}C-glucose supports the ecological importance of an obtained *Psychromonas* strain in sediments. Analysis of 16S rRNA gene amplicons revealed that in some cultures the uncultivated *Lentisphaerae* R76-B128 clade was enriched, which is our current focus of isolation. This clade has been found in anoxic marine waters, including those of the Black Sea. The most closely related isolate (89% 16S rRNA identity) is a halophilic, saccharolytic oligotroph.

Conclusions

By cultivation under environmentally representative conditions with polysaccharides as substrates, we enriched and isolated ecophysiologically relevant marine anaerobes.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

SOLUBILIZATION OF PHOSPHORUS AND PLANT GROWTH PROMOTION BY ACTINOBACTERIA IN SOYBEAN CROP

H. Vargas Hoyos[1], *J. Chiaramonte*[1], *I. Soares de Melo*[2]
[1]*University Of Sao Paulo / Luiz de Queiroz College of Agriculture, Soil Biology, Piracicaba, Brazil*
[2]*Embrapa / Envtironment, Environmental Microbiology, Jaguariúna, Brazil*

Backgrounds

Several studies have already investigated the Actinobacteria as source of raw material for drug discovery. Not less important is the function that they develop in the nutrients cycling making then available for plants. The “3AS4” *Streptomyces rishiriensis* isolate was selected due to its exceptional phosphorus solubilization.

Objectives

The aim of this study was to investigate the possible mechanism of action involved in phosphorus solubilization and access the plant growth promotion ability of this strain.

Methods

In order to recognize its mechanism of action, the crude extract was monitored during 10 days with HPLC. A greenhouse experiment was carried out to evaluate the potential plant growth promotion of the isolate in soybean. Besides the soil with no phosphorous, two phosphate sources: Triple super phosphate (TSP) and Rock phosphate Bayovar (RPB) were added at the soil. Inoculated pots were compared to control pots in the three concentrations of phosphates (0, 20 and 40 Kg/h). Evaluations considered the plants attributes; chlorophyll relative index, height, dry shoot and root biomass. The crude extract presented a chromatographic profile similar to gluconic acid. Significant differences in plant height were observed at 8 weeks when inoculated with the isolate. The Shoot/Root index was significantly higher when applied the higher dose of RPB along with *S. rishiriensis*. When inoculated with the isolate, the plants with non-additional phosphorous showed similar development compared to the control pots with 40 Kg/h of TSP and RPB.

Conclusions

These results suggest that Actinobacteria might be a valuable resource for sustainable agriculture application by reducing phosphate fertilization.

IDENTIFYING GENOME-WIDE GENETIC VARIATION IN POPULATIONS OF BACTERIAL ENDOSYMBIONTS OF INSECTS

C. Vargas-Chavez[1], *A. Latorre*[1]
[1]*Institute for Integrative Systems Biology I2SysBio, Evolutionary Systems Biology of Symbionts, Paterna, Spain*

Backgrounds

Bacterial symbionts are widespread in insects. This has allowed insects to thrive on unfavorable environments and exploit previously inadequate food sources, such as the carbohydrate-rich but amino acid-poor plant sap. Many of these symbionts are harbored inside specialized cells called bacteriocytes. In this constant and isolated environment, the bacterium reduces its functions (genes) to the extreme conserving only those that are relevant to its host. In some cases, more than one endosymbiotic bacteria may reside in the same host, such as the *Buchnera-Serratia* symbiotic consortium in some Lachninae aphids like *Cinara cedri*. The usual method of transmission is vertical, with offspring inheriting the symbionts directly from their mothers. This method of inheritance subjects the bacteria to strong bottlenecks each insect generation.

Objectives

We are interested in detecting the effects this bottleneck has on the diversity of the bacterial endosymbionts population residing in an insect. Our main goal is identifying variation in the population, such as SNPs and indels and if possible identify haplotypes.

Methods

High-quality assemblies from endosymbiotic bacteria of different genus were used as references. Next-Generation Sequencing reads were mapped to these assemblies and SNPs and indels were identified and their frequencies in the population were quantified. The phenotypic effect of each variant was determined and compared among and between members of the different genus used.

Conclusions

Regardless of the bottlenecks the endosymbiotic bacteria are subjected to, it is possible to identify variants in all members evaluated. Some trends on the variation rates and their consequences for the bacterium were identified.

TESTING THE HYPOTHESIS OF ACQUIRED AMINOGLYCOSIDE RESISTANCE IN RALSTONIA SPP.

I. Vaz-Moreira[1,2], P. Ferro[1], O.C. Nunes[2], C.M. Manaia[1]
[1]Escola Superior de Biotecnologia - Universidade Católica Portuguesa/Porto,
CBQF – Centro de Biotecnologia e Química Fina, Porto, Portugal
[2]Faculdade de Engenharia- Universidade do Porto,
LEPABE - Laboratório de Engenharia de Processos- Ambiente- Biotecnologia e Energia, Porto, Portugal

Backgrounds

Ralstonia spp. are ubiquitous in water environments, including drinking water. The species *R. pickettii* and *R. mannitolilytica* have been associated to nosocomial outbreaks and to a wide array of antibiotic resistance phenotypes. Aminoglycoside resistance (AGR) is a variable phenotype in those *Ralstonia* species, suggesting that it can be acquired and not intrinsic as, for example, colistin resistance.

Objectives

Investigate the AGR mechanisms in *Ralstonia* spp. isolated from aquatic environments and assess a possible relationship with the type of water (mineral, tap, wastewater) from which they were isolated. Search hints for a possible AGR acquisition.

Methods

A collection of >50 *Ralstonia* spp. (including some successively transferred in the presence of gentamicin) were characterized for their AGR phenotypes. From this collection two *R. pickettii*, with distinct AGR phenotype and isolated from the same habitat (hospital effluent), were selected for comparative genome sequencing analysis. In this analysis, genetic determinants such as ICEs (integrative conjugative elements), efflux pumps and 16S rRNA methylases that could be worthwhile to screen in the *Ralstonia* spp. were selected.

Conclusions

Beside AGR, resistance to beta-lactams and colistin was frequent in *Ralstonia* spp., regardless the type of water. The comparative whole genome analysis revealed that genes related with tolerance to arsenic and toxic compounds, ICEs, lysozyme inhibitors and with phages/prophages were only present in the AGR strain. Whilst it was not possible to identify AGR determinants associated with ICEs, components of these genes cassettes were detected in most of the AGR strains, leading to the hypothesis that ICEs may be associated with genome dynamics mechanisms. AGR mechanisms through efflux pumps and/or 16S rRNA methylases are being explored in these strains.

BACTERIAL COMMUNITY AND ANTIBIOTIC RESISTANCE DYNAMICS IN A FULL-SCALE WASTEWATER TREATEMENT PLANT WITH UV DISINFECTION

C. Narciso-da-Rocha[1], J. Rocha[1], V.M. Ivone[1], F. Lira[2], J. Tamames[2], I. Henriques[3], J.L. Martínez[2], C.M. Manaia[1]
[1]Universidade Católica Portuguesa - Escola Superior de Biotecnologia,
CBQF - Centro de Biotecnologia e Química Fina – Laboratório Associado, Porto, Portugal
[2]Consejo Superior de Investigaciones Científicas - CSIC, Centro Nacional de Biotecnología, Cantoblanco- Madrid, Spain
[3]CESAM - University of Aveiro, Biology Department, Aveiro, Portugal

Backgrounds

It has been proposed that wastewater treatment plant can be reservoirs and reactors of antibiotic resistance. Since wastewater treatment lead to variations on the bacterial community composition, knowing how such variations impact the dynamics of antibiotic resistance genes (ARGs) is critical to improve ARGs removal during wastewater treatment.

Objectives

To study an urban wastewater treatment plant (UWTP) which includes secondary and UV treatment aiming at: i) identifying populations more fitted during the whole process; ii) measure the impact of each treatment step on the abundance of ARGs; iii) infer how population changes may alter the distribution of ARGs.

Methods

Samples were collected at three dates from the raw inflow, secondary (activated sludge) and tertiary (UV disinfection) effluent of a UWTP. The cultivable enterobacteria, bacterial community composition and 8 ARGs were examined in all samples and after three days storage.

Conclusions

Each of the stages of activated sludge and UV disinfection led to ~2 log-units reductions of enterobacteria. Noteworthy it was the secondary treatment, rather than UV, that led to important changes in the bacterial community composition. In addition, quantitative PCR of ARGs, showed reduction of ~2 log-units after the secondary treatment and a negligible variation after UV disinfection. The effect of treatment was not identical for all ARGs examined, an observation that was consistent with the fact that different genes were most correlated with distinct bacterial populations. For instance, members of *Bacteroidaceae*, *Lachnospiraceae*, *Campylobacteraceae, Aeromonadaceae*, *Enterobacteriaceae* and *Moraxellaceae* were correlated with beta-lactamase and *qnrS* genes, while members of *Comamonadaceae*, *Neisseriaceae* and the classes *TM7-1* and *ZB2* were correlated with the gene *sul2*.

METABOLISM OF SOY ISOFLAVONES BY BACTERIA OF INTESTINAL ORIGIN

L. Vázquez[1], *A.B. Flórez*[1], *B. Mayo*[1]
[1]*IPLA-CSIC, Microbiología y Bioquímica de Productos Lácteos., Villaviciosa-Asturias, Spain*

Backgrounds

High intake of soy or purified isoflavones has been associated with less intense menopause symptoms and a reduced risk of hormone-mediated diseases. Isoflavones from the diet can be metabolized into fully-active compounds or inactive metabolites by bacteria from the human gastrointestinal tract, which at present are poorly characterized.

Objectives

In this work, we assessed the metabolism of the two majority soy isoflavones (daidzein and genistein) by cultures of faecal slurries from menopausal woman with a positive or negative equol-production phenotype.

Methods

Faecal samples of five women were homogenized and inoculated in a general medium for colon bacteria. Faecal homogenates, bulk cultures and isolated colonies from the counting plates were incubated in GAM+0.5% arginine supplemented with 100 µM daidzein or genistein. Isoflavones and their metabolites in the cultures were analysed by UHPLC. In addition, microbial DNA was purified and used in conventional and real-time PCR analysis in order to identify and quantify specific genes involved in equol formation from daidzein.

Conclusions

Equol was only present in cultures derived from equol-producing women inoculated with homogenates and bulk colonies from the counting plates. Variable amounts of genistein and dihydrogenistein were scored when this isoflavone was added. Both *ddr* and *tdr* genes, encoding reductases involved in equol production, were detected in similar amounts in DNA from faeces and cultures thereof of equol-producing women. Occasionally, these genes were also correlated with genistein-derived metabolites. The biological significance of the presence/absence of *tdr* and *ddr* in isoflavone metabolism is currently under study.

ENDOPHYTIC MICROORGANISMS ISOLATED FROM GREEK VARIETY OF SOLANUM LYCOPERSICUM, ENDEMIC MEDICINAL PLANTS AND OLEA EUROPAEA AS BIOSTIMULATING AND/OR BIOCONTROL AGENTS AGAINST PLANT PATHOGENS

K. Nifakos[1], D. Douka[2], T.N. Spantidos[2], I.E. Thomloudi[2], A. Davari[2], P. Tsalgatidou[2], M. Dimou[2], A. Venieraki[2], C. Delis[1], P. Katinakis[2]
[1]Technological Educational Institute of Peloponnese- School of Agricultural Technology and Food Tec hnology and Nutrition-, Agricultural Technology, Kalamata, Greece
[2]Agricultural University of Athens,
Laboratory of General and Agricultural Microbiology- Dept. of Crop Science, ATHENS, Greece

Backgrounds

It is possible to increase and improve the agricultural productivity by stimulating plant yield and protecting crops from phytopathogens. Commercial synthetic fertilizers and pesticides are insecure for public health. Farmers are encouraged to use environmentally friendly alternatives. Biofertilizers and biopesticides may become the preferred substitutions for some conventional synthetic products.

Endophytes colonize an ecological niche similar to that of phytopathogens, which make them candidate for disease suppression.

Objectives

We aim to isolate endophytic bacterial and fungal strains from a Greek (Messinian) variety of Solanum lycopersicum “Chontrokatsari”, greek medicinal plants (Salvia spp., Teucrium spp., Hypericum spp.), and olive tree Olea europaea. In parallel, we investigate and characterize the antifungal, antibacterial activity and other beneficial traits of the endophytic isolates and we test the most promising isolates for their ability to promote plant growth and to antagonist against phytopathogens.

Methods

Isolation of endophytes from leaves, stems, roots and seeds. Beneficial and biocontrol traits such as: phosphate solubilisation, siderophore, IAA, chitinase production, Swarming motility, biofilm formation, NRPs production etc. of the isolated strains.

The antimicrobial activity was confirmed by the visualization and measurement of any inhibition zones.

Conclusions

This is the first report of the endophytic microbial communities that colonize the phyllosphere, stem and seed endo-sphere of Solanum lycopersicum ‘Chontrokatsari’, olive tree plant, and the aforementioned Greekmedicinal plant. Additional greenhouse and field experiments are required to provide more conclusive information about the potential of using endophytic beneficial strains for plant inoculation in soil with limited nutrient resources, for example in combination with different beneficial bacteria.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

MICROBIAL COMMUNITY COMPOSITION AND DIVERSITY OF A LARGE-SCALE SOUTH AFRICAN DRINKING WATER DISTRIBUTION SYSTEM

S. MacRae[1], A. Pinto[2], M. Sigudu[3], N. Esper[3], H. du Preez[3], S. Venter[1]
[1]University of Pretoria, Microbiology and Plant Pathology, Pretoria, South Africa
[2]Northeastern University, Civil and environmental Engineering, Boston, USA
[3]Rand Water, Scientific Services, Vereeniging, South Africa

Backgrounds

Microbial processes play a crucial role in the production and distruibution of safe drinking water. Long-term investigations into drinking water distribution systems can reveal robust processes, infrastructure, and environmental factors that influence the microbial community, offering opportunities to re-think microbial control in drinking water systems.

Objectives

In this 2-year study, we assessed the bacterial community composition and diversity in a large, full scale South African drinking water distribution that uses both chlorine and chloramine as primary and secondary disinfectants, respectively.

Methods

Bulk water samples were collected on a monthly basis at the outlet of the treatment plant and at 17 points in the distribution system spanning nearly 150 kilometres. Illumina Miseq sequencing of the V4 hypervariable region of the 16S rRNA gene revealed a highly diverse bacterial community consisting of 9,756 operational taxonomic units.

Conclusions

Similar to other studies, *Alpha*- and *Betaproteobacteria* dominated the drinking water bacterial communities, with an increase in *Betaproteobacteria* post-chloramination. Temporal variation was consistently stronger than the spatial changes and demonstrated seasonal cycling, which correlated with changes in the temperature. The observed richness, diversity, and evenness of the bacterial communities were higher in the winter months as opposed to the summer months. The bacterial communities also showed distance decay features, with bacterial communities becoming increasingly dissimilar with increasing distance between sampling locations. This study emphasises the significance of a long-term study to fully understand how environmental factors as well as the microbial community within the system could affect the bulk water ecosystem.

FEMS7-1071
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

CHARACTERIZATION OF THE MICROBIAL COMMUNITY FROM HYPERSALINE SOILS AND ITS METABOLIC POTENTIAL

B. Vera-Gargallo[1], *C. Sánchez-Porro*[1], *A. Ventosa*[1]
[1]*University of Sevilla, Microbiology and Parasitology, Sevilla, Spain*

Backgrounds

Hypersaline environments are extreme habitats in which life is limited by a low water activity due primarily to high concentrations of sodium chloride. These particular conditions can be found, among others, in hypersaline lakes, solar salterns, salt-curated food and saline soils. While the microbial communities from aquatic systems have been extensively studied, hypersaline soils have received much less attention.

Objectives

To determine the genomic diversity of hypersaline soils from the Odiel saltmarshes, in the Southwest of Spain, comparing the results with those from solar salterns, from which extensive data exist.

Methods

Two 454 shotgun metagenomes from unvegetated soils located in Odiel saltmarshes were obtained in different years. Quality filtering of the datasets was performed with Prinseq, CDSs were predicted with Prodigal. Newbler was employed for assembly. Taxonomic assignments of the contigs was performed with BLAST+ and MEGAN. Paprika and PathwayTools allowed the analysis of the metabolic potential. MetaBAT, VizBin and CheckM were used for obtaining and curating bins.

Conclusions

At the phylum level, the studied soils are similar to salterns crystallizer ponds, in which the dominant phylum is *Euryarchaeota*, being *Bacteroidetes*, *Betaproteobacteria* and *Actinobacteria* the most represented bacterial phyla. However, we did not find sequences related to the genus *Haloquadratum*. Interestingly, the most complete bin obtained was related to *Sphingobacteriales* and not *Euryarchaeota*, which could be due to the high intra-genus heterogeneity of the organisms from the latter taxon. The phylum *Nanohaloarchaeota* is also present. The metabolic potential of these phyla and the obtained metagenomic bin has also been addressed.

FEMS7-1110
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

FACTORS INFLUENCING THE MICROBIAL COMMUNITY STRUCTURE OF SALINE SOILS FROM THE ODIEL SALTMARSHES

B. Vera-Gargallo[1], T. Roy-Chowdhury[2], J. Brown[2], C. Sánchez-Porro[1], V. Bailey[2], J.K. Jansson[2], A. Ventosa[1]
[1]University of Sevilla, Microbiology and Parasitology, Sevilla, Spain
[2]Pacific National Northwest Laboratory, Biological Sciences Division, Richland, USA

Backgrounds

Studies of saline and non-saline environmental habitats have shown that salinity is a main factor driving the assemblage of microbial communities. However, it is unknown to what extent osmotic stress affects microbial community structure within a set of saline samples. In this study we investigated the relative influence of salinity, metal content and other physicochemical factors on the distribution of taxa in soil samples having a range of salinities.

Objectives

To assess the relationship of salinity, metal content, and other soil properties on the structure of the bacterial and archaeal communities dwelling in saline soils from the Odiel saltmarshes (Southwest Spain).

Methods

Sequencing of 16S rRNA gene amplicons was performed according to the protocols of the Earth Microbiome Project for soil samples from four sites (referred to as Sites 1 to 4) and two depths (0-1 cm and 1-5 cm). The salinity of these samples ranged from 8.2 – 50.1 dS m^{-1}.

Conclusions

Across the range of salinities studied, the main factor influencing the variability in microbial communities was the sampling site and not the level of salinity. This may suggest that all of these samples surpassed a critical threshold of salinity requiring all microorganisms present to be highly adapted and that under these conditions other physicochemical characteristics of the sites were more significant in structuring the microbial community present. Texture, water content and calcium, aluminum, sulfate, sulfur and phosphorous concentration were significant features explaining the variability between the saline soils samples studied.

FEMS7-1647
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

ISOLATION AND DETERMINATION OF NOVEL PLASMIDS FROM BACTERIA OF HONEY AND HONEY STOMACH FLORA

A. Veress[1], *J. Kömüves*[1], *F. Olasz*[1], *J. Kiss*[1]
[1]*NARIC-Agricultural Biotechnology Institute, Department for Genetics, Gödöllő, Hungary*

Backgrounds

Several lactic acid bacteria (LAB) have positive effects on human and animal health, thus they are utilized as probiotics. LAB can be isolated from many sources such as gut flora of vertebrates or insects.

Objectives

The aim of our project was to isolate LAB strains for probiotic use from honey and honey stomach of *Apis mellifera*, however, many other species have also been found. These new yet undescribed strains can be the sources of previously unknown plasmids potentially harbouring new genes of scientific interest.

Methods

According to 16S rDNA-amplicon profiling and restriction analysis of total DNAs indicating the presence of plasmids, three strains have been selected for whole genome sequencing. Bioinformatics analysis revealed the presence of eight *rep*A genes (encoding replication proteins of plasmids) in the three strains, which were classified into *Lysinibacillus*, *Saccharibacter* and *Acinetobacter* genera. Seven *rep*A genes were located on scaffolds that could be converted into circular plasmid sequences, while the last one appeared to belong to a large plasmid of >170 kb. Furthermore, an 8-kb *rep*A-less plasmid could also be identified by restriction analyses.

Conclusions

Altogether, seven novel complete plasmid sequences and one already known plasmid have been validated by PCR, while scaffolds of the >170 kb unnamed *Lysinibacillus* plasmid have to be determined. To date, pAV*Aci*147 and pAV*Lys*47 have been cloned and transferred into *E. coli* cells and the isolation of pAV*Aci*84, pAV*Aci*117, pAV*Sac*7 and pAV*Sac*8 is ongoing. The 45 kb pAV*Aci*14 appears to have a complete set of conjugation genes, thus its mobilization is also in progress.

DETECTION OF HELICOBACTER PYLORI BY PCR OF THE GLMM GENE IN SURFACE WATER FROM BOGOTA (COLOMBIA)

F.J. Vesga Pérez[1,2], Y. Moreno[2], M.A. Ferrús[3], C. Campos[1], A.A. Trespalacios[1]
[1]Pontificia Universidad Javeriana, Microbiology Department- Science Faculty, Bogotá, Colombia
[2]Universitat Politécnica de València, Research Institute of Water Engineering and Environment IIAMA, Valencia, Spain
[3]Universitat Politécnica de València, Biotechnology Department. ETSIAM, Valencia, Spain

Backgrounds

Helicobacter pylori causes gastric diseases and peptic ulcers and plays an important role in gastric cancer and lymphoma, classified by IARC-WHO as a class I carcinogen. It has been detected in different water systems around the world, but few studies have reported successful culture of *H. pylori* from water. Thus, application of molecular methods for rapid, sensitive, and specific detection of *H. pylori* in aquatic environments is of the most importance.

The *glmM* gene is essential for the growth of the microorganism, and it has been used for confirming the presence of *H. pylori* in waters.

Objectives

The aim of this work was to determine the occurrence of *H. pylori* by polymerase chain reaction (PCR) of the *glm*M gene in surface water from San Rafael reservoir (Bogotá, Colombia).

Methods

Fifty surface water samples were collected, centrifuged at 4,000rpm/20min and resuspended in PBS buffer. The suspension was subjected to DNA extraction with the DNeasy Blood & Tissue (Qiagen) kit. PCR for detection of a fragment of 132 base pairs of the conserved region of the glmM gene of *H. pylori* was performed.

Conclusions

The overall detection rates for *H. pylori* DNA in the samples were 32% (16/50). In conclusion, the detection of *H. pylori* at different sampling times indicate either a continual contamination source or persistence of *H. pylori* in surface water.

This study has been supported by Colciencias, convocation #569-2012, and collaboration of Aqueduct and sewage company of Bogotá (EAB) of Colombia and Spanish Ministry of Economy and Competitiveness AGL2014/53875-R grant.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

SPECIES-FUNCTION RELATIONSHIPS SHAPE ECOLOGICAL PROPERTIES OF THE HUMAN GUT MICROBIOME

S. Vieira-Silva[1], G. Falony[1], J. Raes[1]
[1]KU Leuven, O&N Rega, Leuven, Belgium

Backgrounds

The colon microbial ecosystem is characterized by a shallow phylogenetic diversity within only a few deep lineages. Within the microbiota, functional repartition is believed to be driven both by microbial competition and niche specialization and by host selective pressure towards commensalism and functional redundancy. Studying the microbiota complementarity patterns and resulting intricate food webs is now made easier through metagenomic analysis.

Objectives

The main objective is to assess how species-function relationships in the gut microbiota can be linked to gut bacteria fitness and to ecosystem resilience.

Methods

We explore saccharolytic/proteolytic/lipolytic fermentation potential in the human gut using a novel manually curated gut-specific metabolic module framework, made available as a public resource. We first use these metabolic modules on gut reference genomes to identify species metabolic specialization into these 3 main fermentation axes or generalist strategies. We later use these on sequenced gut metagenomes to study ecosystem functional redundancy comparing metagenomes as classifed into enterotypes, and link it to microbial growth rates.

Conclusions

We observe genus-level metabolic specialization, mostly achieved through input-level adaptation. Notably, proteolysis specialization is negatively correlated to capacity for fast growth. Genus-level metabolic consistency varies significantly, being low in Firmicutes genera and higher in *Bacteroides*. Ecosystem-level variation between individuals is also shaped by metabolic preference for specific fermentable substrates, as each enterotype shows distinct saccharolytic/proteolytic/lipolytic profiles. Finally, we find that functional redundancy between gut taxa is reduced in low-richness, *Bacteroides*-type individuals, indicating a potential decreased resilience to perturbation, in line with their frequent association to dysbiosis.

DISENTANGLING MICROBIAL COMMUNITIES IN THE SOUTHERN OCEAN USING METAGENOME BASED GENOME RECONSTRUCTIONS

S. Vikram[1], O. Bezuidt[2], S. Phoma[1], D. Cowan[1], T. Makhalanyane[1]
[1]University of Pretoria, Centre for Microbial Ecology and Genomics, Pretoria, South Africa
[2]Agricultural Research Council, Biotechnology Platform, Pretoria, South Africa

Backgrounds

Understanding how oceanographic features shape marine microbial ecosystems and their implications on biogeochemical cycling remains a major ecological endeavor. Recently, several studies have assessed the contribution of photoautotrophs in surface waters and the factors which shape them. However, in contrast very little is known regarding chemolithoautotrophs in marine ecosystems generally and waters south of 40^{o}.

Objectives

Here, we assess microbial diversity, and functional capacity along the Agulhas current system and the Subtropical convergence in the South Indian Ocean.

Methods

Samples collected from three water columns, epipelagic zone, oxygen minimum zone (OMZ) and bathypelagic zone, were analysed using shotgun metagenomics and bionformatics tools.

Conclusions

We found high taxonomic richness in surface and deep water sample members, with generally low numbers for middle samples, corresponding to the oxygen minimum zones, in contrast to previous studies. Community analysis revealed significant dissimilarity between the three water depths; dominated by marine Proteobacteria, followed by Bacteroidetes, Actinobacteria, and Firmicutes with strikingly low cyanobacterial abundance. Our data showed evidence of extensive carbon, nitrogen and sulphur biogeochemical cycling capacity with a large proportion of functional genes belonging to Alphaproteobacteria (Rhizobiales), Gammaproteobacteria (genus Pseudoalteromonas) and Cyanobacteria (genus Synechococcus). We have reconstructed the bacterial genome bins. The most completed genome bin shows highest similarity to the genus *Psychrobacter*, having genes for the sulfur and iron metabolism, suitable for the South Indian Ocean marine environment. Taken together, our results suggest differential microbial community structure along with the water columns. Functional analysis revealed a variety of traits driven by these taxa together with Proteobacteria, which suggests high functional redundancy.

CHARACTERIZATION AND IDENTIFICATION OF A BACTERIUM WITH HIGH TOLERANCE TO CHROMIUM(III) ISOLATED FROM A MICROALGA CONSORTIUM OF EBRO DELTA MICROBIAL MATS

E. Villagrasa[1], N. Ferrer-miralles[2], L. Millach[1], A. Obiol[1], J. Creus[1], I. Esteve[1], A. Sole[1]
[1]Universitat Autònoma de Barcelona, MICROBIOLOGIA, BELLATERRA, Spain
[2]Institut de Biotecnologia i de Biomedicina, Microbiologia Aplicada, BELLATERRA, Spain

Backgrounds

In the last years, our working group has isolated, from Ebro delta microbial mats, a heterotrophic microorganism (*Ochrobactrum* sp. DE2010) belonging to a microalga consortium. Although, the effect of different metals on this consortium has been investigated, very little is known about the metals effect on this heterotrophic microorganism. In this study chromium(III) has been selected because is considered as a micronutrient, but at high concentrations it can be an important pollutant with toxic effects.

Objectives

Characterize and identify the heterotrophic microorganism. Evaluate the cytotoxic effect of chromium(III) on this bacterium and its capacity to remove it.

Methods

For the first objective, morphological biochemical and physiological analysis and its phylogenetical identification were realized. To evaluate the cytotoxic effect of Cr(III) the changes in biomass/viability of this microorganism were determined by the fluorochrome-CLSM-Image Analysis method. Moreover, its capacity to accumulate Cr(III) extra- and/or intracellularly was evaluated by STEM-EDX, and its uptake efficiency of removal Cr(III) and the specific metal removal (q) were determined by ICP-OES. Finally, changes in its EPS composition were also monitored using different physico-chemical and spectrophotometric methods.

Conclusions

The new microorganism was tentatively identified as *Ochrobactrum* sp. DE2010 and it could be seen capable of restoring polluted environments by chromium(III), since it is: indigenous in Ebro delta microbial mats, an ecosystem polluted by this metal; easy to grow in axenic cultures; able to absorb Cr(III) in EPS and in polyphosphate inclusions and exhibits a great tolerance to and a high removal affinity for chromium(III).

INTERACTIONS OF POLYPORALES SAPROTROPHIC FUNGI AND EFFECT ON WOOD-DECAY ENZYME ACTIVITIES

T. Virolainen[1], J. Kuuskeri[1], H. Mattila[1], F. Shah[1], T. Lundell[1]
[1]Department of Food and Environmental Sciences, University Of Helsinki, Helsinki, Finland

Fungal communities are dynamic in nature. Fungal species and isolates may be tolerant or weak antagonists, or even strong combatants upon interactions. The influence of *Fomitopsis pinicola*, a common brown-rot Basidiomycota species of Polyporales, on the growth and enzyme production of the Polyporales white rot species *Phlebia radiata* and *Trichaptum abietinum* was studied in co-cultivations and on coniferous wood including medium. Production profiles of activities of CAZymes and oxidoreductases (laccase, manganese peroxidase, xylanase, beta-glucosidase) together with enzymes involved in recycling of organic nitrogen and hyphal decomposition were studied. In fungal combination cultures on solid agar media, *F. pinicola* was a supreme colonizer quickly advancing over hyphae of the white rot species. Mycelial blocks against the other white rot species were generated by *P. radiata* but not against *F. pinicola*. In most of the wood-supplemented cultures, fungal production of oxalic acid acidified the medium, which was in correlation to generation of fungal biomass. In solid-state cultures on spruce wood sawdust, wood substrate consumption and mass loss occurred as decrease of total dry weight. Our results indicate that fungal interactions have an outstanding role in wood-degradation processes and carbon cycling in the forest ecosystems.

SPATIAL VARIATION OF ENZYME ACTIVITY AND ORGANIC CONTENT IN SOIL TO ASSESS CROP YIELD ALONG A LATITUDINAL GRADIENT IN NORTH-CENTRAL INDIA

K. Vishwakarma[1], N. Kumar[1], N. Upadhyay[1], S. Sharma[1]
[1]Motilal Nehru National Institute of Technology Allahabad, Department of Biotechnology, Allahabad, India

Backgrounds

Soil is the incoherent matter on Earth's surface having organic and mineral content. Soil health depends on its soil enzymes which mainly originate from soil microbes that indicate microbial activity in soil environment and play an important role in organic matter decomposition. The decomposition helps in nutrient cycling and regulation of soil fertility. This study was facilitated to encompass the effect of climate change, enzyme activity on nutrient cycling i.e. organic carbon, available nitrogen and phosphorous in respective agro-ecosystems.

Objectives

1. To isolate and characterize bacteria from soil of different regions along the latitude gradient in north central India.
2. To analyze the soil enzyme activities and microbial biomass in order to assess soil quality.

Methods

Top soils were sampled in fields at four locations namely, Solan (Himachal Pradesh), Jagatpura (Punjab), Allahabad (Uttar Pradesh) and Satna (Madhya Pradesh). Enzyme activities including dehydrogenase, polyphenol oxidase, urease and catalase along with microbial biomass (nitrogen and carbon) were assessed along the latitudinal gradient. Analysis of soil biological and chemical properties was also done.

Conclusions

With increasing latitude, organic carbon decreases whereas available phosphorous and available nitrogen increases ($P<0.05$). With increase in the latitude, polyphenol activity and urease activity decreases, dehydrogenase activity increases whereas catalase activity showed no significant relation with latitude ($P<0.05$). This distribution of enzyme activities was consequence of alterations in temperature and moisture of soil because of which soil properties changes along the latitudinal transect.

ISOLATION AND CHARACTERIZATION OF PLANT GROWTH PROMOTING RHIZOBACTERIA FROM INDIAN MUSTARD (BRASSICA SPP.)

K. Vishwakarma[1], *N. Upadhyay*[1], *N. Kumar*[1], *S. Sharma*[1]
[1]*Motilal Nehru National Institute of Technology Allahabad, Department of Biotechnology, Allahabad, India*

Backgrounds

Rapeseed-Mustard i.e. *Brassica* spp. is 3rd most important oil-seed crop in the world after soybean and palm. In India, it is second most important edible oilseed after groundnut sharing 27.8% in India's oil-seed economy. To enhance the production and yield of *Brassica* in middle Indo-gangetic plain region of Uttar Pradesh i.e. Allahabad, the plant growth promotion attributes were assessed.

Objectives

1. To isolate and characterize the plant growth promoting rhizobacteria from soils of different regions in Allahabad.
2. To analyze the soil enzyme activities and microbial biomass in order to assess soil quality.

Methods

Bacterial isolates were isolated from the soil samples of *Brassica spp.* taken in triplicates from three different regions by serial dilution method. The soils collected from different regions were also tested for quality by assessing soil enzyme activities (dehydrogenase, polyphenol oxidase, urease and catalase). The isolates were characterized on the basis of their morphological and biochemical characteristics. Furthermore, isolates were screened for plant growth promoting potential *viz.* phosphate solubilization, free nitrogen assimilation, hydrogen cyanide (HCN), indole 3-acetic acid (IAA) and siderophore production.

Conclusions

On the whole, twenty-two bacterial isolates were identified on the basis of their abundance in respective regions. Out of these twenty-two isolates, seven showed plant growth promoting activities. Future studies will incorporate the utilization of potential isolates in plant growth promotion *in vitro*.

INSIDE THE SEED MICROBIOME: FUNGAL AND BACTERIAL SEED ENDOPHYTES IN PLANT RESPONSES TO CLIMATE CHANGE

V. Vujanovic[1], J.J. Germida[2]
[1]University of Saskatchewan, Food and Bioproduct Sciences, Saskatoon, Canada
[2]University of Saskatchewan, Soil Science, Saskatoon, Canada

Backgrounds

Recent studies have found that mycovitality and bactovitaity or the endosymbiotic seed-microbiomes relationship bear tangible benefits for sustainable agriculture production.

Objectives

The aim of the study is to explore the role of endophytes as early plant growth promoters under stressful environment.

Methods

This study used plant micribiome's approaches to advance the concept of plant prenatal care towards enhanced seed vigor/germination and crop production under stressful conditions.

Conclusions

Screening microbiome and testing microbial endophytes for plant growth promotion and resistance over the entire lifecycle may depict a *continuum* of the symbiosis benefits

HYPER-ARSENIC RESISTANCE STRATEGY OF A BACTERIA: ORGANIZATION, FUNCTION AND EVOLUTION OF ARS GENES

L. Wang[1], C. Jing[1]
[1]Research Center for Eco−Environmental Sciences-Chinese Academy of Sciences, State Key Laboratory of Environmental Chemistry and Ecotoxicology, Beijing, China

Backgrounds

Arsenic (As) is a toxic element present in many environmental biotopes. To resist As disruptive effects, microbes have evolved a variety of mechanisms. IMH is the only bacterium found in genus *Pantoea* with a high As resistant capacity, but its molecular mechanism is unknown.

Objectives

The objectives of this study are 1) what genes are involved in the As resistance of IMH, 2) how As resistance genes work in the presence of As, and 3) how these genes are obtained.

Methods

Genome sequencing, genome annotation and analysis were used to find As resistance genes. Deleted mutants, heterologous expression, RT-Q-PCR analysis were performed to explore the function of As resistance genes. Phylogenetic analysis and the deviant G+C content were used to detect the evolution of As resistance genes.

Conclusions

Two *ars* systems - *ars1* (*arsR1B1C1H1*) and *ars2* (*arsR2B2C2H2*) - with low sequence homology and two *arsC*-like genes were found in the IMH genome. Both *ars1* and *ars2* are involved in the As resistance, where *ars1* is the major contributor at 15 ^{o}C and *ars2* at 30 ^{o}C. The contrasting performances of these two *ars* systems is attributed to the disparate activities of their *arsR* promoters under different temperatures. Sequence analysis based on concatenated ArsRBC indicates that *ars1* and *ars2* clusters may be acquired from *Franconibacter helveticus* LMG23732 and *Serratia marcescen*s (plasmid R478), respectively, by horizontal gene transfer (HGT).

METATRANSCRIPTOME SEQUENCING REVEALS SHIFTS IN THE BOVINE EPIMURAL BACTERIAL COMMUNITY COMPOSITION WHICH ARE COMPENSATED ON A FUNCTIONAL LEVEL

S.U. Wetzels[1,2,3], *E. Mann*[1,2], *Q. Zebeli*[2,3], *M. Wagner*[1,2], *S. Schmitz-Esser*[2,4]
[1]*Institute for Milk Hygiene- Milk Technology and Food Science,*
Department for Farm Animals and Veterinary Public Health- University of Veterinary Medicine Vienna, Vienna, Austria
[2]*Research Cluster 'Animal Gut Health', University of Veterinary Medicine Vienna, Vienna, Austria*
[3]*Institute of Animal Nutrition and Functional Plant Compounds,*
Department for Farm Animals and Veterinary Public Health- University of Veterinary Medicine Vienna, Vienna, Austria
[4]*Department of Animal Science, Iowa State University, Ames, USA*

Backgrounds

The exploration of the bovine epimural bacterial microbiota (BEBM) in the rumen is relevant for basic and applied research into explaining the effect of subacute ruminal acidosis (SARA) on BEBM community structure and host-microbe interactions. Comparatively little is known about the metabolic function of the BEBM and whether or how it might be affected by a diet-induced SARA challenge.

Objectives

This study aimed to investigate differences in the gene expression of the BEBM before and after a diet-induced SARA challenge.

Methods

Three ruminally cannulated Holstein dairy cows were fed forage only during the baseline period followed by a five-week SARA challenge induced by a 60% concentrate diet. Cows were slowly adapted to the high-concentrate diet within the first 6 challenge days. Rumen papillae biopsies were taken at the baseline period and after five weeks SARA challenge. The metatranscriptome of the BEBM at the baseline period and after five weeks SARA challenge was obtained using Illumina HiSeq RNA sequencing.

Conclusions

In total, 291,664,242 sequences were obtained, assigned to 25 phyla, with *Proteobacteria*, *Firmicutes* and *Bacteroidetes* being the most abundant phyla. Functional assignments revealed carbohydrate and amino acid metabolism as well as translation to be the most transcribed KEGG/KO pathways. PCoA revealed clustering of BEBM community structure, which was not reflected in the functional data. We conclude that a diet-induced SARA challenge largely affects the composition of the BEBM without strong effects on the functional metatranscriptome, indicating that shifts in bacterial community composition are compensated on a functional level.

THE CONSTRUCTION OF THE CURATED PRETERM GUT MICROBIOME DATABASE (PGMD)

K. Wong[1], P. Fleming[1], M. Millar[2], R. Hutchinson[1], M. Wilks[2], F. Stacey[3], K. Costeloe[1], W. Wade[4]
[1]Blizard Institute Queen Mary University of London, Centre for Genomics and Child Health, London, United Kingdom
[2]Barts and the London NHS Trust, Department of Infection, London, United Kingdom
[3]Homerton University Hospital NHS Foundation Trust, Neonatal Intensive Care Unit, London, United Kingdom
[4]Blizard Institute Queen Mary University of London, Centre for Immunobiology, London, United Kingdom

Backgrounds

The global survival rate for very low birthweight preterm babies has significantly increased over the past 30 years. Morbidity and mortality have shifted from early respiratory failure to intermediate complications such as late-onset sepsis and necrotising enterocolitis (NEC). Investigations into the pathophysiology underpinning NEC are centred on interactions between the preterm infant gut and its microbiome, with recent studies typically using culture-independent techniques such as 16S rRNA gene community profiling and next-generation sequencing to characterise the preterm gut microbiome.

Objectives

Currently available DNA sequence nucleotide databases are typically very large and often include a significant proportion of erroneous or poor-quality 16S rRNA gene sequences. The aim of this study was to construct a 16S rRNA gene Preterm Gut Microbiome Database (PGMD) that is both curated and site-specific, thus providing a robust resource for future preterm gut microbiome studies.

Methods

High-quality full-length 16S rRNA gene sequences representing all bacterial species reported in the literature for the preterm infant gut were compiled. Data from an experimental community profile dataset was used to interrogate the database. Where sequences showed ≥98.5% similarity to named species not in the database, those species were added. Un-named phylotypes represented by a high-quality reference sequence were also added. All species-level taxa were assigned a unique PGMD number.

Conclusions

The first iteration of the PGMD is comprised of 623 species-level taxa from the phyla *Acidobacteria*, *Actinobacteria*, *Armatimonadetes*, *Bacteroidetes*, *Deinococcus-Thermus*, *Firmicutes*, *Fusobacteria*, *Proteobacteria* and *Tenericutes*. The PGMD is a source of phylogeny-designated taxa useful for investigators involved in understanding the human microbiome.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

THE EFFECT OF ENVIRONMENTAL AND SEDIMENT CHARACTERISTICS ON THE SPATIAL AND TEMPORAL DISTRIBUTION OF E. COLI IN INTERTIDAL SEDIMENTS

A. Wyness[1,2], *D. Paterson*[2], *E. Defew*[2], *M. Stutter*[1], *L. Avery*[1]
[1]*The James Hutton Institute, Environmental and Biochemical Sciences, Aberdeen, United Kingdom*
[2]*University of St Andrews, School of Biology- Scottish Oceans Institute, St Andrews, United Kingdom*

Backgrounds

Current bathing water quality monitoring, in accordance with microbial water quality regulations, ignores the presence of faecal indicator organisms (FIOs) in river or estuarine sediments. Sediments act as an environmental reservoir of FIOs, therefore when sediments are resuspended, FIOs are redistributed into the water column and can contribute significantly to adverse microbial water quality. Understanding FIO distribution and abundance in sediments therefore provides an improved understanding of microbial pollution and increase the accuracy of bathing water quality advisories.

Objectives

The aim of this work was to identify and model key driving factors that influence the spatial and temporal variation in the abundance of *E. coli* in intertidal estuarine sediments.

Methods

Intertidal sediments were collected from two estuaries in NE Scotland through seasonal transect sampling, and a spatially and temporally intensive regime. Enumeration of *E. coli* from surface sediments was performed in conjunction with a comprehensive suite of physical, biogeochemical and biological sediment analyses. Data were explored using Spearman's rank correlation coefficients, best subsets models and multiple stepwise linear regression models.

Conclusions

E. coli abundance was largely dependent on biogeochemical variables, with interstitial pore water salinity consistently influential. Multiple linear regression models of the different datasets explained up to 87.4 % of *E. coli* variation suggesting that, with further research, the predictive modelling of FIO abundance in sediments could be included in the designation of bathing water quality advisory notices.

ARCHAEAL COMMUNITIES ALONG A 2M LONG SEDIMENT CORE IN THE DAJIUHU PEATLAND, CENTRAL CHINA

X. Xiang[1], R. Wang[1], Y. Xu[1], W. Tian[1], L. Gong[2], H. Wang[1]
[1]China University of Geosciences- Wuhan,
State Key Laboratory of Biogeology and Environmental Geology, Wuhan, China
[2]Third Institute of Oceanography, Third Institute of Oceanography, Xiamen, China

Backgrounds

Archaea has been recognized as important motor driving various biogeochemical processes in natural environments, while knowledge regarding archaeal community structure and their relationship with environment factors is limited particyularly in peatland ecosystems

Objectives

the vertical distribution of archaeal communities along a 2 m peat sedimentary core from the Dajiuhu Peatland

Methods

quantitative PCR and next sequencing methods

Conclusions

Quantitative analysis showed that archaeal abundance ranged from 10^5 to 10^7 copies per gram sediment, highest at 1 m depth of peat sediments. Taxonomically archaeal communities consisted of 8 archaeal phyla and were predominated by Miscellaneous Crenarchaeota Group (MCG) with a relative abundance of 90%, followed by Thaumarchaeota and Crenarchaeota. Furthermore, members of MCG were split into 9 subgroups suggesting a highly abundant and diverse MCG lineage in peat sediment. Water content and TOC were proved to be the most significant factors to architecture archaeal community structures as indicated by both phylogenetic and taxon-based approaches. Network analysis revealed that MCG strongly control other archaeal lineages through interaction and may play important role in biogeochemical processes in peatland ecosystem. Our results provided overview of archaeal population, community structure, relationship with environmental factors and emphasized the potential ecological function of MCG lineages

MECHANISM OF RADIATION RESISTANCE IN ARTHROSPIRA SP. PCC 8005

A. Yadav[1], N. Leys[1], A. Cuypers[2], A. Misztak[3], K. Waleron[3], M. Waleron[4], P. Janssen[1]
[1]SCK-CEN, Molecular and cellular Biology, Antwerpen, Belgium
[2]University Of Hasselt, Centre for Environmental Sciences, Hasselt, Belgium
[3]University of Gdańsk, Department of Biotechnology, Gdańsk, Poland
[4]Medical University of Gdańsk, Pharmaceutical Microbiology, Gdańsk, Poland

Backgrounds

The cyanobacterium *Arthrospira* is globally used as feed- and foodstock owing to its high nutritional value. We study *Arthrospira* sp. strain PCC 8005 as a principal organism and edible end product of MELiSSA, a life support system developed by ESA. Particular caveats to study this highly versatile organism are its assay-interfering auto-fluorescence and the lack of a genetic system.

Objectives

Two important aspects of our research are (i) to understand the genetic and biochemical pathways involved in the resistance of strain PCC 8005 to high doses of ionizing radiation (IR) and (ii) to define optimal growth conditions for *Arthrospira* to conserve its beneficial properties in radiation-intensive space environments.

Methods

To study the effect of radiation on growth and morphology and to test whether extreme IR-resistance is a general trait in *Arthrospira*, different strains were exposed to increasing doses of gamma radiation (up to 5 kGy) and analyzed for culture-based growth recovery, morphological changes, and cellular and molecular effects (by TEM microscopy and LC-MS). Strain PCC 8005 was also exposed to IR during at least one full cycle of LED-driven photosynthetic growth for RNAseq analysis.

Conclusions

Arthrospira strains and species from different origins display a variable sensitivity towards IR. Even the two morphotypes of *Arthrospira* sp. strain PCC 8005 (straight versus helical) show, in terms of growth recovery, distinct sensitivities towards IR. Once all data are analyzed, LC-MS, TEM, and RNAseq analyses should provide a detailed insight in the cellular responses of *Arthrospira* sp. PCC 8005 towards IR.

GENOME MINING OF NOVEL BACTERIAL STRAINS FOR POTENTIAL CRISPR/CAS SYSTEMS

S. Yadav[1], J. Hurr K[2], S.S. Lee[1]
[1]Kyonggi University, Life Science, Suwon, Republic of Korea
[2]Korea University, Stem Cell Institute-, Seoul, Republic of Korea

Backgrounds

Clustered regularly interspaced short palindromic repeats (CRISPR) are segments of prokaryotic DNA containing short, repetitive base sequences. Each repetition is followed by short segments of spacer DNA from previous exposures to foreign DNA. It is an adaptive immune system of prokaryotes which employ short sequences, called spacers, which guide Cas proteins to cleave foreign DNA. The CRISPR/Cas systems are present in majority of the archaeal and about 40% of the bacterial genome. However, there are very limited numbers of bacteria are explored for the novel CRISPR/cas system. Hence, exploration of previously uncultivated bacterial strains could be the potential target for the novel CRISPR/cas systems.

Objectives

This study was designed to explore the genomes of novel bacterial strains which could be potential target for the novel CRISPR/cas systems. A total of 100 novel bacterial species collected from Korean Environmental Microorganisms Bank (KEMB), Kyonggi University, South Korea.

Methods

Genomes of the all the bacterial strains were sequenced and analysed for the presence of novel CRISPR/cas system. Based on preliminary analysis a total of about 31 bacterial genomes belong to the phyla *Proteobacteria*, *Spirochaetes*, *Planctomycetes* and *Fusobacteria* were found to possess the CRISPR/cas system. Out of these strains only *Enhydrobacter* sp. strain H5 were found to possess a new sub-type of the CRISPR/cas system while rest bacteria contained previously known CRISPR/cas systems.

Conclusions

Genome and transcriptome analysis of *Enhydrobacter* sp. strain H5 confirmed that this strain possess a novel sub-type of CRISPR/cas 9 system.

MICROBIAL DIVERSITY AND ICE NUCLEATION PROPERTIES OF BIOAEROSOL SAMPLES COLLECTED IN THE EASTERN MEDITERRANEAN

P. Yordanova[1], S. Maier[1], N. Lang-Yona[1], A. Tamm-[1], H. Meusel[1], U. Pöschl[1], J. Fröhlich[1], B. Weber[1]
[1]Max Planck Institute for Chemistry, Multiphase chemistry, Mainz, Germany

Backgrounds

Primary biological aerosols (bioaerosols), a subset of atmospheric particles, comprise living and dead microorganisms, reproduction units and organism fragments. Bioaerosols can act as cloud condensation and ice nuclei, therefore they have potential to modify cloud albedo, precipitation, and the hydrological cycle.

Objectives

The present study aims at accomplishing two major tasks: 1) identification and quantification of bioaerosol particles and 2) investigation of ice nucleating (IN) ability of total suspended particles (TSP) collected at the remote site Agia Marina Xyliatou in Cyprus during a field campaign in April 2016.

Methods

Total suspended particles of various types of air masses such as African (Saharan) and Arabian dust and European and Middle Eastern pollution were collected on glass fiber filters at 24 h intervals. During the sampling period, two major dust storms (PM 10_{max} 119 µg/m^3 and 64 µg/m^3) and a rain event were documented.

The samples are investigated for microbial composition by metagenomics and IN properties are characterized by filtration, thermal, chemical and enzyme treatments. Immersion freezing experiments are performed at relatively high subzero temperatures (-1 to -15°C) using a mono ice nucleation assay.**Conclusions**

Preliminary results indicate that highest IN particle numbers (INPs) occurred during the second dust storm event characterized by lower particle concentrations. Treatments at 60°C lead to gradual INP deactivation, indicating the presence of biological INPs. Additionally, first results indicate that bacteria dominate the microbial community with Firmicutes, Actinobacteria, Proteobacteria and Cyanobacteria being the most abundant phyla.

EFFECTIVE BIODEGRADATION OF HEAVY METAL FREE AND POLLUTED FEATHER WASTES BY GELLAN GUM IMMOBILISED BACILLUS SP.

I. Yusuf[1], *S. Yahaya*[1]
[1]*Bayero University Kano- Nigeria, Microbiology, Kano, Nigeria*

Backgrounds

Waste waters from residential areas in many cities in Nigeria are not effectively discharged and constitute part of environmental pollution by forming sludge that harbor many bacteria and parasites.

Objectives

With a view to utilising cells of heavy metal tolerant bacterium- *Bacillus sp.* isolated from domestic waste sludge in degradation of polluted feather wastes, an investigation was made of the ability of gellan gum immobilised cells of the bacterium to degrade heavy metal polluted feathers and produce keratinase.

Methods

The performance of the immobilized cells in the degradation of heavy metal free and polluted feather wastes was evaluated. Compared with the free cells, the immobilised cells was able to tolerate broader range of heavy metal concentration, produced higher keratinase and degrade heavy metal polluted feathers faster. After repeated use, beads of immobilised Bacillus sp retained about 90% of its feather degrading ability (FDA) without need for desorption for 7 consecutive cycles. Although FDA decreased considerably when concentration of Hg, Pb, Mn and As, Cd, is above 5 and 10 ppm respectively, but it maintained about 76% of FDA during repeated degradation of feathers polluted with 5 and 10 ppm respectively. When mixture of Ag, Co, Cu at 25 ppm each were used, FDA decreased to 55 and 32% at the end of 4 and 6 cycles respectively.

Conclusions

The study indicates that, the use of immobilised cells of Bacillus sp offers a promising means of bioremediation of heavy metal polluted feather wastes and in the production of keratinase enzymes.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

ISOLATION OF SULFUR OXIDIZING BACTERIA FROM NAMAKDAN CAVE IN QESHM

N. Zamani[1], M.A. Amozegar[1], M. Mehrshad[2]
[1]Faculty of Biology - College of Science - University of Tehran -, microbiology, Tehran, Iran
[2]institute of hydrobiology, Aquatic microbial ecology, Ceske Budejovice, Czech Republic

Backgrounds

Organisms require energy for life processes such as growth and movement. Those bacteria which oxidize inorganic compounds with molecular Oxygen to acquire energy, are called chemolithotrophic bacteria. They can oxidize Ammonia , Sulfur and reduced sulfur compounds , nitrite , ferrus iron , hydrogen and etc . These kinds of bacteria were discovered by S.N.Winogradsky in 1891 for the first time

Objectives

This study aims at isolating Sulfur Oxidizing chemolithotrophic Bacteria from salt cave Qeshm. Based on the latest findings of geologists, this cave is considered as the longest salt cave in the world. and it is located in the southern coast of Iran (Persian Gulf).

Methods

After primary sampling considering the existing compounds in the natural environment of this cave, the researcher in this study has adapted the amounts of compounds in the culture medium and has been prepared in three NaCl concentrations of 0.2, 2, and4 M. Following the main sampling, the samples were taken to the laboratory and they were inoculated at enrichment medium in 250cc erlen. They were placed into the incubator shaker in a tempreture of 30 ° C and 150 rpm for 8 weeks. The act of second and third subculturing were conducted in 8 weeks intervals. The third subculture were transfered into the solid medium and three steps of purification were carried out and sixteen pure isolates were obtained

Conclusions

Amongst these strains we chose strains SN1 , SN2 , SN3 , SN4 for further characterization and each of these strains showed 16S rRNA gene sequence similarity with *Halothiobacillus hydrothermalis* RT3(98.83% , 99.2 %,98.91% , 98.62 %) respectively.Based on some morphological tests: Cells were gram negative Bacills with different features in catalase and oxidase tests. This study is the first step in characterization of chemolithotrophic bacteria and their role in saline cave ecosystems.

ANTIMICROBIAL ACTIVITY OF PHARMACEUTICALS WITH A CARBAZOLE RING IN THEIR STRUCTURE

K. Zawadzka[1], A. Nejman[1], K. Lisowska[1]
[1]Univesity of Lodz, Department of Industrial Microbiology and Biotechnology, Lodz, Poland

Backgrounds

The mammals stay in close association with their microbiome including archea, bacteria and fungi settle down in their organisms. The microbiome of living organisms is extremly diverse and striking a correct balance of microflora is a key factor in maintaining the positive state of health. In recent years, human and animal microbiomes have been shown to be affected by various drugs especially antibiotics. Carbazole is an N-heterocyclic compound commonly used in the production of dyes and drugs. Carvedilol and ondansetron have a carbazole ring in their structure. Carprofen is a non-steroidal anti-inflammatory drug (NSAID) of the propionic acid class. Ondansetron is a serotonin 5-HT3 receptor antagonist used to prevent nausea and vomiting caused by cancer chemotherapy, radiation therapy and surgery.

Objectives

The aims of this study were to evaluate antimicrobial activity of carprofen and ondansetron against Gram-positive and Gram-negative bacteria and to assess its impact on the mammalian microbiome.

Methods

Antimicrobial activity of the tested drugs was examined by the modified method of serial dilutions in Miller-Hinton medium in accordance with the standard by The European Committee on Antimicrobial Susceptibility Testing involving spectrophotometric measurement of the optical density of microbial growth with serial dilutions of carprofen or ondansetron.

Conclusions

The influence of carprofen and ondansetron on the growth of both Gram-positive and Gram-negative bacteria was confirmed. The obtained results indicate that these drugs may interfere with the microbiome balance by inhibiting and simulating of the growth of different microorganisms.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

INVESTIGATION ON THE DIFFERENTIATION OF TWO USTILAGO ESCULENTA STRAINS - IMPLICATIONS OF A RELATIONSHIP WITH THE HOST PHENOTYPES APPEARED IN THE FIELDS

Y. Zhang[1], *Z. Ye*[1]
[1]*China Jiliang University,*
Zhejiang Provincial Key Laboratory of Biometrology and Inspection & Quarantine, Hangzhou, China

Backgrounds

Ustilago esculenta, a pathogenic basidiomycete fungus, infects *Zizania latifolia* to form edible galls named jiaobai in China. Distinct growth conditions of *U. esculenta* resulted *Z. latifolia* to form three different phenotypes, named male Jiaobai, grey Jiaobai and white Jiaobai respectively.

Objectives

The aim of this study was to elucidate the differentiations of the two *U. esculenta* strains (named T and MT) isolated from grey Jiaobai and white Jiaobai respectively.

Methods

The different infection ability and growth response to environment cues, like pH, distinct nitrogen or carbon sources, between T and MT strains, were verified by morphological observation with microscope and inoculation assay. Meanwhile, the non-synonymous mutation analysis based on the comparative genome sequencing database between the MT and T strains was carried out to be further evidence.

Conclusions

MT strains appeared slower growth rate and fewer growth mass both in sporidia and hyphae, more sensitive to external signals, including pH, oxidative stress and nutritions except arginine. Also, the non-synonymous mutation analysis showed multiple mutations in pathogenic genes of MT strains, in accordance with their reduced pathogenicity when compaired to T-type strains. So it was reasonable to speculate the relationship between *U. esculenta* strains differentiations and their host phenotypes.

PHOSPHATE MINERAL DIFFERENTIATED BACTERIAL AND FUNGAL COMMUNITIES FROM WEATHERED ROCKS IN HESHANG CAVE

J. Zhou[1]
[1]*China University of Geosciences, School of Environmental Studies, Wuhan, China*

Backgrounds

As a unique habitat, rock surface harbor various microbial communities which extract their nutrients from the rocks via their metabolic activities. However knowledge about microbial communities on the surface of cave wall rocks and the environmental factors controlling their distribution are still lacking.

Objectives

This study was designed to investigate bacterial and fungal communities and their correlation with mineral compositions in Karst Cave wall rocks.

Methods

We collected rock samples according to the different zones and different layers on the wall in Heshang Cave, central China. Bacterial and fungal diversity from rocks surfaces, crust layers and loose layers, as well as microbes in photic zone, twilight zone and aphotic zone were examined via 16S rRNA and ITS Illumina amplicon sequencing. Meanwhile mineral composition of samples were analyzed by X-ray diffraction.

Conclusions

In total 4,969 bacterial OTU and 989 fungal OTUs were recovered with an identity of 97 %. Both bacterial and fungal compositions showed significant differences among samples from photic zone and other two zones at the phylum lever and the class level respectively. Actinobacteria and Sordariomycetes dominate bacterial and fungal communities in most samples. RDA analysis indicated that hydroxylapatite significantly impacts bacterial and fungal communities, while fungal communities also showed a close correlation with whitlockite. Together, these results suggest that cave weathered rocks harbor a high diversity of bacterial and fungal communities, which are closely related to phosphate mineral.

HOW TO TRANSMIT A GUT BACTERIAL SYMBIONT IN SOCIAL INSECTS?

M. Zhukova[1], *P. Sapountzis*[1], *M. Schiøtt*[1], *J.J. Boomsma*[1]
[1]*University of Copenhagen, Centre for Social Evolution- Department of Biology, Copenhagen, Denmark*

Backgrounds

The transmission of bacterial symbionts across host generations is crucial for the direction and efficiency of host-symbiont coevolution. Specialized gut microbes of ants are peculiar because within-colony horizontal transmission can produce exclusive vertical transmission across generations. Colony life may thus alleviate constraints in the pupal stage where direct transmission from larval- to adult guts is impossible, particularly when the pupal environment is predictable.

Objectives

We analysed gut microbiome changes across developmental stages and traced the bacterial transmission routes of two abundant gut symbionts of *Acromyrmex* and *Atta* leafcutter ants, which are important functional herbivores in the New World tropics.

Methods

We analysed Illumina MiSeq 16S rRNA gene amplicon sequencing data to determine gut bacterial communities at different developmental stages. We also measured bacterial abundance using droplet digital PCR, and used confocal and electron microscopy to visualize bacteria in different gut tissues.

Conclusions

The larval and pupal guts contained several bacterial species that also occur in the fungus gardens, while adult workers hardly have these bacteria in spite of eating the same fungal material. Non-parasitic *Wolbachia* were most abundant across developmental stages in *Acromyrmex*, but *Atta* had mostly Mollicutes in the worker guts. *Wolbachia* appears to be transovarially transmitted, but Mollicutes were absent in eggs and scarce/absent in larval and pupal guts. After eclosion, callows acquired Mollicutes through interactions with other workers and failed to obtain these bacteria in isolation, suggesting that Mollicutes are socially transmitted. Both pathways result in exclusive vertical transmission across generations and should therefore facilitate host-symbiont coevolution in similar ways.

ENVIRONMENTAL ORDINATION OF FILAMENTOUS BACTERIA IN ACTIVATED SLUDGE

A. Zornoza[1], *S. Serrano*[2], *J.L. Alonso*[1]
[1]*Ingeniería del Agua y Medio Ambiente, Área de Química y Microbiología del Agua, Valencia, Spain*
[2]*Universidad Complutense de Madrid. Facultad de Biología, Departamento de Microbiología III, Madrid, Spain*

Backgrounds

Studies about the dynamics of filamentous bacterial populations in activated sludge, have often been on bulking and foaming episodes, mainly focused to clarify the taxonomic position, in situ ecophysiology, presence and distribution, as well as the strategies for controlling the populations. However, the studies about the filamentous bacteria from the point of view of the environmental interpretation are still scarce.

Objectives

A relationship between filamentous bacteria and environmental variables was carried out. This study have been focused on determining the ordination of the relationships between filamentous bacteria and physicochemical, and operational variables in full-scale wastewater treatment plants (WWTPs) operating in temperate climate.

Methods

Samples from activated sludge, influent and treated effluent were collected fortnightly during a year from six bioreactors belonging to four different WWTPs located in Spain. In our study we combined the conventional microscopy and the fluorescent in situ hybridization (FISH) using 27 FISH probes for filamentous bacteria to estimate the absolute density of filamentous bacteria in the bioreactors. Distance-based linear models (DISTLM) were applied to investigate models of environmental interpretation of biological variables.

Conclusions

The construction of models allows associating the filamentous bacteria to environmental ranges, obtaining valuable information to the knowledge of these dynamic populations. Our results provide insights into dynamics of filamentous bacteria in response to physicochemical and operational parameters changes in activated sludge systems and improve our understanding regarding the effect of these variables on wastewater treatment efficiency.

PLAUSIBLE BIOINDICATORS OF BIOLOGICAL NITROGEN REMOVAL PROCESS IN WWTPS. APPLICATION OF MULTIVARIATE PREDICTED MODELS

A. Zornoza[1], *J.L. Alonso*[1], *S. Serrano*[2]
[1]*Ingeniería del Agua y Medio Ambiente, Área de Química y Microbiología del Agua, Valencia, Spain*
[2]*Universidad Complutense de Madrid. Facultad de Biología, Departamento de Microbiología III, Madrid, Spain*

Backgrounds

The optimization of wastewater treatment involves the search of new tools for the control of the process. Nowadays, restrictions concerning the discharge of certain pollutants, such as nitrogen and phosphorus are imposed, so new configuration of treatment plants have been proposed. Advances in the knowledge of dynamics of the protists and metazoans populations are necessary for the proposal of new biological control tools in activated sludge. Many studies have attempted to relate protists and metazoans with physicochemical and operational variables of wastewater treatment plants (WWTPs) in order to reveal possible bioindicators. However, these studies have been mainly descriptive and/or exploratory and environmental interpretation has not been included in them.

Objectives

The aim of this work is the proposal of biological bioindicators of the nitrogen removal process.

Methods

Samples from activated sludge, influent and treated effluent were collected fortnightly during a year, from six bioreactors belonging to four different WWTPs (Spain). Density of protists and metazoans was obteined by direct counting and different staining procedures, using phase contrast microscopy. Models of environmental interpretation of biological variables, distance-based linear models (DISTLM), as well as the canonical correspondence analysis (CCA), were applied.

Conclusions

The multivariate models constructed with DISTLM and CCA have provided relevant information about the relationships between protists and metazoans and some plant nitrogen compounds, allowing their ecological interpretation and obtaining new bioindicators for monitoring the biological nitrogen removal process in active sludge.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

BACTERIAL POPULATIONS IN NATURAL GAS SEEPAGE POCKMARKS AND ASSOCIATED BIOTOPES IN NORTH-EAST ICELAND

G.V. Thorsteinsdottir[1], A. Blischke[2], T.S. Arnarson[3], O. Vilhelmsson[1]
[1]University of Akureyri, Faculty of Natural Resource Science, Akureyri, Iceland
[2]Iceland Geosurvey, Branch Akureyri, Akureyri, Iceland
[3]Orkustofnun, Hydrocarbon Exploration, Reykjavík, Iceland

Backgrounds

Natural gas seepage pockmarks present ideal environments for bioprospecting for alkane and aromatic degraders, and investigation of microbial populations with potentially unique adaptations to the presence of hydrocarbons.

Objectives

On-shore seepage pockmarks are found at two disparate sites in the Jökulsá á Fjöllum delta in North-East Iceland.

Methods

The origin and composition of headspace gas samples from the pockmarks were analysed by GC-MS and stable isotope analysis, revealing a mixture of thermogenic and biogenic gases with considerable inter-site variability. The warmer, geothermally impacted site displayed a more thermogenic character, comprising mostly methane and CO2 with minor amounts of higher alkanes. The water chemistry of the pockmark sites was determined, revealing considerable heterogeneity between sites. The geothermally impacted site water contained higher amounts of calcium and zink, and lower amounts of iron than the more biologically impacted site. Microbial communities were analysed by 16S rDNA tag sequencing of extracted DNA from the gas seepage pockmarks and additional sediment samples were taken for culturing and isolating bacterial strains on selective media.

Conclusions

The bacterial community of the thermogenic gas site is mostly composed of the phyla *Chloroflexi* (38%), *Proteobacteria* (8%) and *Firmicutes* (4%). *Dehalococcoidia* were by far the most abundant class, indicating a community strongly affected by anaerobic dehalogenation. The biogenic gas site showed higher microbial diversity, dominated by the phyla *Proteobacteria* (31%), *Bacteriodetes* (14%) and *Chloroflexi* (10%). Studies on isolated strains have revealed degraders of naphthalene, hexane and propane, as well as potentially facultative dehalorespirers, and bacteria likely to display bioweathering and biodeposition activities.

CHARACTERIZATION OF THE MOLECULAR DETERMINANTS INVOLVED IN THE COLONISATION ABILITY OF ESCHERICHIA COLI O157:H7 TO THE EXTRACELLULAR MATRIX

V. AGEORGES[1], *N. CACCIA*[1], *C. CHAGNOT*[1], *C. PROVOT*[2], *F. CHAUCHEYRAS-DURAND*[1], *M. DESVAUX*[1]
[1]*French National Institute for Agricultural Research, MICA, Saint-Genès Champanelle, France*
[2]*Biofilm Control, Biofilm Control, Saint-Beauzire, France*

Backgrounds

Among intestinal pathogenic *Escherichia coli* (InPEC), enterohaemorrhagic *E. coli* (EHEC) 0157:H7 are anthropozoonotic agents leading to haemorrhagic colitis and haemolytic-uremic syndrome (HUS). From ruminants (the animal reservoir), EHEC can contaminate some foodstuffs and consequently infect human. While the locus of enterocyte effacement (LEE) is generally considered as a key determinant of EHEC, it is neither sufficient nor systematically present in all EHEC strains. The presence of extracellular matrix (ECM) components along the food chain could increase their colonisation capacity. Numerous proteins can be present at the bacterial cell surface of EHEC and could participate to the bacterial adhesion and biofilm formation at the ECM.

Objectives

This study aimed at identifying and characterizing the respective involvement of cell-surface proteins in the colonisation process of EHEC to some ECM components.

Methods

Target genes were identified by a proteogenomic approach based on the secretome concept. The involvement of these genes in bacterial adhesion and biofilm formation was characterized following functional genetic analysis.

Conclusions

Several organelles and adhesins, either secreted by the Type I secretion system (T1SS) to the Type VIII (T8SS), could identified in EHEC and related enteropathotypes. Following gene knock-out, the ability of the mutants to adhere and/or to form biofilm to ECM components was compared to the wild type strain. Besides the flagella (T3bSS) and pili of the T7SS, some autotransporters belonging the T5aSS appeared to contribute significantly to specific and/or non-specific colonisation of the ECM by *E. coli* O157:H7.

Food Microbiology

RISK ASSESSMENT OF FEED ADDITIVES OF MICROBIAL ORIGIN IN THE EUROPEAN UNION

J. Aguilera[1], *R. Brozzi*[1], *M. Anguita*[1], *J. Galobart*[1]
[1]*European Food Safety Authority- EFSA, FEED Unit, Parma, Italy*

Backgrounds

Microorganisms can be used in animal nutrition as probiotics, silage agents or as a source of other additives like enzymes, amino acids and vitamins. In the European Union, Regulation (EC) No 1831/2003 stipulates that all feed additives intended to be marketed need to undergo a risk assessment, which is conducted by the European Food Safety Authority.

Objectives

A proper characterisation of the microorganism is fundamental for its safety assessment. This includes non-equivocal identification of the species, consideration of its pathogenic or toxigenic potential and its resistance to antimicrobials. Genetically modified strains require a full characterisation of the modification.

Methods

The characterisation of the microorganism determines the need of further tests to be done in the product to address the safety aspects related to the production strain. For example, if the strain is capable of producing toxic compounds, the product should be free of those compounds. Toxicological tests may be necessary if the safety of the strain cannot be established. Conversely, if the production microorganism has a well-documented safety, it may be eligible for a Qualified Presumption of Safety status, in which case it is considered safe without the need of further testing.

Conclusions

Within the activity of updating its guidance documents for the risk assessment of feed additives, EFSA will issue a unique guidance document covering all data needed for the characterisation of microorganisms, both as products or as a source of them. The document aims to streamline the process of preparation and assessment of dossiers for microbial and microbial-based additives.

Food Microbiology

EFFECT OF REPLACING ANTIBIOTIC (AGPS) WITH POLYPHENOLIC BOTANICAL EXTRACTS AND ESSENTIAL OILS IN FEED OF LAYING HENS ON PERFORMANCE, HEALTH, ND TITER AND BLOOD PARAMETERS

A. Ahmad[1]
[1]*Karachi, Pakistan*

Backgrounds

Polyphenolic vegetative extracts and essential oils are very important replacement additives for the antibiotic growth promoters in layer feeds. The goal of this study was to investigate the effect of vegetative extracts and essential oils on egg producing layers' health, immunity against ND virus disease and other blood parameters. One hundred and twelve, nine months old, white Novagin egg producing laying hens (1480+50 grams average live body weight each) were randomly distributed to seven groups equally (n = 16). Each group/treatment was divided four times with four birds per replicate cage unit. Diets (rations) were prepared by adding vegetative polyphenolic extracts of black tea (c), seeds of black cumin (d), fenugreek seed (e) as well as oils from black cumin seeds (f) and fenugreek seeds (g) in the negative control (b; treatment with nil antibiotic and antioxidant added in the ration) and compared with positive control (a) having antibiotic (4.4%) lincomysin 120mg/kg of feed, acetic acid (99.5%) 0.15mL/kg of feed, antioxidant seldox (BHA, BHT, ethoxiquine and citric acid) 120mg/kg of feed. After end of the five weeks trial, weekly feed conversion ratio (FCR) of all treatments were significantly good than negative control (b) ($P<0.05$), however treatments a, b, d, e, f and g had non-significant differences among one another ($P>0.05$). ND titer level remain same of all treatments and overall health performance was good and there was insignificant difference between all blood parameters except negative control ($P>0.05$). These results clarify that polyphenolic vegetative extracts/oils have positive affect on the performance, health and there is no drastic change in blood parameters of the egg producing layers and thus can be replaced by antibiotic growth promoters.

Objectives

Observation of polyphenolic vegetative extracts effect on birds heath and performance.

Methods

Used to see effects by feeding birds

Conclusions

We can replace antibiotics with vegetative extracts.

FEMS7-1851

ANTIBACTERIAL ACTIVITY OF CHILEAN ULMO (EUCRYPHIA CORDIFOLIA CAV.) HONEY AGAINST WOUNDS AND FOOD PATHOGENS

C. Burgos-Díaz[1], M. Farfán[2], F. Acevedo[3], V. Albarral[4]
[1]Agriaquaculture Nutritional Genomic Center- CGNA- Technology and Processes Unit, Technology and Processes Unit, Temuco, Chile
[2]Universitat de Barcelona, Facultat de Farmàcia i Ciències de l'Alimentació- Departament de Biologia Sanitat i Medi Ambient- Se cció Microbiologia, Barcelona, Spain
[3]Universidad de La Frontera, Scientific and Technological Bioresource Nucleus- BIOREN, Temuco, Chile
[4]Universitat de Barcelona, Facultat de Farmàcia i Ciències de l'Alimentació- Departament de Biologia Sanitat i Medi Ambient- S ecció Microbiologia, Barcelona, Spain

Backgrounds

Ulmo honey, derived from the Patagonian Eucryphicean tree (*Eucryphia cardifolia*) native to the rainforest of southern Chile, is considered the only honey in the world of botanical origin. It has been used to treat infections in traditional medicine in the Mapuche culture since ancient times.

Objectives

The main aim of this study was to analyze the antimicrobial activity of Ulmo honey against different pathogen species, including Gram-positive and Gram-negative bacteria and a yeast.

Methods

96-well Microtiter plates were used to determine the minimum inhibitory concentration (MIC). The assays were performed in quadruplicate. The selected bacterial strains comprised five wound pathogens, four food pathogens and one yeast, *Candida albicans.*

Conclusions

Ulmo honey exhibited strong antibacterial activity against *Klebsiella pneumoniae*, *Salmonella enterica* and *Staphylococcus aureus* MRSA (MIC 3.1%, v/v). In comparison with other honeys (e.g. Manuka honey), Ulmo honey presented a higher antimicrobial activity against *Staphylococcus aureus* MRSA, *Salmonella enterica* and *Klebsiella pneumoniae*, and similar activity against *Escherichia coli* and *Pseudomonas aeruginosa*. In contrast, *Bacillus subtilis*, *Enterococcus faecalis* and *Candida albicans* were unaffected, as in assays with other honeys. The results indicated that Ulmo honey displays strong inhibitory activity against pathogens usually isolated from wounds and ulcers and could be used as a potential therapeutic agent to treat bacteria resistant to drugs, such as *Staphylococcus aureus* MRSA, which is responsible for serious skin infections in humans.

Food Microbiology

DEVELOPMENT OF REAL-TIME PCR ASSAYS FOR SEROTYPING LISTERIA MONOCYTOGENES IN MEAT PROCESSING PLANTS

A. Alía[1], A. Rodríguez[1], J.J. Córdoba[1], E. Bermúdez[1], P. Padilla[1], M.J. Andrade[1]
[1]University of Extremadura, Animal Production and Food Science, Caceres, Spain

Backgrounds

Listeria monocytogenes constitutes the main concern of Ready-To-Eat (RTE) meat products since its high risk for consumers, being the serotypes 1/2a, 1/2b, 1/2c and 4b the most frequently involved in human listeriosis. Given that this microorganism is a persistent contaminant in raw materials, equipment and utensils in meat industries, rapid and sensitive methods able to serotype *L. monocytogenes* are needed for characterizing its contamination source.

Objectives

The objective of this work was to develop sensitive SYBR Green-based real-time PCR (qPCR) assays to trace the source of contamination of *L. monocytogenes* in RTE meat processing plants.

Methods

To differentiate the four serotypes, the marker genes used were *lmo0737* (1/2a and 1/2c), *lmo1118* (1/2c), ORF2819 (1/2b and 4b) and ORF2110 (4b). The specificity and reliability of the qPCR methods were evaluated using 4 *L. monocytogenes* serotype reference strains and 20 isolates from meat industries.

Conclusions

The qPCR assays showed Ct values of 26.8 and 28.7 for *lmo0737* (1/2a and 1/2c, respectively), 24.9 for *lmo1118* (1/2c), 25.8 and 26.6 for ORF2819 (1/2b and 4b, respectively) and 19.2 for ORF2110 (4b). Nonspecific amplifications were observed. Results agreed with those obtained by a previously validated PCR method. The optimized qPCR protocols provide sensitive and rapid tools for serotyping *L. monocytogenes* isolates and could be very useful for characterizing sources contamination in RTE meat industries.

GENE EXPRESSION AS INDICATOR OF OCHRATOXIN A CONTAMINATION IN DRY-CURED FERMENTED SAUSAGES

V. Bernáldez[1], M.J. Andrade[1], L. Sánchez-Montero[1], A. Alía[1], M. Álvarez[1], J.J. Córdoba[1]
[1]University of Extremadura, Animal Production and Food Science, Caceres, Spain

Backgrounds

Ochratoxin A (OTA)-producing moulds such as *Penicillium nordicum* and *P. verrucosum* may colonise surface of dry-cured fermented sausages throughout their ripening process. This supposes a hazard of OTA accumulation with the subsequent risk for consumers. For this reason, it is necessary to have sensitive methods for detecting OTA-producing moulds before mycotoxin is produced, which may allow taking corrective actions during processing to avoid production of this mycotoxin. Gene expression analysis by reverse transcription real time PCR methods could allow detecting the presence of viable OTA-producing moulds. For this purpose the key genes involved in OTA biosynthesis could be tested.

Objectives

The objective of this work was to evaluate the temporal changes in OTA-related genes as indicator of phenotypic OTA production in dry-cured fermented sausages.

Methods

For this purpose slices of dry-cured fermented sausage "*salchichón*" were inoculated with *P. nordicum* and *P. verrucosum* and incubated up to 14 days at 97% relative humidity and 25ºC to favour mould growth. Temporal changes in the expression of *otapks* and *otapns* genes and OTA production were then evaluated.

Conclusions

Gene expression was higher in *P. nordicum* than in *P. verrucosum*. The high significant correlation found between the early relative expression of the *otapks* gene and OTA production lead to propose the *otapks* gene expression analysis as indicator of OTA accumulation in this dry-cured meat product.

Acknowledgements: This work was funded by Spanish Ministry of Economy and Competitiveness, Government of Extremadura and FEDER (AGL2013-45729-P, GR15108).

EFFECT OF TEMPERATURE ON THE PREVALENCE OF SACCHAROMYCES NON CEREVISIAE SPECIES AGAINST A S. CEREVISIAE WINE STRAIN: COMPETITION AND INFLUENCE IN WINE COMPOSITION

J. Alonso del Real[1], *M. Lairón Peris*[1], *E. Barrio*[2], *A. Querol*[1]
[1]*Instituto de Agroquímica y Tecnología de Alimentos, Biotecnología, Paterna, Spain*
[2]*Universidad de Valencia, Genética, Valencia, Spain*

Backgrounds

Saccharomyces cerevisiae is the main microorganism responsible for the fermentation of wine. Nevertheless, in the last years wineries are facing new challenges due to current market demands and climate change effects on the wine quality. New starters formed by non-conventional *Saccharomyces* species (such as *S. uvarum* or *S. kudriavzevii*) or their hybrids can contribute to solve some of these challenges. They exhibit good fermentative capabilities at low temperatures, producing wines with lower alcohol and higher glycerol amounts. However S. *cerevisiae* can competitively displace other yeast species from wine fermentations.

Objectives

We analyzed the survival capacity of non-*cerevisiae* strains in competition with *S. cerevisiae* during fermentation of synthetic wine must at different temperatures, and the effect on final wine composition.

Methods

We developed a method based on QPCR to quantify the proportion of different *Saccharomyces* yeasts in mixed cultures, which allowed us to assess the effect of competition on their growth fitness. In addition, fermentation kinetics parameters and final wine composition were also analyzed through weight loss and HPLC.

Conclusions

We observed that *S. uvarum* outcompeted *S. cerevisiae* during competences at lower temperatures, as it does in traditional wineries in certain European regions. From an enological point of view, mixed fermentations using some of our species deteriorated the process or the final product composition compared to single *S. cerevisiae* inoculation, whereas fermentation performance and wine characteristics improvements were obtained from other combinations. Finally, wine strains of *S. cerevisiae* and *S. uvarum* performed better in competition than non-wine strains of the same species.

Food Microbiology

EFFECT OF SEVERAL MODIFIED ATMOSPHERE PACKAGING CONDITIONS ON THE SHELF-LIFE OF REFRIGERATED OSTRICH MEAT

R. Capita[1], T. Álvarez-González[1], C. Alonso-Calleja[1]
[1]Universidad de León, Food Hygiene and Technology, León, Spain

Backgrounds

To allow competitive marketing of ostrich meat it is necessary to know its microbial and sensory characteristics under different conditions with a view to prolonging the shelf-life.

Objectives

This study was designed to investigate the effects of eight atmosphere conditions on microbial loads, physicochemical parameters and sensory properties of ostrich steaks during refrigerated storage in order to determine the most effective packaging atmosphere for extending the shelf-life of this foodstuff.

Methods

Ostrich steaks were packaged in air (AIR), vacuum (VAC), MAP1 (70% O_2 + 30% CO_2), MAP2 (30% O_2 + 30% N_2 + 40% CO_2), MAP3 (20% O_2 + 30% N_2 + 50% CO_2), MAP4 (50% N_2 + 50% CO_2), MAP5 (20% N_2 +80% CO_2) or MAP6 (100% CO_2). Microbial counts, pH, Aw and sensory properties (nine-point hedonic scale) were determined on Days 0, 1, 3, 7 and 15 of storage (4 ºC ± 1 ºC).

Conclusions

On Day 0, microbial counts (log_{10} cfu/g) ranged from undetectable levels (*Brochothrix thermosphacta*) to 3.21 ± 0.63 (total aerobic counts, TAC). The highest and the lowest microbial loads throughout storage were observed in AIR and MAP6, respectively. On Day 15 TAC as high as 9.96 ± 0.20 log_{10} cfu/g were found in AIR. The self-life (time until overall acceptability score fell below 5) was 3 (MAP1, MAP2), 7 (MAP3, AIR) or 15 days (MAP4, MAP5, MAP6). Only for VAC the shelf-life limit extended beyond 15 days. Findings in this study offer practical applications to the meat industry for improving the durability of ostrich.

MICROBIOLOGICAL QUALITY OF RETAIL RAW MEAT PREPARATIONS IN SPAIN

L. Buzón-Durán[1], S. Blanco-Morán[1], C. Alonso-Calleja[1], R. Capita[1]
[1]Universidad de León, Food Hygiene and Technology, León, Spain

Backgrounds

Meat and meat products constitute a substantial portion of the present-day human diet. To the best of our knowledge, studies on microbiological quality of meat preparations are lacking in north-western Spain.

Objectives

The aim or this work was to assess the loads of various indicator microbial groups in raw meat preparations.

Methods

A total of 160 samples of raw poultry, raw beef and raw pork preparations were collected from retail outlets in the Province of León in north-western Spain. Samples included crepes, escalope, hamburgers, meatballs, minced meat, nuggets, red sausages, and white sausages. Microbiological analysis was performed according to standard methods.

Conclusions

The loads (mean ± STD; log cfu/g) for aerobic plate counts (APC), psychrotrophs, *Enterobacteriaceae*, coliforms, *Micrococcaceae* and enterococci were 6.59 ± 1.10, 6.63 ± 1.19, 2.96 ± 0.98, 1.59 ± 0.92, 4.18 ± 0.92, and 2.07 ± 0.81, respectively. APC were regarded as satisfactory (38 samples; 23.75%), acceptable (46; 28.75%) and unsatisfactory (76; 47.50%) according to the EU microbiological criteria. Both animal species and type of product influenced ($P < 0.05$) microbial counts. Pork preparations showed higher bacterial load than did poultry or beef preparations for most microbial groups. Data (log cfu/g) for APC were 7.06 ± 0.89, 6.42 ± 1.13, and 6.45 ± 1.09, respectively.

The relatively high bacterial counts observed raise concerns regarding the potential risks for public health of meat preparations and suggests that it is vital to design education strategies for food handlers in order to prevent cross-contamination and to ensure that foodstuffs are thoroughly cooked.

Food Microbiology

MODELING GROWTH OF VEROCYTOTOXIGENIC ESCHERICHIA COLI THROUGH RESPONSE SURFACE METHODOLOGY AND ARTIFICIAL NEURAL NETWORKS

M. Prieto-Calvo[1], A. Alvarez-Ordóñez[1], S. López[2], M. López[1], M. Prieto[1]
[1]Universidad de León, Food Hygiene and Technology, León, Spain
[2]Universidad de León, Animal Production, León, Spain

Backgrounds

Quantitative risk assessments are needed to take risk management decisions concerning food-borne microbial hazards. The use of predictive models that describe microbial growth helps estimate the concentration of bacteria in foods.

Objectives

Most models available in the literature predicting verocytotoxigenic *E. coli* (VTEC) growth do not take into account the variability associated to strain diversity. This study analyzed the differences in growth of twelve VTEC strains in several conditions of temperature, acidity and salt concentration by using turbidimetric measurements and modeling techniques.

Methods

The non-linear Baranyi equation was fitted to 1,143 growth curves. Two types of secondary models (response surface methodology (RSM) and artificial neural networks (ANN)) were used to describe the individual and combined effects of temperature, pH and NaCl concentration on kinetic parameters (specific growth rate and lag time).

Conclusions

A decrease in temperature from 35ºC to 25ºC caused a gradual decrease in μ_{max} and increase in λ. pH in the range 6.0 to 7.0 barely affected λ or μ_{max}. However, a pH decrease up to pH 5.0 caused a dramatic decrease in μ_{max} and increase in λ. Finally, NaCl concentrations in the range 0 – 3% had minor effects on growth parameters. RSM yielded good results in relation to goodness of fit, but ANN gave rise to better estimates. Interstrain and interserotype variability was low. In fact, no statistical differences could be observed in growth ability between strains from O157 and non-O157 serotypes, or strains with an impaired RpoS and strains with a functional RpoS.

FEMS7-3198
Food Microbiology

REDUCTION OF TYRAMINE IN FERMENTED FOOD

J. Anderegg[1], A. Die[1], L. Meile[1]
[1]Institute of Food- Nutrition and Health, Laboratory of Food Biotechnology, Zurich, Switzerland

Backgrounds

Tyramine belonging to the biogenic amines (BA) can often be detected in fermented food such as cheese and dry sausages due to endogenous tyrosine decarboxylating microorganisms (MO) and represent a consumer health-risk to be reduced in future.

Objectives

To identify the major tyramine-producing microorganisms in fermented food and to improve the knowledge about the tyramine producing mechanism.

Methods

A variety of cheeses and fermented sausages were screened on different selective agars for different lactic acid bacteria (LAB) and staphylococci. All isolated strains were screened by PCR for the tyramine decarboxylase gene *tyrDC*. Furthermore, an Ion exchange chromatography was developed to determine tyramine and other biogenic amines in food.

Conclusions

We screened 89 cheeses and 21 dry sausages by PCR for *tyrDC* and by IC on biogenic amines. A total of 45 cheeses and 9 dry sausages contained tyramine. In 40% of the cheeses containing tyramine a high content of enterococci between 3.0×10^3 and 3.5×10^7 cfu/g was found. All of these enterococci contained *tyrDC* PCR-amplicons. It seems as if cheeses contains tyramine enterococci plays a role. In sausages it looks different. It seems like enterococci does not becomes an important role in tyramine formation. A more interesting role in tyramine formation in dry sausages seems to have staphylococci, which are used as spontaneous or directed starter culture. Sixteen out of seventeen isolated staphylococci from dry sausages contains *tyrDC* PCR-amplicons. In a next step, the conditions for tyramine production in food will be analyzed.

MOLECULAR IDENTIFICATION OF YEASTS AND LACTIC ACID BACTERIA INVOLVED IN THE PRODUCTION OF BENINESE FERMENTED FOOD DEGUE

A.I. Angelov[1], G. Blagoeva[2], A.D. Angelov[1], P. Stefanova[1], I.Y. Bokossa[3], C. Tchekessi[3], M. Petkova[4], V. Gotcheva[1]
[1]University of Food Technologies, Biotechnology, Plovdiv, Bulgaria
[2]Primoris Bulgaria Plc, Microbiological Lab, Plovdiv, Bulgaria
[3]University of Abomey-Calavi, Vegetable Biology, Cotonou, Benin
[4]Agricultural University, Microbiology and Ecological Biotechnologies, Plovdiv, Bulgaria

Backgrounds

Traditional Beninese fermented food Degue is widely consumed in Benin and other countries in West Africa. Nowadays, Degue production occurs by spontaneous fermentation in individual households and information about the microorganisms involved is currently limited. The microbiota in this product from Benin has not been studied so far, but the growing production of Degue in the country sets a demand for revealing the biodiversity of the microbial population involved in the fermentation process in order to take future steps for development of industrial technology and offer products with improved quality and safety.

Objectives

The aim of the present study was to identify the naturally occurring yeast and LAB in cereal raw materials and milk used for the production of Degue, as well as in several types of Degue products.

Methods

In the present study, yeast and lactic acid bacteria (LAB) from raw materials for Degue production and from several Degue products were isolated and identified by molecular methods including RFLP and ITS1-5.8S-ITS2 rRNA gene sequence analysis in yeasts, and 16S rRNA gene sequence analysis in LAB.

Conclusions

Four yeast species were found in the samples of raw materials and various types of Degue - *C. fabianii, C. glabrata*, *K. marxianus* and *M. caribbica,* and identification of the LAB isolates revealed 8 species: *Lb. fermentum*, *Lb. plantarum*, *Lb. pentosus*, *Lb. rhamnosus*, *E. mundtii*, *P. acidilactici*, *S. thermophilus* and *W. paramesenteroides*. The differences of the species diversity in comparison to other similar fermented foods suggest that microbial community structure in Degue is not a simple consequence of the nature of the raw materials used, but it is a result from a variety of abiotic and biotic factors affecting the natural selection of specific microbial populations – origin of the raw materials, climatic and geographical factors, preparation method and work environment, etc.

Food Microbiology

EFFECT OF GLIADIN FRACTIONS ON GROWTH OF PROBIOTIC BACTERIA GENUS LACTOBACILLUS IN VITRO

R. Antolovic[1], *M. Ozbolt*[2], *T. Mančuškova*[3]
[1]*Catholic University of Croatia, Department of Nursing, Zagreb, Croatia*
[2]*University of Rijeka, Department of Biotechnology, Rijeka, Croatia*
[3]*Slovak University of Technology-, Faculty of Chemical and Food Technology, Bratislava, Slovak Republic*

Backgrounds

Incomplete digestion of gliadin in the gastrointestinal tract leads to formation of toxic peptides which can cause immune response in individuals. However, studies have shown that administration of probiotic supplements may prevent or mitigate adverse effects of these peptides. Among probiotic supplements, ones containing probiotic bacteria of genus *Lactobacillus* are standing out a potential therapy.

Objectives

The influence of gliadin on the proliferation of probiotic bacteria has been studied on seven *Lactobacillus* strains *in vitro,* studying two parameters - the growth rate and the lag phase of *Lactobacillus* strains.

Methods

Gliadin used in the sudy was disolved in 70% ethanol in 50 mM Tris/HCl or in 2% sodium chloride solution.

Conclusions

Results show that gliadin dissolved in 70% ethanol and 50 mM Tris/HCl induced proliferation of *L. helveticus* XA/2, *L. plantarum* II/5, *L. rhamnosus* GG and *L. paracasei spp. paracasei* 1753 and had no significant effect on growth of *L. acidophilus* 145, *L. casei* VIIB/6, *L. paracasei* VIIB5. Results with gliadin dissolved in 2% sodium chloride show that gliadin stimulated proliferation of *L. helveticus* XA/2 and *L. plantarum* II/5, but didn't have a significant effect on growth on *L. acidophilus* 145, *L. rhamnosus* GG, *L. casei* VIIB/6, *L. paracasei* VIIB5, *L. paracasei spp. paracasei* 1753. The growth rate of *L. helveticus* XA/2 and *L. plantarum* IIA/5 was higher with increasing concentration of gliadin in solution of 2% NaCl, but the lag fase was also longer because the bacteria needed more time to adjust to new conditions.

IMPORTED POULTRY MEAT PRODUCTS IN PORTUGAL AS A SOURCE OF EXTENDED-SPECTRUM CEPHALOSPORIN-RESISTANT SALMONELLA HEIDELBERG CMY-2-PRODUCING

J. Campos[1], J. Mourão[1], L. Silveira[2], M. Saraiva[3], C. Belo Correia[4], A.P. Maças[5], P. Antunes[6]
[1]UCIBIO/REQUIMTE., Laboratório de Microbiologia- Faculdade de Farmácia- Universidade do Porto., Porto, Portugal
[2]Instituto Nacional de Saúde Doutor Ricardo Jorge, Laboratório Nacional de Referência de Infeções Gastrintestinais- Departamento de Doenças Infecios as, Lisboa, Portugal
[3]Instituto Nacional de Saúde Doutor Ricardo Jorge, Departamento de Alimentação e Nutrição, Porto, Portugal
[4]Instituto Nacional de Saúde Doutor Ricardo Jorge, Departamento de Alimentação e Nutrição, Lisboa, Portugal
[5]Direção Geral de Alimentação e Veterinária, Direção Geral de Alimentação e Veterinária, Lisboa, Portugal
[6]Faculdade de Ciências da Nutrição e Alimentação, Faculdade de Ciências da Nutrição e Alimentação, Porto, Portugal

Backgrounds

Extended-spectrum cephalosporin-resistant (ESC-R) *Salmonella* has been described at low level in EU, including Portugal. Nevertheless, the increasing poultry meat trade involving countries with different animal production practices could be an important source of epidemic clones carrying ESC-R genes.

Objectives

To evaluate ESC resistance and to detail genetic platforms as well as the clonal relatedness of *Salmonella* isolates from Brazilian poultry meat products imported into Portugal

Methods

Seven *Salmonella* isolates from two serotypes (n=6-Heidelberg; n=1-Minnesota) recovered from frozen gizzards imported from Brazil (2014-2015) were studied. Antibiotic susceptibility tests (ampicillin-A/chloramphenicol/ciprofloxacin-Cip/gentamicin/kanamycin/meropenem/nalidixic acid-Na/pefloxacin-P/streptomycin/sulfamethoxazole-Su/tetracycline-T/trimethoprim) and detection of beta-lactamase production (amoxicillin-clavulanic acid-Amc/cefepime/ceftazidime-Cz/cefotaxime-Cx/cefoxitin-Fx) were performed by disk diffusion/microdilution methods (CLSI/EUCAST). Detection of genes encoding for acquired AmpC beta-lactamases (*bla*$_{CMY}$/*bla*$_{MOX}$/*bla*$_{FOX}$/*bla*$_{LAT}$/*bla*$_{ACT}$/*bla*$_{MIR}$/*bla*$_{DHA}$/*bla*$_{ACC}$), extended-spectrum beta-lactamases (*bla*$_{TEM}$/*bla*$_{SHV}$/*bla*$_{CTX-M}$), plasmid-mediated quinolone resistance [*qnrA*/*qnrB*/*qnrC*/*qnrD*/*qnrS*/*qepA*/*aac(6')-Ib-cr*/*oqxAB*] and other antibiotic resistance (PCR/sequencing), plasmid characterization (PCR-PBRT/pMLST/sequencing), conjugation assays and genomic location (I-CeuI/S1-PFGE nuclease hybridization) were performed. Clonal analysis by XbaI-PFGE/MLST included comparison with Portuguese/EU clinical/foodborne strains.

Conclusions

All imported poultry isolates were MDR (mostly AAmcCzCxFxCpPNaSuT), including to extended-spectrum-cephalosporins (MIC$_{Cx}$=8-16mg/L/MIC$_{FX}$=32->256mg/L) and/or fluoroquinolones (MIC$_{Cip}$=0.25-0.5mg/L). All but one isolate carried *bla*$_{CMY-2}$ located on two plasmid-types (IncA/C/ST2; n=4-Heidelberg/ST15; n=1-Minnesota/ST548; IncI1/ST12; n=1-Heidelberg/ST15). *S*.Heidelberg was

associated with 6 PFGE-types, with Brazilian poultry isolates sharing identical PFGE-types with a Portuguese patient or poultry imported into The Netherlands. Introduction in Portugal of CMY-2, mostly associated with MDR *S.*Heidelberg ST15 clone, emergent in American countries, suggest an important role of international food trade for the occurrence of ESC-R in EU. Furthermore this raises questions about the Regulation (EU) Nº1086/2011 setting for fresh poultry meat a criterion covering only *S.*Enteritidis and *S.*Typhimurium.

DISTRIBUTION OF TOP-EIGHT PATHOGENIC O-SEROGROUPS IN SHIGA TOXIN-PRODUCING ESCHERICHIA COLI (STEC) STRAINS ISOLATED FROM DIFFERENT ANIMAL SOURCES IN IRAN

M. Askari Badouei[1], *H. Taban*[2], *H. Ajoudanifar*[2]
[1]*Garmsar Branch- Islamic Azad University, Pathobiology, Garmsar, Iran*
[2]*Damghan Branch- Islamic Azad University, Microbiology, Damghan, Iran*

Backgrounds

Shiga toxin- producing *Escherichia coli* (STEC) have been considered as one of the most important food-borne pathogens worldwide. Although a wide range of *E. coli* serogroups has been implicated in human infections, most severe cases in Europe and the United States were related to certain serogroups known as top-eight STEC serogroups.

Objectives

Lack of the availability of serotyping data in most developing countries including Iran has been a public health challenge, especially to track outbreaks and to monitor the possible sources. Therefore, we aimed to investigate the distribution of major STEC serogroups in a large collection of STEC strains isolated from different provinces and variety of sources for the first time in Iran.

Methods

: Total of 118 non-duplicate STEC strains isolated in previous studies was selected. The isolates were obtained from cattle (35), sheep (25), goats (35), and pigeons (23). All isolates were subjected to a multiplex - PCR assay detecting the major virulence genes (*stx1, stx2, stx2f, eae, Ehly*) and then tested for top- eight O-groups including O26, O45, O103, O111, O113, O121, O145, and O157 by PCR.

Conclusions

The predominant serogroup was O113 as it was detected in 5 cattle and 3 sheep and goats strains. It was followed by O26 and O111 each occurred in 3 isolates from the cattle group, respectively. The pigeon isolates did not belong to any of the tested serogroups.

Food Microbiology

EVALUATION OF GREEN TEA EXTRACT FOR INACTIVATION OF ENTERIC VIRUSES IN FOOD APPLICATIONS

R. Aznar[1,2], I. Falcó[1], W. Randazzo[1], G. Sanchez[1,2]
[1]Universitat de Valencia, Microbiología y Ecología, Valencia- Burjassot, Spain
[2]Institute of Agrochemistry and Food Technology IATA-CSIC, Food Safety and Preservation, Burjassot, Spain

Backgrounds

Green tea extract (GTE) is a polyphenolic and proanthocyanidin rich compound widely used in food and beverage applications with health benefits including antioxidant, anti-inflammatory, and anticarcinogenic properties. In addition, GTE demonstrated antimicrobial activity against Gram-positive and Gram-negative foodborne bacterial pathogens and it has been used as a component in multiple hurdle approaches to enhance food safety and quality.

Objectives

To evaluate the effect of GTE on the infectivity of murine norovirus (MNV) and hepatitis A virus (HAV), and its application as disinfectant in vegetables and food-contact surfaces.

Methods

Virus suspensions (5 log $TCID_{50}$/ml) were incubated for 2 h in the presence of GTE (at 0.5 and 5 mg/ml): a) at pH ranging from 5.5 to 8.5 and 37 °C; b) at 4, 25 and 37 °C and pH 7.2. GTE was evaluated under food industry simulated conditions (ISO 13697:2001) on stainless steel and glass surfaces, lettuce and spinach artificially inoculated with viral suspensions. Antiviral activity was evaluated by cell-culture.

Conclusions

GTE affected both viruses with higher reductions at alkaline pH. Complete inactivation in suspension tests was achieved after overnight exposure at 37 °C for both viruses and also at 25 °C for HAV.

GTE (10 mg/ml) proved efficient after 30 min surface disinfection, since 1.5 log reduction and complete inactivation were recorded for MNV and HAV on stainless steel and glass surfaces, respectively. As a natural disinfectant, GTE (10 mg/ml) reduced MNV and HAV titers in lettuce and spinach by more than 1.5 log after 30 min treatment.

DEVELOPMENT OF KEFIR-LIKE CEREAL-BASED BEVERAGE NATURALLY BIO-FORTIFIED IN RIBOFLAVIN

R. Aznar[1], A. Yépez[1], P. Russo[2], V. Capozzi[2], G. Spano[2]
[1]Universitat de Valencia, Microbiología y Ecología, Valencia- Burjassot, Spain
[2]University of Foggia, Department of the Science of Agriculture- Food and Environment, Foggia, Italy

Backgrounds

Lactic acid bacteria can be used in fermented beverages to enrich their nutritional value, either by vitamins production or increasing nutrients bioavailability. Kefir is a fermented milk that has become very popular because its healthy attributes. The development of cereal-based functional beverages is particularly attractive to avoid dairy intolerances and to use matrices with recognized functional properties. While cereal-based yogurt-like beverages have been developed, scarce information is available about kefir-like products formulated from cereal flours.

Objectives

To develop a kefir-like cereal-based product and to select and inoculate a vitamin overproducer *Lactobacillus plantarum* strain to increase riboflavin content of the fermented beverage.

Methods

Six riboflavin-producer *L. plantarum* strains were evaluated for industrial application by testing growth at different pH, temperature and salinity as indicators of technological stress tolerance. In addition, they were exposed to roseoflavin to obtain riboflavin over-producing mutants. Fermentation of barley, corn and oat infusions was carried out using two commercial kefir starters together with the addition of a riboflavin over-producing strain (selected among the six on the basis of technological stress tolerance and of the over-producing phenotype). Physico-chemical parameters (lactic and acetic acids, CO_2, ethanol and, viscosity) and riboflavin content were monitored during the process and in the final products.

Conclusions

To the best of our knowledge, we report for the first time the design of cereal-based kefir-like beverages. Three novel non-dairy kefir-like products were developed and characterized. Beverages were produced inoculating a riboflavin over-producing *L. plantarum* strain (together with starter cultures) in order to increase final vitamin B_2 content.

THE INFLUENCE OF COLD STRESS ON GENE EXPRESSION IN SHIGA TOXIN-PRODUCING ESCHERICHIA COLI ON ROMAINE LETTUCE

S. Bach[1], C. Harlton[1], M. Gardiner[1], M. Pylatuk[1], M. Kostrzynska[2]
[1]Agriculture and Agri-Food Canada, Science and Technology Branch, Summerland, Canada
[2]Agriculture and Agri-Food Canada, Science and Technology Branch, Guelph, Canada

Backgrounds

Non-O157 Shiga toxin-producing *Escherichia coli* (STEC) have emerged as important human pathogens being implicated in cases of foodborne illness associated with leafy greens. A better understanding of the fitness and stress response of non-O157 STEC is necessary in order to design effective mitigation strategies for their control.

Objectives

The objective of this study was to examine the effect of cold temperature on expression of stress and virulence genes in six STEC strains.

Methods

Logarithmic phase cultures (10^8 CFU/ml) of *E. coli* O103:H2, O26:H11, O111:NM, O157:H7, O145:NM and O104:H4, each stressed at 4 °C for 5 d, were used as inoculum in: 1) STEC + Lettuce (SL); 2) STEC Inoculum, no lettuce (I). Lettuce only was used as a control. Duplicate samples (25 g) of 4 x 10 cm pieces were prepared for each biological sample (n=3, lettuce heads). Expression of virulence (*eae*, *stx1*, *stx2*) and stress genes (*uspA*, *rpoS*, *phoA*, *dps*, *cspA*, *cspC*, *cspE*, *mutS*, *gadW*) was examined using a two-step reverse-transcriptase comparative quantitative real-time PCR. Data was analyzed using Biogazelle's qbasePLUS (ANOVA, $P<0.05$).

Conclusions

CspA was upregulated ($P<0.05$) and *cspC* and *uspA* were downregulated ($P<0.05$) in all serotypes, while *cspE* was not differentially expressed. Cold stress resulted in down-regulation of *dps* in all serotypes except O145:NM. *Stx1A* was differentially expressed among serotypes in which the gene was present (P>0.05). Results provide an increased understanding of the variable cold temperature acclimatization exhibited by O157 and non-O157 STEC, providing knowledge which can be used to develop effective control strategies.

IMPROVED RADICAL-SCAVENGING, METAL ION-REDUCING, AND EX VIVO ANTIOXIDANT ACTIVITY OF WATER EXTRACT OF INULA BRITANNICA FERMENTED BY LACTOBACILLUS PLANTARUM IN HEPG2 CELLS

W.Y. Bae[1], H.Y. Kim[1], K.T. Kim[2], H.D. Paik[1]
[1]Konkuk University, Food Science and Biotechnology of Animal Products, Seoul, Republic of Korea
[2]Konkuk University, Bio/Molecular Informatics Center, Seoul, Republic of Korea

Backgrounds

Inula britannica extract is known to have strong anti-wrinkle effect inhibited by intracellular tyrosinase.

Objectives

The aim of this study was to measure the anti-oxidative activity of a water extract of *I. britannica* fermented by *Lactobacillus plantarum*.

Methods

Radical scavenging assays detected reduced amounts of DPPH$^{\bullet}$, ABTS$^{\bullet+}$, O_2^-, and $^{\bullet}$OH following treatment with the extract. In ABTS radical scavenging assay, antioxidant activity was evaluated based on trolox equivalent antioxidant capacity (TEAC). Metal ion-reducing ability was determined by measuring the reduction of Fe^{3+} and Cu^{2+}. Chelating abilities were evaluated by Fe^{2+}-ferrozine and Cu^{2+}-pyrocatechol violet complex. Cell cytotoxicity and anti-oxidative effect of *I. britannica* extracts in HepG2 cells were determined by the MTT assay and the Enzychrom™ assay kit, respectively.

Conclusions

Fermented *I. britannica* extract had more than 80% radical scavenging activity at a concentration of 500 μg/mL ($p<0.05$). According to an ABTS$^{\bullet+}$ assay, the fermented extract had 85.08–694.25 μM/mL TEAC, whereas the non-fermented control had 59.67–477.17 μM/mL TEAC. Metal ion-reducing abilities were more effective in the fermented extract than those in the control ($p<0.05$), but chelating abilities were more effective in non-fermented extract. The extract had no measurable cell cytotoxicity up to 500 μg/mL in HepG2 cells. The levels of SOD, GPx, catalase, and glutathione in HepG2 cells treated with the fermented extract were increased compared to cells treated with the non-fermented extract. These results suggest that fermentation increased the antioxidant activity of *I. britannica* extract, which could be applied as a natural antioxidant in the food and cosmetic industries.

Food Microbiology

ANTIMICROBIAL ACTIVITY OF INULA BRITANNICA EXTRACT FERMENTED BY LACTOBACILLUS PLANTARUM

W.Y. Bae[1], H.Y. Kim[1], K.T. Kim[2], H.D. Paik[1]
[1]Konkuk University, Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea
[2]Konkuk University, Bio/Molecular Informatics Center, Seoul, Republic of Korea

Backgrounds

Inula britannica is a wild plant in eastern Asia and has been used as a traditional medicine for bronchitis and digestive disorders.

Objectives

The aim of this study was to investigate the antimicrobial activity of water extract of *I. britannica* fermented by *Lactobacillus plantarum* against food-borne pathogens.

Methods

The antimicrobial activity of *I. britannica* extract was measured against 15 strains of food-borne pathogens by disc diffusion assay. Cell membrane integrity was determined by measuring leakage of nucleic acids and proteins, and membrane potential was evaluated using Rhodamine 123. In a time-kill assay, the inhibitory effects of the fermented extract on cell growth of *Bacillus cereus* and *Listeria monocytogenes* were performed in broth containing fermented extract at concentrations of 0.5×MIC, 1×MIC, or 2×MIC.

Conclusions

In a disc diffusion assay, discs treated with the fermented extract had inhibition zone in *B. cereus* (4 stains) and *L. monocytogenes* (4 strains), and the MIC values were 2.5-7.5 mg/mL. The membrane integrity of treated cells was significantly different from that of the control cells, at all concentrations of extract ($p<0.05$). For both *B. cereus* and *L. monocytogenes*, the membrane potential of cells treated with 1×MIC of the fermented extract was significantly different ($p<0.05$) from that of the untreated cells. A time kill assay determined that the fermented extract had bactericidal activity at 2×MIC and bacteriostatic activity at 1×MIC against *B. cereus* and *L. monocytogenes*. These results suggest that fermented water extract of *I. britannica* has antimicrobial activity and potential applications as a natural food preservative in food processing.

MICROBIOLOGICAL SURVEY OF RAW MILK FROM DAIRY PROCESSING UNITS IN SAVADKOOH REGION

B. Saadatmand[1], A. Bapiri[2]
[1]M.Sc.Graduated Student of Food Science and Technology- Department of Agriculture- Savadkooh B ranch- Islamic Azad University, ., Savadkooh, Iran
[2]Department of Agriculture- Savadkooh Branch- Islamic Azad University, ., Savadkooh, Iran

Backgrounds

In the Savadkooh region, the production of milk and dairy products is affected by the application of improper procedures during milking and processing, leading to microbial spoilage of raw milk, especially in local small scale processing plants.

Objectives

The aim of this survey was to identify potential hazards and evaluate the microbial contamination of raw milk in two dairy processing units located in Savadkooh.

Methods

At the beginning of April, May, June, July and August, raw milk samples were collected from processing units and transported to the laboratory. During 5 months period, raw milk samples were evaluated for total microbial load, total Coliform and *Escherichia coli* in accordance with the standards No. 356, 2852 and 2629.

Conclusions

The results showed that contamination levels of raw milk samples varied widely. The total microbial load was April the highest (2×10^4 CFU/ml) and August the lowest (7×10^3 CFU/ml) but total Coliform was the highest (7.85%) in August and (0.00%) in June. E.coli contamination were not observed in any of the samples. Based on microbiological outcomes and milk production flow characterization, preventive and corrective measures were defined for milking and processing phases, focusing on training of farmers and dairy employees to improve the hygiene of the local milk and dairy production chain.

INFLUENCE OF PHYSICAL AND CHEMICAL CHARACTERISTICS OF WINE GRAPES ON THE INCIDENCE OF PENICILLIUM AND ASPERGILLUS FUNGI IN GRAPES AND OCHRATOXIN A IN WINES

L. Freire[1], F. Passamani[1], A. Thomas[1], R. Nassur[1], L. Silva[1], F. Paschoal[2], G. Pereira[3], G. Prado[2], L. Batista[1]
[1]Federal University of Lavras, Food Science, Lavras, Brazil
[2]Fundação Ezequiel Dias, Mycotoxin Lab, Belo Horizonte-MG, Brazil
[3]EMBRAPA SEMI-ÁRIDO, Pós-Colheita, Petrolina-PE, Brazil

Backgrounds

The incidence of filamentous fungi and toxin levels in grapes and wines varies depending on the variety of grapes, the wine region, agricultural practices, weather conditions, the harvest and the winemaking process.

Objectives

The objective of this study was to evaluate the diversity of *Aspergillus* and *Penicillium* fungi isolated from wine grapes of the semi-arid tropical region of Brazil, evaluate the presence of ochratoxin A (OTA) in the experimental wine and verify if there is a correlation between occurrence of these fungi and the physicochemical characteristics of the wine grapes grown in the region.

Methods

For the isolation of fungi we used the direct plating technique. The presence of OTA in the experimental wine was detected by high-performance liquid chromatography.

Conclusions

The species found were *Aspergillus niger*, *A. carbonarius*, *A. aculeatus*, *A. niger* Aggregate, *A. flavus*, *A. sojae*, *Penicillium sclerotiorum*, *P. citrinum*, *P. glabrum*, *P. decumbens*, *P. solitum* and *P. implicatum*. All isolates of *A. carbonarius* were OTA producers and all *P. citrinum* were citrinin producers. The highest concentration of OTA was found in red wine (0.29 µg/L). All species identified in this study, except *A. flavus*, showed a positive correlation with at least one physicochemical parameter assessed, highlighting the pectin content, total sugar, total acidity and phenolic compounds.

CULTURE COLLECTION OF DEPARTMENT OF FOOD SCIENCE (CCDCA), FEDERAL UNIVERSITY OF LAVRAS, BRAZIL

L. Batista[1], M. Terra[1], N. Lira[1], F. Passamani[1], S. Chalfoun[2], J. Machado[1], D. Botrel[1], J. Teodoro[1]
[1]Federal University of Lavras, Food Science, Lavras, Brazil
[2]EPAMIG, Coffee Quality Control, Lavras, Brazil

Backgrounds

Brazil is a country with one of the highest levels of biological diversity due to its large geographical area, high coverage by rainforests, and endemic biomes, such as Brazilian Atlantic Forest, Cerrado and Caatinga. Much of this unknown biodiversity is in the tropics, which is seriously threatened by some agricultural activities, reinforcing the urgent need for biodiversity studies in these areas.

Objectives

The aims of CCDCA are: a) preserve *Aspergillus* and *Penicillium* strains for comparative studies between Brazilian regions and worldwide; b) promote the study of *Aspergillus* and *Penicillium* for (i) biotechnological and toxigenic potential, and (ii) training in identification, preservation and distribution; c) establish quality control of fungal assays; and, finally, d) establish the CCDCA as a member of the global network of culture collections and participate in the international forums and organizations related to culture collections.

Methods

For the identification of the isolates are used techniques proposed by specialized literature, such as specific culture media and identification manuals. All fungal isolates belonging to the CCDCA collection are preserved by the filter paper method in three conditions: ultrafreezer at -80ºC, refrigerator at 4ºC and ambient temperature.

Conclusions

Since then, it has been modernized, monitored and maintained financially through research projects. Currently the CCDCA collection consists of 735 isolates belonging to the genus *Aspergillus* and *Penicillium*, obtained from various substrates, including food, agricultural products, cultivated land, wastewater, agro-industrial waste, mineral exploitation soils, grapes, coffee, cocoa and industrialized products such as cheeses, chocolate, sweets and beverages. The CCDCA is member of WDCM 1081 and WFCC.

IN THE SUBTELOMERIC-DAWN OF SACCHAROMYCES' CHROMOSOME VI

I. Belda[1], *J. Ruiz*[1], *L.J. López-Iglesias*[2], *D. Marquina*[1], *A. Acedo*[2], *A. Santos*[1]
[1]*Biology Faculty- Complutense University of Madrid, Microbiology, Madrid, Spain*
[2]*Biome Makers, WineSeq, San Francisco, USA*

Backgrounds

Genetic recombination, a process in which exogenous DNA is acquired and incorporated into the genome, is a key evolutionary mechanism for several microorganisms. At the megabase scale, the average recombination rate is higher in the subtelomeric regions than in the middle part of chromosomes. Some *Saccharomyces cerevisiae* wine strains showed an introgressed segment (derived from *S. paradoxus*) covers over the last 15 kb near the telomere of chromosome VI. In this context, we observed distinctive metabolic features associated to this event, such as a reduced fitness and differential response to nutrient starvation.

Objectives

The aim of this work is to characterize the chromosome VI subtelomere region in *S. cerevisiae* wine strains, to understand the phenotypic features associated to its different versions.

Methods

Using Whole-Genome-Sequencing (Illumina-MiSeq platform) we obtained the entire genome sequence of 9 wine yeast strains. Genomes were assembled using conventional bioinformatics software (edena, spades…); and public online resources (GenBank, BLAST and CLUSTAL-O) were used to explore the genomic variability of the ORFs contained in this region.

Conclusions

Only an 8% of *S. cerevisiae* wine strains showed the exogenous introgressed version in the subtelomere of chromosome VI. This version includes a longer allele of *IRC7* gene (codifying for a high-active β-lyase enzyme, with enological interest). Relevant genes such as *HXK1*, *RET2* or *RPN12* are close-located to *IRC7*. We are now exploring the existence of non-competitive polymorphisms of these genes, that could be on the basis of their low abundance in wild strains and contributing to the distinctive behavior of this intraspecific clade.

Food Microbiology

GENETIC TYPING AND PHENOTYPIC VIRULENCE FACTORS OF DEBARYOMYCES HANSENII ISOLATED FROM FOOD

C. Belloch[1], *R. Montero*[1], *M. Flores*[1]
[1]*Institute of Agrochemistry and Food Technology, Biotechnology, Paterna Valencia, Spain*

Backgrounds

Phenotypic virulence factors are usually tested on yeasts from clinical origin but not on yeast from food origin. However, several previous studies have found yeast food isolates pertaining to the species *D. hansenii* to be potentially pathogenic. These findings may limit the use of D. hansenii as starter in food to only those strains that exhibit none of few pathogenic traits described in yeasts.

Objectives

In this study, a collection of *D. hansenii* yeasts isolated from meat fermented sausages, matured cheese and fermented vegetables were screened to be used as starters in food fermentation. First, we carried out a genetic typing of the strains which would allow monitoring of starter growth in a fermentative process and its discrimination from wild yeasts. In a second step, the strains were screened for several traits associated with the potential pathogenicity of yeasts.

Methods

Genetic typing was carried out by sequencing of the ITS1-5.8S-ITS2 rDNA region and ACT1 gene as well as RAPDs of minisatellite M13 and inter-LTR PCR fingerprinting. Among the fenotypic virulence factors growth at different temperatures, ability to produce biofilm, pseudohyphal and invasive growth and production of phospholipases, proteases, esterases and haemolysins were tested.

Conclusions

Out results showed that very few *D. hansenii* strains from food origin have the potential to be pathogenic. Sequencing of ACT1 probed to be more discriminating than sequencing of ITS1-5.8S-ITS2 rDNA. However, results produced by sequencing could not reach the level of discrimination generated by PCR amplification using M13 minisatellite primers (RAPDs-M13) or inter-RTL PCR fingerprints.

ANTIMICROBIAL PROPERTIES AND MEMBRANE INSERTION OF PLANTARICIN149 ANALOGUES

J.L.S. Lopes[1], P.S. Kumagai[2], I.L.B.C. Camargo[2], J. Burck[3], B.A. Wallace[4], L.M. Beltramini[2]
[1]USP - IF, Applied Physics, Sao Paulo, Brazil
[2]USP, IFSC, Sao Carlos, Brazil
[3]KIT, KIT, Karlsruhe, Germany
[4]Birkbeck, Cristallography, London, United Kingdom

Backgrounds

Antimicrobial peptides (AMP) produced by lactic acid bacteria are of particular interest in food industry due to their potential application as food biopreservative, and also useful for pharmaceutical industry, since AMPs constitute the first line of defence against invading bacteria, viruses, and fungi. Synthetic Plantaricin149 (Pln149) is a member of this group of cationic AMPs with inhibitory activity against *Staphylococcus aureus*, *Listeria* and *Saccharomyces cereviseae*, causing membrane destabilization via a initial electrostatic interaction with charged lipids.

Objectives

In order to better understand the mechanism of action and plan more active AMPs, a series of Pln149 analogues with modifications at their N-terminus were designed and used to modulate the antimicrobial properties and peptide insertion in model membranes.

Methods

Pln149-analogues inhibitory action were evaluated against pathogenic bacteria by MIC determination, haemolytic activity and correlated to measurements of peptide binding and orientation in different lipid systems, using oriented synchrotron radiation circular dichroism spectroscopy.

Conclusions

Improved bacterial activity was achieved on Pln149 by increasing the non-polar nature (adding Fmoc groups) at its N-terminus. Fmoc-Pln149 had inhibitory activity against *S. epidermidis* ATCC35984*, S. aureus* ATCC25923*, E. faecalis* ATCC29212, *E. faecium* VRE16*, K. pneumoniae* ATCC700603*, E. coli* ATCC25922 (>512 ug/mL) and showed low red blood cells lysis degree. During binding to negatively charged phospholipids, all analogues assume a helix structure which disturbs the packing of lipid bilayers with its insertion parallel to plane of the membrane surface The characterization of more active AMPs could represent an alternative process in the search of powerful antibacterial agents.

Food Microbiology

COMBINE USE OF SCHIZOSACCHAROMYCES POMBE AND LACHANCEA THERMOTOLERANS YEAST STRAINS AS AN ALTERNATIVE TO THE TRADITIONAL MALOLACTIC FERMENTATION IN WINE PRODUCTION

S. Benito[1]
[1]*Polytechnic University of Madrid, Chemistry and Food Technology, Madrid, Spain*

Backgrounds

Most red wines commercialized in the market use the malolactic fermentation process in order to ensure stability from a microbiological point of view. In this second fermentation, malic acid is converted into L-lactic acid under controlled setups. However this process is not free from possible collateral effects that on some occasions produce off-flavors, wine quality loss and human health problems.This biotechnology develops a new red winemaking methodology that consists of combining the use of two non-Saccharomyces yeast strains as an alternative to the traditional malolactic fermentation. In this method, malic acid is totally consumed by Schizosaccharomyces pombe, thus achieving the microbiological stabilization objective, while Lachancea thermotolerans produces lactic acid in order not to reduce and even increase the acidity of wines produced from low acidity musts. The result is more fruity wines that contain less acetic acid and biogenic amines than the traditional controls.

Objectives

To introduce a new biotechnology to produce wine different from classical ones

To get higher quality wines

To get safer wines from a food safety point of view (lower content in histamin)

To show the results of last two years research about the topic from experimental winery of Madrid Polytechnic University.

Methods

Microvinifications at laboratory scale from 50 mL to 100 mL

Industrial vinifications (winemaking) from 500 L to 20000 L at real winery scale (university winery)

HPLC (anthocyanins profile, amino acids profile, biogenic amines profile)

GC/MS (wine aroma profile)

Regular chemical analyses of wine

Conclusions

The combination of the non-Saccharomyces Lachancea thermotolerans and Schizosaccharomyces pombe positively influenced wine quality.

New fermentations produced higher levels of glycerol and pyruvic acid.

New fermentations produced reduced ethanol levels.

New fermentations produced wines stabilised from a malic acid point of view without any need of performing a malolactic fermentation.

Wines showed lower final levels of biogenic amines (mainly histamine).

INVESTIGATION OF THE INOCULATION TIME OF APULIAN AUTOCHTHONOUS OENOCOCCUS OENI AND LACTOBACILLUS PLANTARUM STRAINS IN IN MULTI-STARTER WINE FERMENTATIONS

C. Berbegal[1], L. Beneduce[2], A. Vernile[2], F. Grieco[3], G. Spano[2], V. Capozzi[2]
[1]University of Foggia, Department of Sciences of Agriculture- Food and Environment, Foggia, Italy
[2]University of Foggia, Department of the Sciences of Agriculture- Food and Environment, Foggia, Italy
[3]ISPA, Science of Food Production, Lecce, Italy

Backgrounds

The winemaking process includes two key steps carried out by microorganisms, i.e. alcoholic fermentation (AF) and malolactic fermentation (MLF). The AF primarily produce the conversion of grape must sugars into ethanol. This fermentation is carried out by yeast, mainly by *Saccharomyces cerevisiae* strains: However, this is not the only yeast involved in the process. In fact, several non-*Saccharomyces* species, such as *Hanseniaspora uvarum*, have been proved to positively modify the wine chemical composition, contributing to the sensory characteristics of wines. On the other side, MLF is carried out by lactic bacteria (LAB), principally by *Oenococcus oeni* and *Lactobacillus plantarum* strains.

Objectives

The objective of this work was to identify the best inoculation time of autochthonous of *Oenococcus oeni* or *Lactobacillus plantarum* strains in combination with two autochthonous *S. cerevisiae* strains and one *H. uvarum* strain, all isolated from Apulian wines.

Methods

S. cerevisiae and non-*Saccharomyces,* were co-inoculated in red must, and *L. plantarum* or *O. oeni* strains were co-inoculated or sequentially inoculated during AF, when ethanol content was 2%, 4%, 6%, 8%, 10% or 12% (v/v). Ethanol formation, L-malic acid consumption and bacterial cell viability were monitored during the vinification.

Conclusions

Ethanol concentration at the moment of bacterial inoculation was a crucial factor for the success of MLF. The co-inoculation with *S. cerevisiae* and *H. uvarum* was the best strategy for maintaining the highest LAB concentration, in order to successfully carry out the MLF in red must. Bacterial cell viability and L-malic consumption after AF were strain-dependent (Aupulian Region Grant: QCBRAJ6, 9OJ4W81, LPIJ9P2).

OXIDATIVE AND ACIDIC STRESS RESPONSE OF EXOPOLYSACCHARIDES-PRODUCING LACTOBACILLUS PLANTARUM LP90

C. Berbegal[1], A. Longo[2], M.P. Arena[2], D. Fiocco[3], V. Capozzi[2], G. Spano[2]
[1]University of Foggia, Department of Sciences of Agriculture- Food and Environment, Foggia, Italy
[2]University of Foggia, Department of the Sciences of Agriculture- Food and Environment, Foggia, Italy
[3]University of Foggia, Department of Clinical and Experimental Medicine, Foggia, Italy

Backgrounds

Exopolysaccharides (EPS) are long chains of repeating units of sugar or sugar derivatives released outside of the microbial cell wall. *Lactobacillus plantarum* is one of the most widespread lactic acid bacteria (LAB) species presenting different ecological niches. *L. plantarum* Lp90 is a strain isolated from Apulian (South of Italy) wine and has been characterized for its ability to overproduce EPS, which confers a distinctive ropy phenotype. Although this strain is well characterized (we sequenced the genome and studied different probiotic and technological properties), few studies have been carried out on the significance of the exopolysaccharides responsible of the ropy phenotype in the abiotic stress response of this strain.

Objectives

The objective of this work was to investigate the tolerance of the ropy strain *L. plantarum* Lp90 and the non-ropy mutant strain *L. plantarum* Lp90Δ*cps2* exposed to acidic and oxidative stress.

Methods

L. plantarum Lp90 and the non-ropy mutant strain *L. plantarum* Lp90Δ*cps2* were growth in MRS broth for 16 h and, then, suspended in MRS adjusted to pH 2.5 (with HCl 1M) and in saline solution (0.85% NaCl) with SO_2 70 mg L^{-1}. After 30 min of incubation a 37°C, aliquots were removed and plated onto MRS agar in order to estimate viable cells.

Conclusions

The results showed a higher tolerance to acidic and oxidative stresses by the ropy strain *L. plantarum* Lp90 compared to the non-ropy mutant strain *L. plantarum* Lp90Δcps2, which lacks in cps2 cluster involved in the exopolysaccharides biosynthesis, supporting the protective role of exopolysaccharides (Aupulian Region Grant QCBRAJ6, 9OJ4W81).

FEMS7-1422
Food Microbiology

USE OF ATR-FTIR AND FT-RAMAN SPECTROSCOPY COMBINED WITH MULTIVARIATE ANALYSIS TO DISCRIMINATE STRESS-RESISTANT VARIANTS OF ESCHERICHIA COLI MG1655

D. Berdejo[1], L. Espina[1], R. Pagán[1], D. García-Gonzalo[1], S. de Lamo-Castellví[2]
[1]University of Zaragoza, Producción Animal y Ciencia de los Alimentos, Zaragoza, Spain
[2]Universitat Rovira i Virgili, Departament d'Enginyeria Quimica- Food- Innovation & Engineering, Tarragona, Spain

Backgrounds

Fourier transform infrared (FT-IR) and Raman (FT-Raman) spectroscopy combined with multivariate analysis can be used for detection, classification, and identification of food-related microorganisms because FT-IR and FT-Raman spectra provide bands from all their cellular components.

Objectives

The main objectives of the present research were to study the potential of these techniques combined with soft independent modeling of class analogy multivariate analysis to discriminate and detect biochemical differences of *Escherichia coli* MG1655 wild-type (WT) strain and its genetic stress-resistant variants CAR, CIT and LIM [mutants selected by subculturing with the antimicrobials carvacrol, citral and (+)-limonene oxide, respectively].

Methods

WT and variants were grown at 37°C for 24h. Then, bacterial cultures were centrifuged and washed twice with 0.1% Peptone Water. For IR analysis, pellets were placed onto ATR diamond crystal, vacuum dried and IR spectra were collected in the mid-infrared region (4000-800 cm^{-1}). For Raman experiments, pellets were placed onto a silicon film and Raman spectra were obtained with Argon laser at 514 nm with power of 25 mW (950-1800 cm^{-1}). IR and Raman data were analysed by soft independent modeling of class analogy (SIMCA) building up 2-classes SIMCA models with IR and Raman data from WT and variants CAR, CIT and LIM.

Conclusions

Bacterial components producing their major discrimination were lipids per CAR, phospholipids per CIT and carbohydrates or peptidoglycan per LIM. This study has shown the potential of FT-IR and FT-Raman combined with SIMCA to discriminate *E. coli* variants and detect biochemical differences among the WT and stress-resistant mutants.

Food Microbiology

INCREASED RESISTANCE TO ANTIBIOTICS OF GENETIC VARIANTS OF ESCHERICHIA COLI MG1655 ISOLATED BY INDIVIDUAL CONSTITUENTS OF ESSENTIAL OILS

D. Berdejo[1], *D. García-Gonzalo*[1], *R. Pagán*[1]
[1]*University of Zaragoza, Producción Animal y Ciencia de los Alimentos, Zaragoza, Spain*

Backgrounds

Presence of stable stress-resistance microbes can compromise food safety. Several stresses applied during food preservation treatments, such as heat, acid or high pressure, have been shown to generate genetic stress-resistance variants derived from contaminating microorganisms. In a previous research, we isolated the genetic variants CAR, CIT and LIM after continuous growth of wild-type (WT) *Escherichia coli* MG1655 in presence of sub-inhibitory concentrations of the natural antimicrobials: carvacrol, citral or (+)-limonene oxide, respectively. These mutant strains showed an increased resistance against these antimicrobials. Study of cross-resistance against other antimicrobials, such as antibiotics, would provide information related to bacterial mechanisms of inactivation/resistance against the tested antimicrobials.

Objectives

The main objective of this research was to compare the antibiotic resistance of WT with that of CAR, CIT and LIM mutants.

Methods

The agar disk diffusion assay was used to test the susceptibility of mutant and WT strains to the following antibiotics: ampicillin, trimethoprim, chloramphenicol, tetracycline, rifampicin, kanamycin, novobiocin, norfloxacin, cephalexin and nalidixic acid. Impregnated disks were placed on the surface of inoculated plates with mutants and WT. After incubation of plates at 37ºC for 24h, diameters of the resulting inhibition zones were measured.

Conclusions

The three mutants showed smaller zones of growth inhibition for all the tested antibiotics, except for rifampicin, than WT (p<0.001). The inhibition halos for the CIT strain caused by ampicillin, chloramphenicol and novobiocin were reduced more than 50%. The development of cross-resistance against antibiotics would suggest similar mechanisms of inactivation and/or resistance against the tested natural antimicrobials and antibiotics.

EFFECTS OF GAMMA IRRADIATION ON MICROBIAL AND SENSORY PROPERTIES AND SHELF LIFE OF IRANIAN NATIVE FRESH BARBERRY FRUITS

S. Berenji Ardestani[1], H.R. Akhavan[2]
[1]NSTRI, Research School of Radiation Applications, Tehran, Iran
[2]Shahid Bahonar University of Kerman, Department of Food Science and Technology, Kerman, Iran

Backgrounds

Berberis vulgaris is one of the most important Iranian native fruit with the produce about 16539 tones in 2014. The storage time of fresh fruits is short because of physiological maturity, biochemical changes and ethylene produce. At refrigerator temperature in less than 10 days they will lose their color, texture firmness, flavor and gradually, they will become acidified and spoiled, microbiologically. Gamma irradiation is able to enhance the safety and shelf life of fresh fruits by inhibiting microbial growth.

Objectives

Gamma irradiation has been shown to greatly reduce potential microbiological risk of fresh fruits, resulting in improved microbial safety as well as extending their shelf life. In this study the effects of gamma irradiation at doses of 0.5-2 kGy on spoilage, microbial and sensory properties of fresh barberry (*Berberis vulgaris*) fruits during 40 days refrigerated storage were studied.

MethodsThe percentage of fruits decay, microbial evaluations including fungi total counts (log cfu gr^{-1}) and sensory properties such as color, flavor and taste, aroma and odor, texture and total acceptance by means of 9 points hedonic test by 12 panelists, were studied.**Conclusions**The decay and spoilage of control and irradiated samples at doses of more than 1.25 kGy were different, significantly and they were 44% and 10%, respectively. Irradiation, especially at the doses above 1.5 kGy caused microbial growth inhibition during 40 days storage, completely.
Generally, with respect to gamma irradiation effects on physicochemical, microbial, sensory characteristics and total acceptance by consumers, dose range of 1.25-2 kGy to increase fresh fruits shelf life was optimum and suggested.

Food Microbiology

GENOME SHUFFLING OF LACTOBACILLUS PLANTARUM FOR THE ENHANCEMENT OF PRODUCTION OF BACTERIOCIN

S. Bhutada[1]
[1]*Sanjivani Arts- Commerce and Science College- Kopargaon, Department of Microbiology, Ahmednagar, India*

Backgrounds

Bacteriocins are antibacterial proteins produced by bacteria that kill or inhibit the growth of other bacteria. The application of bacteriocins as food preservatives could be achieved either by using the bacteriocinogenic strain as a starter culture or by using the bacteriocin as a food additive.

Objectives

Genome shuffling is an important method for rapid improvement in microbial strains for desired phenotype. The main objectives of this study were to improve the bacteriocin production from *Lactobacillus rhamnosus* through genome shuffling.

Methods

In the present study, a total of 20 samples, namely unpasteurized milk (5), curd (5), butter (5), and cheese (5) was collected from a local dairy farm. The nine Lactic Acid Bacteria were isolated and screened from 20 different samples. LABs were identified on the basis of standard morphological, biochemical, physiological characteristics. The five mutagens were used; UV radiations, pH variation, temperature variation, Acridine orange and Ethidium bromide. The mutants were selected and tested for their bacteriocin production ability by assay after production and purification by salting out and dialysis, and antibacterial activity was examined. The UV mutation has improved isolated strain of *Lactobacillus plantarum* to enhance the production of bacteriocin to higher level than others. Hence, UV mutation was considered as an effective mutation agent for strain improvement of bacteriocin producer.

Conclusions

The results demonstrated that the genome shuffling has been successful in engineering *L. plantarum*. In the future, this technology is a promising candidate to accelerate poorly characterized strains for enhancement of production of bacteriocin

FEMS7-2478
Food Microbiology

BACTERIAL DIVERSITY OF TRADITIONAL SOURDOUGH MADE FROM THE WHEAT, SPELT AND RYE WHOLEMEAL FLOUR DETERMINED BY CULTURE-INDEPENDENT APPROACH

J. Boreczek[1], J. Gawor[2], D. Izak[1], J. Bardowski[1], R. Gromadka[2], M. Kowalczyk[1]
[1]Institute of Biochemistry and Biophysics Polish Academy of Sciences, Department of Microbial Biochemistry, Warsaw, Poland
[2]Institute of Biochemistry and Biophysics Polish Academy of Sciences, Laboratory of DNA Sequencing and Oligonucleotide Synthesis, Warsaw, Poland

Backgrounds

The use of the sourdough for traditional bread making is one of the oldest biotechnological processes in cereal food production. Sourdough bread is prepared from a mixture of flour and water that is fermented with lactic acid bacteria (LAB). Spontaneously fermented sourdoughs contain a lot of diverse microorganisms, especially LAB.

Objectives

The aim of this study was to identify bacterial diversity and understanding of microbiota changes of the spontaneous sourdoughs made from the wheat, spelt or rye wholemeal flour during 96h fermentation.

Methods

Sourdoughs samples were analysed by culture-independent technique. Next-Generation Sequencing of the V3 and V4 variable regions of the 16S rRNA genes was performed using the Illumina sequencing technology. DNA sequencing data were analysed with MOTHUR software based on the Silva reference database. The taxonomical composition was presented on the Krona Charts and the structures of the communities of all samples were compared using the Yue and Clayton measure.

Conclusions

In conclusion, it is the first attempt to determine microbial biodiversity of sourdoughs made from the wheat, spelt or rye wholemeal flour. Culture independent analyses show how the microbial ecology changes during 96h fermentation. *Weissella* genus dominated after 24h fermentation of the rye sourdough, but as the fermentation progressed, its abundance decreased in favor of the *Lactobacillus* genus. *Lactobacillus* genus was dominant in all sourdoughs after 96h, which is in accordance with our previous results obtained by culture-dependent analyses (data not shown).

This work was supported by the Applied Research Programme of the National Centre for Research and Development. PBS2/B8/12/2014 (FunCHLEB).

STUDY OF ANTIMICROBIAL EFFECT OF STEVIA REBAUDIANA EXTRACTS ON ESCHERICHIA COLI GROWTH

S. Botella[1], *A. Boukharouba*[1], *M.L. Castelló*[2], *E. Doménech*[2]
[1]*Universitat Politècnica de València, Biotechnology, Valencia, Spain*
[2]*Universitat Politècnica de València, Institute of Food Engineering, Valencia, Spain*

Backgrounds

Stevia rebaudiana is a natural alternative to artificial sweetener, which can be used as substitutes for sucrose. In Europe rebaudioside A is accepted as a food additive since 2011. Furthermore, there is an increasing interest in the use of natural ingredients able to avoid the proliferation of microorganisms. In this framework, the potential use of *Stevia* as a natural preservative has recently been studied by various researchers.

Objectives

The present work evaluates the antimicrobial effect of *Stevia* on *E. coli.*

Methods

Two different extracts of *Stevia* were tested by obtaining growth curves of *E. coli*: a marketed purified extract from leaves of *Stevia* which mainly contain steviol glycosides with a high percentage of rebaudioside (98%), and an extract prepared from dried leaves at 2.5 % of concentration. The enumeration of *E. coli* was performed with a modified enumeration method following UNE-EN/ISO 4833:2003.

Conclusions

An antimicrobial effect was observed with the leaf extract in relation to control. However non effect was found with the commercial purified extract under the conditions studied. The leaf extract of *Stevia* is not only a sweetener but also introduces a preservative effect against *E. coli*.

EFFECT OF ERYTHROMYCIN IN GOAT'S MILK ON PROTEOLYSIS AND LIPOLYSIS OF ARTISANAL MATURED CHEESE

S. Botella[1], P. Quintanilla[2], L.V. Ambrosio[2], M.C. Beltrán[2], M.P. Molina[2]
[1]Universitat Politècnica de València, Biotechnology, Valencia, Spain
[2]Universitat Politècnica de València, Institute of Animal Science and Technology ICTA, Valencia, Spain

Backgrounds

The presence of antibiotic residues in dairy products can be a problem for public health because they cause allergies, digestive disorders and development of resistance, and also for the dairy industry as the cause of technical problems and product quality especially in fermented products as cheeses. Information on the effect of the presence of antibiotics in milk on the characteristics of the cheese is very limited.

Objectives

The objective of this study was to analyze the effect of the presence of erythromycin in goat's milk on the proteolysis and lipolysis characteristics and their related microorganism groups of matured cheese.

Methods

The elaborations of cheese were made, in triplicate, from raw goat milk without antibiotic and with addition of erythromycin to a concentration of 40 µg/kg (Maximum Residue Limit-MRL). The proteolysis and lipolysis levels, the enumeration of proteolytic and lipolytic microorganisms and also the presence of the residual antibiotic by HPLC were determined in cheeses, ripening at different times (1, 30 and 60 days).

Conclusions

The presence of erythromycin caused no differences in any of the parameters studied. Instead the period of ripening affects to all parameters, those values more high for the proteolysis, lipolysis and enumeration of proteolytic microorganisms and them more low of lipolytic counts is observed for the cheeses of 60 days of maturation. The content of antibiotic in the cheese was always lower than the MRL established for erythromycin in milk.

Acknowledge

The authors would like to thank the Ministerio de Ciencia e Innovación (Spain), for funding the project AGL2013-45147-R.

Food Microbiology

EFFECT OF LACTOBACILLUS FERMENTUM ON THE ASSOCIATION OF CRONOBACTER SAKAZAKII TO CACO-2 CELLS

D. Brady[1], *C. Kealey*[1]
[1]*Athlone Institute of Technology, Life & Physical Science, Athlone, Ireland*

Backgrounds

Cronobacter sakazakii is an emerging opportunistic pathogen most often associated with the feeding of powdered infant formula (PIF). It has been suggested that breast-fed infants develop a gut microflora richer in *Lactobacilli* and *Bifidobacteria* with reduced levels of pathogenic bacteria when compared to formula-fed infants. *Lactobacilli* have been shown to have many beneficial functions in terms of protecting the host from gastrointestinal pathogens. Recently, a species of *Lactobacillus* has also been isolated from whey protein concentrate (WPC). WPC is a common ingredient in PIF and has been attributed with anti-adhesion and anti-invasion properties against *Cronobacter* spp.

Objectives

The present study aims to investigate the effects of *Lactobacilli sp* on the adhesion and invasion of *C.sakazakii* (ATCC® 29544) in relation to differentiated monolayers of human enterocyte-like cells.

Methods

Association assays were conducted with test material (live or heat killed organisms) added at the same time as the pathogenic organism *C.sakazakii* (ATCC 29544). Differentiated cell monolayers were exposed to the test materials 30 minutes prior to the addition of pathogenic species (*C.sakazakii* ATCC 29544).

Conclusions

A reduction in association was observed for live and heat killed *L.fermentum* (DSM 20052) and live SWPC bacterial isolate when compared to the negative control ($P < 0.01$). Heat killed SWPC bacterial isolate also reduced association ($P < 0.05$) but to a lesser degree than the live organism ($P < 0.05$).

Food Microbiology

EFFECT OF ANTIMICROBIAL LIPIDS AND HUMAN SALIVA ON ORAL PATHOGENS

C. Creavan[1], N. Tumulty-Breslin[1], C. Redmond[1], C. Kealey[1], D. Brady[1]
[1]Athlone Institute of Technology, Life & Physical Science, Athlone, Ireland

Backgrounds

Streptococcus mutans is the primary etiological agent in the formation of human dental caries which is considered a major oral health problem in most industrialised countries. Multiple virulence factors allow the bacterium to successfully colonise the tooth surface and propagate becoming a numerically significant species within dental plaque. Other oral microorganisms assemble in plaque as a polymicrobial biofilm and *Porphyromonas gingivalis*, an important secondary colonizer in oral biofilms, has been implicated in periodontal disease.

Objectives

This study evaluated the *in vitro* antibacterial activity of food grade lipids and their respective fatty acid constituents on both *S. mutans and P. gingivalis growth and biofilm formation*. Micro-broth dilution assays were carried out to assess the viability of the oral pathogen in the presence of these food constituents and also in the presence and absence of saliva.

Methods

S. mutans was cultured from frozen stock on Brain Heart Infusion (BHI) agar supplemented with 5% defibrinated horse blood and grown aerobically for 48 h at 37°C. A single colony was then used to inoculate 20ml BHI broth and grown aerobically for a further 24 h at 37°C. To evaluate biofilm formation by *S mutans* the method described previously by Tamura et al., (2009) was employed. *P. gingivalis* was cultured in TSB supplemented with vitamin K1 and hemin and incubated at 37ºC in an anaerobic chamber.

Conclusions

Bacterial growth was not affected by any of the oils tested. A selection of MCFAs and LCFAs comprising capric, lauric, myristic, oleic and linoleic acid showed varying levels of bacteriocidal and bacteriostatic activity towards *S. mutans and P. gingivalis*. Interestingly saliva interfered with the bacteriocidal activity of the fatty acids *in vitro*.

Food Microbiology

CONTROL OF FUNGAL SPOILAGE IN FEED

P. Bruinenberg[1], J. Dijksterhuis[2]
[1]Trouw Nutrition, R&D, Amersfoort, The Netherlands
[2]CBS-KNAW Biodiversity Centre, Applied and Industrial Mycology, Utrecht, The Netherlands

Backgrounds

Feed safety is a major issue throughout the world. Therefore, much attention is paid to control fungal spoilage of feed and the risk of mycotoxin production, which has adverse effects on farm animals.

Objectives

This study aims to isolate and identify major fungal species on poultry feed samples and to determine the efficacy and mode of action of selected inhibitors of fungal growth.

Methods

Fungal strains were isolated from contaminated poultry feed samples and typed by morphological appearance on feed and agar plates including microscopic evaluation. Furthermore, DNA sequencing of the ß-tubilin and calmodulin gene was applied to identify the fungal species. The minimally inhibitory concentration (MIC) of inhibitors of fungal growth was determined by incubation of spore suspensions in a microtiter plate format. The mode of action of inhibitors was assessed by measuring differences in membrane permeability of germinating conidia using the fluorescent probe TOTO-1 as a viability marker.

Conclusions

Dominant fungi isolated from poultry feed samples belong to the genus *Aspergillus* with an *Eurotium* sexual stadium: i.e. *A. chevalieri* and *A. proliferants*. In addition, *Fusarium equiseti, Penicillium lanosocoeruleum* and *Wallemia sebi* were identified. The *Aspergillus* species and *W. sebi* are known as xerophylic fungi: e.g. they can grow at dry conditions with aw < 0.8. Evaluation of the results of the MIC data set combined with (fluorescent) microscopy of conidia treated with various inhibitors provide insight in understanding their mode of action. The results of this study enable the development of effective solutions to prevent fungal spoilage of feed products.

[6]University of Surrey, Department of Civil and Environmental Engineering, Guilford, United Kingdom
[7]City Analysts Ltd, Water Analysis Testing, Dublin, Ireland
[8]Genetic PCR Solutions, and University Miguel Hernández, Alicante, Spain

Backgrounds

Microbial contamination of fresh produce is a major health concern, and the number of produce associated disease outbreaks has increased in recent years. The development of user-friendly, validated, pathogen detection methods are of key importance for detecting and preventing microbial disease outbreaks and providing enhanced product assurance.

Objectives

The aim of this study is to demonstrate the utility of novel methods developed as part of a European project, Aquavalens, to determine the microbiological quality of water used in the food production, with a particular focus on irrigation water and processing water.

Methods

This study utilised Aquavalens developed methods for the detection of pathogens in water used in the production and/or processing of salad leaves, soft fruits, including raspberries and strawberries and sprouted seeds. Sampling sites were selected in Ireland, Portugal, Serbia and the United Kingdom. Water samples are analysed by qPCR for the presence of *Salmonella*, *E. coli* O157, Hepatitis A and Norovirus and the samples are tested in parallel for the microbiological parameters outlined in the European Union Drinking Water regulations.

Conclusions

A detailed sampling plan and standard operating procedure enabled the successful implementation of these methodologies across Europe. Harmonisation of methodologies enables the direct correlation of results and a robust testing platform for the assays. Advantages include that the method can save time and money because the bacterial, protozoan and viral pathogens are concentrated from water using a single filter and that PCR techniques are quicker than the traditional methods for detecting pathogens.

ANTI-ADHESIVE AND ANTI-BIOFILM ACTIVITY OF ESSENTIAL OILS RICH IN CARVACROL AND THYMOL AGAINST SALMONELLA ENTERITIDIS

I. Cabarkapa[1], R. Colovic[1], O. Djuragic[1], B. Kokic[1], S. Popovic[1], Z. Tomicic[1]
[1]Institute of Food Technology,
RESEARCH CENTER FOR FEED TECHNOLOGY AND ANIMAL PRODUCTS, Novi Sad, Serbia

Backgrounds

Biofilms formed in food processing environments may represent a long-term source of foodstuff contamination. Given that bacteria enclosed into biofilm showed high tolerance/resistance to standard sanitizers, a great number of studies have been focused on evaluation of plant-based compounds as potential sources of antimicrobial agents, as they are effective, safe and eco-friendly.

Objectives

Aim of the present study was to determine the bioactive compounds in four essential oils (EO's) from *Origanum heracleoticum*, *Origanum vulgare*, *Thymus vulgaris* and *Thymus serpyllum* and to assess their antimicrobial, anti-adhesive and antibiofilm activity against *Salmonella* Enteritidis.

Methods

Strains were previously characterized depending on the expression of extracellular matrix components as an rdar (cellulose + curly fimbriae) and bdar morphotype (curly fimbriae). Antiadhesion tests were carried out by crystal violet and metabolic activity assay.

Conclusions

Results indicated that percentage of carvacrol and thymol in EO's of *O. heracleoticum, O. vulgare, Th. vulgaris,* and *Th. serpyllum* (71.60%, 63.60%, 59.77% and 40.04%, respectively) were proportional to their antimicrobial potencies. Comparing the efficacy of EO's to inhibit the initial adhesion and metabolic activity of cells between the strains of rdar and bdar morphotype, statistically significant differences were not observed. EO's showed weaker effect on the preformed biofilms. Results related to the effectiveness of EO's on the total biomass of biofilm and metabolic activity of the cells enclosed into biofilm, indicated that applied EO's caused a reduction in a dose-dependent manner over time. Additionally, in assessing efficacy of EO's in the treatment of preformed biofilms by isolates with expressed rdar morphotype compared to strains with expressed bdar morphotype, statistically significant differences were observed. It is assumed that this is a consequence of the presence of a more complex biofilm matrix that consists of cellulose and curly fimbriae in relation to the biofilm matrix of bdar morphotype isolates that consists of only curly fimbriae.

CO-TRANSFER OF AMINOGLYCOSIDE, TETRACYCLINE AND MACROLIDE RESISTANCE GENES BETWEEN ENTEROCOCCUS STRAINS ISOLATED FROM READY-TO-EAT FOOD

W. Chajęcka-Wierzchowska[1], *A. Zadernowska*[1], *Ł. Łaniewska-Trokenheim*[1]
[1]*University of Warmia and Mazury in Olsztyn, Chair of Industrial and Food Microbiology, Olsztyn, Poland*

Backgrounds

Enterococcus spp. are one of the most common groups of bacteria in foods. Antibiotic resistance has been acquired, and has disseminated throughout enterococci, via horizontal transfer of mobile genetic elements. This transmission has been mediated mainly by conjugative plasmids of the pheromone-responsive.

Objectives

The purpose of this study was to conjugal transfer of resistance genes between a multi-resistant *E. faecium, E. faecalis* and *E. casseliflavus* isolates from ready-to-eat food and a sensitive *E. faecalis* strain.

Methods

Donor strains had tetracycline resistance genes (*tet* M, *tet*L, *tet*K, *tet*O), macrolides genes (*erm*A, *erm*B, *msr*C *mef*A/E) and/or aminoglycoside genes *(aac*(6 ')-*aph*(2' ') Ia, *aph* (3')-IIIa, *ant* (6 ')-Ia). The recipient was a reference strain of *E. faecalis* JH2-2 (LMG 19456) free of plasmids resistant to rifampicin and fusidic acid.

Conclusions

Among the tested strains isolated from food more than 70% were able to transfer by conjugation at least one of the held antibiotic resistance genes. The frequency of gene transfer was dependent on the strain and the transferred gene and was in the range from $1{,}2x10^{-6}$ to $3{,}1x10^{-8}$ transkonjugants per donor. Genes *tet*M, *erm*B and *aac*(6')-*aph*(2'') were transferred with the greatest frequency. Simultaneously with the *tet*M gene, *int* gene was transferred, indicating the participation in the conjugation process of the Tn*916*/Tn*1545* transposon family.
The results of the study indicated that ready-to-eat food can be an important vector in transmitting resistance to antimicrobial agents. This research was financed by the National Science Centre allocated on the basis of a decision number DEC-2013/09/N/NZ9/01630.

ENTEROTOXIGENIC POTENTIAL, VIRULENCE FACTORS AND ANTIMICROBIAL RESISTANCE OF S. EPIDERMIDIS STRAINS ISOLATED FROM READY-TO-EAT FOOD

W. Chajęcka-Wierzchowska[1], *A. Zadernowska*[1], *Ł. Łaniewska-Trokenheim*[1]
[1]*University of Warmia and Mazury in Olsztyn, Chair of Industrial and Food Microbiology, Olsztyn, Poland*

Backgrounds

Coagulase-negative staphylococci (CoNS) are among the most widespread microorganisms in nature. For many years they were classified as microflora unable to cause disease. A consistent increase in the role of CoNS (especially *S. epidermidis*) in causing hospital infections has been observed in recent years.

Objectives

The aim of this work was to study the enterotoxigenic potential, virulence factors and phenotypic and genotypic antimicrobial resistance profile of *S. epidermidis* isolated from ready-to-eat food of animal origin.

Methods

Isolates were tested for resistance to 15 antibiotics by the disk diffusion method according to CLSI. PCR was used for the detection of antibiotic resistance genes encoding: methicillin resistance *mec*A; macrolide resistance; *erm*A, *erm*B, *erm*C, *mrs*A/B; efflux proteins *tet*K and *tet*L and ribosomal protection proteins *tet*M. The genes encoding enterotoxins as well as ACME element, *ica*ADBC operon and insertion sequence element IS256 were also investigated.

Conclusions

Almost 25% of staphylococcal isolates were multidrug resistant. Most of them were resistant to cefoxitin, clindamycin, rifampicin and erythromycin. All methicillin resistant staphylococci harboured *mec*A gene. Isolates, phenotypic resistant to tetracycline, harboured at least one tetracycline resistance determinant on which *tet*(M) was most frequent. In the erythromycin resistant isolates, the macrolide resistance genes *erm*C or *msr*A/B were present. *S. epidermidis* strains were also able to form biofilm. Over a half of them harbored ACME element, known to promote microbial growth and survival in infected organism. Additionally, 36% of strains harboured *ica*ADBC operon, and almost 15% of them possessed IS256.

IN VITRO EVALUATION OF ANTI¬¬-LISTERIA ACTIVITY OF TWO LACTIC ACID BACTERIA ISOLATED FROM DONKEY MILK

I. Chemsi[1], *B. Ali*[1], *E. Bouchra*[1], *S. Abdelaziz*[1]
[1]*Faculty of Sciences, Biology, Casablanca, Morocco*

Backgrounds

The interest of scientists for natural molecules with an antimicrobial effect has continued to increase. With a view to reducing the use of synthetic food additives, research and study of natural antibiotics such as bacteriocins is gaining more attention. Bacteriocins constitute a set of proteins produced by lactic acid bacteria (LAB) and possessing antagonistic activity directed against pathogenic bacteria colonizing the food products.

Objectives

The aim of the study is to identify some LAB that produce bacteriocins directed against one of the most common pathogenic bacteria: *Listeria monocytogenes.*

Methods

The isolation of the LAB was carried out on M17 and MRS medium from donkey milk. The preliminary identification is effectuated with conventional microbiological method and biochemical (Gallery API20E) processes. Genotypic identification of the LAB strains is carried out by DNA fragments amplification then the resulting DNA is sequenced. The sequences are analized with bioinformatics tools. After optimization of the bacteriocin secretion, the antagonistic activity of LAB effect was tested through the well diffusion assay. The indicator strains used is the pathogenic bacterium *Listeria monocytogenes.*

Conclusions

Among the isolated and identified bacteria, Leuconostoc mesenteroidess and Staphylococcus succinus showed major antimicrobial activity. This study highlights the important biotechnological potential of these bacteriocins that can be exploited in the agro-food industry (bio-preservatives) and pharmaceutical (therapeutic antibiotics).

PREVALNECE OF FOODBORNE PATHOGENS IN SLAUGHTERED CHICKEN CARCASSES IN SOUTH KOREA

B. Choi[1], O. Jeong[1], C. Lim[1], S. Youn[1], B. Jeon[1], H. Lee[1], H. Lee[1], M. Kang[1]
[1]Animal and plant quarantine agency, Avian Disease Division, Gimcheon-si, Republic of Korea

Backgrounds

Backgrounds: Public health issues have gradually increased for decades especially focusing on foods including meat and meat products. Chicken meat and products are considered as a common source of foodborne diseases in humans. There are a variety of pathogenic bacteria contaminating chicken meat such as *Salmonella* spp., *Staphylococcus aureus*, *Clostridium* perfringens, *Campylobacter* spp., *Escherichia coli*, *Yersinia enterocolitica*, and *Listeria moncytogenes*.

Objectives

Objectives: This study was intended to evaluate the prevalence of pathogenic bacteria in chicken carcasses freshly slaughtered in South Korea.

Methods

Methods: Two hundred seventy samples of chicken carcasses were collected from 27 chicken slaughterhouses throughout the nation in South Korea during 2014 -2016. All samples was tested for presence of *Salmonella* spp., *Staphylococcus aureus*, *Clostridium perfringens*, *Campylobacter* spp., pathogenic *Escherichia coli*, *Yersinia enterocolitica*, and *Listeria moncytogenes* according to the procedure of Korean Food Standard Codex for meat and meat products.

Conclusions

Conclusions: *Clostridium perfringens* (33.7%), *Staphylococcus aureus* (24.1%), and *Salmonella* spp. (17.4%) are frequently isolated from chicken carcasses tested in this study. The prevalence of other pathogenic bacteria were as follows: *Campylobacter coli* (15.6%), *Campylobacter jejuni* (10.4%), *Escherichia coli* O111 (3.6%), *Yersinia enterocolitica* (1.9%), *Escherichia coli* O145 (1.5%), O26 (1.1%), and *Listeria monocytogenes* (0.7%). This study indicates stronger safety systems are needed to decrease bacterial contaminations in chicken meat in South Korea.

PROTECTION ACTIVITY OF A NOVEL PROBIOTIC STRAIN OF LACTOBACILLUS SP. AGAINST FOOD BORNE PATHOGEN INFECTION

H. Choi[1], H. Park[1], S. Lee[1], J. Park[1], D. Jo[1], S. Oh[1], S. Kim[1]
[1]National Institute of Crop ScienceNICS Rural Development AdministrationRDA, Crop post harvest technology, Suwon, Republic of Korea

Backgrounds

Lactobacillus enhances intestinal epithelial barrier function; they also compete with and suppress pathogenic bacteria, and modulate immune system activity. Thus, Lactobacillus has significant therapeutic potential to overcome intestinal disorders and can be used as usual functional food ingredients and biological preservatives. However, general mechanisms of action by which probiotic Lactobacilli exert their beneficial effects are still largely unknown.

Objectives

In this study, we investigated the effects of Lactobacillus sp. on the growth of S. Typhimurium.

Methods

We previously isolated Lactobacillus sp. from traditional Korean fermented soybean food, and exhibits strong enzymatic and antimicrobial activity against food-borne pathogens. We analyzed S. Typhimurium-induced cytotoxicity by stimulating the host immune response using tools with genetic and protein levels.

Conclusions

The results showed that when S. Typhimurium was co-incubated with Lactobacillus sp., the growth of S. Typhimurium was reduced, and the S. Typhimurium-induced NF-κB activation, Akt and p38 phosphorylation were decreased. This study indicates that Lactobacillus sp. has the potential probiotic properties, and exhibits strong inhibition activity against S. Typhimurium infection. Our findings also could be used as therapeutic and preventative agents, to control of pathogenic diseases.

Food Microbiology

PRESENCE OF NOROVIRUS AND HEPATITIS A IN RASPBERRIES

R. Čobanović[1], *K. Mihajlović*[1]
[1]*SP Laboratory, Microbiological, Bečej, Serbia*

Backgrounds

Serbia is the largest exporter of raspberry in EU. Raspberry is a perishable food which can be consumed as fresh or minimally-processed as well as a frozen ingredient added to many foods. According to EFSA, contamination by Noroviruses and Hepatitis A viruses may occure at various stages of berry production chain.

Objectives

Based on above mentioned, the aim of this study was to evaluate virological safety of raspberry grown in Serbia.

Methods

Analyzed samples were collected from various independent producers from January 2014 untill December 2016. Samples were analyzed on Norovirus (NoV) genogroups I (GI) and II (GII) - 545 samples and Hepatitis A (HAV) - 418 samples. The applied method was based on ISO/TS 15216-2:2013 Microbiology of food and animal feed -- Horizontal method for determination of hepatitis A virus and norovirus in food using real-time RT-PCR -- Part 2: Method for qualitative detection. Out of 963 analyzed samples neither one showed unsatisfactory positive result concerning both NoV genogroups I (GI) and II (GII) and HAV viruses.

Conclusions

As far as obtained results are concerned it can be concluded that Good Agricultural Practices (GAP), Good Hygiene Practices (GHP) and Good Manufacturing Practices (GMP) are properly implemented throughout raspberry production chain in Serbia. Due to high risk of contamination during raspberry production it is necessary to conduct permanent monitoring in order to provide microbiologicaly safe products that are exported to the EU.

MINING MICROBES FROM DAIRY PRODUCTS AND ASSOCIATED PROCESSING ENVIRONMENTS FOR THE IDENTIFICATION OF NOVEL INHIBITORS OF QUORUM SENSING AND BIOFILM FORMATION

L. Coughlan[1,2], P. Cotter[1,3], C. Hill[2,3], A. Alvarez-Ordóñez[4]
[1]Teagasc Food Research Centre, Food Biosciences, Cork, Ireland
[2]University College Cork, School of Microbiology, Cork, Ireland
[3]APC Microbiome Institute, Microbiology, Cork, Ireland
[4]University of León,
Department of Food Hygiene and Technology and Institute of Food Science and Technology, León, Spain

Backgrounds

Coordinated by the quorum sensing (QS) gene regulatory system, biofilm formation can allow spoilage and pathogenic bacteria to persist in the dairy industry, impacting food safety and quality.

Objectives

This study focused on mining microbes from dairy products and associated environments for the identification of bacterial species with QS inhibitory activity for further evaluation as biofilm inhibitors.

Methods

Culturable bacterial collections comprising ~3,000 strains were constructed from 12 samples of milk, cheese and dairy processing environments after plating of serial dilutions on brain heart infusion (BHI) agar and de Man, Rogosa and Sharpe (MRS) agar and incubation for 48h under anaerobic (for BHI) or anaerobic (for MRS) conditions at 5, 37 and 55°C. Strains retrieved (up to ten of each morphology per sample) underwent an initial screening process in which isolates displaying QS inhibitory (QSI) activity were readily detected using overlay assays employing *Chromobacterium violaceum* (auto-inducer 1 QS) and *Vibrio harveyi* (auto-inducer 2) as indicator organisms. All strains presumptively identified as QSIs were identified through 16S rRNA gene sequencing and are currently being characterized for their ability to inhibit biofilms of various common spoilage and pathogenic microorganisms (*Pseudomonas* spp., *Listeria monocytogenes*, *Cronobacter sakazakii*, *Geobacillus stearothermophilus*).

Conclusions

Sixteen confirmed AI-1 QSIs were identified as *Hafnia alvei* and 54 AI-2 QSIs as *Lactococcus lactis* and *Lactobacillus plantarum*. Current work assesses the ability of these strains to inhibit biofilms of selected common spoilage and pathogenic microorganisms. Future study will include examining their efficacy in preventing biofilm formation in dynamic biofilm models and industrial settings.

[2]Universidade do Vale do Rio dos Sinos UNISINOS,
Instituto Tecnológico em Alimentos para a Saúde itt Nutrifor, São Leopoldo RS, Brazil
[3]Università degli Studi di Padova,
Centro Interdipartimentale per la Ricerca in Viticoltura ed Enologia C.I.R.V.E., Conegliano, Italy

Backgrounds

Saccharomyces is a worldwide spread yeast genus. It includes the most important fermenting agent in wine industries, *Saccharomyces cerevisiae* and it is adapted to several environments. The use of autochthonous *Saccharomyces* strains in the winemaking process can emphasize the wine *terroir*. Compared to Europe, South of Brazil has high oenological potential. Besides the climate, the main difference between the two areas is the winemaking and vine growing history: ancient for the former and recent for the latter.

Objectives

We investigated the characteristics of a group of *Saccharomyces* strains collected in "Vale dos Vinhedos" vineyards (RS – Brazil) in order to find out the oenological properties of the local yeast population. We analyzed the genetic variability of the yeast isolates, some important genetic traits and their impact on yeast phenotypes, in order to better understand the adaptation of the population to the vineyard environment.

Methods

MtDNA RFLP analysis has been used to genotype the yeast population. Fermentations were run in synthetic must to obtain yeast fermentation performance. Sulfite tolerance under fermentation conditions was evaluated and copper resistance, as well.

Conclusions

The collected isolates, generally, showed good oenological properties, regarding both fermentation kinetics and sulfite/cupper tolerance. Thus, they can be further investigated to select strains able to improve the quality and the terroir of Brazilian wines.

IMPACT OF PLANT STEROLS ON INTESTINAL MICROBIOTA FROM LEAN AND OBESE SUBJECTS USING TIM-2 IN VITRO MODEL

M. Cuevas Tena[1], C. Bussolo[2], A.D. Silva[3], A. Alegría[1], M.J. Lagarda[1], K. Venema[4]
[1]Universitat de Valencia,
Medicina Preventiva y Salud Pública- Ciencias de la Alimentación- Toxicología y Medicina Legal, Valencia, Spain
[2]University of Groningen, Department of Microbiology, Groningen, The Netherlands
[3]University of Sao Paulo, Department of Biochemical and Pharmaceutical Technology, Sao Paulo, Brazil
[4]Maastricht University-Campus Venlo, Healthy Eating and Food Innovation, Venlo, The Netherlands

Backgrounds

Plant sterols (Ps) are poorly absorbed in the small intestine (1-2%) (Quilez et al., 2003) reaching the colon where they are biotransformed by intestinal microbiota. Some authors have studied this biotransformation (Rosenfeld et al., 1954; Snog-Kjaer & Dam, 1956; Eyssen et al., 1973 and 1974). Baumgartner et al, (2016) are the only ones who analyze the effect of microbiota from individuals after consumption of plant stanol ester enriched margarines (3.0g/day), and they have not observed significant changes in microbiota composition. Therefore, the effect of Ps on the microbiota remains unknown.

Objectives

To know the influence of Ps on the microbial population from lean and obese individuals using a validated *in vitro* dynamic fermentation system.

Methods

The TNO Intestinal Model 2 (TIM-2) was applied to a Ps standard and a Ps ingredient used in the manufacture of a fruit-based milk beverage. Changes of the colonic microbiota were evaluated by next generation sequencing. In addition, short chain fatty acids (SCFA), lactate and ammonia produced during fermentation were determined by ion exclusion chromatography (IEC*), Boehringer* UV-method and *Berthelot* reaction (spectrophotometry), respectively. For this purpose, the lumen and dialysate obtained after *in vitro* colonic fermentation at different times (0, 24, 48 and 72 hours) were analyzed.

Conclusions

Results will be available for presentation by the time of the congress.

FEMS7-3093

CHANGES OF BIOLOGICALLY ACTIVE COMPOUNDS IN APPLE POMACE UNDER THE INFLUENCE OF LACTIC ACID BACTERIA.

A. Czyżowska[1], *A. Wilkowska*[1], *I. Motyl*[1], *A. Nowak*[1]
[1]*Institute of Fermentation Technology and Microbiology,*
Department of Biotechnology and Food Sciences- Lodz University of Technology, Łódź, Poland

Backgrounds

Apple pomace is a waste product in the fruit industry. It may be a rich source of polyphenols such as quercetin glycosides, dihydrochalcones, cinnamic acid derivatives, flavan-3-ols. During the process it is subjected to enzymatic treatment in order to facilitate processing. One of the ways of using, is to add it as a prebiotic component.

Objectives

In this study, apple pomace from Cortland variety was used, and subjected to hydrolysis by preparations Cellulosoft and Viscozyme.

Methods

On the obtained hydrolyzates were cultivated lactic acid bacteria: *Lactobacillus rhamnosus* 900 and 908, *L. casei* 904, 919 and 906, and *L. paracasei* 915 and 920. Cultures were grown for 17 days at 37°C. Test samples were cultures for the days on which the microorganisms were in the final stage of the logarithmic phase or reached a stationary phase.

Conclusions

Gallic acid was reported in highest amounts from 5.269 mg/100ml (H/920) to 0.573 mg/100ml (H/919). Catechin and procyanidin B2 were identified in two samples (H/904 and H/906). In all the samples revealed the presence of procyanidin B1 and quercetin derivatives. Procyanidin B1 concentration ranged from 0.076 to 0.435 mg/100 ml. Among the derivatives of quercetin highest amounts of quercetin-glucoside and quercetin-rutinoside were found. Phloretin was found in five, and phloridzin in six samples. Chlorogenic acid was identified in seven, neochlorogenic in only four samples, its concentration was in the range from 0.066 to 0.360 mg/100ml. The highest concentration of identified substances was found in samples H/920 and H/915, while the lowest in the H/906.

This work was supported through Narodowe Centrum Badań i Rozwoju (NCBiR) grant GEKON nr Gekon2/05/267284/15/2015.

ARONIA BEVERAGES FERMENTED BY LACTIC ACID BACTERIA (LAB).

A. Czyżowska[1], A. Żołek[1], I. Motyl[1], A. Nowak[1]
[1]Institute of Fermentation Technology and Microbiology,
Department of Biotechnology and Food Sciences- Lodz University of Technology, Łódź, Poland

Backgrounds

The experimental material were beverages reconstituted from chokeberry concentrate.

Objectives

The concentrate was diluted with water to a pH of about 4.6, followed by adding sucrose to obtain approximately 6°BLG. Beverages were divided into two groups, one of which was pasteurized at 121°C for 10 minutes, and were inoculated with lactic acid bacteria in order to conduct lactic acid fermentation.

LAB: *Lactobacillus rhamnosus* 908 and 900*, Lactobacillus casei* 919, *Lactobacillus paracasei* 920*, Lactobacillus plantarum* 861 and *Lactobacillus brevis* strains M18 and 0945 were used. Inoculated beverages were incubated at 30°C for 2 and 7 days.

Methods

In all the samples was tested lactic acid concentration as lactic acid fermentation indicator. In addition: citric, acetic and propionic acids and ethyl alcohol were determined. In samples were also examined concentration of polyphenols.

Conclusions

The control samples contained only citric acid, lactic acid concentration was the highest (0.25 g/100 ml) in samples inoculated with strain 0945, the lowest with 920 strain, wherein traces of lactic acid were determined. In pasteurized samples containing strains 0945, 919 and 861, lactic acid content after 7 days of fermentation increased in comparison with 2-day fermentation.

Among the anthocyanins five cyanidin glycosides: galactoside, glucoside, rutinoside, arabinoside and xyloside were found. Among the phenolic acids four: neochlorogenic, p-coumaroylquinic, chlorogenic and cryptochlorogenic has been detected. It was also found the presence of six quercetin derivatives: sophoroside, vicianoside, robinobioside, rutinoside, galactoside and glucoside.

The content of the above-mentioned compounds, varied depending on the method of treatment of the samples and the strain used.

EFFECT OF NISIN-BASED ADDITIVES ON THE GROWTH RATE OF LISTERIA MONOCYTOGENES AND LACTIC ACID BACTERIA IN RTE MEAT PRODUCTS

A. de Benito[1], A. Roijals[2], S. Porta[1], J. García-Pina[2], J. Gonzalez[2], B. Ruiz[1]
[1]AINIA- technological centre, Bioassays, Valencia, Spain
[2]CHEMITAL Food Techniques, Calidad, Barcelona, Spain

Backgrounds

Ensuring food security can still be a challenge for food producers and authorities, as new safety issues are arising regarding the use of artificial additives, antimicrobial resistance and emmerging pathogens. There is a need for the development of novel and more natural additives that meet the consumers‘ needs and preferences. This work is aligned with the recent recommendation by the Codex Alimentarius to discuss the draft provision for the use of nisin in heat-treated processed comminuted meat, poultry, and game products at a maximum level of 25mg/Kg

Objectives

To assess the antimicrobial effect of new additives formulated with nisin in cooked meat products

Methods

The effect of newly developed nisin-based additives was assessed by using microorganisms representatives of this type of products: *Listeria monocytogenes* and lactic acid bacteria (LAB). Tests were done in a cooked meat product that was produced with the addition of different doses of the additives. Cooked meat products were sliced, inoculated, vacuum packed and stored for at least 45 days under refrigeration conditions. Analysis of samples to estimate the growth rate of *Listeria monocytogenes* and lactic acid bacteria was done at several time intervals

Conclusions

Results show an inhibitory effect on the growth of *Listeria monocytogenes* and lactic acid bacteria by the use of the new additives on the products from doses of 11,2 mg nisin/Kg meat product This effect was increased in combination with refrigerating temperatures and enables to provide a safety barrier against *Listeria monocytogenes* as well as increase the shelf life of the products

OCHRATOXIN A PRODUCTION BY PENICILLIUM NORDICUM IN DRY-FERMENTED SAUSAGES FOLLOWING TWO RIPENING PROCESSES

J. Delgado[1], *B. Peromingo*[1], *F. Núñez*[1], *M.A. Asensio*[1], *M. Rodríguez*[1]
[1]*Research Institute of Meat and Meat products University of Extremadura, Hygiene and Food Safety, Cáceres, Spain*

Backgrounds

Dry-fermented sausages are highly appreciated products from the South of Europe. Bacteria, yeasts and molds contribute to the generation of the desired sensory qualities. However, some molds are able to produce mycotoxins on sausages. Ochratoxin A (OTA), which is mainly produced by *Penicillium nordicum* and *Penicillium verrucosum* in dry-cured meat products, is the main mycotoxin of concern. OTA production is influenced by environmental factors such as temperature and moisture. Dry-fermented sausages are typically processed at either *c.a.* 12 °C or at about 15-18 °C.

Objectives

The objective of this work was to evaluate OTA production on dry-fermented sausages at two ripening temperatures.

Methods

Raw sausages were inoculated with 10^3 spores/cm^2 of *P. nordicum* and fermented in separate ripening chambers set at 12 °C, 84% relative humidity (RH) and 15 °C, 86% RH, for 28 days. Mycotoxin extraction was based on QuEChERS method and analyzed by HPLC-FLD (Agilent Technologies).

Conclusions

Ripening at 12 °C led to 2.6 mg/kg OTA production in 14 days, whilst ripening at 15 °C led to 2.9 mg/kg OTA in 7 days. Therefore, even ripening at the lower temperature was not adequate to ensure safe sausage processing. Therefore, effective means to control OTA production on sausages are required. Strategies based on biocontrol agents, such as molds or yeasts endowed with antifungal activity, should be proposed.

DEVELOPMENT AND OPTIMIZATION OF A UHPLC–MS/MS METHOD FOR DETECTION AND QUANTIFICATION OF CYCLOPIAZONIC ACID IN DRY-CURED HAM

B. Peromingo[1], J. Delgado[1], F. Núñez[1], P. Padilla[1], L. Sánchez-Montero[1], M. Rodríguez[1]
[1]Research Institute of Meat and Meat Products University of Extremadura, Hygiene and Food Safety, Cáceres, Spain

Backgrounds

Cyclopiazonic acid (CPA) is a mycotoxin produced by *Penicillium* and *Aspergillus* species that are able to grow on the surface of dry-cured meat products during the ripening process. CPA is a molecule difficult to detect because it can be degraded throughout chemical and physical processes.

Objectives

The objective of this study was to optimise an uHPLC–MS/MS method for detection and quantification of CPA in dry-cured ham-based matrices.

Methods

Four different extraction methods were evaluated. Mobile phases, flow rates, gradient mode and nature of extract solvent for optimising chromatographic parameters were tested. Results showed that for CPA isolation from cured matrices a QuEChERS-based method with some modifications was the most effective one. The extracts were redissolved in buffered ammonium acetate/methanol (30/70) before analysis by uHPLC-MS/MS. Regarding chromatographic parameters, the mobile phase contained 10 mM ammonium acetate (pH 5.75, acetic acid)/methanol. Elution was carried out in gradient mode and the flow rate was 0.2 mL/min. MS detection of CPA was performed using the precursor ion 335, and the quantitation ion 180. The run time was 15 min, being CPA detected at 5.6±1 min.

Conclusions

In conclusion the uHPLC-MS/MS method offers a useful, rapid and efficient tool for screening CPA in dry-cured meats. The early detection of CPA in these products would allow taking corrective actions to avoid risks associated with CPA contamination.

Acknowledgements: Funded by Spanish Ministry of Economy and Competitiveness, Government of Extremadura and FEDER (AGL2013-45729-P, GR15108). B. Peromingo and P. Padilla are recipient of a pre-doctoral fellowship (BES-2014-069484 and PEJ2014-P-0057 respectively).

RAPID DETECTION OF MICROBIAL CONTAMINATION IN UHT MILK: PRACTICAL APPLICATION IN DAIRY INDUSTRY

K. Demnerova[1], M. Kracmarova[1], H. Stiborova[1]
[1]University of Chemistry and Technology Prague, Department of Biochemistry and Microbiology, Prague, Czech Republic

Backgrounds

The formation and impacts of biofilms on quality of milk in dairy industry is proven. Therefore, the contamination in manufacturing chain has to be identified quickly. Microbial quality of ultra-high temperature (UHT) milk is usually analysed by a traditional cultivation technique known as total bacterial count (TBC). However, this method is time demanding.

Objectives

Therefore, we tested and compared two faster methods based on different principles. The comparison was directed on: (i) the overall time required for the detection of bacterial spoilage; (ii) the length of pre-incubation time of UHT milk, which plays a key role in proliferating bacteria; (iii) simplicity of procedure and (iv) accuracy of results.

Methods

The first method, tested by two separate instruments from different producers, detects microbial contamination by measuring adenosine triphosphate (ATP) bioluminescence; the second, which is more novel and was tested by another instrument, detects it by analysing oxygen consumption. In the laboratory experiments, samples of UHT milk were inoculated with a low concentration of microorganisms (colony-forming unit per litter). These methods, together with TBC as a control, were used to measure microbial contamination in the samples. Then, all methods were trialled in a dairy processing plant.

Conclusions

While both methods determined microbial quality in a significantly shorter time, only one instrument satisfied all the requirements for operations in the dairy industry. Indeed, the dairy processing plant introduced this instrument into their microbial control process as an alternative to TBC.

COLONISATION OF MEAT BY ESCHERICHIA COLI O157:H7: BACTERIAL TROPISM RESPECTIVE TO THE DIFFERENT TYPES OF SKELETAL MUSCLES, SUBTYPES OF MYOFIBERS AND POSTMORTEM TIME

M. Desvaux[1], C. Chagnot[2], A. Venien[3], S. Renier[2], N. Caccia[2], M. Refregiers[4], R. Talon[2], T. Astruc[3]
[1]INRA Auvergne-Rhône-Alpes, UMR MEDiS, Saint-Genès Champanelle, France
[2]INRA, UMR454 MEDIS, Clermont-Ferrand, France
[3]INRA, UR370 QuaPA, Clermont-Ferrand, France
[4]Synchrotron SOLEIL, Disco Beamline, Gif-sur-Yvette, France

Backgrounds

Escherichia coli O157:H7 are enterohaemorrhagic *E. coli* (EHEC) responsible for serious pediatric diseases and of great concern for the meat industry. Meat contamination by EHEC occurs at slaughtering, essentially at dehiding stage, where bacteria can be transferred from hides to carcasses. The skeletal muscle tissues are constituted of four major types of myofibers surrounded by the extracellular matrix (ECM).

Objectives

Despite the frequency of the associations between bacteria and meat, the molecular mechanisms of adhesion and the tropisms of bacteria across the different types of muscle fibers are totally unknown.

Methods

Bacterial adhesion to meat was investigated considering the different constituent myofibers of different skeletal muscles as well as postmortem evolution of muscle following fluorescence and electronic microscopy as well as immunohistochemical analyses.

Conclusions

Differential *E. coli* O157:H7 adhesion occurred at the surface of divergent skeletal muscle types. By analysing the adhesion of *E. coli* O157:H7 to model glycolytic and oxidative skeletal muscles, we provide the first in-depth interaction of EHEC with meat at cellular and tissue levels. While no significant differences could be observed for bacteria adhering to the different types of myofibers, bacterial adhesion essentially occurred at the ECM. Information on spatial localization of *E. coli* O157:H7 to meat was further provided and demonstrated their ability to adhere to skeletal muscle tissue, especially at the ECM. Besides, the postmortem evolution of muscle tissue significantly influenced adhesion to the ECM. This information is relevant to mitigate the contamination of meat, the food chain and ultimately human infection.

GENOMIC EVIDENCE OF THE CLOSE RELATEDNESS OF FOOD, POULTRY, WILDLIFE AND HUMAN CLINICAL ISOLATES OF ESBL- PRODUCING ESCHERICHIA COLI O153:H10-A-ST10 EAE-BETA1

D. Diaz Jiménez[1], *Z. Zhou*[2], *A. Herrera Estévez*[1], *S. Viso González*[1], *M. Blanco Álvarez*[1], *L. Costoya Seco*[1], *A. Mora Gutiérrez*[1]
[1]*Universidad de Santiago de Compostela, Departamento de Microbioloxía e Parasitoloxía, Lugo, Spain*
[2]*University of Warwick, Warwick Medical School- Microbiology and Infection Unit, Coventry, United Kingdom*

Backgrounds

During the last decade, it has been widely recognized that the dissemination of extended-spectrum beta-lactamase (ESBL) producing *Enterobacteriaceae* is no longer restricted to the health care system but represents a growing problem involving food production and environmental integrity.

Objectives

In a ten-year surveillance study (2006-2016) on the presence of ESBL producing *E. coli* from human diarrhea, food, farm environment and wildlife in the north-west of Spain, we repeatedly detected an unusual atypical enteropathogenic *E. coli* O153:H10 ESBL-producing group. The aim of this study was to determine the degree of relatedness between human and other sources´ isolates.

Methods

Twenty representative isolates were characterized by conventional molecular typing, being all O153:H10-A-ST10 *fim*H54 *eae*-beta1 CTX-M-32/SHV-12 (19 and 1 isolates, respectively). By PFGE, the 20 clustered with ≥84.8%.

Additionally, 17 of the 20 isolates were whole genome sequenced. In the Minimum Spanning Tree of the core genome analysis based on the presence / absence of 2,513 genes included in the cgMLST scheme from Enterobase (https://enterobase.warwick.ac.uk/), the 17 genomes showed <40 differences (range 5-35) in relation to the human clinical isolate LREC-113. The number of SNPs in the core genomic regions present in 90% of the compared genomes was <62 for 13 of the 17. Interestingly, we detected 5 genomes in Enterobase showing 84-264 differences in the cgMLST comparison, carriers of *fim*H54 and *eae*-beta1 genes but non-ESBL producers.

Conclusions

Our results demonstrate that highly genomic related isolates of ESBL-producing EPEC O153:H10-A-ST10, implicated in human diarrhea, are presently spread in different niches of our region.

ANTIMICROBIAL ACTIVITY FROM STREPTOCOCCUS LUTETIENSIS A45212 ISOLATED FROM POZOL, A FERMENTED MAIZE DOUGH

G. Diaz Ruiz[1], *S. Samano*[1], *C. Maldonado*[1], *C. Wacher*[1]
[1]*UNIVERSIDAD NACIONAL AUTONOMA DE MEXICO, ALIMENTOS Y BIOTECNOLOGIA, Mexico D. F., Mexico*

Backgrounds

In a previous study, a collection of antimicrobial-producing strains of *Streptococcu*s spp. isolated from Mexican pozol was identified. *Streptococcus lutetiensis* A45212, exhibited important antimicrobial activity against some pathogenic microorganisms by the well diffusion assay, being *L. monocytogenes* one of them.

Objectives

The purpose of the present study was to evaluate the antimicrobial effects of *S. lutetiensis* A45212 against *L. monocytogenes*, also to determine the suitability of low-cost carbon sources for antimicrobial production by *S. lutetiensis* A45212.

Methods

The antagonistic effect of the strain A45212 against *L. monocytogenes* was determined in MRS broth and also in a neutralized and concentrated cell free supernatant from the same culture medium. Molasees and whey were utilized as carbon sources in flask experiments.

Conclusions

In MRS broth, strain A45212 completely eliminated *L. monocytogenes* within 48h incubation at 30°C and in a neutralized and concentrated cell free supernatant of the strain, the bactericide effect against *L. monocytogenes* was only observed after 6h. Whey and molasses added in the culture medium proved to be suitable for both biomass and antimicrobial production by *S. lutetiensis* A45212 but the highest antimicrobial production was obtained in presence of whey medium.

B-XYLOSIDASE ACTIVITY IN W. CONFUSA L9, PREDOMINANT IN POZOL FERMENTATION

G. Diaz Ruiz[1], M. López-Hernández[1], M.E. Rodríguez-Alegría[2], A. López-Munguía[2], C. Wacher[1]
[1]UNIVERSIDAD NACIONAL AUTONOMA DE MEXICO, ALIMENTOS Y BIOTECNOLOGIA, Mexico D. F., Mexico
[2]Instituto de Biotecnología- UNAM, Ingeniería celular y biocatálisis, Cuernavaca, Mexico

Backgrounds

Pozol is a Mexican refreshing, non-alcoholic acid beverage, consisting of a water suspension of hot-alkali treated and fermented maize dough. Although starch is the main carbohydrate available for the microbial development, it has been demonstrated that non-amylolytic lactic acid bacteria (NALAB) play an important role, such as particularly *Weissella* spp. is one of the predominant groups microorganisms during this fermentation.

Objectives

The aim of this work was to study *Weissella* spp. strains isolated from pozol from the carbon source perspective. In particular if *W. confusa* L9, a predominant NALAB, is able to grow on xylan or partially hydrolyzed xylan, also available in this fermentation environment.

Methods

Weissella confusa L9, *W. confusa* L17, *W. confusa* Snc40, *W. paramesenteroides* and *W. cibaria*, isolated from pozol, were used in this study. The carbohydrate consumption profile of each strain was obtained by Api 50CH; an enzymatic activity screening was also performed using Api Zym. Growth in xylan from beechwood was evaluated in all strains but only *W. confusa* L9 was chosen to grow with partially hydrolyzed xylan as carbon source. Xylooligosaccharides (XOS) analysis throughout fermentation time was performed by thin layer chromatography as well as high performance anion exchange chromatography with pulsed amperometric detection.

Conclusions

All *Weissella* strains evaluated showed interesting biochemical properties some related to pozol fermentation, such as xylose consumption, β-glucosidase and β-galactosidase activities, as well as different capacities to use xylan as the sole carbon source. Nevertheless, β-xylosidase activity was only found in *W. confusa* L9 since XOS consumption by this microorganism was demonstrated.

[3]Laboratoire de Microbiologie Appliqué à l'Agroalimentaire au Biomédical et à l'Environnement. Tlemc en-Algérie, Biology, Tlemcen, Algeria

Backgrounds

Bacillus cereus is an endospore-forming bacterium frequently found in dairy products and dairy environment.

Objectives

We investigated if the exosporium and spore surfaces, the length and the number of appendages were important for spore adhesion to the stainless steel surface.

Methods

In this study, molecular identification (M13 RAPD, Rep PCR,PFGE), the hydrophobicity and surface electrical charge of spores from fourteen (14) *Bacillus cereus* strains isolated from a dairy plant located in north-western Algeria (were studied using microbial adhesion to hydrocarbon (MATH) method, and zeta potential measurements, respectively.Four spore morphologies were investigated by transmission electron microscopy (TEM) after negative staining.The ability of spores to adhere to stainless steel was also studied.

Conclusions

The presence of an exosporium was not sufficient to explain the ability of spores to adhere to stainless steel surfaces. When physico-chemical surface characters of *B. cereus* spores were compared: the hydrophobicity, the appendages length, the surface of spore and exosporium were found as the significant adhesion parameters.

GENOTYPING OF BACTERIAL ISOLATES FROM PIROTSKA "IRONED" SAUSAGE

S. Bogdanović[1], A. Jelušić[2], B. Danilović[3], T. Berić[2], I. Nikolić[2], S. Stanković[2], I. Dimkić[2]
[1]High Agrifood School of Professional Studies, Professional Veterinary, Prokuplje, Serbia
[2]Faculty of Biology - University of Belgrade, Microbiology, Belgrade, Serbia
[3]Faculty of Technology University of Niš, Food Technology and Biotechnology, Leskovac, Serbia

Backgrounds

The Pirotska "ironed" sausage is a traditional dry fermented product from south-eastern region of Serbia, made of different types of meat (e.g. horse, goat, sheep and beef) and spices, without additives or starter cultures. The flat sausage is a totally organic, unprocessed product without heat and smoke treatment applied.

Objectives

The aim of this study was to characterize 120 isolates of lactic acid bacteria (LAB) from Pirotska sausage produced by six different brands in two-year period using phenotypic and genotypic identification.

Methods

The phenotypic characterization and preliminary identification of LAB was based on general morphology and biochemical tests (gas production, growth at different temperatures, arginine hydrolysis etc.). The repetitive elements (REP, BOX, $(GTG)_5$-PCR) found in the genome of these bacteria and randomly amplified polymorphic DNA-polymerase chain reaction (RAPD-PCR) using M13 primer were used for determination of genetic polymorphism. Sequencing of 16S rRNA gene was used for species level identification.

Conclusions

The 16S rRNA sequencing showed presence of only two species. *Lactobacillus sakei* was the dominant species (76%), followed by *Leuconostoc mesenteroides* (24%). However, plenty of genetic polymorphism within these two species was detected using $(GTG)_5$-PCR fingerprinting. The results after comparing fingerprinting patterns of bacterial populations from different brands, due to the use of different meat types as well as different percentages of meat content, revealed some genetic similarity in few clusters and emphasized significant polymorphism within others.

INHIBITION OF ENTEROPATHOGENS BY LACTOBACILLUS AND BIFIDOBACTERIUM SPP. ISOLATED OF CHILDREN'S FECES

M. Santos do Carmo[1,2], E.P. Moraes Lopes[1], F.C. Morais Maia[1], C.C. Rocha[2], L.X. de Brito Rodrigues[1], C. R A V Monteiro[1], V. Monteiro-Neto[1,2]
[1]Ceuma University, Centro de Ciências da Saúde, São Luís, Brazil
[2]Federal University of Maranhão, Centro de Ciências Biológicas e da Saúde, São Luís, Brazil

Backgrounds

The diarrhea is responsible for 526,000 deaths annually in children under 5 years old. The classical approaches for its treatment such as electrolyte replacement and antibiotic therapy are not sufficient to solve all the deleterious effects generated to the organism. Thereby, the use of probiotic microorganisms is an innovative option for the regression or elimination of this infectious process.

Objectives

The goal of this study was to investigate the probiotic potential of microorganisms isolated from the feces of healthy children.

Methods

The methodology included phenotypic and molecular identification of bacteria, tolerance assays to the gastrointestinal tract (resistance to lysozyme, pH2 and 4, bile salts 0.5% and 1%), mucin adhesion, inhibition of pathogen adhesion to mucus and antagonism against enteropathogens EAEC 042, EHEC EDL933, EPEC E-2348/69, ETEC 1661-1 LT/ST+, Salmonella Choleraesuis INQS 028 and *Shigella flexneri* 2a.

Conclusions

Collectively, the species *B. bifidum* 14.2, *B.longum* subsp. *longum* 25.3, *B. longum* 49.3, *B.animalis* subsp. *lactis* 56.1 and *L. fermentum* 54.2 endured the gastrointestinal stress ($p<0.001$), adhered to the mucin similarly or more that the controls *L. fermentum* ATCC 23271 and *B. longum* subsp. *longum* ATCC 15707 ($p<0.001$ and $p<0.05$, respectively), inhibited the adhesion of the pathogens to gastric mucin in 77.17-99.83% ($p<0.001$) and produced antimicrobial substances. These data suggest that the isolated microorganisms are potential candidates for probiotics because they inhibited the main bacterial pathogens associated with moderate and severe childhood diarrhea and can represent an important strategy for the treatment of this infection.

EVALUATION OF PROBIOTIC PROPERTIES OF BIFIDOBACTERIUM ISOLATES OF NEWBORNS FECES

V. Monteiro-Neto[1,2], E.P. da Silva Costa[1], M. Santos do Carmo[1,2], C. Regina Aragão Vieira Monteiro[1], E.P. Moraes Lopes[1], F. Carolina Morais Maia[1], L.X. de Brito Rodrigues[1], C. Cunha Rocha[1], M.R. Quaresma Bomfim[1]
[1]Ceuma University, Centro de Ciências da Saúde, São Luís, Brazil
[2]Federal University of Maranhão, Centro de Ciências Biológicas e da Saúde, São Luís, Brazil

Backgrounds

The normal microbiota of the newborns feces is composed of different genera of microrganisms, including *Bifidobacterium* species that play an important role in human health by regulating the pH of the large intestine by release lactic and acetic acid. Futhermore, there is evidence that they inhibit the growth of potential pathogens and putrefactive bacteria.

Objectives

The goal of the study was to investigate the probiotic potential of *Bifidobacterium* species isolated from feces of newborns, as well as to evaluate the period of intestinal colonization in three different moments of breastfeeding, including colostrum, transition milk and mature milk.

Methods

The methodology included mucin adhesion assay, tolerance assays to the gastrointestinal tract (resistance to lysozyme, pH2 and 4, bile salts 0.5% and 1%), *in vitro* antagonism of bacterial isolates against enteropathogens, molecular identification of bacterial isolates, and quantitative analysis by Polymerase Chain Reaction in (qPCR) of *Bifidobacterium* present in newborn feces

Conclusions

BF31, BF46 and BF51 isolates were found to be able to withstand conditions simulating the gastrointestinal tract, including acid pH and high concentrations of bile salts. In addition, these bacteria had a mucin adhesion capacity ($p < 0.05$) and inhibited enteropathogens of clinical relevance, with a mean variation of inhibition halos between 13.5 (± 2) mm and 25.5 (± 0, 7) mm. The isolates were identified as belonging to the *B. breve* by sequencing the 16S subunit rDNA. Quantification of bacterial DNA by qPCR showed a high estimate of *Bifidobacterium* spp. in newborn feces collected in all phases of breastfeeding (colostrum, transition and mature). These results suggest that these microrganisms play an important role in balancing the microbiota of newborns and that they are potential candidates for probiotics that can be used to control intestinal infections.

SCREENING OF STRAINS ISOLATED FROM KOREAN TRADITIONAL FOOD AND EVALUATION ON BIOFUNCTIONAL EFFECTS OF GINSENG FERMENTED USING THESE STRAINS

S.J. Eom[1], H.S. Kim[1], J.E. Hwang[1], K.T. Kim[2], H.D. Paik[1]
[1]Konkuk university, Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea
[2]Konkuk university, Bio/Molecular Informatics Center, Seoul, Republic of Korea

Backgrounds

Panax ginseng Meyer is known as an Asian traditional herb that has diverse health benefits such as antiaging effects, immune regulation, prevention of cancer, and pain relief. A compound bioconverted by microorganisms (such as lactic acid bacteria) can have higher biofunctional activities and also has an advantage: it is nontoxic because it is isolated from food.

Objectives

The aims of this study were to screen lactic acid bacteria to find those suitable for ginseng fermentation and to evaluate the biofunctional effects of this fermented ginseng.

Methods

A total of 205 bacterial strains were isolated from Korean traditional foods including cabbage kimchi, doenjang, green onion kimchi, and gochujang and were used for screening. After the screening test for esculin hydrolysis and β-glucosidase activity, the selected strain was identified using 16S rRNA. A β-carotene assay, ex vivo NO assay, and MTT assay were conducted to evaluate beneficial effects of fermented ginseng extracts.

Conclusions

As a result, a strain isolated from cabbage kimchi showed the highest β-glucosidase activity (550 μM pNP/[min·mL]). Via analysis of 16S rRNA gene sequences, this isolate was identified as *Leuconostoc mesenteroides*. In β-carotene assays, fermented extracts showed 10% higher activity than did the nonfermented ones. In the case of MTT assays on HepG2 cells, cytotoxic activity of extracts fermented for 2 days (72%) was higher than that of nonfermented extracts (20%). Thus, ginseng extract fermented with lactic acid bacteria may serve as a nutraceutical agent for food industries.

NITRIC OXIDE SCAVENGING OF GINSENG MARC EXTRACT FERMENTED BY PEDIOCOCCUS ACIDILACTICI IN YOGURT

S.J. Eom[1], J.E. Hwang[1], H.S. Kim[1], K.T. Kim[2], H.D. Paik[1]
[1]Konkuk university, Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea
[2]Konkuk university, Bio/Molecular Informatics Center, Seoul, Republic of Korea

Backgrounds

Panax ginseng is major commercial ginseng in Asia. Although the demand for ginseng has been continuously increasing, lots of by-products of ginseng (marc) have been scrapped or used as animal feed resources. Previously, we have reported that a *P. ginseng* by-product fermented with lactic acid bacteria has an antioxidant activity judging by ferric reducing power and a β-carotene bleaching assay. *Pediococcus acidilactici* is known to include representative strains of fermented dairy products and can inhibit growth of pathogens and cancer cells.

Objectives

The purpose of this study was to evaluate microbial enzymatic activities of *Pediococcus acidilactici*, changes in ginseng flavonoids, and nitric oxide scavenging activities of fermented milk supplemented with ginseng marc extract.

Methods

Ginseng marc was extracted with ethanol and lyophilized. Enzymatic activity of the microorganisms was determined by means of the API kit and flavonoid contents were measured by an aluminum chloride assay. Kaempferol served as a standard. Fermented milk was made by adding 5 g skimmed milk, 0.1% pectin, 1% ginseng marc, and 10^7 CFU/mL *P. acidilactici* to 500 mL of milk. Nitric oxide scavenging effects were measured by sodium nitroprusside.

Conclusions

As a result, a β-glucuronidase-induced carcinogenic substance was not detected in the *P. acidilactici*. After fermentation, flavonoid contents of the ginseng marc increased to 10.5 mg kaempferol per gram of solids. The viable cell count of fermented milk was 10^8 CFU/mL, and NO synthesis inhibition rate was 28.3% (control: 6.4%). According to these data, ginseng marc may be used in fermented food processing as a high-value functional material.

THE ASSOCIATION OF SALMONELLA SHEDDING AND COLONIZATION WITH SINGLE NUCLEOTIDE VARIANTS IN THE PORCINE INNATE IMMUNE SYSTEM GENES

V. Farzan[1], M. Ainslie[2], R. Friendship[3], M. Jafarikia[4], C.F.M. de Lange[5], B. Lillie[2]
[1]University of Guelph, Population Medicine and Pathobiology, Guelph, Canada
[2]University of Guelph, Pathobiology, Guelph, Canada
[3]University of Guelph, Population Medicine, Guelph, Canada
[4]University of Guelph, Animal Biosceonces, Guelph, Canada
[5]University of Guelph, Animal Biosciences, Guelph, Canada

Backgrounds

Salmonella is commonly found on pig farms posing a food safety threat to humans due to direct contact with infected pigs, through consumption of contaminated pork, or via transmission to ground water and produce if the pig manure is used as land fertilizer. Genetic selection for resistance against *Salmonella* carrier-state can be considered as effective method to control *Salmonella* in pigs.

Objectives

The objectives of this study was to investigate the associations between single nucleotide variants (SNVs) in the porcine innate immune system genes and *Salmonella* shedding/colonization.

Methods

Fecal samples collected from 809 pigs 4 to 5 times from birth up to marketing, and tissue samples obtained at slaughter were cultured for *Salmonella*. DNA extracted from tissue samples were analyzed for SNVs in the several genes related to innate immune response. A multilevel mixed-effects logistic regression modelling method was used to analyze association between SNVs and *Salmonella* shedding and colonization.

Conclusions

Overall, 35 and 23% of pigs were tested positive on farm and at slaughter, respectively. SNVs analysis showed an association of on-farm *Salmonella* shedding with the mannan-binding lectin (MBL) 1-A (MBL1-A) variant (C/T), found in 18% of the study population (P= 0.02). In addition, the A variant allele of the nucleotide binding oligomerization domain containing 1 (NOD1-A), found in 63% of the study population, was associated with *Salmonella* colonization (P = 0.04). These findings indicate that *Salmonella* in pigs is controlled by genetic elements and can be used to breed the pigs that are resistance against *Salmonella* shedding and colonization.

LACTOBACILLUS PLANTARUM B391 BACTERIOCIN EX-SITU STUDIES USING FRESH CHEESE AND PORK MEAT

D. Loureiro[1], J. Santos[1], V. Monteiro[1], C. Ramos[1], P. Fernandes[1]
[1]Instituto Politécnico de Viana do Castelo, Escola Superior de Tecnologia e Gestão, Viana do Castelo, Portugal

Backgrounds

Naturally occurring molecules able to inhibit the growth of food pathogens, as bacteriocins, are of great interest to the food industry due to their potential role in food safety.

Objectives

A bacteriocin produced by *Lactobacillus plantarum* B391, has been characterized and its use has been tested for the prevention of *Listeria monocytogenes* growth in cheese and pork meat to promote food safety in particular of products where *Listeria monocytogenes* is able to grow.

Methods

The effect on the reduction of an initial load of *Listeria monocytogenes* spiked on the food materials tested was determined by plating on ALOA agar. Bacteriocin B391 activity was determined using the spot-on-lawn method and successive dilutions.

Conclusions

The bacteriocin B391, a small peptide of 6KDa, showed to be very stable in a range of pH between 3.95 and 8.09. Its thermal stability is very high but pH dependent, being thermolabile at alkaline pH. In the present work, the activity of the purified bacteriocin was tested in fresh cheese and also in pork meat. In fresh cheese, when using an initial inoculum (10^5 CFU/ml) of *Listeria monocytogenes* in the presence of bacteriocin B391, more than 1 log of reduction of the initial population was obtained in a period of 2 months at 4ºC. The bacteriocin B391 was also used to obtain a coated plastic packaging film (PA/EVOH/PE). This film was tested in pork previously contaminated with *Listeria monocytogenes*, and it was possible to observe a reduction of 1 log after 24 h at 4ºC

YEASTS FOUND IN BRINES USED IN THE SALTING STAGE OF MANCHEGO CHEESE

M. Fernández González[1], *R. Díaz Ceca*[1], *M. Arévalo Villena*[1]
[1]*University of Castilla La Mancha, Food Science, Ciudad Real, Spain*

Backgrounds

The salting stage during cheese processing is very important because regulates and selects the microbial populations and brine is a source that provides a great variety of yeasts to cheeses, although their population must be controlled in order to not cause problems in later stages.

Objectives

Identify the different yeast species that can be found in two types of "Manchego" type cheese brines made from both raw or pasteurized milk.

Methods

Serial dilutions of samples were seeded onto YPD (Yeast peptone dextrose) plates supplemented with diphenyl (150mg/L) and cloramphenicol (100mg/L) and incubated at 25ºC for three days. Yeast colonies were isolated from plates containing between 30 and 300 colonies and purified by streaking onto YPD. With the purpose of identifying the isolates to specie level, PCR (ITS-5.8 S rDNA)-RFLP was used and then one isolated of each molecular profile obtained was sequencied by using the domains D1/D2 and ITS region when necessary.

Conclusions

The microbial count was 2100 UFC/mL on the pasteurized cheese brines and 2900 UFC/mL on raw milk cheese. A total of 30 yeast colonies were isolated and 11 different species were identified. In both types of brines were isolated mainly *Debaryomyces hansenii (30%)* followed by *Candida pararugosa (20%), Pichia cactophila (10%) and Yarrowia lipolitica (6,7%).* Up to five different species were isolated exclusively in the brine of raw milk cheeses such as *Rhodotorula diobovata*, *R. mucilaginosa, Sporisorium cruentum, Filobasidium Uniguttulatum* and *C. zeylanoides*, and only two species were isolated in brines from pasteurized milk cheeses: *Kluyveromyces marxianus* and *C. atlantica*.

ANTIMICROBIAL ACTIVITY OF SEVERAL YEAST SPECIES ISOLATED FROM FOOD AGAINST BACTERIAL PATHOGENS

M. Fernández González[1], *H.M. Gómez Gaona*[2], *A.I. Briones Pérez*[1]
[1]*University of Castilla La Mancha, Food Science, Ciudad Real, Spain*
[2]*University of Santander UDES, Industrial Microbiology, Bucaramanga, Colombia*

Backgrounds

In response to the increasing consumers demand for so-called minimal processing food with least amounts of chemical preservatives, it has begun to promote alternative methods of food preservation, such as the use of natural antimicrobials from microorganisms mainly lactic acid bacteria, but there are few studies of yeast antimicrobial activity against pathogenic bacteria in food.

Objectives

this work aims to study growth inhibition of five food pathogenic bacteria (*Salmonella enteritidis, Escherichia coli, Staphylococcus aureus, Listeria monocytogenes* and *Clostridium perfringens*) by using 208 yeast strains from 18 different genera and more than 50 species, isolated from several food ecosystems and conserved at the University of Castilla La-Mancha yeast collection .

Methods

YPD (Yeast peptone dextrose) plates were inoculated by a sterile swab using a suspension of the pathogenic bacteria from 18 to 24 hours incubation adjusted to 1.5 x 10^6 bacteria/mL, and then 2.5 µL of yeast preculture standardized to 10^8 cells/mL was added to the plate. Plates were incubated at 30 ° C for 48 hours and finally, the inhibition halo was observed. For yeasts that showed antimicrobial activity against some pathogen, tests were performed at different pH (4.5, 5.5 and 6.5) and temperatures (20, 30, 37ºC).

Conclusions

90 yeast strains showed antimicrobial activity in varying degrees against any pathogens tested, being *S.aureus* and *C. perfringens*, more sensitive to yeasts action, Only *Metschnikowia pulcherrima, Kluyveromyces thermotolerans, Pichia galeiformes* and *P.caribbica* have inhibitory activity against the five pathogens. Further research on the potential of these strains as biological control agents is needed.

HELICOBACTER PYLORI GROWTH/NO GROWTH PREDICTIVE MODEL IN REFERENCE MEDIA AND LETTUCE

M.C. Pina-Pérez[1], A. González[1], Y. Moreno[2], M.A. Ferrús[1]
[1]Universitat Politècnica de València, Biotecnología, Valencia, Spain
[2]Universitat Politècnica de València, Instituto de Ingeniería del Agua y Medio Ambiente IIAMA, Valencia, Spain

Backgrounds

Helicobacter pylori is one of the most widespread pathogens worldwide, causative agent of upper digestive tract diseases. It has been identified in raw and minimally processed foods. However, its isolation and quantification is really complex due to its capability to become into viable but non-culturable forms (VBNC), maintaining the infective potential. Predictive models are valuable mathematical tools to determine in which measure this microorganism could represent a risk, contributing to implement future reliable exposure assessment procedures.

Objectives

This work aims to fit by the first time the *H. pylori* growth/no growth kinetics in reference growth liquid broth and lettuce, under isothermal controlled conditions (37 ºC), by means the modified Gompertz equation.

Methods

Sterilized Brucella Broth supplemented with 5% (v/v) fetal bovine serum and filter sterilized lettuce extracts were inoculated with *H. pylori* 11638 NCTC to a final concentration of 1 x 10^3 CFU/mL, and incubated under microaerobic conditions. Culture absorbance was measured at 600 nm at regular intervals during 7 days. The viability of the culture was determined by plating in agar Dent at each sampling time.

Conclusions

Modified Gompertz equation accurately fitted the *H. pylori* growth in reference media (R^2 = 0.988; *RMSE* = 0.080). No significant growth was observed in lettuce, possibly due to variations of pH, nutrient availability, or additional components present in leafy extracts. In spite of this, the microorganism remained viable up to 5 days in lettuce.

ALGERIAN EXTRA VIRGIN OLIVE OIL: ANTIBACTERIAL EFFECT

L. Firdousse[1], A. Tamendjari[2], N. Iaccarino[3], P. Rovellini[4], A. Randazzo[3]
[1]A. Mira University, Microbiology, Bejaia, Algeria
[2]A. Mira University, Biochemestry, Bejaia, Algeria
[3]University of Naples "Federico II", Pharmacy, Naples, Italy
[4]INNOVHUB-SSI- Via Giuseppe Colombo 79- 20133 Milano- Italy, INNOVHUB-SSI-, Milano, Italy

Backgrounds

Olive oil has a peculiar fatty acid composition and also contains several micronutrients and a variety of minor components responsible for its particular nutritional characteristics.

Objectives

Evaluation of antibacterial activity of different varieties of Algerian Extra virgin olive and their phenolic extracts

Methods

For antibacterial activity assay five extra virgin olive oils came from different Algerian varieties are used. The bacterial strains target three Gram negative (*Escherichia coli*, *Vibiro cholerea and Selmonella typhi*) and three Gram positive (*Bacillus subtilis*, *Staphylococcus aureus méthiciline résistant and Staphylococcus aureus*) with an initial inoculum 10^6 CFU/mL. The bactericidal activity assay was based on the method reported by Friedman et al 2003. To identify and quantify the phenolic compounds from various olive oils we using a reverse-phase high-performance liquid chromatography. Evaluation antibacterial activity for phenolic compound extracts is performed against same strains

Conclusions

Results revealed that the olive oils had a strong bactericidal action against a broad spectrum of microorganisms. Samples showed bactericidal activity, all Microorganisms target with an initial inoculum 10^6 CFU/mL did not survive after 1h of contact with olive oils. The analysis of individual phenolic compounds by HPLC reveals a similar qualitative composition which differs quantitatively depend the varieties oleuropein and ligstrosid derivatives were the phenolic compounds that statistically correlated with bacterial survival. These findings were confirmed by testing phenolic extracts of olive varieties against same bacterial.

These results indicate that not all oils classified as "olive oil" had similar bactericidal effects and that this bioactivity depended on their content of particular phenolic compounds.

PHAGE BIOCONTROL OF SALMONELLA IN VITRO AND ON SPROUTING ALFALFA SEEDS

K. Fong[1], *S. Wang*[1]
[1]*University of British Columbia, Food- Nutrition & Health, Vancouver, Canada*

Backgrounds

Emerging *Salmonella* strains exhibiting antibiotic resistance represent a major challenge in food safety. Lytic bacteriophages were proposed as antimicrobials for mitigation of *Salmonella.*

Objectives

Specific objectives of our study were: (i) to investigate lysis profiles of bacteriophages isolated from British Columbia, Canada; (ii) to characterize four promising bacteriophage isolates on their morphological and genetic determinants; and (iii) to investigate their ability to inhibit *Salmonella* Enteritidis *in vitro.*

Methods

Salmonella phages (n=60) were isolated from irrigation water and sediment samples in BC. Host ranges were determined by spot-assay, using 20 outbreak serotypes, eight of which exhibited resistance to one or more antibiotics. Four broad-spectrum phages, SI1, SS1, SF1 and SS4, were further characterized by determination of genetic material (i.e., DNA or RNA), burst size and latent periods. Transmission electron microscopy (TEM) was performed for morphological classification. Finally, their efficacy to control *S.* Enteritidis, a serotype causing highest proportion of salmonellosis worldwide, was analyzed by conducting an *in vitro* spectrophotometric lysis assay.

Conclusions

The four phages lysed *S.* Enteritidis and seven of eight antibiotic-resistant strains. Burst sizes ranged from 20-83 phages/cell with short latent periods of 25-30 minutes. Nuclease digestion indicated a genome composed of DNA and TEM revealed phages belonging to *Siphoviridae* (i.e., non-contractile tails and ~200 nm length). Lastly, an *in vitro* lysis assay showed inhibition of *Salmonella* Enteritidis at a multiplicity of infection=100 over a 36-hour period.

These findings showed the promise of these phages in eliminating *Salmonella in vitro.* Future research should evaluate their lysing ability using a food model.

PRODUCTION OPTIMIZATION AND CHARACTERIZATION OF ANTIFUNGAL COMPOUNDS FROM INDIGENOUS LACTOCOCCUS LACTIS SUBSP. CREMORIS PB6

M. Gajbhiye[1]
[1]*Tuljaram Chaturchand College, Microbiology, Baramati, India*

Backgrounds

Lactic acid bacteria are known for their use in biopreservation due to the ability of the production of several antimicrobial compounds.

Objectives

The major objective of this investigation was purification and characterization of antifungal compounds from an indigenous strain of *Lactococcus lactis* subsp. *cremoris* PB6.

Methods

Production optimization was done on the basis of pH, temperature and, static and stationary conditions.
Effect of pH, temperature and proteases on the antifungal activity of culture supernatant was determined. The antifungal compounds were concentrated by freeze drying and ultrafiltration followed by extraction with ethyl acetate. Antifungal compounds were isolated by silica gel column chromatography and further analysis was carried out by GC-MS.

Conclusions

Maximum antifungal activity was recorded at pH 5.5 and 6.5, and at temperature 30^{o}C on MRS agar and under stationary conditions. The activity of culture supernatant was pH dependent and resistant to the action of proteases. The activity was significantly reduced (P<0.05) with increase in temperature from 50 to 121^{o}C. Maximum antifungal activity was observed in the culture filtrates of 1 KDa membrane indicating their low molecular weight. Ethyl acetate extract gave the highest recovery of the antifungal compounds as the solvent extract from the ultrafiltrate showed strong antifungal activity. Two active fractions of antifungal compounds were obtained following silica gel column chromatography. GC-MS analysis revealed the presence of tetradecanoic acid and cyclo-(Leu-Pro). This is the first report of antifungal cyclo-(Leu-Pro) and tetradecanoic acid from *L. lactis* subsp. *cremoris*.

EFFECTS OF EXPOSURE TO BIOCIDES ON SUSCEPTIBILITY TO ESSENTIAL OILS AND CHEMICAL PRESERVATIVES IN BACTERIA FROM ORGANIC FOODS

A. Galvez[1], R. Gadea[1], G. Nicolás[1], R. Pérez Pulido[1], O. Elena[1]
[1]University of Jaén, Ciencias de la Salud, Jaén, Spain

Backgrounds

In recent decades, reduced susceptibility of isolates to commonly-used biocides among important pathogenic bacteria genera has been observed, particularly in healthcare settings. This was often seen in association with an elevated frequency of antimicrobial resistances. The aim of this study was to determine the tolerance to essential oils and chemical preservatives in biocide-adapted bacterial isolates from organic foods.

Objectives

To determine the sensitivity of biocide-adapted bacterial strains to essential oils and chemical preservatives

Methods

A collection of 38 biocide-adapted strains with significant increases in their tolerance to biocides after step-wise exposure to these compounds were screened for sensitivity to essential oils and chemical preservatives.

Conclusions

Strains grown in presence of sublethal concentrations of quaternary ammonium compounds (benzalkonium chloride, hexadecylpyridinium chloride or cetrimide) showed a generalized increase in the sensitivity to preservatives. Similar results were found among hexachlorophene- or chlorhexidine-adapted strains. Moreover, tolerance to hexadecylpyridinium chloride showed a very strong positive correlation with 4-hydroxybenzoic acid, thyme oil and sodium nitrite increased susceptibility, as well as a strong correlation with clove oil, potassium sorbate and potassium nitrate increased sensitivities. On the contrary, an increase in the tolerance to preservatives among triclosan-adapted strains was detected.

Results from this study suggest that exposure of bacteria from foods to biocides is not always associated with co-selection for other antimicrobial resistances, especially against essential oils or chemical preservatives usually handled in the food industry, so these compounds could be used in food environments with no subsequent influence on the antimicrobial resistance selection along the food chain.

EFFICACY OF PLASTIC FILMS ACTIVATED WITH NATURAL ANTIMICROBIALS AND HIGH PRESSURE TREATMENTS IN TWO MODEL FOOD SYSTEMS

A. Galvez[1], I. Ortega Blázquez[1], M.J. Grande Burgos[1], R. Pérez Pulido[1], A. Cobo[1], R. Lucas López[1]
[1]University of Jaén, Ciencias de la Salud, Jaén, Spain

Backgrounds

One of the alternatives to prevent the growth of pathogenic or altering microorganisms in foods is the use of films activated with antimicrobials, such as essential oils or bacteriocins, singly or in combination with high pressure hydrostatic treatments (HHP).

Objectives

To determine the efficacy of activated films in combination with HHP treatments on inactivation of foodborne pathogens.

Methods

Plastic films activated with different antimicrobials were tested against *Listeria innocua*. Then, fish fillets and fruit purees challenged with *L. innocua* were packaged in activated films and pressurized at 300 MPa. Viable counts of *Listeria* in the samples at 0, 3, 5, 7 and 10 days of incubation at 4 °C were determined.

Conclusions

Films with greater antimicrobial activity against *L. innocua* were those activated with carvacrol and thymol plus the enterococcal bacteriocin enterocin AS-48. A remarkable decrease in the counts was detected after 24h for the combination of thymol and bacteriocin. In fish samples, the most effective treatment was the combination of the activated film (thymol plus bacteriocin) with HHP treatments. In the fruit samples, no *Listeria* were detected from day 5, in none of samples treated. The results suggest that the combination of antimicrobials either alone or with HHP treatments would be of great interest for increasing bactericidal activity, reducing the amount of antimicrobials and minimizing the impact of thymol on the food organoleptic properties.

HIGH PREVALENCE OF MCR-1 IN ESCHERICHIA COLI ISOLATES FROM DIARRHOEIC PIGLETS IN SPAIN, ASSOCIATION WITH ST10 AND ST131 CLONES

V. García Menéndez[1], I. García Meniño[1], S.C. Flament-Simon[1], M.P. Alonso García[2], J.E. Blanco Álvarez[1], J. Blanco Álvarez[1]
[1]Universidad de Santiago de Compostela, Microbioloxia e Parasitoloxia, Lugo, Spain
[2]Hospital Universitario Lucus Augusti, Microbiology, Lugo, Spain

Backgrounds

Antimicrobial resistance is one of the most important threats in food-production animals since it can lead to spread of resistant bacteria to humans. The emergence of colistin resistance, an antibiotic used in pig production to prevent infections those mainly produced by *E. coli*, and particularly the current finding of plasmid encoded *mcr*-1 colistin resistance gene, has aggravated this worldwide problem.

Objectives

This study focuses on the detection of *mcr-1* gene in *E. coli* isolates from diarrhoeic piglets recovered in Spain during the years 2006-2016, and on the molecular typing of positive *mcr-1* isolates.

Methods

A total of 536 isolates were examined by PCR for the presence of *mcr-1*, obtaining 140 (26,1%) positives isolates of which 82 were further characterized.

All isolates, except one, showed colistin MIC of ≥4 mg/ml and by serotyping it was detected high diversity of O:H serotypes (35), being O157:HNM, O25b:H4 and O141:H4 the most commons. ETEC (37), STEC (4), ETEC/STEC (5) and aEPEC (23) pathotypes were identified by detection of LT, STa, STb, Stx1, Stx2, Stx2e toxins and the *bfp*A gene.

According to phylogenetic grouping, isolates were distributed in phylogroups A (50), B1 (16), B2 (7) and E (9). Different clonotypes (25) and ST (20) were detected by sequencing *fumC-fimH* alleles and MLST respectively, identifying CH11-24 and ST10 as the commonest followed by CH4-24, ST29 and CH40-22, ST131.

Conclusions

Our results highlight the high prevalence of colistin resistance in diarrogenic isolates from swine in Spain and the important association with ST10 as well as with the successful ST131 clones.

MYCOTOXIN-PRODUCING FUNGI IN DIFFERENT STAGES OF MAIZE PRODUCTION CYCLE

M. García-Díaz[1], B. Patiño[1], C. Vázquez[1], M.T. González-Jaen[2], J. Gil-Serna[1]
[1]Universidad Complutense de Madrid, Facultad de Biologia- Microbiología III, Madrid, Spain
[2]Universidad Complutense de Madrid, Facultad de Biologia- Genética, Madrid, Spain

Backgrounds

Maize (*Zea mays* L.) is one of the main cereals as a source of food, feed and processed products for industry. Contamination by mycotoxins represents a significant risk to human and animal health.

Objectives

The objective was to evaluate the presence of mycotoxin producing fungi in order to detect the moment when contamination occur during maize production cycle.

Methods

Maize samples were evaluated in two different plots located in Madrid (Spain). Three different stages were sampled: Anthesis (R0, 25 male flowers and 25 female flowers), kernel dent (R5, 25 cob) and physiological maturity (R6, 3 kg of grain). DNA extraction was performed after 24 h of incubation at 28 ºC in Sabouraud-cloramphenicol broth and species-specific PCR protocols were carried out to detect the most important mycotoxigenic *Aspergillus* and *Fusarium* species. The results obtained were confirmed using morphological identification.

Conclusions

The aflatoxin-producing *Aspergillus flavus* was detected in all staged sampled indicating that contamination occur in the earlier period of the production cycle. In R5 stage, many new species were detected including fumonisin (*Fusarium proliferatum* and *F. verticillioides*) and trichothecene producers (*F. sporotrichioides*) as well as ochratoxin A producing species (*A. tubingensis*). All these species were also detected in the last step evaluated together with *A. welwitschiae*, potential ochratoxin A producer. The knowledge of the moment when contamination occurs is crucial to stablish a correct treatment schedule to prevent mycotoxin entering the food chain.

SYNERGISTIC EFFECT OF A HEAT TREATMENT IN PRESENCE OF INDIVIDUAL COMPOUNDS OF ESSENTIAL OILS IN THE INACTIVATION OF HYPER-RESISTANT STRAINS OF ESCHERICHIA COLI

E. Geens[1], D. Berdejo[2], R. Pagán[2], E. Gayán[1], A. Aertsen[1], C. Michiels[1], D. Garcia-Gonzalo[2]
[1]KU Leuven- Laboratory of Food Microbiology,
Department of Microbial and Molecular Systems M2S- Faculty of Bioscience Engineering, Leuven, Belgium
[2]Instituto Agroalimentario de Aragón IA2, Universidad de Zaragoza-CITA, Zaragoza, Spain

Backgrounds

Heat treatments in presence of individual compounds (ICs) of essential oils have shown a synergistic lethal effect in food preservation treatments. However, it is unknown whether the presence of stress-resistant variants in bacterial populations might jeopardize the efficacy of food preservation combined treatments.

Objectives

The objective of this investigation was the evaluation of the lethal effect of a combined process (heat + ICs) against genetic stress-resistant variants of *Escherichia coli* MG1655.

Methods

The strains used were wild-type (WT) and its variants selected for IC (CAR, CIT, LIM), heat (DVL1) or HHP resistance (DVL10 and LMM1020). These strains also developed cross-resistance to heat.

Suspensions were independently treated at 53ºC in presence or absence of 200 ppm of ICs: carvacrol, citral or cinnamaldehyde (MES buffer pH 5.3; $3 \cdot 10^7$ CFU/mL). Survivors were plated in TSA and incubated at 37ºC for 24h.

Conclusions

Individual application for 10 min of heat or ICs treatments caused less than 1 $\log_{10}$ cycle reduction of populations of any strain. Simultaneous application of heat in presence of each IC showed a synergistic lethal effect against WT, causing the inactivation of more than 5 $\log_{10}$ cycles of bacterial population. The synergistic effect of these combined processes against stress-resistant variants was variable (1-4 $\log_{10}$ cycles), but remarkably a heat treatment in presence of carvacrol inactivated more than 5 $\log_{10}$ cycles of the initial population of every strain. This study shows the synergistic lethal effect of a combination of heat and carvacrol against not only WT strain, but also against genetic stress-resistant strains.

INCIDENCE OF LISTERIA MONOCYTOGENES IN RETAILED CHEESES AND CHARACTERIZATION OF PERSISTENT STRAINS IN TWO CZECH PRODUCERS

T. Gelbíčová[1], Z. Tomáštíková[1], A. Pietzka[2], W. Ruppitsch[3], R. Karpíšková[1]
[1]Veterinary Research Institute, Department of Bacteriology, Brno, Czech Republic
[2]Austrian Agency for Health and Food Safety, National Reference Laboratory for Listeria, Graz, Austria
[3]Austrian Agency for Health and Food Safety, Institute of Medical Microbiology and Hygiene, Vienna, Austria

Backgrounds

The ability of *L. monocytogenes* to persist in different environments is the main factor contributing to food contamination. Ripened cheeses are risk commodity regarding *L. monocytogenes* contamination and their consumption has been implicated with human listeriosis outbreaks.

Objectives

The study was focused on the finding of incidence and characteristics of *L. monocytogenes* in retailed cheeses with respect to their safety for human.

Methods

The detection and enumeration of *L. monocytogenes* in 387 samples of ripened and steamed cheeses was carried out at the time of purchase and at the end of the shelf-life. The obtained isolates were characterized by serotyping, multilocus sequence typing (MLST), macrorestriction analysis and sequencing of the *inlA* and *inlB*. The selected persistent strains were analysed using core genome (cg) MLST.

Conclusions

L. monocytogenes was detected in 5.2% originally packaged cheeses from different producers and none sample exceeded the limit of 100 CFU/g. The possibility of *L. monocytogenes* isolates to cross protective host barriers was verified by sequencing of *inlA* and *inlB*. Persistent *L. monocytogenes* strains were found in blue-veined cheeses (serotype 1/2a, pulsotype 719) and smear-ripened cheeses (1/2a/713) from two producers. Persistent strains had the same sequence type ST204 and showed very similar pulsotypes in contrast with non-persistent strains. The clonal similarity of persistent strains was confirmed also on the basis of cgMLST. The persistent strains may carry some specific characteristics which enable their adaptation for surviving in the cheese-processing.

EFFECT OF NATIVE FOOD MICROFLORA ON THE DETECTION OF PATHOGENIC YERSINIA ENTEROCOLITICA AND YERSINIA PSEUDOTUBERCULOSIS

E.T. Gensberger[1], L. Antonielli[1], A. Sessitsch[1], T. Kostic[1]
[1]AIT Austrian Institute of Technology GmbH, Center for Health & Bioresources, Tulln, Austria

Backgrounds

Yersiniosis, mainly caused by *Yersinia enterocolitica* and *Yersinia pseudotuberculosis*, was ranked as the third most commonly reported foodborne disease in Europe since 2008-2015 [EFSA 2016, 14(12):4634]. However, the reported numbers are almost certainly an underestimation, due to the fact that the recovery using the standardized method (ISO 10273:2003) has been reported as suboptimal. Accordingly an action has been called for at the EU level [EFSA 2007, 595] to improve current methods for detection of pathogenic *Yersinia* spp. in food.

Objectives

Our study was based on the hypothesis that native food microflora plays a key role in the enrichment and thus detection efficiency of pathogenic *Yersinia* spp. from food, and that better understanding of the microbial ecology of the enrichment is essential for its adaptation and improvement.

Methods

Diverse food samples including meat and meat products, dairy products and fresh produce that were inoculated with high and low concentration of *Y. enterocolitica* (biovar 1A, 2, 4) and *Y. pseudotuberculosis* were investigated. Enrichment was performed using both selective (ISO 10273:2003) and non-selective broths and detection was assessed using selective agars. In total 3078 samples were analyzed, and the determined detection efficiency for *Yersinia* spp. was between 0% and 100%. Interestingly, the performance of enrichment method differed for the food sample analyzed, indirectly confirming our hypothesis about the influence of native microflora. In order to better understand the microbial community composition and its changes in relation to enrichment procedure, a comprehensive sequencing analysis using Illumina 16S rRNA (V3-V4 region) amplicon sequencing was performed. Microbial communities were analyzed in 846 selected samples that showed high and low recovery of *Yersinia* species. As a reference non-spiked enriched and native food samples were included.

Conclusions

The observed differences in the microbial community composition should allow identification of inhibitory microflora providing valuable basis for the development of more efficient detection methods.

ESTABLISHING THE ANTIBACTERIAL EFFECT AND KINETICS OF ACTION OF RANDOM PEPTIDE MIXTURES AGAINST METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS

V. Ghate[1], T. Stern[1], R. De Leo[2], Z. Hayouka[1]
[1]The Hebrew University of Jerusalem - The Faculty of Agriculture, Institute of Biochemistry- Food Science and Nutrition, Rehovot, Israel
[2]University of Modena and Reggio Emilia, Life Sciences, Modena, Italy

Backgrounds

Antibiotic resistance is a growing problem in food and agriculture. To combat antibiotic resistance, interventions need to be designed cleverly to outsmart microbes. One such intervention is the use of random peptide mixtures. Random peptide mixtures are mixtures of two or more peptides that may be random in their sequence but are highly controlled in their stereochemistry.

Objectives

1. To determine the antibacterial effect of five different random peptide mixtures against methicillin-resistant *Staphylococcus aureus* (MRSA).
2. To establish the kinetics of action of these mixtures.

Methods

Five 20-mer mixtures – L-leucine-L-lysine (LK), L-phenylalanine-L-lysine (FK), L-phenylalanine-D-lysine (F^DK), L-ornithine-L-leucine (OL) and L-tryptophan-L-lysine (WK) were synthesized using Fmoc-assisted solid phase peptide synthesis. A culture of MRSA was incubated with these mixtures at 37 °C for 24 h, at concentrations ranging from 1.563 to 200 µg/mL. The fate of the bacterial cells was monitored by tracking the absorbance of the culture at 595 nm. Subsequently, the mixtures were ranked on the basis of their minimum inhibitory concentration (MIC) and the minimum bactericidal concentration (MBC) values. To elucidate the kinetics of the antibacterial effect, the Gompertz model was fitted to the growth curves.

Conclusions

OL was the most potent random peptide mixture, with bactericidal effects observed 50 µg/mL onwards and a bacteriostatic action taking place at lower concentrations. The next most effective mixture was LK, followed by FK, F^DK and WK. Going forward, this study will elucidate the mechanism of action of these mixtures by shedding light on their effect on critical cellular targets.

ASPERGILLUS NIGER AGGREGATE SPECIES ON SPANISH FOOD MATRICES AND THEIR PUTATIVE ABILITY TO PRODUCE MYCOTOXINS

J. Gil Serna[1], M. García-Díaz[1], C. Vazquez[1], M.T. Gonzalez-Jaen[2], B. Patiño[1]
[1]Complutense University, Microbiology III, Madrid, Spain
[2]Complutense University, Genetica, Madrid, Spain

Backgrounds

Aspergillus niger aggregate contains at least 11 species which are morphologically indistinguishable but vary widely in their ability to produce mycotoxins.

Objectives

The objective was to determine the most important *A. niger* aggregate species in Spain as well as their potential mycotoxin-producing ability.

Methods

More than 180 strains included in *A. niger* aggregate were isolated from several sources including cereals, grapes and pulses among others. Identification of the most common species (*A. tubingensis*, *A. niger* and *A. welwitschiae*) were performed using species-specific PCR protocols. When no positive amplification was obtained, a partial region of the calmodulin gene was sequenced. Moreover, the putative ability of the isolates to produce ochratoxin A (OTA) and fumonisin B2 (FB2) was checked testing the presence of the genes involved in their biosynthesis by PCR.

Conclusions

72% of the isolates obtained were identified as *A. tubingensis*, followed by *A. niger* (16%) and *A. welwitschiae* (8%). Only 3 isolates were sequenced and identified as *A. brasiliensis*. Presence of the complete specific OTA cluster was only found in two isolates (one *A. niger* and one *A. welwitschiae*) demonstrating that OTA production is not widespread in *A. niger* aggregate. All *A. niger* and 10% of *A. welwitschiae* isolates presented the complete cluster of genes involved in FB2 biosynthesis. The rest of *A. welwitschiae* isolates only contained *fum1*, *fum19* and *fum15*. Therefore, the presence of *A. niger* aggregate species in Spanish food product does not seem to suppose a real risk of OTA contamination and only *A. niger* appears to be related to FB2 contamination.

OCCURRENCE OF FUSARIUM TOXINS IN OATS MARKETED IN SPAIN

J.V. Gómez[1], A. Tarazona[1], J.V. Gimeno-Adelantado[2], M.A. García-Esparza[3], R. Mateo-Castro[2], M. Jiménez[1], E.M. Mateo[1]
[1]Universitat de Valencia, Microbiología y Ecología, Burjassot, Spain
[2]Universitat de Valencia, Química Analítica, Burjassot, Spain
[3]Universidad CEU-Cardenal Herrera, Farmacia, Moncada, Spain

Backgrounds

The health-beneficial properties of oats (dietetic properties, high beta-glucan content and anticarcinogenic effects) have led to an increase in consumption of oats and oat-based food products in the recent years. Contamination of this cereal with toxigenic *Fusarium* spp. is a global problem resulting in important economic losses. In addition, some *Fusarium* spp. produce mycotoxins, such as fumonisins (FUMs), zearalenone (ZEA) and trichothecenes, such as deoxynivalenol (DON), nivalenol (NIV), T-2 and HT-2 toxins. These fungal metabolites are usually related to esophageal cancer, oestrogenic activity or gastrointestinal problems, DNA and RNA fragmentation and protein synthesis inhibition in both humans and animals.

Objectives

The aim of this study was to determine the presence of FUMs (FB1 + FB2), ZEA, DON, NIV, and T-2/HT-2 toxins in oats marketed in Spain.

Methods

Mycotoxins were determined by optimized and validated analytical chromatographic methods.

Conclusions

These mycotoxins were detected in 11%, 10%, 14%, 7% and 19% of the oat samples, respectively, at levels below European Union limits in all cases. The obtained results were compared with the presence of possible toxigenic *Fusarium* spp. responsible for their biosynthesis. However, the co-occurrence of different toxins in some samples suggested that synergistic activity of these mycotoxins should be evaluated. The main *Fusarium* spp. detected were members of the *Sporotrichiella*, *Liseola*, and *Discolor* sections. Correlation was found between the presence of certain *Fusarium* species and mycotoxin contamination in the same sample. This is the first report on the occurrence of *Fusarium* toxins in oats in Spain.

EFFECT OF (SUB)LETHAL LEVELS OF FOOD-RELATED STRESSES (BIOCIDES AND PROCESSING TREATMENTS) ON THE EMERGENCE OF ANTIMICROBIAL RESISTANCE THROUGHOUT THE FOOD CHAIN

A. Alvarez-Molina[1], D. Fernández[1], C. Andrés[1], M. López[1], M. Prieto[1], A. Alvarez-Ordóñez[1]
[1]Universidad de León, Food Hygiene and Technology, León, Spain

Backgrounds

The latest report on Antimicrobial Resistance (AMR) by EFSA/ECDC shows a trend towards an increase in the detection of foodborne pathogens with multi-drug resistance (MDR) and the appearance of AMR to some antibiotics which are the last effective treatment for MDR infections.

Objectives

This study assessed the contribution of disinfection and food processing treatments to the generation of AMR. We aimed at isolating AMR mutants of *Salmonella spp, Listeria monocytogenes* and *Escherichia coli* after serial (sub)lethal treatments of Ultraviolet (UV) light, non-thermal atmospheric plasma (NTAP) and biocides (peracetic acid, benzalkonium chloride, sodium hypochlorite).

Methods

Five strains of *Salmonella* spp., three of *L. monocytogenes* and four of *E. coli* were grown overnight in BHI and exposed to repeated cycles (10 cycles) of treatment at various (sub)lethal intensities. After each cycle, survivors were recovered and grown in fresh broth to initiate a new treatment cycle, and an aliquot was stored under freezing. Frozen samples were grown overnight in BHI and spread plated on Mueller-Hinton agar plates supplemented with inhibitory concentrations (established for the wild-type strains) of ampicillin, cefotaxime, ciprofloxacin, erythromycin, gentamycin, streptomycin, tetracycline, colistin and vancomycin. Resistant variants were pheno-typically characterized in terms of their resistance against various clinically relevant antibiotics.

Conclusions

Our results confirm that disinfection practices and food processing technologies used in food industries may select for AMR microorganisms that pose a serious risk to the food chain. Whole Genome Sequencing of the most relevant strains will be carried out in the future to identify mutations responsible for the AMR phenotypes.

Food Microbiology - Part II

MONITORING TETRACYCLINE RESISTANCE IN CHEESE BY FUNCTIONAL METAGENOMICS

A.B. Florez Garcia[1], *L. Vazquez*[1], *B. Mayo*[1]
[1]*IPLA-CSIC, Departamento de Microbiología y Bioquímica, Villaviciosa-Asturias, Spain*

Backgrounds

Metagenomics techniques have been successfully applied for monitoring antibiotic resistance genes in environmental, animal, and human ecosystems. However, in spite of the food chain being claimed to be a key player in the spread of antibiotic resistances, metagenomics approaches have been scarcely used in foods.

Objectives

In this work, we report on the prevalence and evolution of tetracycline resistance (Tc^r) determinants in a blue-veined, raw milk cheese by functional metagenomics.

Methods

The same cheese batch was sampled at manufacturing (day 3) and ripening (day 60) stages. Dilutions were plated in the presence of tetracycline on non-selective and selective conditions for lactic bacteria. DNA from cultures in the counting plates was then isolated and used to construct four fosmid libraries. Clones were analysed by restriction enzyme digestion, PCR and sequencing.

Conclusions

Four different Tc^r genes were identified among 300 clones, *tet*(A), *tet*(L) *tet*(M), and *tet*(S). *tet*(A), *tet*(M), and *tet*(S) were detected in libraries at day 3 and *tet*(L) was the single gene identified in the two libraries at day 60, suggesting an evolution of the Tc^r gene types along with that of the microbial populations during ripening. Six representative clones were completely sequenced. All Tc^r genes characterized in this study resided on plasmids and/or were flanked by insertion sequences, mobilization- and conjugation-associated protein-encoding genes.

- Metagenomic techniques can be a valuable tool to evaluate the resistome of cheeses and other fermented dairy products.
- Raw-milk made cheeses should be considered as reservoirs of Tc^r genes with a high potential for horizontal transference.

ECOLOGICAL ANTIFUNGAL AGENTS AND OCHRATOXIN A PRODUCTION BY A. STEYNII AND A. TUBINGENSIS IN OAT GRAINS

A. Tarazona[1], J.V. Gómez[1], J.V. Gimeno-Adelantado[2], M.A. García-Esparza[3], R. Mateo-Castro[2], M. Jiménez[1], E.M. Mateo[1]
[1]Universitat de Valencia, Microbiología y Ecología, Burjassot, Spain
[2]Universitat de Valencia, Química Analítica, Burjassot, Spain
[3]Universidad CEU-Cardenal Herrera, Farmacia, Moncada, Spain

Backgrounds

Oats constitutes a nutritious and popular cereal with high beta-glucan content. Beta-glucans are prebiotics and new oat-based functional food products have been developed. However, cereals are the first source of ochratoxin A (OTA) in the diet and OTA is a potent nephrotoxic, teratogenic, immunosuppresive and carcinogenic compound. The most important ochratoxigenic *Aspergillus* spp in cereals are *A. steynii*, followed by *A. ochraceus* and *A. westerdijkiae* from section *Circumdati* and *A. tubingensis* followed by *A. niger* complex (especially *A. niger* and *A. welwitschiae*, which is considered a phylogenetic cryptic species contained in *A. niger*) from section *Nigri*. Application of chemical fungicides is the most widely used strategy to control fungal growth and OTA biosynthesis in cereal crops. The health risks associated with fungicide residues in foods are considered less relevant than the potential impacts of mycotoxins on public health.

Objectives

The aim of this study was to assess the activity of two ecological antifungal agents (copper oxychloride and sulfur) and a non-ecological fungicide (mancozeb) on the control of OTA biosynthesis by *A. steynii* and *A. tubingensis* in oat grains under different environmental conditions linked to climate, such as relative humidity and temperature.

Methods

OTA was determined by an optimized/validated method involving liquid chromatography with fluorescence detection.

Conclusions

Temperature, fungicide dose, and time significantly influenced ($P<0.05$) OTA accumulation in oats. Sub-inhibitory doses of antifungal agents can enhance OTA production. Mancozeb proved more effective that the other chemicals to prevent OTA production under similar conditions.

FEMS7-0884
Food Microbiology - Part II

PREVALENCE OF LISTERIA MONOCYTOGENES IN POULTRY DURING PROCESSING IN SLAUGHTERHOUSE AND IN POULTRY MEAT PRODUCTS

E. Gonzalez-Fandos[1], *I. Perez-Arnedo*[1]
[1]*University of La Rioja, Food Technology, Logroño, Spain*

Backgrounds

Meat and poultry products are often identified as the source of foodborne pathogens. Raw poultry is a well-recognized source of *L. monocytogenes*, and many surveys have confirmed the presence of this pathogen on fresh poultry. Some authors have associated cases of listeriosis with the consumption of undercooked chicken

Objectives

The pesent study was conducted to determine the prevalence of *Listeria monocytogenes* during slaughter and processing of poultry.

Methods

Broiler carcasses were examined at selected stages of slaughter: after defethering, after evisceration, after washing and after chilling. Also carcasses and fresh poultry legs, breast and wings were collected in the processing plant after cutting.

Conclusions

Listeria monocytogenes was not detected in any sample after defeathering. After eviscerati uon *L. monocyogenes*was detected in 13.3% of the carcasses examined. A higher percentage of carcasess were *L. monocytogenes* positive after washing (43.33%). After chilling, this pathogen was detected in 33.3% of carcasses. In processing plant, *L. monocytogenes* was detected in 22% of carcasses, 84% of legs, 88% of breasts and 100%, of wings .*L. monocytogenes* counts were below 2 log cfu/g in all the samples analyzed.

Higher prevalence of *L. monocytogenes* was observed in poultry meat products (legs, breasts and wings) than in carcasses. Since carcasses were *L. monocytogenes* negative at defeathering stage and percentage of carcasses contaminated with *Listeria* increase in the late stages of processing, it can be conclude that carcass were contaminated during slaughter and handling.

FEMS7-0900
Food Microbiology - Part II

EFFECTIVENESS OF IMMERSION TREATMENTS WITH LACTIC AND ACETIC ACIDS AND MODIFIED ATMOSPHERE PACKAGING AGAINST CAMPYLOBACTER JEJUNI IN POULTRY

E. Gonzalez-Fandos[1], *I. Perez-Arnedo*[1]
[1]*University of La Rioja, Food Technology, Logroño, Spain*

Backgrounds

Raw poultry is a well-recognized source of *Campylobacter jejuni.*

Objectives

The aim of this study was to evaluate the combined effect of a mixture of lactic and acetic acids and packaging in modified atmospheres on the growth of *Campylobacter jejuni* on poultry legs stored at 4ºC.

Methods

Fresh chicken legs were inoculated with *Campylobacter jejuni*. After the inoculation, the chicken legs were dipped into a mixture containing 1% lactic acid (v/v) and 1% acetic acid (v/v). Control legs were treated with distilled water. Inoculated samples were packaged under different gas mixtures: vacuum, 20%CO_2 / 80%N_2, 40%CO_2/ 60% N_2 or air.

Conclusions

Significant differences ($p<0.05$) in mesophiles and psychotrophs counts were found between the legs treated with a mixture of lactic and acetic acid and the control legs after treatment. The lowest mesophiles counts were observed in those samples treated and packaged in 40%CO_2/ 60% N_2. Legs washed with a mixture of 1% lactic acid and 1% acetic acid solution showed a significant ($p<0.05$) inhibitory effect on *Campylobacter jejuni* compared to control legs, being about 1.35 log units lower in the first ones than in control legs after treatment. No significant reduction on *Campylobacter jejuni* was observed in samples packaged under vacuum, 20%CO_2 / 80%N_2 or 40%CO_2/ 60% N_2 .

In conclusion, immersion of chicken legs in a mixture of 1% lactic acid and 1% acetic acid solution can reduce *Campylobacter jejuni* populations on fresh poultry. Atmospheres containing 20%CO_2 / 80%N_2 or 40%CO_2/ 60% N_2 are not able to reduce *Campylobacter jejuni*.

Food Microbiology - Part II

SULPHITE TOLERANCE REQUIRES PROPER AUTOPHAGIC FUNCTION IN SACCHAROMYCES CEREVISIAE

E. Valero[1], J. Tronchoni[2], R. Gonzalez[2], P. Morales[2]
[1]Universidad Pablo de Olavide, Dpto. Biología Molecular e Ingeniería Bioquímica, Sevilla, Spain
[2]ICVV CSIC-Universidad de La Rioja-Gobierno de La Rioja, Enología, Logroño, Spain

Backgrounds

Sulphur dioxide (often dosed as bisulphite salts) has had widespread use in winemaking for centuries. It is used at several stages of the process, and for several purposes, mainly as antioxidants and as antimicrobials, even before the onset of fermentation. Sulphites are also used as preservatives in many canned and processed foods. Its usefulness during wine fermentation depends on the relatively high tolerance to sulphites of industrial wine strains of the yeast *Saccharomyces cerevisiae*. Sulphite tolerance of these yeast strains is related to mutations that promote high level transcription of *SSU1*, the gene coding for a plasma membrane sulphite pump required for efficient sulphite efflux.

Objectives

This work was designed, in order to better understand sulphite cellular targets in yeast, as well as microbial sulphite resistance.

Methods

By competition of bar-coded Yeast Knockout (YKO) collections we have identified some of the cell functions that are more specifically required in order to survive sulphite insult.

Conclusions

Our results show increased sulphite sensitivity for most KO strains involving genes required for autophagy, so pointing to this process as a key one in the detoxification of sulphite, probably through recycling of damaged proteins. Conversely, some deletion yeast strains, that were impaired under no-stressed conditions, recovered some competitiveness in the presence of sulphite. These functions are probably specifically sensitive to sulphite, so that already defective strains do not suffer from an additional impairment in the presence of sulphite.

SALMONELLA FUNCTIONAL GENOTYPING: PREDICTING PHENOTYPIC TRAITS FROM WHOLE GENOME SEQUENCES

J. Goris[1], P. Scheldeman[1], H. Pouseele[1], K. De Bruyne[1]
[1]Applied Maths, N.V., Sint-Martens-Latem, Belgium

Backgrounds

Surveillance of food-borne illnesses such as salmonellosis has shifted from microbial genotyping to Whole Genome Sequencing (WGS) over the last couple of years. Not only does WGS enable high-resolution strain typing via e.g. whole genome MLST or SNP analysis, it also holds the potential to replace or complement conventional methods for antimicrobial susceptibility testing, virulence profiling and serotyping.

Objectives

We developed and validated a *Salmonella* genotyping plugin for the BioNumerics® software, resulting in a push-button application detecting antibiotics resistance genes, virulence genes and predicting *Salmonella* serotypes starting from WGS data.

Methods

The *Salmonella* genotyping plugin uses public databases for serotype, virulence and resistance prediction. Virulence and resistance prediction tools start from the assembled genomic sequences and use a BLAST-based approach to detect and identify the genes of interest. Serotypes are determined directly on the raw reads, using an implementation of SeqSero (Zhang et al., 2015 J. Clin. Microbiol. 53(5), 1685-1692) on the BioNumerics® calculation engine.

A large set of publically available WGS data from food-related *Salmonella enterica* isolates were analyzed with the *Salmonella* genotyping plugin and results were validated with traditional typing information.

Conclusions

The *Salmonella* functional genotyping plugin proofs to be an accurate predictive tool for *Salmonella* phenotypes, implemented/integrated on the BioNumerics® platform next to the read quality assessment, (de novo) assembly algorithms, and wgMLST and wgSNP tools This user friendly WGS workflow provides accurate pathogen identification, antimicrobial resistance profiling and virulence factor determination, possibly improving transmission tracking and biological risk assessment in food-borne *Salmonella* outbreaks.

Food Microbiology - Part II

LACTOBACILLUS REUTERI STRAINS FOR NATURALLY PREVENT CAMPYLOBACTER COLONIZATION IN CHICKEN

A. Greppi[1], P. Tetteh Asare[1], C. Schwab[1], C. Lacroix[1]
[1]Institute of Food- Nutrition and Health, Department of Health Sciences and Technology HEST, Zurich, Switzerland

Backgrounds

Campylobacter is a commensal of chickens infecting entire flocks at early age, and Campylobacteriosis is the most frequently reported food-borne illness in the EU. Reuterin is a antimicrobial system produced by *Lactobacillus reuteri* glycerol dehydratase activity from glycerol. In aqueous solution at physiological conditions, reuterin consists of 3-HPA, its hydrate and dimer, and acrolein, which was identified as the active antimicrobial component. *L. reuteri* forms natural biofilms in the crop.

Objectives

Here, we want to exploit reuterin formation of chicken isolates of *L. reuteri* to reduce *Campylobacter* contamination *in vivo*.

Methods

In a first step, *Lactobacillus* strains were isolated from crop and feces of chicken using modified MRS, species identity was confirmed using species specific 16S rRNA gene PCR and reuterin formation potential was detected using PCR targeting *pduC*. A total of 200 strains were isolated from 4 different farms in Switzerland, 26 of them were confirmed as *L.reuteri*, 14 were pduCDE positive. RepPCR was applied to identify clonal isolates. Reuterin production during incubation of *L. reuteri* and during growth in 500 mM glycerol solution and mMRS supplied with 100 mM was quantified by IC-PAD and HPLC. Inhibition activity of reuterin were tested on a large panel of *Campylobacter* spp. isolated from chicken and human infections. *L. reuteri* isolates were also tested for antibiotic resistance against tetracycline, erythromicyin and chloramphenicol.

Conclusions

In conclusion, a collection of characterized *L. reuteri* strains isolated from chicken was established. They represent a ground for application of *L. reuteri* produced reuterin to prevent/reduce colonization of enteropathogens in poultry.

Food Microbiology - Part II

BACTERIOPHAGE-MEDIATED ELIMINATION OF SALMONELLA FROM RAW MILK

B. Grygorcewicz[1], X. Stachurska[1], J. Laskowska[1], P. Nawrotek[1]
[1]West Pomeranian University of Technology- Szczecin- Faculty of Biotechnology and Animal Husbandry, Department of Immunology- Microbiology and Physiological Chemistry, Szczecin, Poland

Backgrounds

Salmonella enterica , especially serovars such as Enteritidis and Typhimurium, are major causes of global food-borne diseases. The transmission of *Salmonella* could also be linked with raw or filtered milk and products made from them. Bacteriophages could be applied as an effective, alternative agent for biocontrol of these pathogens.

Objectives

The aim of study was the evaluation of the lytic activity of bacteriophage sall_v2 against *Salmonella* Enteritidis and *Salmonella* Typhimurium and application of the phage as a biocontrol agent in the *in vitro* studies.

Methods

Bacteriophage was isolated from wastewater using *Salmonella enterica* ssp. *enterica* sv. Enteritidis ATCC 13076 as a host. The morphology, host range, pH and thermal stability as well as the adsorption rate and one step growth of the isolated phage was evaluated by plaque assay using the double agar layer method. *The lytic activity of bacteriophage in Lysogeny broth medium was assessed* by measurements of optical density (OD) at wavelength 600 nm. In-milk activity of bacteriophage was evaluated by culture methods.

Conclusions

This study indicates that isolated bacteriophage can effectively reduce the quantity of *Salmonella* in raw milk. Bacteriophages used as the biocontrol agent could reduce the risk of food-borne salmonelloses associated with milk and products made from the raw, filtered, and un-pasteurised milk, such as cheeses.

Food Microbiology - Part II

IDENTIFICATION OF ENTEROBACTERIACEAE BACTERIA IN FRESH FRUITS AND VEGETABLES AND THEIR RESISTANCE TO ANTIBIOTICS AND CHLORHEXIDINE.

N. Guizani[1], Z. Al-Kharousi[1], I. Al-Bulushi[1], A. Al-Saadi[2]
[1]Sultan Qaboos University, Food Science and Nutrition, Muscat, Oman
[2]Sultan Qaboos University, Crop Sciences, Muscat, Oman

Backgrounds

Many outbreaks due to consumption of fruits and vegetables are caused by bacteria belonging to Enterobacteriaceae which are considered among the most potent and prevalent pathogens that have acquired resistance to most antibiotics.

Objectives

Objectives

To identify isolated bacteria from fresh produce, screen them for their resistance to antibiotics and to chlorhexidine and identify some antibiotic or disinfectant resistance genes in these bacteria.

Methods

Enterobacteriaceae count was performed using violet red bile glucose agar. Bacteria were identified by Polymerase Chain Reaction targeting bacterial 16S rRNA gene. Bacteria were screened for their resistance to antibiotics using disc diffusion method. Susceptibility of isolates to chlorhexidine was investigated by determining the minimum inhibitory concentration (MIC) using broth microdilution method.

Conclusions

Fresh produce marketed in Oman contain diverse bacteria including opportunistic pathogens and antibiotic-resistant bacteria. Enterobacteriaceae bacteria showed resistance to chloramphenicol (1%), resistance/intermediate resistance to ampicillin (63%), cephalothin (54%), amoxicillin/clavulanic acid (32%), cefoxitin (29%), tetracycline (10%), kanamycin (7%), nalidixic acid (7%) and trimethoprim (7%) and intermediate resistance to ertapenem (1%) and imipenem (3%). Four types of ampC β-lactamase genes (CIT, EBC, FOX and MOX) and three Tetracycline resistance genes of tet(A) and tet(K) were detected in 9 bacteria. All bacteria were susceptible to chlorhexidine. The MIC of chlohexidine ranged from 1 to 64 µg/ml which is below the recommended concentration in food production areas (100-200 µg/ml). The resistance genes of qac EΔ1, qacE and qacG which can confer resistance to various biocides including chlorhexidine were detected in some bacteria as well as the integron integrase IntI 1 gene.

Food Microbiology - Part II

MOLECULAR CHARACTERSATION OF VIM-1 PRODUCING E. COLI IN GERMAN LIVESTOCK

A. Irrgang[1], J. Hammerl[1], B.A. Tenhagen[1], M. Grobbel[1], S. Schmoger[1], K. Daehre[2], N. Roschanski[2], U. Rösler[2], A. Käsbohrer[1]
[1]German Federal Institute for Risk Assessment, Biological Safety, Berlin, Germany
[2]Freie Universität Berlin, Institut für Tier und Umwelthygiene, Berlin, Germany

Backgrounds

In 2015, a VIM-1 carbapenemase-producing *E. coli* was detected in the colon content of a pig at slaughter in Germany. Later, additional *E. coli* isolates were obtained from another slaughter batch of the same farm. Molecular characterization revealed close phylogenetic relationship of the isolates. Interestingly, in one isolate the *bla*$_{VIM-1}$ integron seemed to be integrated in the genome, whereas other isolates carried *bla*$_{VIM-1}$ also on a plasmid.

Objectives

In this study, molecular characterisation of selected isolates will be presented.

Methods

Faecal samples, boot swabs and environmental samples of the swine fattening farm were used for isolation of bacteria according to the EFSA protocol for ESBL detection. VIM-1-producing *E. coli* were characterised by PFGE, Southern Blot hybridisation, MLST and NGS.

Conclusions

bla$_{VIM-1}$ *E. coli* were isolated from samples of different barns. In two isolates, *bla*$_{VIM-1}$ is located on a plasmid whereas other isolates harbour *bla*$_{VIM-1}$ on the chromosome. Results of the WGS proofed the localisation of the class 1 integron and provided some hints explaining the genome stability for more than four years.
VIM-1-producing *E. coli* are present in German pig farming. Persistence in one farm over a period of at least five months and transmission between different barns of the farm was observed. Further investigations were conducted to identify the route of entry and ways of transmission.

FEMS7-1083
Food Microbiology - Part II

NOVEL STRESS SURVIVAL ISLET SSI-2 IN LISTERIA MONOCYTOGENES ST121 SUPPORTS SURVIVAL UNDER ALKALINE AND OXIDATIVE STRESS

E. Harter[1], E.M. Wagner[1], A. Zaiser[1], S. Halecker[1], M. Wagner[1], R. Kathrin[1]
[1]University of Veterinary Medicine, Institute for Milk Hygiene- Milk Technology and Food Science, Vienna, Austria

Backgrounds

Listeria (L.) monocytogenes is able to survive environmental stresses and to persist in food processing environments. Two genes from non-pathogenic *L. innocua*, *lin0464* and *lin0465*, have been found to be inserted in a hypervariable genetic hotspot in *L. monocytogenes*. Lin0464 is a putative transcriptional regulator and Lin0465 an intracellular pfpI protease. Strains devoid of *lin0464-lin0465* harbor either the stress survival islet 1 (SSI-1) or the gene *LMOf2365_0481*.

Objectives

PCR screening revealed that strains of sequence type (ST) 121 predominantly harbor *lin0464-lin0465*. To elucidate the function of Lin0464 and Lin0465, non-polar deletion mutants were exposed to distinct stress conditions.

Methods

While oxidative and alkaline stress resulted in decreased survival of the *lin0465* deletion mutant, acidic, cold and salt stress did not have any effect. In parallel, deletion of *lin0464* decreased survival under oxidative and alkaline stress. Additionally, we could show that constitutive expression of *lin0465* but not of *lin0464* in strain F2365, harboring the *LMOf2365_0481* insert, resulted in increased survival under oxidative and alkaline stress. qRT-PCR revealed increased expression of both genes under oxidative stress conditions after 10 minutes at 20°C in a σ^B-independent manner. Furthermore, we detected that the expression of *lin0465* is regulated by the transcription factor *lin0464*.

Conclusions

This indicates that *lin0464* and *lin0465* are a functional unit. In conclusion we could identify a new stress survival islet 2 (SSI-2), predominantly present in *L. monocytogenes* ST121, which is involved in alkaline and oxidative stress response and could support survival and persistence of *L. monocytogenes* in the food processing environment.

Food Microbiology - Part II

ADAPTIVE RESPONSE OF LISTERIA MONOCYTOGENES BIOFILMS TO A DEHUMIDIFICATION STRESS

J. Esbelin[1], C. Chambon[2], D. Viala[2], M. Hebraud[1,2]
[1]French National Institute for Agricultural Research, Centre Auvergne-Rhône-Alpes- UMR MEDiS- Site de Theix, Saint-Genès Champanelle, France
[2]French National Institute for Agricultural Research, Centre Auvergne-Rhône-Alpes- PFEMcp- Site de Theix, Saint-Genès Champanelle, France

Backgrounds

Listeria monocytogenes is a foodborne pathogen able to adhere and form biofilms on various surfaces. Associated with a high mortality rate, it is one of the major biological concerns in food hygiene. Since few years, industries attempt to reduce the environmental impact of hygiene operations in the workshops of refrigerated food processing, through optimized use of dehumidification after cleaning disinfection treatments

Objectives

Our study was focused on the adaptive response of *L. monocytogenes* cells, growing in biofilms, to a dehumidification stress mimicking food plants conditions.

Methods

The intracellular and surfaceome subproteomes were analyzed by shotgun proteomics through three complementary extraction methodologies (enzymatic shaving, biotinylation and cell fractionation). *L. monocytogenes* EGD-e and L028 biofilms were grown on stainless steel discs at 25°C during 24h, pre-adapted to 10°C and placed in a desiccation chamber where the air Relative Humidity was stabilized to 75%. The different subproteomes were analyzed after 3h and 24h dehumidification by comparison with non-stressed biofilms.

Conclusions

Among the surface proteins identified, 21 and 29 were differentially expressed during dehumidification for EGD-e and L028, respectively. Three of them were common to both strain, an autolysin, Iap and an ABC transporter. Among intracellular proteins, 38 and 65 were differentially expressed in EGD-e and L028 respectively. Five proteins were common to the two strains. The majority of these proteins belongs to information pathway (35%) and intermediary metabolism (25%) functional categories. These results could contribute to a better comprehension of mechanisms involved in the resistance and persistence of this pathogen in food plants despite the daily hygiene procedures.

FEMS7-0345
Food Microbiology - Part II

SELECTION OF METABOLIC BIOSENSORS FOR SCREENING OF LACTOCOCCUS LACTIS CELLS WITH INCREASED PRODUCT-YIELD FOR INDUSTRIAL FERMENTATIONS

J. Hernandez-Valdes[1], *A. Solopova*[1], *O.P. Kuipers*[1]
[1]*GBB, Molecular Genetics, Groningen, The Netherlands*

Backgrounds

Some molecules are desired products for the food industry and are by-products of fermentation by many microorganisms. One example of these compounds is diacetyl, a volatile aromatic compound, giving a buttery flavor, associated with dairy products, and produced by species of the lactic acid bacteria (LAB) family. The identification of individual cells that produce an increased amount of diacetyl is complicated with existing technologies.

Objectives

Even though there are previous studies with engineering strategies to increase its production, the yields are low. Thus, in this project we aim to develop a high throughput method for identification of existing cells with increased product-yield, based on a recently established protocol to culture individual microbial cells in micro-droplets of emulsions.

Methods

The first step is to select the indicator strains that bear fluorescent reporter constructs under regulation of suitable promoters that are activated by diacetyl. To accomplish this, we tested the toxicity to diacetyl in *Lactococcus lactis* MG1363, and performed a transcriptional analysis with the maximum tolerable concentration of diacetyl added during exponential growth. In this way we identified candidate promoters responding to diacetyl.

Conclusions

We observed up-regulation of the genes in the riboflavin operon (*ribDBAH*). Subsequently, we amplified the promoter region ($P_{ribDBAH}$) and cloned it upstream of the *gfp* gene in the pSEUDO integration vector. Preliminary results with the *L. lactis* strain (MG1363 pseudo10 gene::$P_{ribDBAH}$-*sfgfp(Bs*)) in microtiter plate assays and flow cytometry show an increased GFP expression, proportional to serial concentrations of diacetyl. This potential biosensor strain for diacetyl is now under further characterization.

Food Microbiology - Part II

CROSS SECTIONAL STUDY OF HEPATITIS E VIRUS IN SPANISH PIG SLAUGHTERHOUSES

M. Hernández[1], D. Rodriguez-Lazaro[2], A. Navarro[3], L. Domínguez[3], J. Goyache[3], N. García[3]
[1]Instituto Tecnológico Agrario de Castilla y León ITACyL,
Laboratory of Molecular Biology and Microbiology, Valladolid, Spain
[2]University of Burgos,
Departamento de Biotecnología y Ciencia de los Alimentos. Área de Microbiología, Burgos, Spain
[3]VISAVET Health Surveillance Centre - UCM, Neglected and Emerging Diseases Unit, Madrid, Spain

Backgrounds

Hepatitis E virus (HEV) represents the main cause of enterically transmitted hepatitis worldwide, mostly by drinking contaminated water and by the ingestion of infected pork meat. HEV is a single-stranded positive-sense RNA virus which is increasingly being recognized as the cause of zoonotic acute liver disease in many western countries.

Objectives

We report serological and PCR data of the analysis of HEV in individual samples (faeces, liver and serum) taken between July to October 2015 in 20 different Spanish pig slaughterhouses located in 29 provinces that represents the 50% of national pig production, to estimate the prevalence of the virus in Spain.

Methods

RNA extraction from 244 faeces and 241 livers was performed using QIAamp® viral RNA mini kit and RNeasy Midi kit (QIAGEN) and analysed by RT-PCR (Jothikumar *et al.*, 2006). 241 serum samples were tested using the ID Screen Hepatitis E multi species indirect ELISA (ID.vet).

Conclusions

From a total of 726 samples analysed, 19,67%, 21,99% and 71,37%, resulted positive in liver, faeces and sera samples, respectively. Results indicate that the virus is circulating among most of the Spanish swine hut, and a significant percent of animals (almost 20%) were indeed infected when the sample was taken, as the virus RNA was present in liver as well as in faeces. HEV should no longer be considered of little importance in Spain and further studies on the circulation of the virus in both domestic and wild animals (swine, wild boar, deer), including the whole food chain, are needed.

CAN FRESH PRODUCE BE PROTECTED FROM COLONISATION BY HUMAN PATHOGENS THROUGH THE APPLICATION OF PLANT GROWTH PROMOTING RHIZOBACTERIA (PGPR) AS BIOCONTROL?

A. Holmes[1], M. Kalamara[2], N. Stanley-Wall[2], N. Holden[1]
[1]The James Hutton Institute, Cell and Molecular Science, Dundee, United Kingdom
[2]University of Dundee, College of Life Sciences, Dundee, United Kingdom

Backgrounds

The consumption of fresh produce, such as lettuce and tomato, is increasingly being linked to foodborne outbreaks of verotoxigenic *Escherichia coli* and *Salmonella enterica*. Strategies need to be implemented to improve food safety by reducing the risk of infection from ready to eat (RTE) horticultural products. One strategy would be to restrict the colonization of fresh produce by human pathogens through the pretreatment of crops with PGPR.

Objectives

A number of commercially available PGPR treatments were tested in an *in vitro* competition assay with *E. coli* O157:H7 isolate Sakai. PGPR which were able to out-compete Sakai *in vitro* were tested under glasshouse conditions.

Methods

PGPR were applied to lettuce seedlings at transplant and a second application after seven days. Fourteen days after transplant, lettuce plants were challenged with 10^7 cfu/ml *E. coli* O157:H7 Sakai by root-soak. Colonisation of Sakai on lettuce roots was measured after seven days by viable count on selective media.

Conclusions

Bacillus amyloliquefaciens strain GB03 (commercially available as Companion®) and a naturally occurring *Pseudomonas putida* isolate SCRI_5304 were able to outcompete *E. coli* O157:H7 Sakai *in vitro.* However, when tested in glasshouse conditions, there is no significant difference in the numbers of *E. coli* O157:H7 strain Sakai recovered from PGPR treated versus untreated lettuce roots.

Application of PGPR, which are effective in competition against *E. coli* O157:H7 Sakai *in vitro,* are not able to reduce colonisation of human pathogens *in planta*. Continued research into controls and treatments are required to reduce the risk of foodborne illnesses arising from RTE produce.

PARTIAL 16S RRNA SEQUENCING IS USEFUL METHOD FOR SPECIES IDENTIFICATION OF STAPHYLOCOCCI ISOLATED.

L. Hoveida[1], S. Rostami[2], M. Halaji[3]
[1]Department of Microbiology, Falavarjan Branch - Islamic Azad University, Isfahan, Iran
[2]Infectious Diseases and Tropical Medicine Research Center, Isfahan University of Medical Sciences, Isfahan, Iran
[3]Department of Microbiology - School of medicine, Isfahan University of Medical Sciences, Isfahan, Iran

Backgrounds

Some species of *staphylococci* isolated are considered technologically important in the manufacturing processes of various meat-derived products, especially dry fermented sausages which can potentially cause food poisoning.

Objectives

The aim of this study was, using partial 16S rRNA sequencing for the species identification of *staphylococci* isolated and determining antimicrobial susceptibility pattern of *Staphylococcus* isolated from sausages.

Methods

During august 2015 to march 2016, 61 sausages samples were collected and were sub-cultured on Giolitti- Cantoni broth and Baird-Parker agar media. Isolates were identified based on morphological and physiological characteristics of *Staphylococci* spp. Partial 16sRNA sequencing was used for species identification of *Staphylococci* isolates. Furthermore, antimicrobial susceptibility test of *Staphylococci* isolates was performed by the Disc diffusion method on Mueller– Hinton agar according to CLSI guideline.

Conclusions

We detected Staphylococci spp. in 26 different samples. These identified isolates were belonged to 9 different species and included: 5 (19.5) S. vitulinus, 5 (19.5) S. epidermidis, 3 (11.5) S. pasteuri, 3(11.6) S. saprophyticus 2 (7.7) S. warneri, 2(7.7) S. succinus, 3 (11.5) S. aureus, 2 (7.7) S. equorum, 1(3.8) S. gallinarum,. About 88.5% of species were assessed negative for coagulase test. The most sensitivity isolates were toward levofloxacin and ciprofloxacin and gentamycin each with 100%. Also, the highest antibiotic resistances among isolates were observed against penicillin (73.1%) and tetracycline (42.3%).

In conclusion, 16srRNA sequencing was an objective and accurate method for proper identification of *Staphylococci* species. Further studies on molecular characterization of resistant *staphylococci* isolated from meat-derived products should be carried out.

[2]Institut de Recherche en Sciences Appliquées et Technologies, Département Technologie Alimentaire, Ouagadougou, Burkina Faso

Backgrounds

Folate deficiency is still common in developing countries as well as in many industrialized contexts. Beneficial effects of mandatory food fortification programs have already been demonstrated but concerns still exist over their possible adverse effect. To improve folate content of fermented foods, it is also possible to use *in situ* fortification through fermentation. This has been validated in dairy products, but data on cereal-based fermented foods are still scarce even if these types of foods are highly consumed around the world.

Objectives

The objective of this work is to produce a traditional cereal-based fermented food made from pearl millet enriched into folate through fermentation. This product is consumed by all population in different countries of West Africa, especially by at risk population such as young children.

Methods

We have studied the ability to produce folate into a collection of 150 lactic acid bacteria isolated from traditional fermented food made from pearl millet and called ben-saalga. After detection of genes coding enzymes involved in folate biosynthesis pathway, we checked the production of folate in culture medium. We used the most active strains to inoculate ben-saalga in order to increase its folate content.

Conclusions

We were able to increase the folate content of the pearl millet porridge using the most active strains. This work is an example of the use of the diversity of microorganisms naturally present in cereal-based fermented food in improve the nutritional quality of the traditional food. This strategy is now used in different countries, representing various nutritional contexts.

FEMS7-0200
Food Microbiology - Part II

BROAD IN VITRO INHIBITION OF FOOD-BORNE PATHOGENS, ANTIMICROBIAL-RESISTANT, AND SPOILAGE BACTERIA BY MARINILACTIBACILLUS PSYCHOTOLERANS ISOLATED FROM CHEESE SMEAR

N. Bianco[1], N. Javorka[1], E. Arias-Roth[1], J. Hummerjohann[1]
[1]Agroscope Institut für Lebensmittelwissenschaften ILM, Bacteriological Food Safety, Bern, Switzerland

Backgrounds

Protective cultures are an innovative tool to control pathogens, antimicrobial resistant (AMR) and spoilage bacteria in food.
We have previously shown anti-listerial activity of *Marinilactibacillus psychotolerans*, a Gram-positive rod isolated from natural cheese smear, in cheese-ripening experiments.

Objectives

Here, we aimed to measure the *in vitro* activity of *Marinilactibacillus psychotolerans* strains against a broad range of food-borne pathogens, spoilage and AMR bacteria in order to develop an effective protective culture in the future.

Methods

20 different Gram-positive and Gram-negative strains including methicillin-resistant *S. aureus* (MRSA), *Proteus*, ESBL-positve *E. coli*, *L. monocytogenes* were used as indicators. The inhibition potential of 2 genetically-different protective cultures of *Marinilactibacillus psychotolerans* FAM208060 (already used in the cheese exoeriments) and FAM23170 (new isolate) against these bacteria were tested in quadruplicate. The *in vitro* inhibition test was conducted at 12 °C during 96 hours after inserting 10^9 cfu/ml protective culture in wells punched in BHI soft agar inoculated with 10^6 cfu/ml indicator strain and the extent of the inhibition zone was measured.

Conclusions

The results showed inhibition of all strains tested by both *Marinilactibacillus psychotolerans* strains. Strain FAM23170 always exhibited stronger inhibition than FAM20860. Comparative analysis showed that different strains of MRSA, *Proteus*, and *Morganella* were statistically significantly stronger inhibited than *Listeria innocua* FAM20870, of which inhibition has already been described in cheese-ripening experiments.
In conclusion, the obtained *in vitro* data are showing the potential of *Marinilactibacillus psychotolerans* to be used as an effective protective culture with broad-spectrum activities against pathogens, spoilage and AMR bacteria, in particular MRSA.

SHIGA TOXIN-PRODUCING ESCHERICHIA COLI (STEC) PREVALENCE AND VIRULENCE GENES IN CATTLE AND SHEEP

B. Oporto[1], M. Ocejo[1], A. Hurtado[1]
[1]NEIKER-Tecnalia, Department of Animal Health, Derio, Spain

Backgrounds

Ruminants are sources of food-borne infections by Shiga toxin-producing *Escherichia coli* (STEC) in humans.

Objectives

To investigate the prevalence of STEC in cattle and sheep in the Basque Country (northern Spain), and assess the potential health risk of livestock-carried STEC isolates according to their virulence gene profile.

Methods

Rectal faeces collected between February 2014 and June 2016 from 301 farms (115 dairy sheep, 104 beef, 82 dairy cattle) were pre-enriched in modified TSB-novobiocine. *E*. *coli* O157 was isolated after immunomagnetic separation and chromogenic isolation, and non-O157 STEC were recovered from lactose-positive colonies in MacConkey agar. Isolates were identified and characterized by amplification of *stx*1, *stx*2, *eae*A and E-*hly*A genes. Serotype O157:H7 was identified by PCR amplification of *rfb*E and *fli*C genes and serogroups O5, O26, O91, O103, O111, O121 and O145 with primers targeting the *wzx* or *wzy* genes.

Conclusions

STEC were isolated from 63.5% of beef cattle herds, 56.5% of sheep flocks and 30.5% of dairy cattle herds. Prevalence of STEC O157:H7-positive herds was 18.3% in beef cattle, 20.0% in sheep and 14.6% in dairy cattle. Serogroups O26, O103, O111 and O145 were never detected, and O5, O91 and O121 were isolated in a small proportion of herds/flocks. Most O157:H7 isolates (96.5%) had the toxigenic profile *stx*2+*eae*A+E-*hly*A, which was very uncommon in non-O157 STEC isolates (4.4%). Proportion of herds/flocks that harboured non-O157 STEC isolates carrying the *eae*A gene and thus considered potentially pathogenic to humans, was 3.8% in beef cattle, 7.3% in dairy cattle and 7.0% in sheep.

Food Microbiology - Part II

LACTOBACILLUS CASEI N87 ADAPTED UNDER ANAEROBIC VS RESPIRATORY CONDITIONS AS A MICROBIAL STARTER IN FERMENTED SAUSAGES PRODUCTION.

L. Iacumin[1]
[1]*University of Udine, Department of Agriculture- Food- Environmental and Animal Science, Udine, Italy*

Backgrounds

Lactic acid bacteria had a central role in fermented sausages (FS). *Lactobacillus casei* is used in several fermented foods, such as dairy, bakery and fermented meat products. This microorganism can be used as starter to ferment meat and to improve health benefit, considering the possibility to use this matrix as a probiotic carrier. The adjunction of *L. casei* strains, adapted under respiratory (R) vs anaerobic conditions (A), can affect the physiological response of cells, influencing growth, survival and capabilities of meat fermentation.

Objectives

Investigation of the effects of the anaerobic and respiratory conditions of growth, prior to inoculation, on *L. casei* N87 during fermented sausages ripening.

Methods

Three trials were conducted and compared. A) FS with no starter addition; b) FS inoculated with *Lactobacillus casei* N87 adapted under A; FS inoculated with *Lactobacillus casei* N87 adapted under R. The evolution of microflora, chemical/physical parameters (pH, a_w, weight loss, colour), production of volatile compounds, antioxidant capabilities, proteolysis and survival of the strains, were evaluated.

Conclusions

Results demonstrated similarities in the major part of the chemical/physical parameters. Different concentrations of the inoculated strains were observed during ripening, and this probably affected the proteolysis, which was the most significantly different parameter monitored at the end of the ripening period.

Food Microbiology - Part II

IN VIVO ASSESSING OF NANOMETRIC CHANGES ON THE SURFACE OF WHOLE TOMATOES INOCULATED WITH CANDIDA GUILLIERMONDII YEAST USING ATOMIC FORCE MICROSCOPY

E.D.P. Infante Luna[1]
[1]*Universidad Distrital Francisco José de Caldas, Facultad de Ciencias y Educación, Bogotá, Colombia*

Backgrounds

Studies with *Candida guilliermondii* have shown that this endophyte yeast is able to penetrate the cuticle and colonize the apoplastic spaces without harming the cells, help to protect it against phytopathogens and loss of water and therefore extend its post-harvest life

Objectives

Evaluate changes on the surface of whole tomatoes inoculated with *Candida guilliermondii* Yeast Using AFM

Methods

Measurements of the surface topography were taken in the same area of the control tomatoes and the inoculated tomatoes at 0 (before inoculation), 2, 5, 8, 24, 48, and 72 hours after inoculation, the size of the scanned area was 50x50 μm^2. In addition to gauging the three-dimensional images of the surfaces, the changes in the roughness of the fruit in contact mode and in phase on non-contact mode were measured each time

Conclusions

The changes in fruit roughness were not perceived just 2 h after having been inoculated however, as time passed, the downward trend of this parameter was perceivable. Phase images taken in taping mode, made it possible to observe the changes in the mechanical properties on the surface of the fruit related to the adhered yeast and quantified by changes in phase. The variation in phase value compared with the control samples suggests that the biomechanics of the tomato's surface characteristics did change after having been inoculated with the yeast. The results would indicate that the surface of the fruit was homogenized after 72 hours due to the presence of a biofilm based on yeast that helps keep water inside the fruit

Department of Food Science- Nutrition and Technology- College of Agriculture and Veterinary Sciences, Nairobi, Kenya
[6]Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, CSRS,
Adiopodoumé Yopougon- Abidjan, Ivory Coast

Backgrounds

Staphylococcus aureus is a major pathogen responsible for food intoxication, human and animal diseases. *S. aureus* is a frequent contaminant of milk products in sub-Saharan Africa (SSA). SSA hospital-derived and human commensal *S. aureus* strains are well studied. However, the population structure and genetic features of foodborne *S. aureus* in SSA are largely unknown and hinder efforts to better identify possible staphylococcal food poisoning sources and mitigation strategies.

Objectives

The aim was to assess the population structure of milk-derived *S. aureus* isolates from Côte d'Ivoire, Kenya and Somalia in parallel with the presence of virulence and antibiotic resistance genes.

Methods

The population structure of *S. aureus* was assessed by *spa* typing, MLST, and DNA microarray analysis in comparison to the respective data repositories.

Conclusions

S. aureus isolates (n=70) obtained from milk samples of the three countries were assigned to 27 *spa* (7 new) and 23 (12 new) MLST sequence types. Genetically diverse human and livestock-associated clonal complexes (CCs) were observed among the milk-derived *S. aureus* isolates in this study. Isolates were predominantly assigned to CC5 (n=10) and CC30 (n=9). Virulence factors such as Panton-Valentine leukocidin, toxic shock syndrome toxin and enterotoxin encoding genes were predominantly observed among human-associated CCs. Penicillin, fosfomycin and tetracycline resistances were frequently detected. No methicillin resistance genes were detected. The population structure suggests that milk-derived *S. aureus* in SSA originates from human and animal sources alike. An overarching One Health approach to reduce *S. aureus* disease burdens through improving production processes, animal care and hygienic measures is thus recommended.

FEMS7-0786
Food Microbiology - Part II

PROBIOTIC PROPERTIES AND SAFETY ASSESSMENT OF BACILLUS STRAINS ISOLATED FROM KOREAN TRADITIONAL FERMENTED FOOD

H.L. Jeon[1], N.K. Lee[1], S.J. Yang[1], H.D. Paik[1]
[1]Konkuk University, Department of Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea

Backgrounds

The probiotics market is being expanded worldwide. Lactic acid bacteria (LAB) probiotics are usually studied and commercialized, whereas *Bacillus* strains are less popular as probiotics than LAB are.

Objectives

To isolate *Bacillus* strains from Korean traditional fermented food and to characterize their probiotic properties like acid and bile salt tolerance, adhesion ability, and enzymatic activity. In addition, the presence of toxic genes, antibiotic sensitivity and hemolysis were determined to evaluate safety.

Methods

Bacillus strains (p229, p230, and p231) were isolated from *cheonggukjang*, a fermented soybean food. According to 16S rRNA analysis, p229 was identified as *B. subtilis* and p230, and p231 were *B. licheniformis*. The spore cells of these strains showed high resistance to artificial gastric juice (pH 2.5, 0.3% pepsin) and bile salts (pH 7.0, 0.3 % oxgall). In addition, the spore cells of the strains had strong capacity for adhesion to HT-29 cells. The API zym kit was used to evaluate enzymatic activity; *Bacillus* strains did not produce β-glucuronidase, a carcinogenic enzyme. Antibiotic sensitivity was measured by a disk diffusion method and eight antibiotics (ampicillin, gentamicin, kanamycin, streptomycin, tetracycline, ciprofloxacin, chloramphenicol, and doxycycline) were tested. To evaluate safety, the presence of toxic genes was determined by a polymerase chain reaction and electrophoresis. Six kinds of toxic gene primers were used, and the *Bacillus* strains showed negative results for all these toxic genes. All strains showed no hemolysis on blood agar

Conclusions

The *Bacillus* strains isolated from *cheonggukjang* have a potential as probiotics for functional foods

SCREENING AND CHARACTERIZATION OF LACTIC ACID BACTERIA AS POTENTIAL PROBIOTICS ISOLATED FROM KIMCHI

H.L. Jeon[1], S.H. Son[1], N.K. Lee[1], Y.J. Kim[2], H.D. Paik[1]
[1]Konkuk University, Department of Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea
[2]Korean Cultrue Center of Microorganisms, Korean Cultrue Center of Microorganisms, Seoul, Republic of Korea

Backgrounds

Lactic acid bacteria (LAB) as probiotics are being studied, and the probiotics market is expanding worldwide.

Objectives

To isolate LAB strains from a Korean traditional plant fermented food, kimchi, and to screen them for potential probiotics.

Methods

For isolation of strains, selective media were use: MRS, PES (phenyl ethyl alcohol sucrose), and LBS (*Lactobacillus* selective) agar. Thirty isolates were obtained. At first screening for acid tolerance, 5 strains showed strong acid tolerance (over 70%) to pH 2.5 MRS broth for 24 h. The survival rate of 2 strains (KCCM 200060 and KCCM 200070) in artificial gastric juice (pH 2.5, 0.3% pepsin for 3 h) and bile salt (pH 7.0, 0.3% oxgall for 24 h) was over 80%. For identification of strains, 16S rRNA analysis was used. KCCM 200060 was identified as *Lactobacillus fermentum* and KCCM 200070 as *Pediococcus damnosus*. Enzymatic activity was determined using the API zym kit. KCCM 200060 did not produce β-glucuronidase, a carcinogenic enzyme, but KCCM 200070 did. The cytotoxicity of these bacteria to normal cells (MRC-5, human lung fibroblast cell) was measured by an MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay, and KCCM 200060 had no cytotoxicity toward MRC-5 cells. KCCM 200060 showed strong capacity for adhesion to human colon adenocarcinoma cells (HT-29). Antibiotic sensitivity was determined using a disk diffusion assay. KCCM 200060 was resistant to 4 of 8 antibiotics; gentamicin, kanamycin, streptomycin, and ciprofloxacin.

Conclusions

L. fermentum KCCM 200060 has a potential as a probiotic starter.

Food Microbiology - Part II

GENOMIC INSIGHTS OF STAPHYLOCOCCUS EQUORUM AS A STARTER CANDIDATE FOR HIGH-SALT-FERMENTED FOODS

D.W. Jeong[1], S. Heo[2], H. Lee[2], K. Jeong[2], J.H. Lee[2]
[1]Dongduk Women's University, Department of Food and Nutrition, Seoul, Republic of Korea
[2]Kyonggi University, Department of Food Science and Biotechnology, Suwon, Republic of Korea

Backgrounds

Staphylococcus equorum has been identified as a predominant bacterial species in jeotgal, a traditional Korean high-salt-fermented seafood. Little has been known about its contribution and metabolic process in the fermentation of jeotgal.

Objectives

The objectives of the current research are to understand roles of the *S. equorum* in jeotgal fermentation.

Methods

The gene repertoire contributing to the lifestyle of the jeotgal starter candidate *S. equorum* KS1039 was deduced from its complete genome sequence.

Conclusions

S. equorum KS1039 genome is equipped with several genes for fermentations and color developments and can confer the capability to catabolize cellobiose, maltose, mannose, mannitol, sucrose, and trehalose. *S. equorum* KS1039 can produce flavor compounds including acetoin, butanediol, and branched chain fatty acids. While, *S. equorum* KS1039 does not possess decarboxylase genes, which can contribute to produce biogenic amines. Uniquely, *S. equorum* KS1039 possesses the genes encoding bacteriocin and CRISPR/Cas system. This genome analysis of *S. equorum* KS1039 revealed genetic insight into the safety and efficacy of this strain as a candidate starter culture for high-salt food fermentation.

Food Microbiology - Part II

PCR AND ELISA FOR STAPHYTAPHYLOCOCCAL ENTEROTOXINS AND DETECTION OF SOME EXOTOXINS FROM STAPHYLOCOCCUS SPP. STRAINS BY PCR

S. Kahya Demirbilek[1], *Ö. Yılmaz*[1]
[1]*Veterinary Faculty, Microbiology, bursa, Turkey*

Backgrounds

A PCR assay was used to investigate the presence of important exotoxins (enterotoxins, *eta-etb*, and *tst*) in CNS and CPS strains isolated from ground beef and lamb meat for the first time in Turkey.**Objectives**The aims of this study were to determine the existence of some staphylococcal enterotoxin (SE) (*sea, seb, sec, sed,* and *see*) proteins and genes in coagulase-positive staphylococci (CPS) by ELISA and PCR and to assess SE-like toxin (SEI) (*seg, seh, sei, sej, sem, sen,* and *seo*), exfoliative toxin (*eta* and *etb*), toxic shock syndrome toxin-1 *(tst*) and 16S rRNA genes in 11 different *Staphylococcus* strains [90 CPS and 118 coagulase-negative staphylococci (CNS)] isolated from 250 ground meat samples by either monoplex or multiplex PCR.**Methods**

ELISA

SEs from 90 CPS isolates were assessed using commercially available kits (Ridascreen SET A, B, C, D, E, R-biopharm, Germany, Art no: R1101).

Detection of SE, SEI, *eta-etb*, *tst* and 16S rRNA genes by PCR

Six different mixtures were prepared for monoplex and multiplex PCR analyses**Conclusions**

SEs were identified in 36 (40%) out of 90 CPS isolates by both ELISA and PCR with the following distribution: *sea* was identified in 7 (7.7%), *seb* in 5 (5.5%), *sec* in 3 (3.3%), *sed* in 4 (4.4%), and *see* in 17 (18.8%). In addition, a total of 90 CPS and 118 CNS isolates were investigated for the presence of 11 SE, SEI, *eta-etb, tst,* and 16S rRNA genes. Overall, 145 (69.7%) of the *Staphylococcus* spp. isolates tested positive for one or more toxin genes. These results indicate that CNS may play an important role in food poisoning and that SEI toxins must be investigated in greater detail in future studies of both CPS and CNS.

[6]Swiss Tropical and Public Health Institute- University of Basel,
Department of Epidemiology and Public Health, Basel, Switzerland
[7]ETH Zurich,
Health Sciences and Technology- Institute of Food- Nutrition and Health- Laboratory of Food Biotechn ology, Zurich, Switzerland

Backgrounds

High amounts of *Streptococcus infantarius* subsp. *infantarius* (*Sii*) are consumed in traditional fermented dairy products in East and West Africa. However, the population structure of *Sii* of human and dairy origin and their health risks as *Streptococcus bovis/Streptococcus equinus* complex (SBSEC) members has not been elucidated.

Objectives

To elucidate the population structure of *Sii*/SBSEC obtained from clinical specimen and to compare the isolates with globally relevant *Sii*/SBSEC strains of dairy, commensal and potentially pathogenic lineages as a proxy for assessing risk to human health.

Methods

Sii/SBSEC strains (n=40) from rectal swabs of persons undergoing colonoscopy at Kenyatta National Hospital, Nairobi, Kenya were analyzed by SBSEC-MLST for phylogeny and screened for dairy adaptation marker genes. For comparison, 43 other *Sii* strains were included from Kenyan infant faeces (n=8), dairy products of East (n=20) and West Africa (n=9), human blood (n=3), animal source (n=1), Grana cheese (n=1) and fermented maize (n=1).

Conclusions

The 40 SBSEC strains from rectal swabs comprised *Sii* (n=33), non-*Sii* SBSEC pathogens (n=6) and *Streptococcus macedonicus* (n=1). One of these 33 *Sii* clustered with presumed pathogenic *Sii* strains obtained from blood cultures. The remaining 32 rectal swab *Sii* clustered with *Sii* from human faeces from Kenyan infants and West African dairy products, clearly separated from East Africa dairy *Sii*. In the African context, this suggests a complex exchange of *Sii* across ecologic niches to feature a shared *Sii* human commensal and West African dairy clade and the evolution of a specific East African *Sii* dairy lineage possibly relevant for local dairy fermentation.

FEMS7-1610
Food Microbiology - Part II

PREVALENCE AND POPULATIONS OF PATHOGENIC BACTERIA IN BRAZILIAN ARTISANAL CHEESES

B.A. Kamimura[1], L. Pereira Margalho[1], V. Ortiz Alvarenga[1], L. do Prado Silva[1], R. Peres Brexó[1], A. de Souza Sant'Ana[1]
[1]State University of Campinas, Food Science, Campinas, Brazil

Backgrounds

The production of artisanal cheeses (AC) is characterized by tradition and culture of producing regions. Every cheese has unique sensory characteristics typical of its region.

Objectives

This study aimed to determine the incidence and concentration of *Listeria monocytogenes*, *Salmonella* and *Staphylococcus* spp. in Brazilian AC.

Methods

We analyzed 582 samples of Brazilian AC, divided according to their production region: North (Marajó; n=8); Northeast (Curd cheese; n=78) and (Butter cheese; n=23); Central (Caipira cheese; n=108); Southeast (Araxá; n= 56), (Campo das Vertentes; n= 54), (Cerrado; n= 54), (Serra da Canastra; n= 48) and (Serro; n= 50) and South cheeses (Colonial; n= 55) and (Serrano; n= 48). Detection and enumeration of *L. monocytogenes* was performed according to ISO 11290-1 and ISO 11290-2. Detection of *Salmonella* based on ISO 6579: 2002, while for enumeration ISO 6579-2: 2012 was used. *Staphylococcus* spp. was performed according to ISO 6888-3: 2003 and ISO 6888-1: 1999 for detection and enumeration. Identification of *L. monocytogenes* and *Staphylococcus* spp. were performed by biochemical tests and real-time PCR (RT-PCR) with amplification of listeriolysin gene (*hlyA*) and *femA* gene.

Conclusions

L. monocytogenes and *Salmonella* were not detected in any samples analyzed. The highest concentration of *Staphylococcus* spp. was 6.85 ± 1.27 log CFU.g^{-1} in Campo das Vertentes cheeses. The data obtained in this large survey indicates that *Staphylococcus* spp. seems to be the main bacterial genus present in cheeses that may impact on their safety and public health. Further studies are being performed to characterize the pathogenic potential of *Staphylococcus* strains isolated from AC.

FEMS7-2660
Food Microbiology - Part II

RETROSPECTIVE STUDY OF LISTERIA MONOCYTOGENES ORIGINATING FROM FOODS AND HUMANS IN OUTBREAK INVESTIGATION

R. Karpíšková[1], *Z. Tomáštíková*[1], *M. Zobaníková*[1], *T. Gelbíčová*[1]
[1]*Veterinary Research Institute, Department of Bacteriology, Brno, Czech Republic*

Backgrounds

L. monocytogenes is an emerging foodborne pathogen, causative agent of listeriosis. Ready-to-eat foods are often the source of listeria infections especially those with long shelf life that support the bacterial growth.

Objectives

The aim of the study was to identify cases with possible epidemic context by typing of *L. monocytogenes* isolated from food and human.

Methods

Altogether 116 human and 141 ready-to-eat food isolates of *L. monocytogenes* were collected in years 2013 – 2016. The isolates were characterized by serotyping, PCR clonogrouping, and macrorestriction analysis. Selected strains were analysed using the core genome multilocus sequence typing (cgMLST).

Conclusions

In the Czech Republic (CZ) serotype 1/2a, clonal complex CC8 belongs to the most frequent ones in both the human population and food isolates. Since 2013 an increased number of listeriosis caused by strains of serotype 1/2a, pulsotype 810, sequence type ST8 (22 cases from one locality of CZ) and strains of serotype 4b, pulsotype 203, ST6 (18 cases from different localities of CZ) were observed. The typing of *L. monocytogenes* from food enabled to confirm the vehicle (turkey meat delicatessen) of local outbreak in the Moravian-Silesian Region. On the other hand only one food strain of serotype 4b, pulsotype 203 was detected from pork ham. With respect to the occurrence of geographically separated cases and rare findings in foods it was not possible to identify the source of infection.

ENTEROTOXIGENIC STRAINS OF STAPHYLOCOCCUS AUREUS ISOLATED FROM FOODSTUFF IN THE CZECH REPUBLIC

I. Koláčková[1], M. Zobaníková[1], H.A. Tegegne[2], R. Karpíšková[1]
[1]Veterinary Research Institute, bacteriology, Brno, Czech Republic
[2]University of Veterinary and Pharmaceutical Sciences Brno, Milk Hygiene and Technology, Brno, Czech Republic

Backgrounds

The importance of *Staphylococcus aureus* in food is assessed by the potential of enterotoxins production and their ability to cause foodborne diseases - staphylococcal food poisoning. Mixed food, dairy and meat products, poultry and pork meat are frequently reported as source of such foodborne outbreaks.

Objectives

The study was conducted to find out the relationship between the potential of enterotoxins production and the origin of *S. aureus* strains.

Methods

The collection of 341 *S. aureus* strains were isolated from meat and liver (pork, beef, and poultry), milk (cow, goat and sheep) and milk products, food of plant origin, delicatessen and desserts. All strains were screened for the presence of five classical enterotoxin genes (*sea*, *seb*, *sec*, *sed*, *see*) and 4 enterotoxin-like genes (*seg*, *seh*, *sei, sej)* by using PCR method.

Conclusions

At least one gene was found in 54% of isolates. Classical enterotoxins were found in 35% of strains isolated across the whole spectrum of monitored food. Out of enterotoxins-like genes, *seg* and *sei* were most often positive in almost all types of food but mainly in poultry (43%). Findings of *seh* gene were strongly connected with pork meat and liver (71%). Due to the thermostability of staphylococcal enterotoxins, such contaminated pork could serve as a vehicle for intoxication. Nowadays laboratory testing for the presence of enterotoxins in food may produce false negative results due to the commonly used methods, which cannot detect the new types of toxin.

Food Microbiology - Part II

THE ABILITY OF LACTIC ACID BACTERIA ENTERING INTO A CONSORTIUM TY SYNTHESIZE EXOPOLYSACHARIDES

A. Sadanov[1], G. Jakibaeva[1], A. Molzhigitova[1]
[1]Institute of microbiology and virology, GS MES RK, Almaty, Kazakhstan

Backgrounds

A significant place among microorganisms capable of producing exopolysaccharides is occupied by lactobacillus bacteria of the genus Lactobacillus.

Lactobacilli have a great potential for the synthesis of exopolysaccharides, but the functions of these biopolymers are not fully understood. To form a concept of the influence of exopolysaccharides of lactic acid *bacteria* on physiological reactions in the animal body, it is necessary to accumulate data on the chemical structure, physical and biological properties of polysaccharides of different species and strains. Check the ability of lactic acid bacteria entering into the consortium ty synthesize polysaccharides.

Objectives

The objects of the study were collection milk acid bacteria: *Lactobacillus plantarum* 53H, *Lactobacillus plantarum* 22,*Lactobacillus plantarum* 2*, Lactobacillus cellobiosus* 20,*Lactobacillus acidophilus* 27*W, Lactobacillus curvatus* 18д, *Lactobacillus casei* 139, *Lactobacillus casei* 173a, *Lactobacillus salivarius* 8д, *Lactobacillus fermentium* 27 and milk acid bacteria: *Lactococcus lactis* K-1, *Streptococcus thermophilus* K-2, *Lactobacterium bulgaricus* K-3, *Lactococcus lactis* 8, *Streptococcus lactis* 6, *Saccharomyces lactis* 14c , *Saccharomyces lactis* 19, included in consortia.

Methods

Microbiological methods of research were used in the work.

Conclusions

Testing the ability of collection strains to synthesize exopolysaccharides showed that of the tested 10 cultures, only three lactic cultures (Lactobacillus casei 139, Lactobacillus plantarum No. 2, Lactobacillus cellobiosus No. 20) synthesized exopolysaccharides. Moreover, in the culture of Lactobacillus plantarum No.2 basically, all the colonies remained white and only a few colonies acquired a pink color. This indicates the heterogeneity of the population in terms of biochemical characteristics. The results obtained can be used in the food industry.

COMPARISON OF THREE TYPES JUICY, UNDER COOKED AND COOKED PERFECTLY STEAKS IN TERMS OF MICROBIAL LOAD

Z. Mirzaei[1], N. Khakipour[2]
[1]M.Sc graduated student of Food Science & Technology- Department of Agriculture- Savadkooh Bran ch- Islamic Azad University- Savadkooh- Iran, ., Savadkooh, Iran
[2]Department of Agriculture- Savadkooh Branch- Islamic Azad University, ., Savadkooh, Iran

Backgrounds

Due to population increases, the need for resources protein becomes more. Thus providing enough food has always been regarded with attention to health. On the other hand, given that *Escherichia coli* and Salmonella.sp that cause food-borne illnesses. The world's hundreds of millions of people are suffering from diseases transmitted through food and water.

Objectives

The preparation of food without pollution to the bacteria in the food manufacturing industry has been a constant concern.

Methods

In this study 12 samples of raw meat, juicy steak, cooked medium were examined in term microbial contamination to total count, E. coli and Salmonella in accordance with standard guidelines to numbers 1-5272, 2946 and 1810 respectively.

Conclusions

The results showed that all samples of the bacterial contamination was detected in standard and disposable. According to tests carried out by microbial all raw and cooked meat samples, in three juicy, medium and perfectly cooked in terms of bacterial contamination was less than the standard limit as well as was not observed significant differences between the three samples juicy steak, under cooked and cooked perfectly ($p>0.05$). Therefore result was considered consumable. That their consumption, there is not concern for the consumer. By examining the two parameters of time and temperature on the bacterial contamination of the tested meat steaks, the results of microbiological tests showed that Bacterial contamination, the samples were perfectly cooked steak compared to the state is less than half cooked and juicy. It is recommended the meat perfectly cooked steaks with full thermal process, should be used.

Food Microbiology - Part II

INHIBITION OF LISTERIA MONOCYTOGENES IN MINCED FISH BY USE OF DIFFERENT ALGAE EXTRACTS

M. Khezri[1], M. Rezaei[1], S. Rabiei[1], M. Zolfaghari[1], G. Pesavento[2]
[1]Tarbiat Modares University, Department of Seafood processing- Faculty of Marine Sciences, Noor, Iran
[2]University of Florence, Health Sciences Department- Applied Microbiology Laboratory, Florence, Italy

Backgrounds

Listeria monocytogenes, causative of listeriosis, is one of the most virulent food-borne pathogens worldwide which is frequently reported in seafood products.

Objectives

The aim of this study was to evaluate the inhibitory activity of different algae extracts against *Listeria monocytogenes* in minced fish.

Methods

In this study, Methanol, acetone and chloroform extracts of seven marine algae including *Hypnea hamulosa, Gracilaria corticata, Sargassum angustifolium, Colpomenia sinuosa, Dictyota dichotoma, Chaetomorpha* sp. and *Enteromorpha intestinalis* were investigated for their antibacterial activity against *Listeria monocytogenes* using paper disc diffusion method (Experiment 1). The dried methanol extract of *E. intestinalis* was also applied in minced fish at 0.05%, 0.075%, and 0.1% (w/w) (experiment 2) and the numbers of *Listeria monocytogenes* were counted during storage in refrigerator.

Conclusions

The highest inhibitory activity was shown by methanol extract of *E. intestinalis*. The main identified bioactive component by GC/MS analysis were Cycloheptasiloxane, tetradecamethyl (19.76%), (Z, E)-3,13-octadecadien-1-ol (14.98%), Cyclohexasiloxane, dodecamethyl (12.17%), cis-13,16-Docasadienoic acid, methyl ester (8.80%), 13-Octadecenal, (Z) (8.61%), Cyclodecasiloxane, eicosamethyl (7.58%) and 9-Octadecenoic acid (Z) (5.62%). Methanol extract of *E. intestinalis* at 0.05%, 0.075%, and 0.1% (w/w) reduced respectively the *L. monocytogenes* viable count by 3.23, 3.32 and 3.47 log $cfu.g^{-1}$ after 10 days of storage ($p<0.05$). In conclusion, the methanol extract of *E. intestinalis* showed favorable inhibitory effect against *L. monocytogenes,* which could be considered in the food and pharmaceutical industry.

Food Microbiology - Part II

THE APPEARANCE OF VIABLE BUT NON CULTURABLE STATE IN LISTERIA MONOCYTOGENES DURING FISH BRINING

M. Zolfaghari[1], M. Rezaei[1], A. Mohabbati Mobarez[2], H. Hosseini[3], M. Khezri[1]
[1]Tarbiat Modares University, Department of Seafood processing- Faculty of Marine Sciences, Noor, Iran
[2]Tarbiat Modares University, Department of Bacteriology- School of Medical Sciences, Tehran, Iran
[3]Shahid Beheshti University of Medical Sciences,
Department of Food Science and Technology- Faculty of Nutrition Sciences and Food Technology, Tehran, Iran

Backgrounds

Listeria monocytogenes is a foodborne pathogen which has high resistance for unfavorable conditions. This pathogen is able to entering Viable but non culturable (VBNC) state in harsh conditions.

Objectives

The present study was aimed to consider the possibility of entering of *Listeria monocytogenes* in to VBNC state in heavy brine which used to produce brined fish.

Methods

L. monocytogenes was monitored in three treatments during time: brine containing 30% salt (ES30), brine containing 10% salt (ES10) and starvation condition (DE). For considering alive cells method of gene expression of 16S rRNA was used.

Conclusions

The obtained results showed that this pathogen in ES30 and DE treatments after three days enter in to VBNC state. According to obtained results ES10 treatment entering in to VBNC state on 5 days after inoculation. The results showed that there is the possibility of *L. monocytogenes* to enter into VBNC state during brined and smoked fish or every other brined food product as well as the defect of standard detection methods.

FEMS7-0137
Food Microbiology - Part II

IMPROVED CHARACTERISTICS OF KIMCHI AFTER USING LEUCONOSTOC STRAINS AS A STARTER AND OPTIMIZED CULTIVATION OF THE LEUCONOSTOC STRAIN

B.C. Kim[1], J.H. Lee[1], S.C. Song[1], P. Yong-Ha[1]
[1]ProBionic Corp., Research division, Jeonju-si, Republic of Korea

Backgrounds

Kimchi, fermented vegetable side dishes in Korea, is made with a variety of ingredients, mainly with Korean cabbage and radish, with or without Jeotgal, a salty fermented fish. After mixing all ingredients, the vegetables in Kimchi are fermented by lactic acid bacteria (LAB) during its storage. The taste and storage period of Kimchi is mainly determined by the quality of ingredients and fermentation. During fermentation process, the pH is decreased according to the increase of LAB, and the frequency of some LAB such as *Weissella* sp. *Lactobacillus* sp. and *Leuconostoc* sp. are increased. Among diverse LAB, some hetero fermentative LAB especially *Leuconostoc* spp. mainly influence the taste and flavor of Kimchi.

Objectives

In this study, the improved characteristics of Kimchi after using *Leuconostoc* strains as Kimchi starter were surveyed for the production of high-quality Kimchi. In addition, the growth of *Leuconostoc* strain at diverse culture conditions was observed for commercial production of Kimchi starter.

Methods

Korean cabbage Kimchi was made by a standard recipe for Kimchi. In the initial mixing process, *Leuconostoc* strains used as Kimchi starter were mixed with other ingredients without Korean cabbage. Then the mixture was applied to Korean cabbage. The taste and storage time of Kimchi were measured for the understating of the effects of Kimchi starter. The growth characteristics of *Leuconostoc* strains were observed according to the basic bacteria cultivation protocol for the production of Kimchi starter.

Conclusions

Application of *Leuconostoc* strains as a starter to Korean cabbage enhanced the taste and the storage period of Kimchi. It seems the addition of starter influenced the acidity of Kimchi at initial fermentation stage. Similarly to other LAB, the cell number of *Leuconostoc* strain for Kimchi starter increased at its optimum growth pH range, and three times increase in cell number was observed at pH regulated fermentor culture.

Food Microbiology - Part II

COMPARATIVE GENOME ANALYSIS OF VIBRIO PARAHAEMOLYTICUS REVEALED GENETIC CHARACTERIZATION OF V. PARAHAEMOLYTICUS FORC_004

S. Ahn[1], H. Kim[2]
[1]Seoul National University, Interdisciplinary Program in Bioinformatics, Seoul, Republic of Korea
[2]Seoul National University, Department of Food and Animal Biotechnology, Seoul, Republic of Korea

Backgrounds

Vibrio parahaemolyticus is one of the significant pathogenic agents and capable of causing seafood poisoning in humans in case of consumption of contaminated raw or undercooked seafood. Until recently, *V. parahaemolyticus* pathogenicity of which has been characterized by the presence of *tdh*, *trh* and type three secretion systems(TTSSs). Here, we completed genome sequence of suspected pathogen causing food borne illness *V. parahaemolyticus* FORC_004 without *tdh* and *trh.*

Objectives

V. parahaemolyticus FORC_004, which is suspected pathogen related food poisoning was sequenced to characterize of its genome and investigate the pathogenicity.

Methods

The *V. parahaemolyticus* FORC_004 was isolated from aquarium water in Korea. Whole genome sequencing was performed using Pacbio RS II. Subsequently, reads from sequencing platform were assembled using SMRT portal system with HGAP assembly-3 algorithm. The bioinformatic analysis was performed using various programs such as RAST, Prokka, BASys, JSpecies, WebMGA, BLAST and Roary.

Conclusions

The *V. parahaemolyticus* FORC_004 is composed of two circular chromosomes and one plasmid which are 3,348,850 bps, 1,758,762 bps and 64,049 bps with a GC content of 45.48%. We identified 4,723 protein coding genes in FORC_004 chromosomes and plasmid and among these, 3679 genes assigned to COGs. The FORC_004 strain contains various virulence genes such as *toxR*, collagenase, and TTSS-1 related genes without *tdh* and *trh*. The ANI analysis revealed that FORC_004 strain clustered with BB22OP, RIMD2210633, and CDC_K4557 which are reported virulence strains. Furthermore, we conducted pan-genome analysis. As a result, antitoxin *chpS* and Type IV secretion system protein VirB3, VirB4, and VirB11 were found in only FORC_004.

Food Microbiology - Part II

COMPARATIVE TRANSCRIPTOME ANALYSIS OF CLINICAL ISOLATES OF SALMONELLA ENTERICA ENTERITIDIS IN CONTACT WITH FRESH CABBAGE AND LETTUCE

S. Hong[1], M. Shim[1], B.R. Kim[1], J. Shin[1], J. Lee[1], R.B. Guevarra[1], J.H. Lee[2], H. Yoon[3], S.I. Kim[3], H.B. Kim[1]
[1]Dankook University, Animal Resources Science, Cheonan, Republic of Korea
[2]Kyung Hee University, Department of Food Science and Biotechnology, Yongin, Republic of Korea
[3]Ajou University, Department of Applied Chemistry and Biological Engineering, Suwon, Republic of Korea

Backgrounds

Salmonella enterica is one of the leading causes of food borne disease in the world. Recently, many cases of Salmonellosis outbreaks are caused by *Salmonella*-contaminated fresh vegetables, and *S. enterica* serotype Enteritis is one of the most common *Salmonella* serotypes associated with food borne diseases.

Objectives

The aim of this study was to understand the systemic gene regulations of *S. enterica* serotype Enteritis in contact with fresh cabbage and lettuce.

Methods

S. enterica serotype Enteritis isolated from the feces of infected patients in South Korea were inoculated onto cabbage and lettuce leaves in a minimal medium broth for 2.5 hours, respectively. The bacterial mRNA was sequenced using MiSeq RNA-Seq chemistry. All the experiments were duplicated.

Conclusions

The nitrate-responsive two-component system NarX-NarL genes were significantly up-regulated in *S. enterica* serotype Enteritis in contact with fresh cabbage and lettuce.Also, genes associated with flagella assembly, chemotaxis, and T3SS were significantly up-regulated in both cases. High concentration of nitrate is often found on cabbage and lettuce because of nitrate fertilizer used to grow vegetables, thus up-regulation of the nitrate-responsive two-component system NarX-NarL genes can be beneficial to bacteria growing and colonizing fresh vegetables. It has also been suggested that up-regulations of genes associated with motility, chemotaxis, and T3SS are required for bacteria to colonize vegetables through open stomata. In conclusion, results from this study suggest that the nitrate-responsive two-component system NarX-NarL and genes associated with motility, chemotaxis, and T3SS of *S. enterica* can be potential targets for genetic regulations to reduce *Salmonella* colonization in vegetables.

PAN-GENOME AND METATRANSCRIPTOME ANALYSES REVEAL INSIGHTS INTO THE GENOMIC AND METABOLIC FEATURES OF LEUCONOSTOC MESENTEROIDES DURING KIMCHI FERMENTATION

K.H. Kim[1], B.H. Chun[1], S.E. Jeong[1], C.O. Jeon[1]
[1]Chung-Ang university, life science, Seoul, Republic of Korea

Backgrounds

Leuconostoc (*Leu*) *mesenteroides*, a typical heterofermentative lactic acid bacterium, is generally predominant during kimchi fermentation. However, genomic and metabolic features of *Leu. mesenteroides* have not been extensively explored yet.

Objectives

To investigate genomic features and metabolic properties during kimchi fermentation of *Leu. mesenteroides*, its comprehensive pan-genome and metatranscriptome analyses were performed.

Methods

High quality genomes of *Leu. mesenteroides* were retrieved from GenBank and pan-genome and COG analyses were performed for the estimation of genomic and functional properties. In addition, for the analysis of metabolic features of *Leu. mesenteroides*, all protein sequences were mapped into KEGG pathways and carbon metabolic pathways of *Leu. mesenteroides* were reconstructed. Finally, metatranscriptomic analysis of *Leu. mesenteroides* against the carbon metabolic pathways was performed during kimchi fermentation.

Conclusions

Pan-genomes of eighteen *Leu. mesenteroides* strains consisted of 3,948 pan-genes and 825 core-genes. Phylogenetic analysis based on core-genes showed that *Leu. mesenteroides* strains were differentiated into five different lineages, which was a little different from that based on 16S rRNA gene sequences. Functional properties of *Leu. mesenteroides* by COG analysis were relatively similar with those of other *Leuconostoc* species and *Weissella* species, while they were a little different with those of *Fructobacillus* species. KEGG analysis showed that *Leu. mesenteroides* have abundant carbohydrate metabolic genes and sugar phosphotransferase systems. Metabolic pathway reconstruction suggested that *Leu. mesenteroides* may various metabolites including lactic acid, acetate, ethanol, CO_2, mannitol, 2,3-butanediol, acetoin, and dextran as fermentation products. In addition, metatranscriptomic analysis was performed to investigate metabolic properties of *Leu. mesenteroides* during kimchi fermentation.

FEMS7-1346
Food Microbiology - Part II

NEW KNOWLEDGE ABOUT AN OLD ENEMY: THE HEAT RESISTANT SALMONELLA SENFTENBERG 775W

S. Knøchel[1], *E.J. Boll*[2]
[1]*University of Copenhagen, Dept. Food Science, Frederiksberg, Denmark*
[2]*Statens Serum Institut, Department of Microbiology and Infection Control, Copenhagen, Denmark*

Backgrounds

Salmonella is a common cause of food poisoning and much effort has gone into predicting the heat inactivation of different strains. More than 50 years ago, a particular strain, *Salmonella* senftenberg 775W (=ATCC 43845), originally isolated from dried egg in 1946, was observed to be extremely heat resistant. Several researchers have reported D_{60} -values of this strain to be in the order of 10 times longer compared with strains of "normal" heat resistance. Although the strain has since been used in numerous inactivation studies, the reason for this unusual resistance has never been elucidated and other enhanced resistance phenotypes of this strain have not been reported

Objectives

The aim was to investigate the possible involvement of a recently described locus of heat resistance (LHR) found in some isolates of gram-negative bacteria in the heat resistance of *Salmonella* senftenberg 775W

Methods

The published genome of *Salmonella* senftenberg 775W was used to identify two LHR in this strain. The *clpK* genes as well as the LHR1 and LHR2 clusters of *Salmonella* Senftenberg 775W were subsequently deleted by allelic exchange and inactivation studies were performed

Conclusions

Salmonella senftenberg 775W harbors two variants of a locus of heat resistance (LHR) genes. The heat resistant phenotype of 775W is attributable to the two LHRs and, more specifically, to the LHR-encoded ClpK belonging to the family of Clp ATPases with chaperone activity. Notably, the wild type also exhibited another non-thermal stress resistant phenotype compared with the mutants indicating that LHR-containing strains have an enhanced survival potential in different settings.

FEMS7-3204
Food Microbiology - Part II

VANCOMYCIN RESISTANCE IN LACTOBACILLUS SP. IS AN EVOLUTIONARY TRAIT AND NOT DEPENDENT ON FERMENTATIVE PATTERNS

G.M. Knudsen[1], *B. Stuer-Lauridsen*[1], *Y. Agersø*[1], *E.J. Boll*[1], *A. Wind*[1]
[1]*Chr. Hansen, Identification, Hørsholm, Denmark*

Backgrounds

Some species of *Lactobacillus* such as *L. plantarum* are vancomycin resistant, whereas others such as *L. acidophilus* are sensitive. For food and feed cultures, the European Food Safety Authority (EFSA) set cut-off values to identify antimicrobial resistant strains as they may contain transmissible antibiotic resistance. For the heterogeneous group of *Lactobacillus* sp. the cut-off values are mainly based on fermentative status i.e. homofermentative species being sensitive and heterofermentatives being resistant. However, the homofermentative *L. mali* is vancomycin resistant.

Objectives

The aim of this study was to elucidate the vancomycin resistance pattern of the *Lactobacillus* genus.

Methods

A BlastX search of the genome of *L. mali* LBA-20315 against the ResFinder database was performed, but no hits with more than 50% identity (E value > 1.9×10^{-54}) to vancomycin resistance genes were detected. To investigate the vancomycin resistance pattern in a broader context, the susceptibility towards vancomycin of 25 species (N= 398) was investigated. In addition to *L. mali,* vancomycin resistance was observed within the homofermentative species *salivarius* and *farciminis*. The presence of genes involved in vancomycin resistance i.e. *ldh*, *aad*, *lar* and *ddl* was investigated in 11 species and no correlation with vancomycin resistance was observed. However, phenotypic vancomycin resistance correlated with different alleles of *ddl* encoding a D-alanine-D-alanine ligase also referred to as *vanA*.

Conclusions

Thus, this study indicates that vancomycin resistance is an evolutionary trait depending of variation within the *ddl* gene causing intrinsic resistance and is independent of fermentative status. Sequencing of further species is ongoing to support these conclusions.

FEMS7-2855
Food Microbiology - Part II

BIOFILM FORMATION BY LISTERIA SPP., LACTOBACILLUS SPP. AND PSEUDOMONAS SPP. AND INACTIVATION OF CELLS IN SINGLE-SPECIES BIOFILMS

A. Kocot[1], M. Olszewska[2], Ł. Łaniewska-Trokenheim[2]
[1]University of Warmia and Mazury in Olsztyn,
Faculty of Food Science- Chair of Industrial and Food Microbioogy, Olsztyn, Poland
[2]University of Warmia and Mazury in Olsztyn,
Faculty of Food Science- Chair of Industrial and Food Microbiology, Olsztyn, Poland

Backgrounds

The biofilm is the most common mode of bacterial existence in various environments, including food processing environments. In the food processing context, the biofilm is considered as a serious hygienic challenge and a greater risk factor of bacterial transmission. Therefore studies concerning formation dynamics and inactivation of biofilms are crucially important parts of food safety.

Objectives

1. Estimation of the ability of *Listeria* spp., *Lactobacillus* spp. and *Pseudomonas* spp. to form biofilms.
2. Examination of the formation dynamics of single-species biofilms.
3. Evaluation of the biofilm resistance to disinfectants used in the food industry.

Methods

The ability to form biofilms was studied using the microtiter plate assay with crystal violet (CV) staining. The biofilm formation dynamics in 24-h intervals and cell inactivation after 72-h incubation were examined by plate counting and fluorescence staining with calcein-AM and TOTO-1, which gave an insight into changes in the bacterial culturability and cell membrane integrityat the single cell level.

Conclusions

Listeria spp., *Lactobacillus* spp. and *Pseudomonas* spp. showed differences in the ability to form biofilms and the biofilm formation dynamics over 72-h incubation. *Listeria* spp. and*Lactobacillus* spp. grew well and to higher cell counts whereas *Pseudomonas* spp. grew slowly and to lower cell counts. Although all disinfectants used in this study reduced cell numbers in biofilms to some extent, their persistence may still pose a risk of food contamination.

This study was supported by a grant from the National Science Centre, Poland, no. 2016/21/N/NZ9/01327.

Food Microbiology - Part II

GENE PROFILING-BASED PHENOTYPING FOR IDENTIFICATION OF CELLULAR PARAMETERS THAT CONTRIBUTE TO FITNESS, ROBUSTNESS AND VIRULENCE OF ACID RESISTANT LISTERIA MONOCYTOGENES VARIANTS

J. Koomen[1], K.I. Metselaar[1], M.H. Tempelaars[1], L.M. Wijnands[2], M.H. Zwietering[1], H.M.W. den Besten[1], T. Abee[1]
[1]Wageningen University & Research, Laboratory of Food Microbiology, Wageningen, The Netherlands
[2]The National Institute for Public Health and the Environment RIVM, Centre for Zoonoses and Environmental Microbiology, Bilthoven, The Netherlands

Backgrounds

When bacterial populations are subjected to food relevant lethal stresses, such as heat and low pH, a small fraction of the population may survive. Previous studies reported isolation of stable stress resistant *Listeria monocytogenes* variants after a single exposure to acid stress. Phenotypic clustering and subsequent whole genome sequencing of the stress resistant variants revealed various mutations in *rpsU*, encoding ribosomal protein S21, in the largest phenotypic cluster.

Objectives

To elucidate features that can contribute to fitness, robustness and host interaction of stress resistant variants using a comparative gene profiling and phenotyping approach on two different *rpsU* variants.

Methods

Using a microarray we found 332 genes differentially expressed with 173 upregulated in the variants including a major contribution of Sigma-B controlled genes encoding for example the acid resistance-associated glutamate decarboxylase (GAD) system and genes involved in glycerol metabolism (*glpF*, *glpK*, *glpD*), compatible solute uptake (*OpuA*, *OpuC*) and virulence (*IntA*, *IntB*). In contrast, a strong downregulation was observed in the variants for genes involved in flagella synthesis and motility.

Conclusions

Phenotyping results matched the gene profiling data including enhanced acid resistance, higher glycerol utilisation rates, enhanced freezing resistance conceivably mediated by higher intracellular levels of compatible solutes, and better adhesion to Caco 2 cells presumably linked to higher expression of internalins. Finally, bright field and electron microscopy analysis confirmed the downregulation of flagella in the variants. Our study provides further insights in cellular parameters, that can affect robustness, fitness, and virulence of *L. monocytogenes rpsU* variants selected after exposure to food relevant stress conditions.

HYDROGEN PEROXIDE TREATMENT OF FOOD-BORNE PATHOGENS

M. Kostrzynska[1], *J. Tang*[1], *G.Y. Mei*[1]
[1]*Agriculture and Agri-Food Canada, Guelph Research and Development Centre, Guelph, Canada*

Backgrounds

Shiga toxin-producing *Escherichia coli* (STEC) O103:H2 is one of the most common non-O157 serotypes linked to infections in humans. Hydrogen peroxide and other oxidative-based sanitizers are widely used in the food industry to control STEC and other food-borne pathogens.

Objectives

The objective of this study was to examine the response to oxidative stress in *E. coli* O103:H2 logarithmic and stationary phase planktonic cells, and in biofilms.

Methods

Transcriptional responses of *E. coli* O103:H2 stress and virulence genes induced by hydrogen peroxide treatment were examined using quantitative real-time RT PCR. Key virulence genes such as gene encoding intimin (*eae*), Shiga-toxin gene *stx1A* and flagellin gene (*fliC*) were included in this study. In addition, expression of well-known stress-associated genes such as genes involved in response to oxidative damage (*oxyR, sodA, soxR*), general stress (*uspA, rpoS*), starvation (*phoA, dps*), acid resistance (*gadW*), cold shock (*cspA, cspC, cspE*) and gene related to UV radiation stress (*mutS*) was also investigated.

Conclusions

Different gene expression patterns induced by hydrogen peroxide treatment were observed in *E. coli* O103:H2 logarithmic cells compared to biofilms and planktonic cells in stationary phase. Results derived from this study demonstrate the importance of considering biofilms and stationary phase planktonic cells when evaluating novel sanitizing methods.

FEMS7-2829

COMPARISON BETWEEN SWABBING DEVICES IN ORDER TO ANALYZE THE MICROBIAL FLORA FOUND IN SURFACES OF COMMUNITY KITCHENS BY CLASSICAL MICROBIOLOGY AND METAGENOMICS

S. Krings[1], C. Rodriguez[1], B. Taminiau[1], G. Daube[1]
[1]University of Liège - Faculty of Veterinary Medicine, Food Science Department - Food Microbiology, Liège, Belgium

Backgrounds

The work in community kitchens involves several manual steps which justifies accurate control of surfaces to prevent foodborne illnesses. Different sampling methods have been proposed to isolate bacteria from surfaces. However, recovery efficiencies of these methods are very different and not always comparable.

Objectives

The aim of this study is to evaluate different sampling methods to detect the presence of pathogenic bacteria on surfaces in contact with foods. The recovery efficiency was examined by classical microbiology an culture-independent metagenomic analysis.

Methods

To mimic surfaces which can be found in community kitchens, sterile polypropylene stainless steel surfaces and cutting boards were spiked with serial dilutions of *Escherichia coli, Salmonella enterica* and *Bacillus cereus*. They were left to dry for 1-2 hours before collection of the surviving bacteria with different moistened swabs, including commercial swabs (sponges-HS10NB2G, Sponge-Sticks-SSL100; 3M) and cotton and gauze pads. Different solutions were tested to moisten the swabs (physiological water (0,85% NaCl), Maximum Recovery Diluent and quarter-strength Ringer solution). Bacterial population analysis was performed by classical methods and metagenomics.

Conclusions

Important differences on bacterial survival were observed depending on their nature and the solution used to collect them from the surfaces. Maximum Recovery Diluent and cotton pads showed the best results in relation with bacteria recovery and required technical skills. Metagenomic analysis showed a higher detection sensibility than classical microbiology. However, preliminary results showed that both methods are necessary to improve the detection of pathogens in surfaces.

FEMS7-0364
Food Microbiology - Part II

ENTEROTOXIGENIC CLOSTRIDIUM PERFRINGENS SPORES IN U.S. RETAIL SPICES

R. Labbe[1], *C. Lee*[1]
[1]*University of Massachusetts, Food Science, Amherst, USA*

Backgrounds

Recent outbreaks of illness due to pathogens in spices has highlighted this commodity as a potential vehicle of foodborne illness. High levels of bacterial spores have long been known to be associated with spices. *Clostridium perfringens* is a leading cause of foodborne illness in the U.S. due to its ability to produce an enterotoxin. Previous surveys of its presence in spices did not assess its toxin-producing potential. The public health importance of this organism cannot be determined by its presence alone but also by the enterotoxigenicity of isolates

Objectives

To determine the levels and enterotoxigenicity of *C. perfringens* spores in U.S. retail spices.

Methods

A initial three-tube MPN procedure was used. Samples of 246 spices were diluted at 1:10, heated at 75°C, inoculated into iron milk medium and incubated at 37°C overnight. Template DNA was isolated from mid-phase cells using a boiling procedure. The presence of the enterotoxin (*cpe*) and alpha toxin (*cpa*) genes were determined using previously published primers. Spores were produced using the sporulation medium of Duncan and Strong.

Conclusions

Levels of *C. perfringens* spores ranged from 3.6 to 2400/gm from 43 of the 246 samples . Of these 27 possessed the *cpe* gene, a level much higher than the standard distribution of approximately 5% from retail, non-outbreak foods such as meat and poultry. *C. perfringens* sold in packages was isolated from 22% of samples compared to 14% purchased in bulk. Given the heat resistance of bacterial spores it is possible that spices are a potential vehicle for foodborne illness by this organism when used in food preparation.

Food Microbiology - Part II

LIQUID CHROMATOGRAPHY-HIGH RESOLUTION MASS SPECTROMETRY-BASED METABOLITE PROFILING OF SALMONELLA ENTERICA BIOFILM

A. Lamas[1], *P. Regal*[1], *B. Vazquez*[1], *A. Cepeda*[1], *C.M. Franco*[1]
[1]*University of Santiago de Compostela, Analytical Chemistry- Nutrition and Bromatology, Lugo, Spain*

Backgrounds

Salmonella enterica is responsible for foodborne diseases worldwide. *Salmonella* strains persist in the food chain partially thanks to their ability to produce biofilm. Environmental conditions and surfaces affect in different ways the biofilm formation. There are few studies defining in detail the particular metabolome of these structures under different scenarios

Objectives

The aim of this study was stablishing the metabolite profile of the *Salmonella* biofilms cells growth under different conditions.

Methods

Two strains of *S.* Typhimurium and *S.* Enteritidis with great ability to produce biofilm were used. The strains were allowed to form biofilm under different environment conditions and the metabolites were measured using LC-HRMS profiling.

Conclusions

Metabolomics appears as a good tool to explore the biofilm formation pathways in *Salmonella*.

Food Microbiology - Part II

INFLUENCE OF SURFACE, TEMPERATURE AND GROWTH MEDIUM ON THE TRANSCRIPT PROFILE OF SALMONELLA ENTERICA

A. Lamas[1], A.M. paz[1], B. Vazquez[1], A. Cepeda[1], C.M. Franco[1]
[1]University of Santiago de Compostela, Analytical Chemistry- Nutrition and Bromatology, Lugo, Spain

Backgrounds

Salmonella enterica is a major foodborne pathogen. One of the principal concerns about this microorganism in their capacity to persist in the food environment through biofilm formation. Previous studies had demonstrated the capacity of *S. enterica* to form biofilm in different surfaces as polystyrene, glass or stainless steel.

Objectives

The aim of this study is determine how different surfaces and conditions of temperature and nutrients affect to gene expression of biofilm related genes (*adr*A, *csg*D), quorum sensing genes (*lux*S and *sdi*A) and small RNA (*brc*Z, *bxy*S, *bcs*A, *rpr*A). A total of 12 strains belonging to 5 different serotypes of *S. enterica* (*S.* Typhimurium, *S.* Enteritidis, *S.* Newport, *S.* Infantis, *S.* Bardo) were used in this study

Methods

The cells were able to produce biofilm in polystyrene and stainless steel surfaces and incubated at 6ºC, 28ºC and 37ºC. Two growth media were used: a high nutrient concentration media and a low nutrient concentration media. After incubation, the RNA was extracted and cDNA synthetized. Relative quantification of genes and small RNAs expression was measured using Real-Time PCR and SYBR® Green.

Conclusions

The transcript profile of biofilm cells of *Salmonella* enterica is influenced by the conditions used.

COMPATIBILITY OF SELECTED PROBIOTIC STRAINS WITH PREBIOTIC CARBOHYDRATES AND THEIR SYNBIOTIC APPLICATION IN CHEESE

S. Langa[1], E. Van del Bulk[2], Á. Peirotén[1], P. Gaya[1], H.A. Schols[2], J.L. Arqués[1]
[1]Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria INIA, Tecnología de Alimentos, Madrid, Spain
[2]Wageningen University, Laboratory of Food Chemistry, Wageningen, The Netherlands

Backgrounds

To increase the beneficial effects of probiotic bacteria, prebiotics can be introduced in order to selectively stimulate the growth and/or activity of probiotics, giving rise to symbiotic products.

Objectives

The aim of this study was to test the compatibility of bacteria strains, selected based on their technological and probiotic characteristics, with different commercial prebiotic carbohydrates in order to select the optimal combination for the development of a symbiotic cheese.

Methods

The growth of three lactobacilli and one bifidobacteria strains in combination with different carbohydrates was monitored in optimized growth media and milk. Cheese was manufactured containing the selected synbiotic combination of *Lb. paracasei* INIA P272 and fructo-oligosaccharides (FOS). INIA P272 viability and physico-chemical characteristics of cheese were analysed after 28 days of ripening and compared with control cheeses.

Conclusions

Addition of FOS enhanced the growth of *Lb. paracasei* INIA P272 in optimized growth media, whereas this combination did not result in a higher number of probiotic bacteria in the synbiotic cheese. However, organic acid analysis detected higher lactic and acetic acid levels when FOS was included, suggesting an increase of *Lb. paracasei* INIA P272 metabolism upon addition of FOS to the cheese. Thus, the inclusion of FOS in the probiotic cheese could have a beneficial effect in the survival of *Lb. paracasei* INIA P272 and in host microbiota.

HUMAN BIFIDOBACTERIUM STRAINS PERFORMANCE DURING MANUFACTURE AND RIPENING OF SEMI-HARD CHEESE

E. Mínguez[1], Á. Peirotén[1], S. Langa[1], J.L. Argués[1], P. Gaya[1], M. Nuñez[1], M. Medina[1]
[1]Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria INIA, Tecnología de Alimentos, Madrid, Spain

Backgrounds

Bifidobacterium strains have been commercially exploited as probiotic due to their associated health benefits and GRAS status. Bifidobacterial survival and growth require anaerobic environments, conditions found in cheese.

Objectives

Evaluation of bifidobacteria strains as adjunct cultures during manufacture and ripening of semi-hard cheeses, made with a commercial starter, and their viability after their passage through simulated gastrointestinal conditions (SGC).

Methods

B. pseudolongum INIA P2, *B. longum* INIA P678 and *B. breve* INIA P734 were selected for this study according to their good technological properties. Viability of the strains was monitored in cheese and after its exposure to SGC during the ripening period. Physico-chemical and sensory analysis of cheeses was performed after 7 and 28 d of ripening.

Conclusions

INIA P2 and INIA P734 exhibited a high survival in 28 d cheese and reductions lower than 1 log units after SGC. The addition of these strains did not affect physico-chemical quality of cheeses. In contrast, low survival of INIA P678 was observed in cheese, receiving lower scores for odour, texture and taste quality after sensory analysis. Our study suggest that *B. pseudolongum* INIA P2 and *B. breve* INIA P734 are suitable as adjunct cultures for probiotic cheese production.

COMPLETE GENOME SEQUENCE OF GLUCONOBACTER OXYDANS GV30-1 ISOLATED FROM FERMENTED VINEGAR IN SOUTH KOREA

H.Y. Lee[1], J.H. Lee[1], H.J. Kwon[1], J.Y. Kim[1], Y.J. Goh[1], M.S. Ahn[1]
[1]Gangwondo Agricultural Research and Extension ServicesGARES, Agro-food Research Institute, Chuncheon, Republic of Korea

Backgrounds

Acetic acid bacteria (AAB) are obligate aerobes and a widely divergent group in the alpha-proteobacteria. It is unique microorganisms to oxidize alcohols such as ethanol. *Gluconobacter oxydans* GV30-1 has been used to produce traditional vinegar in many countries. We isolated *G. oxydans* GV30-1 from fermented vinegar in South Korea. The chromosome consists of 3,198,950 base pairs and contains 3,069 open reading frames. The numbers of ribosomal RNA and transfer RNA genes are 12 and 57 respectively. The GC ratio is 60.54%.

Objectives

The objectives of this study is to isolate novel acetic acid bacteria producing high acetic acid.

Methods

A total 3,198,950 bp of data corresponding to 92,319 reads with Pacbio 20kb. For assembly, we used CLC Genomics workbench 6.5.1.

Conclusions

The genome analysis of *A. G. oxydans* GV30-1 provided detail insights into understanding metabolic fermentation of *G. oxydans* GV30-1. We will study more genetic information to manufacture high-quality of vinegar.

Food Microbiology - Part II

CHARACTERIZATION AND PURIFICATION OF THE NOVEL BACTERIOCIN PRODUCED BY BACILLUS SP. AMP-18

J.Y. Lee[1], *D.O. Kang*[1]
[1]*Changwon National University, Department of Bio Health Science, Changwon-si, Republic of Korea*

Backgrounds

Bacteriocins are ribosomally synthesized by diverse bacteria exhibit antibacterial activity against bacteria closely related to producer strains. Korean traditional foods are good source for screening bacteriocin-producing bacterial strains.

Objectives

This study was performed to obtain a novel bacteriocin from bacterial strains isolated from fermented foods. We characterized and purified the bacteriocin.

Methods

We collected various fermented foods and isolated bacteria, followed by cultivation at 37°C, 24-h. The antibacterial activity of culture supernatant was confirmed by agar well diffusion method. The physicochemical properties such as heat, pH and solvent resistance were studied. The bacteriocin was purified via three steps. Molecular weight and N-terminal amino sequences were determined.

Conclusions

Maximum inhibitory activity were achieved at an initial pH of 7.5 and at 37°C for 24-h growth. The antibacterial activity was retained at the pH range from 2.0 to 8.0 but decreased more than at 8.0. The bacteriocin activity was stable at up to 80°C for 40 min but 80% of activity was lost at 100°C for 10 min. The bacteriocin was highly resistant to solvents such as acetonitrile, methanol, isopropanol at up to 100% concentration but sensitive to 100% butanol. Its molecular weight was determined to be 3.4 kDa by mass spectrometry. The 15-N-terminal amino acid sequences of the purified bacteriocin were determined to be L-P-I-P-A-D-L-V-D-G-P-X-G-P-R. Amino acid sequence alignment analysis showed this bacteriocin is possibly novel one. The bacteriocin exhibited its antibacterial activity against through bacteriostatic action. The bacteriocin inhibited growth of *Listeria monocytogenes* KCCM 40307 in beef stored at 4°C for 15 days.

FEMS7-1619
Food Microbiology - Part II

SYNERGISTIC EFFECT OF DNASE I PRETREATMENT COMBINED WITH SODIUM HYPOCHLORITE SANITIZER TREATMENT IN INACTIVATION OF CAMPYLOBACTER BIOFILMS

J.Y. Lee[1], J.S. Kim[2]
[1]Korea Food Research Institute, Food Analysis Center, 1201 Anyangpangyo-ro- Bundang-, Republic of Korea
[2]Korea Food Research Institute, Research Group of Food Safety, 1201 Anyangpangyo-ro- Bundang-gu- Seong-nam si, Republic of Korea

Backgrounds

Campylobacter jejuni is a foodborne pathogenic bacterium associated with poultry. It can form biofilms on food contact surfaces, which can pose a raised threat because biofilms are likely to be highly resistant to environmental stresses including sanitizers. Therefore, an effective control method needs to be developed for *Campylobacter* biofilms.

Objectives

The objective of this study was to evaluate synergistic effect of DNase I and sodium hypochlorite combinations in inactivation of *campylobacter jejuni* biofilms.

Methods

The biofilms of two *Campylobacter jejuni* strains, NCTC 11168 reference strain and a strain, Y23-5 from chickens were evaluated for sensitivities to DNase Ⅰ and sodium hypochlorite treatments. Biofilms grown in 96-well plates were pre-treated with DNase I with subsequent sodium hypochlorite treatment (10 or 20 ppm). The detached cells after vigorous shaking were serially 10-fold diluted up to 10^{-4}, then 100 ul aliquots were spread on blood agar plates, and the colonies were enumerated after incubation.

Conclusions

In strain 11168, neither DNase I or sodium hypochlorite treatment was effective in inactivation of biofilms. However, sodium hypochlorite treatment (10 or 20 ppm) after DNase I pre-treatment effectively inactivated biofilms by 2.7 log CFU and more than 4.3 log CFU at 10 ppm and 20 ppm, respectively ($P<0.05$). Similarly, in strain Y23-5, sodium hypochlorite treatment (10 ppm) after DNase I pre-treatment effectively inactivated the biofilms by more than 3.5 log CFU ($P<0.05$), while either method was not effective when used alone. This study clearly shows that DNase I combined with Sodium Hypochlorite has a synergistic effect in inactivation of *Campylobacter* biofilms.

PHYLOGENETICAL AND PAN GENOME ANALYSES OF FOOD-BORNE PATHOGENS, BACILLUS CEREUS ISOLATED FROM SOUTH KOREA

Y.T. Kim[1,2], H. Kim[2,3], S. Ryu[2,3], S.H. Choi[2,3], J.H. Lee[1,2]
[1]Kyung Hee University, Food Science and Biotechnology, Yongin, Republic of Korea
[2]Seoul National University, Food-borne Pathogen Omics Research Center-FORC, Seoul, Republic of Korea
[3]Seoul National University, Food and Animal Biotechnology, Seoul, Republic of Korea

Backgrounds

Pan genome analysis is useful technique to compare whole genome sequences. It offers core proteins and strain specific proteins to users. Recently, it used to compare complete genomes of *Bacillus cereus* strains isolated from food samples causing food-borne outbreaks in South Korea with other foreign *B. cereus* genomes.

Objectives

Nine genomes of *B. cereus* were obtained from FORC genome database and comparatively analyzed to reveal distinct features between South Korean *B. cereus* and other foreign *B. cereus* strains in phylogenetic and Pan-genome level.

Methods

Nine genomes of South Korean *B. cereus* strains were completely sequenced and assembled using PacBio system. The open reading frames (ORFs) were predicted by merging with GeneMarks and Glimmer, and their functions were annotated using BlastP and Interproscan. Other *B. cereus* genome information was obtained from GenBank database. Comparative genome analysis was performed using JSpecies program for average nucleotide identity (ANI) analysis and Roary program for Pan-Genome analysis.

Conclusions

The phylogenetical tree using ANI method showed that *B. cereus* has two phylogenetic tree groups, Group I and II. Interestingly, all South Korean *B. cereus* strains belong to the Group II . Most of *B. cereus* strains in the Group II are clinical isolates with high pathogenicity, suggesting that all South Korean *B. cereus* are pathogenic indeed. In addition, Group II consists of four subgroups in the phylogenetic tree. To clarify and determine the distinct features of strains in the subgroups, their pan-genome analysis was performed. This analysis revealed that each subgroup strain has different specific genes. Based on these comparative results, Group- or subgroup-specific primer sets targeting specific genes can be designed. Using this specific PCR primer set, Group I vs. II as well as each subgroup in the Group II will be able to be distinguished using specific PCR to identify the isolated *B. cereus* strain quickly.

SELECTION, VERIFICATION, PARTIAL OPTIMIZATION OF IN VITRO EFFICACY OF ANTI-AFB1 ACTIVITY OF CHRYSEOBACTERIUM SP. C4A USING EXTRACELLULAR FRACTION AND ISOLATION OF ACTIVE PROTEIN

A. Limaye[1], *J.R. Liu*[2,3,4]
[1]*Institute of Biotechnology, National Taiwan University, Taipei, Taiwan R.O.C.*
[2]*Institute of Biotechnology, National Taiwan Iniversity, Taipei, Taiwan R.O.C.*
[3]*Agricultural Biotechnology Research Center, Academia Sinica, Taipei, Taiwan R.O.C.*
[4]*Department of Animal Science and Technology, National Taiwan University, Taipei, Taiwan R.O.C.*

Backgrounds

Aflatoxins, the difuranocoumarin derivatives; are the hazardous mycotoxins secreted mainly by the filamentous fungi *Aspergillus flavus* as secondary metabolites. Among different aflatoxins, aflatoxin B1 (AFB1) is identified as the most toxic hepatocarcinogen.

Objectives

Our objectives are 1) to screen and select best AFB1 degrading bacteria, 2) to identify degradation metabolites, and 3) to identify anti-AFB1 active compound and responsible gene.

Methods

Using coumarin minimal selection medium we screened for AFB1 degraders from chicken ileo-cecal digesta sample. Additionally we also compared coumarin degrading potential for keratinolytic soil bacterium *Chryseobacterium* sp. c4a. The cell free anti-AFB1 activity was validated by MALDI/TOF and RP-HPLC as qualitative and quantitative methods respectively. Anti-AFB1 activity of c4a strain was partially optimized for optimum reaction temperature, pH, theromstability and essential metal co-factors. We used a UPLC/LTQ Orbitrap LC/MS to analyze chemical profile of cell free supernatant in presence of AFB1. Upon protein concentration of active cell free fraction using tangential flow filtration, we performed the FPLC size exclusion chromatography followed by AFB1 degradation for all collected fractions.

Conclusions

Strain c4a demonstrated exclusively extracellular, constitutive anti-AFB1 degradation ability. It showed upto 85% AFB1 degradation for concentrations exceeding to 2 ppm when originally grown in plain nutrient broth containing gelatin. HPLC profile showed a cleavage of original AFB1 peak. LC/MS/MS analysis showed bixin as a major metabolite present in active fraction which is a natural apocarotenoid. Currently, we are sequencing the whole genome of c4a strain using NGS along with protein purification and anti-AFB1 gene identification studies to establish its anti-AFB1 role.

ENDOPHYTIC FUNGUS FUSARIUM GRAMINEARUM AS A BIOSYNTHESIS FACTORY OF SILVER NANOPARTICLES WITH BROAD ANTIMICROBIAL ACTIVITY

X. Liu[1], H. Peng[2], Y. Hu[1], Y. Liu[2], J. Zhou[1]
[1]Jiangsu Academy of Agricultural Sciences, Institution of Argo-product Processing, Nanjing, China
[2]Shanghai Ocean University, College of Food Science and Technology, Nanjing, China

Backgrounds

Synthesis of nanoparticles, especially silver nanoparticles (AgNPs) with the antimicrobial activity, is an emerging field. But conventional physical and chemical methods proved to be toxic due to the aid of reducing agents or under extreme temperature and pressure conditions. Green synthesis using microorganisms could be an attractive advancement.

Objectives

This study aims to isolate and identify an endophytic fungus from *Dendrobium candidum*, and to evaluate its biosynthesis capacity of antimicrobial silver nanoparticles(AgNPs).

Methods

The fungus, isolated from the stem of *D.candidum* after surface sterilization, was identified based on internal transcribed spacer (ITS) sequence and morphological traits. The filtrate solution of the fungal biomass in distilled water was subjected for extracellular biosynthesis of AgNPs. The AgNPs were characterized by UV-visible spectroscopy and transmission electron microscopy (TEM), and were tested for antimicrobial activity by the agar well diffusion method against several food-borne pathogens including bacteria and fungi.

Conclusions

Endophytic fungus DO-1 was identified as *Fusarium graminearum*. UV-visible spectroscopy showed AgNPs had the surface plasmon resonance at 440~450 nm. Darkness and suitable high temperature (80 ºC) were helpful for the biosynthesis of AgNPs and the increase of antimicrobial activity. As the increase of pH, the absorbance at 440~450 nm increased, but the highest antimicrobial activity was observed at pH 7~8. TEM revealed AgNPs to be spherical with the diameter of 2~50 nm. The antimicrobial activity of AgNPs against the tested pathogens showed the inhibition zone ranging from 11 to 18 mm. The biosynthesis of AgNPs using endophytic *F.graminearum* in a facile way is simple and eco-friendly.

Food Microbiology - Part II

GALACTOMYCES GEOTRICHUM ISOLATED FROM KEFIR GRAINS: ADHESION INTERACTION WITH OTHER BACTERIA

X. Liu[1], H. Peng[2], Y. Hu[1], J. Zhou[1]
[1]Jiangsu Academy of Agricultural Sciences, Institution of Argo-product Processing, Nanjing, China
[2]Shanghai Ocean University, College of Food Science and Technology, Shanghai, China

Backgrounds

Kefir grains possess a complex and stable microbiota association. Current studies on the microbial population and symbiotic interactions laid special emphasis on the role of lactic acid bacteria. There's no detailed report about the role of fungi.

Objectives

This study aims to investigate the adhesion properties of a yeast-like fungus obtained from kefir grains, and to evaluate its role on the microflora formation of kefir grains.

Methods

The isolate KG-1 was identified morphologically and phylogenetically. The adhesion ability of the fungus with other bacteria was observed using optical microscope and scanning electron microscope observation. Different pretreatments, including heat, sodium hydroxide (NaOH), acetic acid, and lithium chloride (LiCl), were used to evaluate the adhesion activity of the nonviable or partially damaged cells. Auto-aggregation, co-aggregation abilities and cell surface hydrophobicity were determined spectrophotometrically.

Conclusions

The fungus KG-1, identified as *Galactomyces geotrichum*, had great adhesive activity with various bacteria. Exposure to LiCl aroused the marked loss of attached bacteria, while acetic acid treatment led to a thicker adhesion. Heat and NaOH treatment had non-significant effect on the interaction. A strong affinity to xylene (83.49%) and chloroform (87.5%) as well as a low affinity to ethyl acetate (42.22%) indicated the hydrophobic and basic phenotype of *G. geotrichum* KG-1, with strong electron donor property, contributing to the extremely strong auto-aggregation ability (97.48%). Different treatments changed the surface properties greatly. The unique adhesion and aggregation properties of *G.geotrichum* contribute greatly to the biofilm and grain formation in kefir.

FEMS7-0955
Food Microbiology - Part II

LYOPHILIZATION: EFFECT ON HUMAN MILK BACTERICIDAL PROPERTIES AND EFFECT ON MICROBIAL OCCURRENCE

M. Lozano Fuentes[1], L.M. Carmen[1], M. Gormaz[2], J. Salcedo[3], S.C. Dolores[1]
[1]UNIVERSIDAD CEU CARDENAL HERRERA,
ANIMAL PRODUCTION- ANIMAL AND PUBLIC HEALTH- FOOD TECHNOLOGY AND SCIENCE, Alfara del Patriarca, Spain
[2]Hospital Universitario La Fe de Valencia, Banco de Leche Humana, Valencia, Spain
[3]UC Davis, UC Davis, Davis, USA

Backgrounds

Lyophilization is highly valued as a storage technique for complex products that require quality guarantees. Thus, it may be a good alternative to storing Human Milk (HM) in Human Milk Banks (HMB) because this technique, can offer maximum preservation of the properties of the original product, such as bactericidal properties.

Objectives

Study of the effects of lyophilization in HM as a method of storage in HMBs on mesophilic aerobic microorganisms occurrence and HM bactericidal properties.

Methods

Lyophilization

A total of 125 HM samples from 65 healthy donors in the HMB of La Fe Hospital (Valencia, Spain) were analyzed. Each sample collected, was thawed and divided into 2 aliquots of 10ml each. One of this was used to lyophilization (Telstar Cryodos, Mannheim) and the other aliquot was used as a control, freezing at -20°C.

Microbial occurrence

Mesophilic aerobic counts were determined in each aliquot using plate count agar and incubating at 31°C for 72 hours. The results were expressed as colony-forming units per milliliter (CFU/ml).

Determination of Bactericidal Capacity

The bactericidal effect against *Escherichia coli* was assessed using the method described by Silvestre et al (2006) [1].

[1] Silvestre D., Lopez M.C., March L., Plaza A. and Martinez-Costa C. 2006. Bactericidal activity of human milk: stability during storage. *British Journal of Biomedical Science*, 63(2):59-62

Conclusions

Lyophilization significantly lowered the counts of mesophilic aerobic microorganisms compared with freezing at -20°C (*average*= $29 \cdot 10^3$ CFU/mL in frozen samples at -20ºC and *average* = $15 \cdot 10^3$ CFU/mL in lyophilized samples). In the other hand, there are not significant differences of bactericidal capacity attributable to the storage method used.

FEMS7-0264
Food Microbiology - Part II

ISOLATION AND CHARACTERIZATION OF A BACTERIOPHAGE AGAINST SALMONELLA ENTERICA SEROVAR MONTEVIDEO

Z. Lu[1], S. Kim[1], F. Breidt[2], J. Niedermeyer[3], S. Kathariou[3]
[1]Kennesaw State University, Molecular & Cellular Biology, Kennesaw, USA
[2]NC State University and USDA/ARS, Food- Bioprocessing- and Nutrition Sciences, Raleigh, USA
[3]North Carolina State University, Food- Bioprocessing- and Nutrition Sciences, Raleigh, USA

Backgrounds

Salmonella enterica serovar Montevideo is globally distributed. It is among the most common serovars isolated from humans and animals. Numerous foodborne outbreaks in different countries have been linked to *S*. Montevideo. Effective control of *S*. Montevideo is important to public health. Using bacteriophages to control foodborne bacterial pathogens is a promising novel biocontrol method.

Objectives

The objectives of this study were to isolate and to characterize a bacteriophage infecting *Salmonella* serovar Montevideo.

Methods

The phage (named ΦMont) was isolated from turkey feces and characterized based on its morphology, host range, one-step growth kinetics, and structural protein profile.

Conclusions

Phage ΦMont formed very large clear plaques on its host lawn. Transmission electron microscopy revealed that the phage belongs to the *Podoviridae* family. Host range analysis showed that the phage was serovar-specific and only infected *S*. Montevideo, *S*. Infantis, and *S*. Braenderup among 20 tested *Salmonella* serovars. The phage infection led to very rapid cell lysis. One-step growth kinetics study showed that the latent period was 20 min (including 10 min for adsorption) and the average burst size was 70,000 phage particles per infected cell. SDS-PAGE profile of the phage revealed six structural proteins ranging from 20 KDa to 80 KDa. The large burst size, high lytic activity, and narrow host range suggested that phage ΦMont has a high potential for use as a biocontrol agent specifically against *Salmonella enterica* serovar Montevideo in food systems.

Food Microbiology - Part II

THE MICROBIOTA OF LUTEFISK, A TRADITIONAL NORWEGIAN COD DISH WITH A HIGH PH

B.T. Lunestad[1], D.H. Grevskott[1], I.S. Roiha[1], C.S. Svanevik[1]
[1]National Institute of Nutrition and Seafood Research, Section for contaminants and biohazards, Bergen, Norway

Backgrounds

Lutefisk is a fish preparation with long traditions in Norway, especially during Christmas time. It is produced from dried cod soaked in water for six to seven days, then transferred to lye for two to four days and put in water to dilute the lye. Traditionally the lye was made by boiling 1 L of wood ash in 2.5 L water. As the muscle are partially digested, *lutefisk* have a gel like appearance and characteristic smell, both appreciated by dedicated connoisseurs. A *lutefisk* meal is commonly accompanied by boiled potatoes, Swedish stew, pees, fried bacon and mustard.

Objectives

The objective of this study was to examine the microbiota of *lutefisk*.

Methods

Four commercially available *lutefisk* were purchased during December 2016, and examined for plate count (aerobic and anaerobic), indicator organisms for faecal contamination, staphylococci and specific pathogens. Colonies with unique appearance on different agar plates were grown into pure cultures and identified by 16S Sanger sequencing and BLAST alignment with <97% hit.

Conclusions

Despite a pH above 10.5 in all samples, the *lutefisk* had aerobic and anaerobic counts of up to $1.2x10^6$ and $3.0x10^4$, respectively. The fish did not harbour indicator organisms of faecal contamination or pathogens in the genera *Listeria*, *Salmonella* or *Vibrio*. The pure culture isolates were identified as *Carnobacterium maltaromaticum*, *Pseudomonas fragi*, *Staphylococcus warneri, S. hominis, Aeromonas salmonicida*, *Kurthia zopfii*, *Microbacterium oxydans*, *Exiguobacterium oxidotolerans*, *Alishewanella* sp. and *Bacillus licheniformis*.

LACTIC ACID BACTERIA WITH POTENTIAL FOR OCHRATOXIN A DEGRADATION IN VITRO

C. Luz Mínguez[1], J. Ferrer Roig[1], F. Saladino[1], F.B. Luciano[2], J. Mañes[1], G. Meca[1]
[1]Universidad de Valencia, Medicina Preventiva, Burjassot, Spain
[2]Pontificia Universidade Católica do Paraná,
Departamento de ciência animal- Escola de Ciências da Vida, Curitiba, Brazil

Backgrounds

Ochratoxin A (OTA) is a mycotoxin produced by the metabolism of fungus belonging to the genus *Aspergillus* and *Penicillium*. It is classified by the International Agency for Research on Cancer (IARC) as possibly carcinogenic to humans (group 2B) and it has been proven to be nephrotoxic and hepatotoxic, amongst other toxic properties. Human exposure to OTA occurs mostly by dietary intake, since it's a common contaminant in many foodstuffs such as cereal and coffee grains, grapes, etc. In the same way, the possibility that farming animals may result intoxicated by exposure to contaminated agricultural products and fodder represents a risk for public health.

Objectives

In the present study, the capacity of different cultures of lactic acid bacteria (LAB) to degrade OTA present in Man Rogosa Sharpe (MRS) liquid medium, specific for LAB growth, was evaluated.

Methods

For that purpose, 17 different bacteria strains, most of them provided by the *Colección Española de Cultivos Tipo* (CECT), were grown in MRS broth at both pH 3.5 and 6.5, contaminated with 1mg/L of OTA. The tubes were kept at 37°C for 48h. After that, the samples were centrifuged and the remaining OTA was quantified, both in the cell-free supernatant (CFS) and in the cellular precipitate.

Conclusions

The results obtained show that the OTA concentration in the mediums suffered a total reduction up to 98% when the pH was 6.5 and 97% at pH 3.5. The reduction is mostly due to molecular hydrolysis of the OTA, while the cell-adsorption mechanism seems to have little influence.

FEMS7-0440
Food Microbiology - Part II

CHARACTERIZATION OF A SS-GLUCOSIDASE ISOLATED FROM AN ALPEORUJO STRAIN OF CANDIDA ADRIATICA

J. Lilao[1,2], S. Callejón[1], J.J. Mateo[1], S. Maicas[1]
[1]Universitat de València, Microbiologia i Ecologia, Burjassot, Spain
[2]University of Bath, Biology and Biochemistry, Bath, United Kingdom

Backgrounds

Olives have a bitter compound namely oleuropein, which should be removed during the table olives and the olive oil production process. Industrial debittering procedures comprise treatment of the olives with a sodium hydroxide solution to hydrolyze the oleuropein. A substitute strategy is based on biological debittering when microbial ß-glucosidases participate in hydrolysis of oleuropein.

Objectives

The aim of the present work was to characterize the ß-glucosidase from a strain of *Candida adriatica* isolated from an olive oil mill. The isolation, purification and characterization of the enzyme could generate valuable information for the commercial use of this enzyme.

Methods

A total of 216 yeast strains were isolated from alpeorujo samples in an olive mill located in Villamalea (Eastern Spain) during the 2012 olive oil production campaign. The isolates were analysed by RFLP analysis of the 5.8S-ITS rDNA region. For sequence analysis of the D1/D2 domains of the 26S rDNA gene, PCR amplification was performed. Enzyme purification and basic characterization (pH, T, kinetic constants, metal ion effects) of a selected strain was carried out.

Conclusions

The isolation, purification and characterization of ß-glucosidase derived from non-*Saccharomyces* yeasts are of biotechnological interest because this enzyme is involved in the degradation of oleuropein for the debittering of table olives and olive oil. This study shows the potential of the ß-glucosidase produced by *C. adriatica* CECT13142 in this process.

Grants: This work was supported by the project “Identification and biotechnological characterization of yeasts isolated from agrifood residues of the Valencian Community”, grant AICO-2016-079.

EXOCELLULAR PROTEASES PRODUCED BY ENOLOGICAL HANSENIASPORA ISOLATES CAN BE USED FOR BIOTECHNOLOGICAL INDUSTRIES

C. Thießen[1], S. Maicas[1], J.J. Mateo[1]
[1]Universitat de València, Microbiologia i Ecologia, Burjassot, Spain

Backgrounds

Hanseniaspora are yeasts mainly found in soil, on fruits and trees and in spoiled foods and beverages. They are characterized by apiculate cells with vegetative reproduction by bipolar budding in basipetal succession. The six validly described species in the genus are physiologically very similar; they ferment glucose, assimilate few carbon compounds (arbutin, cellobiose, glucose, glucono-δ-lactone and salicin), and require inositol for growth. Most of these species have been previously reported in wine and grape juice. From a biotechnological point of view, although these yeasts can produce spoilage of fruits, they also possess many interesting technological properties. In this way, esterases, glycosidases, lipases, proteases, catalase of relative yeast species in different ecosystems have been previously described in our laboratory.

Objectives

The aim of this work was to characterize, from a biotechnological point of view, exocellular proteases produced by *Hanseniaspora* yeasts isolates from grape juice in order to evaluate the suitability of these proteins to be used in industrial processes.

Methods

Molecular identification was carried out by rDNA sequencing. Exocellular protease production was determined by spreading yeast colonies onto YPD agar plates containing 20 g/L casein. Effect of sugars, ethanol, temperature, pH, metal ions and other compounds on protease activity were obtained after standard laboratory procedures.

Conclusions

This is, to our knowledge, the first work showing the induction process to induce proteolytic activity in *Hanseniaspora* isolates. In this study some isolates have been characterized, and they are now available to be used in biotechnological processes.

This work was supported by the project “Identification and biotechnological characterization of yeasts isolated from agrifood residues of the Valencian Community”, grant AICO-2016-079.

Food Microbiology - Part II

DIVERSITY DYNAMICS OF THE FERMENTATION OF IDLI BATTER

M. Mandhania[1], *M. Suryavanshi*[2], *M. Patole*[1]
[1]*National Centre For Cell Science, Pathogenesis And Cellular Response, Pune, India*
[2]*National Centre For Cell Science, Microbial Ecology, Pune, India*

Backgrounds

Idli, a fermented food of India, prepared from rice (*Oryza sativa*) and black gram (*Phaseolus mungo*), consists of a consortium of micro-organisms, which initiate a natural fermentation, leading to acidification and leavening of the *Idli* batter. The steamed *Idli* cakes prepared from the fermented batter are popular for their nutritional content, unique taste and appetizing aroma. However, a detailed analysis of the microbial community structure responsible for fermentation of *Idli* batter has received little attention.

Objectives

To determine the microbial population enabling the fermentation process and also study the microbial succession patterns involved over the course of 24h fermentation.

Methods

In order to study the microbial diversity responsible for *Idli* batter fermentation, 16S rRNA V3 region amplicon sequencing was performed. Polymerase chain reaction–denaturing gradient gel electrophoresis (PCR-DGGE) was used to analyse the microbial succession pattern based on 16S rRNA partial sequences of the microflora. The abundant genera were also confirmed by q-PCR.

Conclusions

Analysis of the 16S rRNA gene sequencing results by QIIME pipeline revealed that the fermentation process was typically dominated by the hetero-fermentative bacterial genus *Weissella*. Using PICRUSt for microbial functional composition analysis, an enrichment of metabolic functional features including amino acid and carbohydrate metabolism was observed, implying that vigorous microbial metabolism occurred during the fermentation process. Comprehensively, our results illustrate the dynamic nature of *Idli* batter fermentation and microbial succession pattern therein and can be applied to optimize the fermentation processes, flavours and health-related attributes of this and other fermented foods.

Food Microbiology - Part II

GENETIC CHARACTERIZATION OF LISTERIA MONOCYTOGENES ISOLATES FROM FOOD AND FOOD ENVIRONMENT

B. Manso[1], B. Stessl[2], M. Wagner[2], J. Rovira[1], B. Melero[1], D. Rodríguez-Lázaro[1]
[1]University of Burgos, Biotechnology and Food Science, Burgos, Spain
[2]University of Veterinary Medicine, Institue for Milk Hygiene- Milk Technology and Food Science, Vienna, Austria

Backgrounds

Listeria monocytogenes is a major foodborne pathogen that can survive frequently in food processing environments.

Objectives

The aim of this study was to characterize 15 strains of *L. monocytogenes* of different sequence types (ST) and sources.

Methods

Thirteen isolates were from a poultry slaughterhouse -ST1 (15.38 %), ST5 (7.69 %), ST8 (7.69 %), ST9 (15.38 %), ST87 (7.69 %), ST121 (15.38 %), ST199 (7.69 %) and ST388 (7.69 %) - and 2 were seafood isolates -ST2 and ST321-. The characterization consisted of the identification by PCR of different genetic markers related with the environmental stress adaptation and virulence; the presence of Stress Survival Islet (SSI-1), listeriolysin S (*lls*), Internalin A truncation (*inl*A) and tolerance to benzalkonium chloride due to Transposon 6188 and *bcr*ABC cassette gene.

Conclusions

ST1, ST2, ST5, ST87 and ST388 were the most virulent isolates, as they were positive to Listeriolysin S and possess the complete Internalin A. Only the isolates belonging to ST9 and ST8 had the 10 Kb fragment of SSI-1, and only a fragment of 2Kb was detected in the ST121 isolate, but they showed a truncated Internalin A. Only the ST121 isolates had Tn 6188, with the exception of one isolate, and the ST2 and ST321 isolates were positive to *bcr*ABC cassette being usually, environmental.

Results showed that *L. monocytogenes* isolated from food processing environment not only have genetic markers that could allow the pathogen to survive better in the environment but also have virulence markers increasing the risk of listeriosis in the consumers.

FEMS7-3009
Food Microbiology - Part II

EFFECT OF SANITIZERS AND DISINFECTANTS USED IN FOOD INDUSTRY ON LISTERIA MONOCYTOGENES GROWTH

B. Manso[1], I. Jaime[1], A.M. Diez[1], J. Rovira[1], D. Rodríguez-Lázaro[1], B. Melero[1]
[1]University of Burgos, Biotechnology and Food Science, Burgos, Spain

Backgrounds

Listeria monocytogenes is a foodborne pathogen able to adapt to food processing environmental conditions such as sanitizer agents due to some genetic markers.

Objectives

The aim of this study is to know the behavior of *L. monocytogenes* isolates in the presence of an acid sanitizer and a disinfectant based on ammonium quaternary compounds (QAC).

Methods

Seven strains of *L. monocytogenes* were isolated from food products and environmental surfaces from 3 different food industries: a poultry slaughterhouse, a cheese factory and a seafood company**.** The behavior was analyzed in the presence of different concentrations of the detergent (2 %, 1 %, 0.25 %, 0.1 %, 0.05 % and 0.0025 %) and the disinfectant (0.0125 %, 0.00625 % and 0.003125 %). Isolates were inoculated at 10^7 cfu/mL and the growth was measured at OD_{600} during 24 hours at 37 °C.

Conclusions

All the strains were sensitive to the highest detergent concentration but they grew similar to the control in the presence of the remaining concentrations**.** Only 2 isolates were resistant to 0.0125 % of disinfectant although all the isolates were tolerant to the lowest concentration**.**

L. monocytogenes could tolerate benzalkonium chloride (QAC derivated) and antibiotics because of its ability to exchange genes with other microorganisms. These molecular mechanisms are activated during lag phase, when *L. monocytogenes* needs to growth on the stressful environment.

Results showed the importance of applying good hygiene and disinfection protocols to avoid the contact of *L. monocytogenes* with sublethal concentrations that lead to an increasing resistance of the pathogen in food industries.

HIGH-THROUGHPUT SEQUENCING ANALYSIS OF THE MICROBIOTA INVOLVED IN SPANISH DRY FERMENTED PORK SAUSAGE ("CHORIZO") RIPENING

N.M. Quijada[1], F. De Filippis[2], J.J. Sanz[3], D. Rodríguez-Lázaro[4], D. Ercolini[2], M. Hernández[1]
[1]Instituto Tecnológico Agrario de Castilla y León ITACyL,
Laboratory of Molecular Biology and Microbiology, Valladolid, Spain
[2]University of Naples Federico II, Department of Agricultural Sciences, Portici, Italy
[3]Instituto de Ciencia y Tecnología de los Alimentos ICTAL, Microbiology, León, Spain
[4]Universidad de Burgos, Department of Biotechnology and Food Science, Burgos, Spain

Backgrounds

Fermentation is one of the oldest technologies used to preserve food for long periods. It involves different microorganisms, such as lactic acid bacteria, that are responsible of improving safety and organoleptic properties. "*Chorizo"* is the most popular Spanish dry fermented pork sausage. High-Throughput Sequencing (HTS) targeting 16S rRNA gene allows deep investigation of the microbial ecology of different environments saving time and money, respect to classic microbiological methods. New approaches such as oligotyping allow sub-genus classification and avoid the bias of clustering-based methods.

Objectives

This study aims to elucidate the microbiota involved in the ripening process of *"chorizo"* using HTS technologies.

Methods

"Chorizo" samples were taken from 6 factories at different time points along its production. Total DNA was extracted, 16S rRNA gene amplified and sequenced using Illumina platform. Quality-filtered sequences were analyzed by using QIIME 1.9.0 and sub-genus level analysis of *Lactobacillus*-assigned sequences was performed by using oligotyping package v.2.1.

Conclusions

"Chorizo's*"* microbial composition changes along the ripening process. The first steps (when the meat is minced and marinated) are characterized by a high bacterial diversity where several genera (*Bacillus, Staphylococcus* and the air storage-related spoilers *Pseudomonas* and *Brochotrhyx*) can be observed in high abundance. Sausage production (and thus ripening starts) makes a shift in the microbial composition, where *Lactobacillus* develops and becomes the most abundant genus at the end of the process. Sub-genus level investigation revealed that the most abundant oligotype correspond to *Lactobacillus sakei*, one of the most frequently bacteria isolated from fermented meat products.

PROPIDIUM MONOAZIDE (PMA) COUPLED WITH QPCR ENABLES THE DETECTION OF INFECTIOUS VIRUSES IN FOOD

N.M. Quijada[1], G. Fongaro[2], C.R.M. Barardi[2], M. Hernández[1], D. Rodríguez-Lázaro[3]
[1]Instituto Tecnológico Agrario de Castilla y León ITACyL,
Laboratory of Molecular Biology and Microbiology, Valladolid, Spain
[2]Universidade Federal de Santa Catarina,
Departamento de Microbiologia- Inmunologia e Parasitologia, Florianópolis, Brazil
[3]Universidad de Burgos, Department of Biotechnology and Food Science, Burgos, Spain

Backgrounds

PCR and qPCR appeared as promising alternatives for food safety monitoring, but they are not able to discern between infectious/non-infectious viruses. Propidium monoazide (PMA) is a nucleic acid intercalating dye that only crosses damaged lipid membrane barriers and binds covalently to DNA/RNA after exposure of strong visible light, interfering DNA amplification. Entire-lipid membrane genomes are not affected by PMA and DNA can be amplified with PCR.

Objectives

This study assesses the use of PMA with qPCR/RT-qPCR to distinguish between infectious and non-infectious viruses in two food matrices: clam and Spanish dry fermented pork sausage ("*chorizo*").

Methods

Clam and *"chorizo*" samples were artificially contaminated with decreasing amounts of infectious and thermally inactivated adenovirus-2 (HAdV-2) and mengovirus (vMC_0) (representatives of DNA and RNA viruses, respectively). Samples were processed and mixed or not with PMA. Photo-activation was performed in treated samples. Nucleic acids were extracted and qPCR/RT-qPCR was performed. Infectious viruses were quantified by plaque assay (PFUs) and results were compared to those obtained by qPCR/RT-qPCR.

Conclusions

No differences were shown between infectious-contaminated samples regarding its treatment with PMA. Significant reductions in GCs were observed in thermally inactivated-contaminated samples when were treated with PMA prior qRT/RT-qPCR. IT represented a mean PCR derived signal reduction of 99.96 and 99.92% for HAdV-2 and 99.70 and 99.93% for vMC_0, in clam and *"chorizo"*, respectively. Linear regression (R^2 from 0.92 to 0.99) demonstrated correlation between PFUs-GCs. PMA coupled with qPCR/RT-qPCR represent a promising alternative for virus investigation in food safety, especially for non-cultivable viruses.

Food Microbiology - Part II

ANTIMICROBIAL SUSCEPTIBILITY AND PATHOGENICITY OF C. COLI STRAINS ISOLATED FROM HUMANS AND CHICKEN FOOD CHAIN

A.J. Martinez-Rodriguez[1], *D. Perez-Boto*[1], *A. Garcia-Bravo*[1]
[1]*Institute of Food Science Research CIAL- CSIC-UAM, Microbiology and Biotechnology, Madrid, Spain*

Backgrounds

Campylobacter is the leading cause of bacterial food-borne gastroenteritis worldwide and the species *C. jejuni* and *C. coli* cause more than 95% of the infections attributed to this genus. In the European Union, campylobacteriosis was the most commonly reported bacterial zoonosis, with 236,851 confirmed human cases in 2014. Although *C. jejuni* is the most diagnosed species, in the last years C*. coli* has become increasingly important, mainly due to the high antibiotic resistant levels.

Objectives

To study the incidence and virulence of *C. coli* and its relationship with the human infection in 201 *Campylobacter* strains isolated from the chicken food chain and humans patients.

Methods

The response to 14 different antibiotics was analyzed following the Kirby-Bauer. The results obtained showed that *C. coli* had the highest levels of drug multiresistance (MRD) with an 84.6%. They also presented a 20.5% of resistance to erythromycin (Ery-R) among human isolates, the first therapeutic option in campylobacteriosis. The presence of three relevant genes associated to *Campylobacte*r virulence (*cdt*ABC complex, *cia*B and virB11) were investigated in *C. coli* strains. *cia*B polymorphisms found in the food chain strains suggested that infective strains could be from a source other than chicken meat. Chicken strains clustered in a unique clone after MLST+flaA typing of *C. coli* strains. Data suggest that a significant proportion of human isolates might be considered of no-chicken origin.

Conclusions

C. coli MRD-EryR isolated from humans with no-chicken origin could be an emerging risk for the European consumer.

Food Microbiology - Part II

ISOLATION AND CHARACTERIZATION OF QUAMBALARIA CYANESCENS FROM UNRIPENNED GRAPES.

J.J. Mateo Tolosa[1], *S. Maicas*[1], *F. Rosa*[1], *Z. Raquel*[1]
[1]*Universitat de Valencia, Microbiología y Ecología, Valencia- Burjassot, Spain*

Backgrounds

Quambalaria cyanescens is a hyaline basidiomycete isolated from a broad range of ecological niches, including air, soil, and insect larvae as well as in association with diverse plant sources in various countries. *Q. cyanescens* is frequently associated with bark beetles feeding on numerous plants. This fungus, however, is predominantly known as non-pathogenic to plants and has been reported as a symbiont of plants, including *Corymbia* and *Eucalyptus* species, but it has never been isolated from grapes.

Objectives

The aim of this work was to isolate, identify and characterize the fungus *Quambalaria cyanescens* from unripenned grapes.

Methods

Q. cyanescens was isolated on Malt Agar plates and were analysed by RFLP analysis of the 5.8S-ITS rDNA region. For sequence analysis of the D1/D2 domains of the 26S rDNA gene, PCR amplification was performed Physiologically characterization was developed in both API ZYM and API C AUX strips and also in specifc plates.

Conclusions

Q.*cyanescens* was positively identified on the surface of unripenned grapes. Some of the isolates show different enzymatic activities with potential biotechnological interest.

This work was supported by the project “Identification and biotechnological characterization of yeasts isolated from agrifood residues of the Valencian Community”, grant AICO-2016-079.

BACTERIAL ECOLOGY OF BLACK RIPE OLIVE PROCESSING

E. Medina[1], *C. Romero*[1], *M. Brenes*[1], *P. García*[1], *A. de Castro*[1]
[1]*Instiuto de la Grasa - CSIC, Food Biotechnology, sevilla, Spain*

Backgrounds

Black ripe olives are one of the two most important types of table olives. However, the microbiology during their production is lacking.

Objectives

The objective of this research was to characterize the biochemistry and bacterial biodiversity along the different stages of the black ripe olive processing.

Methods

The research was carried out on Manzanilla and Hojiblanca cultivar samples from a leading table olive factory.

Conclusions

Biochemical analysis showed a high amount of total sugar and polyphenol concentrations in the preservation first stage (43.32 mmoles/Kg and 15.60 mM, respectively). These compounds decreased along the processing to 1.41 mmoles/Kg and 2.54 mM at the final wash before packing. High populations of lactic acid bacteria (LAB), yeast and moulds, and *Enterobacteriaceae* were differentially detected by using culture-dependent techniques.

The novelty of this research was the study of the microbial ecology of black ripe olive processing using high-throughput DNA sequencing of 16s rDNA. During preservation, first wash, and ferrous gluconate stages, the predominant genera were *Lactobacillus* and *Acetobacter*. The microbiota showed a greater biodiversity at the last two phases of the process, and other microorganisms were found, as other LAB genera (*Enterococcus*, *Leuconostoc*, *Weissella*, *Lactococcus*, *Streptococcus*). Besides, this is the first time that genera such as *Shewanella*, *Marinomonas*, *Alteromonas*, *Acinetobacter*, and *Vibrio*, among others, were identified in this type of table olive processing. Although black ripe olives are sterilized before commercialization, this study will contribute to the knowledge of the bacterial communities present in this product and their overall significance on the final quality.

Agricultural Research- Education and Extension Organization AREEO-Shiraz-Iran, virology, Shiraz, Iran
[2]Razi vaccine and serum research institute- Shiraz branch, Microbiology, Shiraz, Iran
[3]Razi vaccine and serum research institute-Hesark-karaj, Bactriology, karaj, Iran
[4]Islamic Azad Universty- colleage of veterinary-Kazeroun-Iran, Microbiology, Kazeroun, Iran

Backgrounds

Salmonella spp. is a group of gram negative bacillus bacteria which should be considered as an important zoonotic disease including poultry and their products. This bacterium is scattered all around the world from Asia to America and Africa. It is recently shown that poultry, meat products and eggs which had been infected or contaminated by those bacteria are the main source of contamination. Therefore, prevention and killing salmonella in source should be mentioned.

Objectives

The aim of this study is evaluating the antibiotic sensitivity of different salmonella serotypes isolated from Fars province poultry farms.

Methods

For this reason, 713 cloacal swab samples from 25 poultry farms were collected. Then all the microbiological examinations on the samples were done. Six of them were suspected for salmonella infection and with specific examinations; two samples with *Salmonella Enteritidis* and one sample with *Salmonella Thyphymurium* were accurately detected. Finally, the antibiotic susceptibility of them was evaluated using antibiotic assay discs (disc diffusion).

Conclusions

The results were shown that all the isolated bacteria were sensitive to Ciprofloxacin, Tetracycline, Gentamycin, Kanamycin and Nalidixic acid. But, they had different reactions to other antibiotics. It seems that antibiotic resistance has been emerged between salmonella serotypes, even in the various isolate from one serotype.

FEMS7-2381
Food Microbiology - Part II

MOLECULAR IDENTIFICATION AND ANTIMICROBIAL RESISTANCE OF SALMONELLA SEROTYPES IN MEAT PRODUCTS FROM ECUADOR

L. Mejia Castaneda[1], *G. Vela*[1], *A.L. Freire Vélez*[1], *S. Zapata Mena*[1]
[1]*Universidad San Francisco de Quito, Institute of Microbiology, Cumbayá, Ecuador*

Backgrounds

Salmonella is responsible for foodborne infections worldwide and it is one of the four global causes of diarrhoeal diseases. It is generally transmitted by the consumption of contaminated food from animal products. On the other hand, antimicrobial resistance is one of the most important topics on public health. Also, some multidrug resistant Salmonella serotypes have emerged in different parts of the world.

Objectives

The aim of this study was to determine the prevalence and antimicrobial resistance of Salmonella serotypes isolated from meat products in Ecuador.

Methods

Sample collecting was done during 2015 and the microbial analysis was done with 3M Molecular Detection Assay Salmonella ® and by McCormick Method M0740 for isolation of Salmonella. Serotypes were determined by multiplex PCR. Antimicrobial resistance patterns for 14 antibiotics (CLSI recommendations) were obtained by disk diffusion assay-Kirby-Bauer method.

Conclusions

A total of 580 samples were collected. The prevalence for Salmonella was 43,10%. For the aim of this study, 70 isolates and 130 lysates corresponding to 140 samples were further analized. The most common serotype was Infantis (79,3%), followed by Gallinarum (15%). Typhimurium and Cholera suis were found in 2,14% of the samples while Enteritidis and Dublin in only 1,42%. All isolates were sensitive to Amoxicillin/clavulanate and azithromycin but most (more than 80%) were resistant to tetracycline, streptomycin, nalidixic acid, cefotaxime, ciprofloxacin, gentamicin, ampicillin and ceftriaxone. Most of the isolated strains showed high resistance patterns affecting the food chain in Ecuador. This is the first study on serotype identification and antimicrobial resistance on Salmonella from meat products.

BACTERIAL COMMUNITIES IN BOVINE MILK DURING PROCESSING AND STORAGE

D. Porcellato[1], M. Aspholm[2], S.B. Skeie[1], M. Monshaugen[2], J. Brendehaug[3], H. Mellegaard[2]
[1]Norwegian University of Life Sciences, Faculty of Chemistry- Biotechnology and Food Science, Ås, Norway
[2]Norwegian University of Life Sciences, Faculty of Veterinary Medicine, Oslo, Norway
[3]TINE SA, R&D, Stavanger, Norway

Backgrounds

Bovine milk is a valuable nutriment worldwide. It contains a complex microbial community, which may affect the quality and safety of the product. Detailed knowledge of this microbiota during processing and storage is therefore of importance for the dairy industry in their quality and safety assurance work.

Objectives

Our goal was to characterize the bovine milk microbiota, also capturing seasonal variations, from raw to processed milk at the dairy plant, and throughout the shelf life period of full fat milk cartons.

Methods

Monthly samples from two Norwegian dairy plants, differing in their production volume, were collected over a 13 months period. 16S rRNA marker gene sequencing and standard culturing techniques were applied to study the bacterial composition during processing, from raw milk to full fat milk during processing at the dairy plant, and during product storage at 4 °C and 8 °C, where the latter temperature simulate suboptimal storage conditions.

Conclusions

The examined milk samples contained a high bacterial diversity where sampling month, processing stage and storage temperature had a significantly impact on the level and composition of the bacterial community. Especially, storage at 8 °C resulted in a significant increase in the level of *Bacillus* spp. compared to storage at 4 °C. Despite this variation, a core microbiota was identified in samples from both dairies. This large-scale study provide detailed insight into the dynamics of the bacterial community along the milk value chain.

Food Microbiology - Part II

ENTEROTOXIGENIC STAPHYLOCCOCUS AUREUS IN BRINED CHEESE FROM WEEKLY MARKETS IN TURKEY

B. Mercanoglu Taban[1], S. Karimihachehsoo[1], Ö. Akineden[2], M. Gross[3], E. Usleber[2]
[1]Ankara University- Faculty of Agriculture, Dairy Technology Department, Ankara, Turkey
[2]Institute of Veterinary Food Sciences- Justus-Liebig-University Giessen, Dairy Sciences, Giessen, Germany
[3]Institute of Veterinary Food Sciences- Justus-Liebig University Giessen, Junior Professorship of Veterinary Food Diagnostics, Giessen, Germany

Backgrounds

Traditionally produced brined cheeses (White pickled cheese, Tulum cheese) are frequently offered as unpacked local produce on weekly markets in Turkey, and are both very popular and economically important products.

Objectives

In this study, *Staphylococcus* (*S*.) *aureus* was determined in a total of 63 unpacked brined cheeses from weekly markets in the Turkish province of Ankara. Isolates from positive samples were analyzed for staphylococcal enterotoxin (SE) genes by PCR, and for SEA-SEE by ELISA.

Methods

S. aureus was found in 11 (17.0%) cheeses (8/33 Tulum cheeses, 3/30 other white pickled cheeses), the highest contamination was 5.0 x 10^6 cfu/g. All 22 tested isolates from these samples were positive for SE genes. By ELISA, several isolates from Tulum cheeses produced SEA or SED. By PCR, the corresponding genes (*sea*, *sed*) were found in these isolates. Further, many trans-SE genes (*seg*, *sei*, *selj*, *sem*, *sen*, *seo*, *sep*, *ser,* and *selu*), but only three different gene combinations, were detected by PCR in isolates from both types of cheeses. Likewise, further characterization of the 22 isolates by macrorestriction analysis yielded three different pulsed-field gel electrophoresis (PFGE) profiles only, which corresponded well with the three SE gene profiles (*sea*+*sed*+*selj*; *sed*+*ser*; *seg*, *sei*, *sem*, *sen*, *seo*, *sep*, *selu*).

Conclusions

This contamination pattern indicates that all 11 *S. aureus*-positive cheeses, which had each been sold as “unique produce” by different sellers, in fact originated from three sources only, and thus did not comply with labelling requirement. This also shows the strength of PFGE for contamination-based fingerprinting of artisanal food products relatively high frequency and levels of enterotoxigenic *S. aureus*. In conclusion, the findings presented here demonstrate the need of a more intensive and efficient hygiene control of unpackaged, traditionally produced brined cheeses to avoid health hazards for food safety.

Food Microbiology - Part II

PHAGE HOST-ADAPTATION IMPROVES BIOCONTROL IN CHEESEMAKING AND WIDENS THE LYSIS SPECTRUM OF ENTEROBACTERIA

F. Molina[1], A. Simancas[1], R. Tabla[2], I. Roa[2], J.E. Rebollo[1]
[1]Universidad de Extremadura, Genetics, Badajoz, Spain
[2]Technological institute of Food and Agriculture, Dairy products, Badajoz, Spain

Backgrounds

Bacterial contamination in food production suppose both a health issue and an economic loss for food manufacturers. In dairy industry, *Escherichia coli* strains coming from animal stool have been identified as a threat, as they spoil cheese-making processes, thus rendering a final product not suitable for human consumption. Along with *E. coli*, other *Enterobacteria* species have been identified in cheese spoilage, being some *Shigella* strains among them. Due to the high molecular similarity between *E. coli* and these *Shigella* strains, we looked towards obtaining a phage therapy treatment involving the use of viruses able to infect both bacterial genus.

Objectives

Based on lysis spectrum analysis results, we wanted to enhance crossed infection activity of bacteriophages isolated on *E. coli* against *Shigella* strains in order to obtain a phage cocktail suitable for a wider range of bacterial targets in dairy industry biocontrol.

Methods

Bacteriophages were isolated for local sheep farms and tested with an *Enterobacteriaceae* lab collection and cheese contaminant strains. After screening the two most efficient viruses against both E. coli and several *Shigella* strains were selected. *Shigella* strains were infected in consecutive five-hours infection cycles, up to a total of 80 cumulative hours. Assays were then conducted to measure relative viral particles production, plaque size and both bacterial lysis and growth inhibition.

Conclusions

Local adaptation assays proved to be a useful way to improve the host range of our bacteriophages, hence leading to an improvement on the phage therapy treatments used on dairy industry.

Food Microbiology - Part II

VALIDATION OF A SYBR GREEN REAL TIME PCR ASSAY FOR RAPID ENUMERATION OF SALMONELLA SPP.

S. Momtaz[1], J. Mandal[1], M.A. Siddique[1], M. Sultana[1], M.A. Hossain[1]
[1]University of Dhaka, Microbiology, Dhaka, Bangladesh

Backgrounds

Salmonellosis, a major food borne infection in human, is caused by *Salmonella* spp. and has become a prominent public health concern in Bangladesh.

Objectives

The classical detection techniques for *Salmonella* are limited due to time consumption and requirements of series of tests for confirmation. This study was designed to develop a rapid, reproducible, and robust method for detection and quantification of *Salmonella* spp. based on Quantitative real-time PCR (qPCR).

Methods

qPCR corresponds to absolute copy number for a particular target gene directly implicating the cell numbers. Therefore, a gold standard of template implicating in direct quantification of the cell number is required. In this study, copy number of *Salmonella* spp. specific gene *invA* was considered. Three types of template standards were used such as purified *invA* amplicon products of 284 bp, cloned *inv*A amplicon (284bp) in the TOPO TA vector and *Salmonella* Enteritidis IFO 3313 gDNA. Suitable DNA extraction methods were chosen among Phenol Chloroform DNA extraction method, boiling method, automated DNA extraction method (Maxwell® 16 DNA extraction system,) and commercial kit based method such as solution based kit (Jena Bioscience GmbH, Germany) and column based kit (ATP Biotech Inc, USA). The specificity of the reaction was confirmed by the melting temperature (T_m) of the amplicon obtained.

Conclusions

Findings of this study demonstrate that recombinant plasmid DNA (cloned *inv*A amplicon) based standard curve, phenol Chloroform DNA extraction method and SYBR Green I Real-time PCR constitutes an effective and easy-to-perform method for detecting *Salmonella* spp.

Food Microbiology - Part II

THE FIRST DETECTION OF FLORFENICOL RESISTANT GENE IN SHIGA-LIKE TOXIN PRODUCING ESCHERICHIA COLI ISOLATED FROM PORK IN KOREA

J.S. Moon[1]
[1]*Animal and plant quarantine agency, veterinary pharmaceutical management, Gimcheon-si, Republic of Korea*

Backgrounds

Florfenicol is fluorinated derivative of chloramphenicol and represent highly protein inhibitors of bacterial protein biosynthesis. It is used in veterinary medicine or feed additives for pigs in Korea. The transfer of antibiotic resistance gene among the bacterial strains has become a problem worldwide, so drug resistant bacterial phenotypes should be identified.

Objectives

In this study, antimicrobial resistance and resistance gene were investigated for shiga-like toxin producing *E. coli (*STEC) isolated from pork in Korea.

Methods

We monitored 301 pork samples in slaughter houses and retail markets, and isolated 50 strains of *E. coli* in 2013. Among these isolates, six isolates resulted in STEC. Minimum inhibitory concentration (MIC) on six strains was performed for 14 antibiotics, ampicillin, amoxicillin/clavulanic Acid, cefoxitin, ceftiofur, cephalothin, florfenicol, ciprofloxacin, colistin, gentamicin, nalidixic acid, neomycin, streptomycin, tetracycline and trimethoprim/Sulphamethoxazole, and three strains showed high MIC to florfenicol and chloramphenicol (64 ug/mL). PCR was conducted to detect the florfenicol resistant gene (*floR*) and the chloramphenicol resistant gene (*cat*).

Conclusions

All of 3 strains contained the *floR*, while none of them had the *cat*. These PCR products were sequenced and aligned to obtain homology with other available genes in reference GenBank. A BLAST search showed that they contained sequences with homology to the *floR* gene of *E. coli* or *Salmonella enteric* serovar Heidelberg.This is the first report to detect *floR* gene in STEC isolated from slaughtered pigs in Korea. These results suggest that some STEC isolates in Korea carry florfenicol resistant gene and transfer this gene to other bacterial strains.

FEMS7-0154
Food Microbiology - Part II

PREDICTIVE MODEL FOR SALMONELLA GROWTH IN UNPASTEURIZED LIQUID WHOLE EGG, EGG YOLK AND EGG WHITE IN KOREA

J.S. Moon[1]
[1]*Animal and plant quarantine agency, veterinary pharmaceutical management, Gimcheon-si, Republic of Korea*

Backgrounds

There are concerns on the quality of non-pasteurized liquid eggs depending on storage temperature and time because they are processed without heat-treatment and marketed.

Objectives

The objective of this study was to determine the risk of *Salmonella* by investigating the growth rate according to the time of various storage temperatures of the unpasteurized liquid whole egg, egg yolk, and egg white.

Methods

Samples were inoculated with a mixed culture (approximately 3.0 log CFU/ml) containing equal proportions of five strain cocktail of *Salmonella* (*S.* Bareilly, *S.* Richmond, *S.* Typhimurium monophasic, *S*. Enteritidis and *S*. Gallinarum) egg isolates. After inoculating *Salmonella* spp. onto samples, the effects of storage temperatures (5-40℃) on the growth of *Salmonella* spp. were investigated by the 960 hours.

Conclusions

The results showed that the population of *Salmonella* in liquid whole egg and yolk increased at over 10℃, while *Salmonella spp*. in egg white did not grow at any temperature. Growth curves of *Salmonella* in liquid whole egg and yolk were fitted to the Baranyi model, and lag phase duration (LPD) and maximum specific growth rate (μ_{max}) were obtained. LPD significantly ($p<0.05$) decreased with a storage temperature and it were higher in egg yolk than liquid whole egg. μ_{max} significantly ($p<0.05$) increased as the storage temperature increased. The secondary model, verified as suitable model, can be used for predicting the growth of *Salmonella spp*. in liquid whole egg and egg yolk under a variety of storage temperature and time conditions.

OPTIMIZATION OF PARAMETERS FOR ETHANOL REDUCTION IN WINE BY RESPIRATION

M. Callerand[1], R. Gonzalez[1], P. Morales[1]
[1]ICVV CSIC-Universidad de La Rioja-Gobierno de La Rioja, Enología, Logroño, Spain

Backgrounds

The increase in alcohol levels in wine during the last decades is a main concern for the wine industry. One of the solutions under study consists in the use of non-*Saccharomyces* strains in aeration condition to respire the excess of sugars. Some species of non-*Saccharomyces* have been identified as good candidates for this purpose, but a fine tuning of conditions is required to get a quality product.

Objectives

In this work, the conditions for the co-culture of *S. cerevisiae* and *C. sake* with the aim to reduce alcohol levels of wine were investigated.

Methods

Three parameters, the moment of addition of *S. cerevisiae*, the amount of *S. cerevisiae* inoculum, and the amount of air used during aeration period were studied. Three levels of each parameter were combined in a Box-Behnken design, and modeling of the effect of these parameters on metabolite production and sugar consumption was obtained after statistical analysis of experimental data.

Conclusions

The glycerol yield and sugars consumed during aeration were dependent on the three variables studied, while ethanol yield was not dependent of the amount of *S. cerevisiae* used. Conditions for maximal sugar consumption were close to the central point of the experiment. Model equations were:

Ethanol Yield =0.349 -0.018*TSc - 0.026*Air +0.018*TSc ^{2}

Glycerol Yield =0.032 -0.003*Air +0.004*Tsc *[Sc] +0.003 *Air^{2}

Consumed sugars in day 2 =56.460 –2.979*TSc*[Sc] -3.598*TSc^{2} -4.474*[Sc]^{2} -4.982*Air^{2}

SCALING-UP AERATED FERMENTATION FOR ETHANOL REDUCTION. EFFECT ON WINE AROMA

J.A. Curiel[1], J. Tronchoni[1], M.P. Sáenz-Navajas[2], A. de la Fuente[2], P. Fernández-Zurbano[1], V. Ferreira[2], P. Morales[1], R. Gonzalez[1]
[1]ICVV CSIC-Universidad de La Rioja-Gobierno de La Rioja, Enología, Logroño, Spain
[2]Instituto Agroalimentario de Aragón IA2- Universidad de Zaragoza,
Laboratory for Flavor Analysis and Enology-LAAE, Zaragoza, Spain

Backgrounds

The process for ethanol reduction by using aerated fermentation conditions, and a combination of *Metschnikowia pulcherrima* and *Saccharomyces cerevisiae* as starter cultures, has been previously optimized at laboratory scale.

Objectives

Since previous trials indicated a limitation of non-*Saccharomyces* strains in a non-sterile, sulfite treated, natural grape must, the objective of this work was scaling-up the process to 20 L vats. In addition, we wanted to minimize acetic acid production, also identified as a potential drawback of oxygenated fermentation.

Methods

Dominance was reached by preadaptation of non-*Saccharomyces* strains to grape must conditions and relatively high inoculation titles. The other big challenge has been to change the automatic control of aeration based on dissolved oxygen detection (as used in small scale bioreactors) to a controlled but constant aerated period (more amenable to industrial application).

Conclusions

Wines made with *M. pulcherrima* or *Torulaspora delbruekii* under aeration, followed by a final step with *S. cerevisiae* under standard conditions, contained less alcohol than the control wines (*S. cerevisiae* under standard conditions). Acetic acid levels were not increased by aeration.

A classification based on aroma of replicates of wines by a trained panel, divided wines by strain. *S. cerevisiae* wines were linked to white fruit/pear and tropical fruit/banana aroma descriptors; while *T. delbruekii* wines were linked to dried fruit/nuts and reduction descriptors; and *M. pulcherrima* wines were linked to oxidation/spirits-like descriptors. The later can be explained by the higher amount of isoamyl and isobutyl alcohols and ethyl acetate found in these wines.

AMINO ACID METABOLISM DURING THE SECOND FERMENTATION IN THE ELABORATION OF CAVA BY TWO SACCHAROMYCES CEREVISIAE WINE STRAINS: A FIRST PROTEOMIC APPROACH

M.D.C. Gonzalez Jiménez[1], J. Moreno García[2], J.A. Porras Agüera[1], F. Capdevila Mestres[3], A. Puig Pujol[3], J.J. Moreno Vigara[4], J.C. García Mauricio[1], T. García Martínez[1]
[1]University of Córdoba, Microbiology, Córdoba, Spain
[2]University of Córdoba, Microbiology, Cordoba, Spain
[3]IRTA-INCAVI, Oenological Research, Vilafranca del Penedès, Spain
[4]University of Córdoba, Agricultural Chemistry, Córdoba, Spain

Backgrounds

Cava is a sparkling wine characterized by the occurrence of two consecutive fermentations in its elaboration process: a first fermentation, where the base wine is obtained; and a second fermentation, which occurs in a closed bottle. During the second fermentation carbonic gas, characteristic of this type of wine, is originated. The main nitrogen source for yeasts involved in this process are amino acids, which metabolism can contribute to the aroma and the flavor of the obtained wines.

Objectives

The objective of this work is to compare the amino acid metabolism through a proteomic approach in the middle of the second fermentation in closed bottle in two different yeast wine strains of *Saccharomyces cerevisiae*: a traditionally used strain used for sparkling wine elaboration and a flor yeast strain commonly used for the elaboration of sherry wines which is also able to survive after the fermentation.

Methods

To carry out the proteomic analysis cells were broken, and extracted proteins were separated using OFFGEL protein fractionation, LTQ Orbitrap MS analysis. For the treatment and discussion of results, the *Saccharomyces* Genome Database was used.

Conclusions

A total of 113 proteins were identified for the sparkling wine strain, from which 28 were specific, 8 proteins involved in the amino acid biosynthesis and 6 proteins in the amino acid catabolism pathways. 108 proteins were obtained in the flor yeast, resulting 23 to be specific to this strain. In this case, 10 proteins related to amino acid synthesis pathways and 6 proteins in catabolic pathways were identified.

Food Microbiology - Part II

INTEGRATED TREATMENT: A SENSIBLE APPROACH TO PRODUCE SAFETY, QUALITY AND SUSTAINABILITY

S. Mukhopadhyay[1]
[1]*United States Department of Agriculture, Agricultural Research Service, Wyndmoor, USA*

Backgrounds

Current chlorine based washing method for fresh produce has limited effectiveness and poses serious public health concern.

Objectives

The purpose of present study was to investigate the efficacy of different combined non-thermal treatments against food borne pathogens and natural spoilage organisms.

Methods

Smooth surface and stem scars of tomato and spinach leaves inoculated with a bacterial cocktail containing a three serotype mixture of *S. enterica* and a three strain mixture of *E. coli* O157:H7 were subjected to different integrated treatments. Treatment combining UV-C light (0.6 kJ/sq. m) and wash in mixed acid (1% lactic plus citric acid) for 2 min provided 3.9 ± 0.6 log CFU/fruit reduction for *Salmonella* on tomato compared to 2.6 ± 0.4 log CFU/g reduction for *E. coli* on spinach leaves. A combination treatment of 0.6 kJ/sq. m UV-C followed by 2 min wash in a novel antimicrobial solution of HEN (mixture of H_2O_2, EDTA and Nisin) provided synergistic inactivation of 4.71 ± 0.25 logs for *Salmonella* on tomato which is superior to current chlorine based decontamination practice providing only 2.4 ± 0.37 logs reduction. These treatments also significantly ($p < 0.05$) reduced populations of native aerobic plate count, and yeasts and molds of tomato fruits and spinach leaves. Furthermore, firmness and color of samples were not significantly affected by the treatment.

Conclusions

Results indicated that the efficacy of the integrated treatment depended on types of inoculated bacteria and produce, and the technology presented here could potentially be used as a replacement for current chlorine based produce sanitizing practice.

SAFETY RISKS LINKED TO HOME SPROUTING MODULES

E. Mulaosmanovic[1], S. Farkas[1], J. Linden[1], M. Sousa[1], S. Gharaie[1], L. Mogren[1], I. Vågsholm[2], B. W. Alsanius[1]
[1]Swedish University of Agricultural Sciences SLU, Department of Biosystems and Technology-Microbial Horticulture Unit, Alnarp, Sweden
[2]Swedish University of Agricultural Sciences SLU,
Department of Biomedical Science and Veterinary Public Health-Division of Bacteriology and Food Safety, Uppsala, Sweden

Backgrounds

Escherichia coli O157:H7, a hazardous foodborne pathogen, has been in the spotlight several times during the last decades due to its infectivity and epidemic nature of dispersal. Recent outbreaks of *E. coli* infections associated with consumption of raw vegetables, predominantly sprouted seeds, have been reported in several countries around the world. At the same time growing and raw consumption of sprouted seeds is associated with a healthy lifestyle in Scandinavia, and different types of sprouting modules for home production are available. During sprouting ideal conditions for emergence, but also for bacterial proliferation are prevailing. As the seeds are non-sterile, also human pathogens may propagate, which poses a great risk of foodborne illness.

Objectives

We studied the dynamics of *E. coli* O157:H7 *gfp+* in two types of three-layered sprouting modules, using organic fenugreek seeds (*Trigonella foenum-graecum*) as a model crop.

Methods

E. coli O157:H7 *gfp+* was introduced to either bottom or top layer of the modules and its dispersal was analyzed after 3.5 days. Using Beta-Poisson model we assessed the risk for consumer exposure.

Conclusions

We found that the inoculated strain dispersed both vertically up and down between the layers. Our results indicate that risk for dispersal of *E. coli* O157:H7 is high in both directions within the sprouting module, posing a high risk for consumer exposure. Data on the bacterial background biota is presented in the poster. We conclude that high hygiene standards are needed for both seeds and modules used for home sprouting of seeds.

THE ROLE OF NITROGEN UPTAKE ON COLONIZATION ABILITY OF AUTOCHTHONOUS SACCHAROMYCES CEREVISIAE STRAINS

C. Vendramini[1], G. Beltran[2], C. Nadal[1], G. Crosato[1], A. Giacomini[1,3], A. Mas[2], V. Corich[1,3]
[1]University of Padova, DAFNAE, Legnaro, Italy
[2]Universitat Rovira i Virgili, Departament de Bioquímica i Biotecnologia, Tarragona, Spain
[3]University of Padova, CIRVE, Conegliano, Italy

Backgrounds

Saccharomyces cerevisiae is the main actor of the alcoholic fermentation and the use of selected strains as starter cultures to initiate and control alcoholic fermentation nowadays is a worldwide practice. However, produced wines are standardized and with poor complexity. For this reason, a wide pool of autochthonous yeasts was isolated from grape bunches coming from vineyards of different winemaking regions in the North-East of Italy. Their fermentation performances were studied to select strains for the production of wines with enriched complexity.

Objectives

The aim of this work was to understand if nitrogen availability could influence vineyard strain colonization ability during must fermentation.

Methods

Selected vineyard strains of *Saccharomyces cerevisiae* were assayed in competence with a commercial industrial strain. Pairwise-strain fermentations and co-fermentations were performed in synthetic musts at two nitrogen levels: control nitrogen condition (CNC), assuring the suitable assimilable nitrogen amount required by the yeast strains to complete the fermentation, and low nitrogen condition (LNC), where nitrogen is present at very low level. Single-strain fermentations were also run in both conditions and the nitrogen metabolism analyzed.

Conclusions

The high nitrogen assimilation rate seems to be an additional strategy that allowed vineyard yeasts successful competition during must colonization.

PENICILLIUM ROQUEFORTI DEVELOPMENT DURING SWEET GORGONZOLA CHEESE PRODUCTION

E. Neri[1], S. Arioli[1], S. Colombo[1], G. Della Scala[1], G. Gargari[1], M. Stuknyte[2], I. De Noni[2], F. Dal Bello[3], A. Bernacchi[3], E. Nicita[4], D. Mora[1]
[1]University of Milan, Department of Food- Environmental and Nutritional Sciences DeFENS, Milan, Italy
[2]University of Milan, Department of Biochemistry, Milan, Italy
[3]Sacco SRL, Research & Development, Cadorago, Italy
[4]Caseificio fratelli Oioli, Quality Control, Cavaglietto, Italy

Backgrounds

Sweet gorgonzola is a blue-veined, mould-ripened cheese, made from pasteurized cow's milk inoculated with starter cultures of lactic acid bacteria along with *Saccharomyces cerevisiae* and *Penicillium roqueforti.* Fungal growth during the ripening process is crucial for the final quality of the cheese. Traditional microbiological methods along with alternatives (ergosterol, dry weight, spores counting) are not suitable for hyphal filaments quantification in the cheese matrix.

Objectives

Here we monitored and compared the *P. roqueforti* development in two Gorgonzola productions during all the steps of the cheese production process.

Methods

We developed a qPCR assay based on a species-specific primer set targeted on *ari1* gene. The development of *P. roqueforti* in the cheese matrix was compared with data related to cheese proteolysis obtained with a mass spectrometry-based chemical analysis and using a glutamate-sensitive *S. thermophilus* luminescent biosensor.

Conclusions

The results obtained showed a good agreement between the proteolysis dynamics, measured during cheese ripening, and the qPCR data. The overall data obtained underlined that the production of sweet Gorgonzola is characterized by high degree of variability related to the growth of *P. roqueforti* within the cheese matrix. A limited growth of the mould is reflected in a limited proteolysis with a consequent reduction of creaminess and cheese sensory properties. Sugar consumption measurements during the first stages of cheese production led to hypothesize that the development of *P. roqueforti* during cheese ripening is strictly dependent on the appropriate growth and galactose fermenting capability of *Saccharomyces cerevisiae* during the first 36 h of Gorgonzola production process.

[2]Instituto de Catálisis y Petroleoquímica ICP-CSIC, Biocatálisis Aplicada, Madrid, Spain
[3]Biopolis S.L., Microbiology, Valencia, Spain
[4]Lifesequencing S.L., Lifesequencing, Valencia, Spain

Backgrounds

Xylooligosaccharides (XOS) are nutraceutics derived from xylan hydrolysis, which are receiving increasing attention since their potential as emerging prebiotics is becoming evident. These carbohydrates are composed of β-1,4-linked xylopyranose residues. XOS have demonstrated their capacity to selectively stimulate the growth of probiotic microorganisms present in the lower gastrointestinal tract, as *Lactobacillus* and *Bifidobacterium* species. They are obtained from the xylan fraction of lignocellulosic materials by physicochemical or enzymatical methods. The latter displayed the advantages of being environment-friendly, requiring mild conditions, and producing low monosaccharide yield without toxic by-products.

Objectives

The main goals of this work were the application of a novel GH11 endoxylanase, isolated from the ascomycete *Talaromyces amestolkiae*, to convert birchwood xylan into XOS, the characterization of the obtained mixture, and the assay of its prebiotic potential.

Methods

XOS were produced using the purified endoxylanase in its optimal reaction conditions. The production yields were evaluated by HPLC (HPAEC-PAD), while the polymerization degrees' distribution and the composition of the mixture were assessed by HPAEC-PAD and ESI-MS. Biological activity of the obtained XOS mixture was evaluated by fecal-fermentation, determining the profiles of organic acids and analyzing bacterial microbiomes up to the species level.

Conclusions

By this way a mixture of birchwood XOS including neutral and charged species was obtained in a yield comparable to other reports, with negligible content of xylose. These oligosaccharides displayed prebiotic properties, promoting the growth of bifidobacteria together with the potential probiotic strain *Staphylococcus hominis*.

TRANSCRIPTIONAL AND TRANSLATIONAL CHANGEOVER DURING B. SUBTILIS SPORE GERMINATION

B.N. Swarge[1], D. Beaty[1], W. Roseboom[2], S. Brul[3], C.G. de Koster[2], L.J. de Koning[2]
[1]Swammerdam Institute for Life Sciences- University of Amsterdam,
Molecular biology and Microbial Food Safety- Mass spectrometry of Biomacromolecules, Amsterdam, The Netherlands
[2]Swammerdam Institute for Life Sciences- University of Amsterdam,
Mass spectrometry of Biomacromolecules, Amsterdam, The Netherlands
[3]Swammerdam Institute for Life Sciences- University of Amsterdam,
Molecular biology and Microbial Food Safety, Amsterdam, The Netherlands

Backgrounds

In response to nutrient limitation Gram positive organisms like *Bacillus subtilis* form dormant spores. These cellular entities are survival capsules, resistant to chemical and environmental assaults. They pose challenges to the food and medical sectors. Upon contact with germinants spores return to vegetative life through a process called 'germination and outgrowth'. Spores reactivate their metabolism and develop in vegetative cells. The molecular machinery that triggers and progresses the germination is still unsettled.

Objectives

Gain insight in the germination molecular machinery by mapping the progression of the transcriptome and proteome changeover during germination and outgrowth of spores.

Methods

For the time-resolved monitoring of the transcriptome and the proteome *of B. subtilis spores* during germination, the spores are sampled in time-intervals from germination initiation to the stage of vegetative cell outgrowth. Intact and purified RNA is isolated from spores, at each time-point, for transcriptome analysis. We thus trace the different functional groups of genes expressed during the germination and outgrowth process. Next, the changes in the proteome are quantitatively monitored relative to the proteomes of ^{15}N metabolically labelled dormant spores and ^{15}N metabolically labelled vegetative cells.

Conclusions

The time-resolved transcriptomics and proteomics data provide new insight in the cellular control level of novel protein synthesis during the awakening of spores. The data will offer input for the development of a mathematical model of the germination process.

PREVALENCE OF NON-TUBERCULOUS MYCOBACTERIA WITH VIRULENCE PROPERTIES ISOLATED FROM RAW MILK AND STREET-VENDED DAIRY PRODUCTS

D.E. Rios-Muñiz[1], J.F. Cerna Cortesa[1], E.B. Angeles-Morales[1], M. Bodadilla-del Valle[2], A. Ponce-de Leon[2], M.T. Estrada-Garcia[3]
[1]Instituto Politécnico Nacional, Microbiology, Mexico City, Mexico
[2]National Institute of Medical Science and Nutrition, Infections Diseases, Mexico City, Mexico
[3]CINVESTAV-IPN, Molecular Biomedicine, Mexico City, Mexico

Backgrounds

Reports of human infectious and illness due to non-tuberculous mycobacteria (NTM) and NTM isolation from a variety of food samples have recently increased worldwide. Biofilm formation and sliding motility are characteristics that allow NTM to persist on human tissues and natural reservoirs.

Objectives

To establish NTM prevalence in dairy products and raw milk and the antibiotic susceptibility, biofilm formation and sliding motility of the NTM isolates

Methods

During two years, from each season, dairy products and raw cow milk were purchased from three street markets of Mexico City and three cow stables of the state of Mexico. 120 samples were collected and analysed for the presence of several food-borne pathogens, including mycobacteria. Mycobacteria speciation was done using three molecular markers: *hsp*65, *rrs*, and *rpo*B genes. NTM isolates were further characterized by: biofilm and motility assays, and antimicrobial susceptibility testing. **Results.** A total of 72 cheese, 24 cream, and 24 raw milk samples were collected. From 3 cheese, 5 cream, 3 raw milk samples (n=11, 9.1%), mycobacteria strains were isolated. Only one NTM species was recovered from 8 samples: *M. fortuitum* (n=3), *M. porcinum* (n=3), *M. rhodesiae* (n=1), *M. abscessus* (n=1); while *M. abscessus* and *M. chelonae*, were concurrently recovered from three samples. Biofilm formation and sliding motility were observed among 93% and 71% of NTM isolates, respectively. Besides 57% of the isolates were resistant to Linezolid and 50% to Clarithromycin.

Conclusions

Consumption of cheese, cream and raw milk harbouring NTM with virulence properties may represent a public health risk.

FEMS7-3320
Food Microbiology - Part III

HUMAN BIOTOPE HEALTHY STATUS SUPPORTED BY GLYCOCONJUGATES RECOGNITION PROBIOTIC SYSTEMS

M. Lakhtin[1], V. Lakhtin[1], S. Afanasiev[1], A. Bajrakova[1], V. Aleshkin[1]
[1]Medical Biotechnology, G.N.Gabrichevsky Institute of Epidemiology and Microbiology, Moscow, Russia

Background
Microbial communities participate in biotope healthy status.
Objectives
One more strategy to support healthy biotope.
Methods
Glycoconjugates recognition probiotic systems **(**GRPS) of probiotic bacterial cultures; intestinal and urogenital microbial clinical strains were used. Microbes were growth in standard media and conditions in the absence or presence of GRPS.
Conclusions
1. *Features of GRPS*. GRPS are localized, organized and act as cell layer mosaic surface and secreted truncated/ modified and assembled active or activated systems which imitate probiotics. GRPS are represented by synergistically cofunctioned bifidobacteria and lactobacilli probiotic lectins and their complexes, glycosyl hydrolases. GRPS function as soluble signals and cell pools. GRPS reveal properties of quorum sensing molecules, cross-talking agents, metabolomebiotics, net switchers; antifungal and antistaphylococcal effectors. **2.** *Biotope communications. L.acidophilus, L.casei* and *L.brevis* suppress or significantly limit fungal growth of *C.albicans, C.tropicalis, C.krusei* and/or *C.albicans+A.niger*; influence subspecies microecological niches within fungal group (*C.albicans* and *C.tropicalis*). *L.acidophilus* and *L.casei* probiotic-like pools (main sources of GRPS) contain leader strains which desorganize communications between *Candida* species/ subspecies or within *C.albicans* strain massive. GRPS help in elimination of changeable lactobacillus strains. Biotope *Candida* pools contain leader strains which desorganize *Lactobacillus* species communications. **3.** *Strategy to support healthy biotope*: screening probiotic and potentially pathogenic yeast-like leader strains; delivery of synbiotic (probiotic lectins and strains); elimination of antimycotic sensitive leader strains. **4.** Universal conception of healthy biotope microbiocenose involving GRPS and leader strains is proposed.

Food Microbiology - Part III

STRESS RESISTANCE OF BIOFILM AND PLANKTONIC CELLS OF LACTOBACILLUS SPP

M. Olszewska[1], A. Kocot[1], A. Nynca[2]
[1]University of Warmia and Mazury in Olsztyn,
Faculty of Food Science- Chair of Industrial and Food Microbiology, Olsztyn, Poland
[2]University of Warmia and Mazury in Olsztyn,
Faculty of Biology and Biotechnology- Laboratory of Molecular Diagnostics, Olsztyn, Poland

Backgrounds

Although the biofilm formation by *Lactobacillus* species has been reported, stress responses of Lactobacilli biofilms associated with food production and spoilage have not been the subject of detailed studies. As a result, we have elucidated in detail the difference in resistance between planktonic and biofilm Lactobacilli cells to food acidulants, preservatives, disinfectants.

Objectives

1. Assess the ability to form biofilms by *Lactobacillus* species that cause food contamination or deterioration. 2. Examine the response of *Lactobacillus* biofilm formers to acetic acid, sucrose, ethanol, sodium dichloroisocyanurate-based and didecyl dimethyl ammonium chloride-based biocides. 3. Gain a better understanding of single cell physiology and properties of planktonic versus biofilm cells.

Methods

The biofilm formation was tested using the microtiter plate assay. Before survival test, biofilm formers were grown either as planktonic cultures or biofilms on polycarbonate coupons. For viability studies, we applied flow cytometry (FCM) which provided the insight into damage of cell membrane integrity. Plate counts were performed for cell culturability and/or cell recovery evaluation.

Conclusions

Isolates showed differences in the ability to form biofilms and tolerance to stress conditions relevant for food processing. Noteworthy is that biofilm cells were more resistant to ethanol, which strongly inhibits the growth of bacteria and is important in food preservation, and the treated biofilm cells were injured or damaged to a lesser extent than planktonic counterparts. These results indicate the significance of controlling Lactobacilli biofilms in the food industry.

This study was supported by a grant from the National Science Centre, Poland, no. 2014/13 /D/NZ9/04803.

Food Microbiology - Part III

CORRELATION BETWEEN BIOFILM FORMATION AND COMPOSITION AND MOLECULAR ASPECTS OF METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS

E.A. Oniciuc[1,2], F.I. BUCUR[1], D. RODRÍGUEZ-LÁZARO[2], V. BARBU[1], M. Hernández[3,4], A.I. NICOLAU[1]
[1]Dunarea de Jos University of Galati, SAIABA Department, Galati, Romania
[2]University of Burgos, Department of Biotechnology and Food Science, Burgos, Spain
[3]Instituto Tecnológico Agrario de Castilla y León, Laboratory of Molecular Biology and Microbiology, Valladolid, Spain
[4]Universidad de Valladolid, Departamento de Ingeniería Agrícola y Forestal, Palencia, Spain

Backgrounds

There is a growing concern regarding potential transmission of methicillin-resistant *Staphylococcus aureus* (MRSA) by illegal entrance of food to Europe. From a food safety perspective, different MRSA lineages can be acquired *via* food manipulation and/or consumption, and consequently circulation of multidrug resistant strains may arise. Resistance to antimicrobial agents can be also related to different responses in attachment and biofilm formation.

Objectives

More information regarding MRSA strains capacity to build biofilms and their composition of a matrix of extracellular polymeric substances involved in the attachment and colonization of food-contact surfaces is presented.

Methods

Forty-nine MRSA isolates recovered from animal food origin were evaluated for the ability of biofilm formation (24h) using TSB supplemented with 0.4% glucose. Experiments were performed in static conditions on 96-well hydrophobic surfaces at 37°C and a starting inoculum of ~ 10^6 CFU/mL. Biofilm compositions (48h) was evidenced by confocal laser scanning microscopy (CLSM) after exposure to three types of dyes: SYTO9 (nucleic acids), SYPRO Ruby (proteins), and WGA-TRITC (*N*-acetyl-D-glucosamine residues). Image stacks of biofilms were analysed further.

Conclusions

All MRSA isolates tested have the capacity to form biofilms. Time prolongation (48h) shows strong biofilm formation (OD>3) for 8 isolates, while the remaining 41 strains were weakly or moderate biofilm formers. A correlation between the formation of biofilms and MRSA lineages was observed, whereas a higher biomass was observed for those harboring SCC*mec* type IV. Half of the isolates formed flat and compact structures, while the rest of them developed highly fluorescent cell aggregates areas within the three-dimensional structures.

CHARACTERIZATION OF BACTERIOPHAGE–RESISTANCE IN ORAL PHAGE THERAPY

J. Otero[1], M. Sánchez-Osuna[1], P. Cortés[1], M. Llagostera[1]
[1]Universitat Autònoma de Barcelona,
Grup de Microbiologia Molecular. Departament de Genètica i de Microbiologia. Facultat de Biociència s. Edifici C, 08193 Cerdanyola del Vallès, Spain

Backgrounds

Bacteriophages have proved to be interesting therapeutics agents. Nevertheless, bacteriophage therapy may result in the selection of resistant bacterial cells, preventing an effective treatment.

Objectives

To study the emergence of bacteriophage-resistant *Salmonella* during *in vivo* oral phage therapy, with a cocktail composed by three virulent bacteriophages, and also in *in vitro* infected cultures.

Methods

The *in vivo* emergence of cells resistant to bacteriophages was studied in commercial broilers infected with *Salmonella enterica* serovar Typhimurium ATCC14028 after oral therapy with a cocktail of three bacteriophages. The selection of resistant cells *in vitro* was studied by infecting liquid cultures of ATCC14028 with the three bacteriophages individually or as a cocktail.

Conclusions

Resistance was not detected in the treated broilers after oral phage therapy, while resistant cells were found in the untreated ones. These results can be explained by the significant reduction of the *Salmonella* population due to the bacteriophage treatment and by the lower fitness and persistence of resistant cells in the cecum. Moreover, *Salmonella* isolates with an atypical behaviour to bacteriophages were recovered from untreated and treated animals.
Unlike the results found *in vivo*, different populations of resistant cells were found in the *in vitro* bacteriophage infected cultures. Results seem indicate that the emergence of bacteriophage resistance could be different in *in vivo* and *in vitro* scenarios, which suggest the need for caution in extrapolating *in vitro* results. Furthermore, a deeper phenotypic and genomic characterization of the different resistance cells is required in order to understand the mechanisms of resistance to bacteriophages.

Food Microbiology - Part III

A COMPARATIVE STUDY ON PULLULAN PRODUCTION BY VARIOUS AUREOBASIDIUM PULLULANS STRAINS

G.N. Kara[1], M.T. Bozdemir[2], Z.Y. Ozbas[3]
[1]Hitit University, Food Engineering, Corum, Turkey
[2]Hacettepe University, Chemical Engineering, Ankara, Turkey
[3]Hacettepe University, Food Engineering, Ankara, Turkey

Backgrounds

Aureobasidum pullulans is a yeast-like fungus that is particularly known as a producer of an extracellular polysaccharide; pullulan. Pullulan is an economically important polymer which is used in food, pharmaceutical, agricultural and chemical industries because it is nontoxic, biodegrable, tasteless, odorless, white and non-hygroscopic.

Objectives

The aim of this study was to investigate pullulan production characteristics of seven *A. pullulans* strains in a batch system.

Methods

A. pullulans strains BJ20p4, TreCisz2, G. Kaukaska B-1, CCF 4532, MAFF 425047, 100716 and AZ-6 were used in the experiments for pullulan production. The shake-flask fermentations were performed in 150 mL liquid media containing (g/L) sucrose; 50, $(NH_4)_2SO_4$; 2.0, yeast extract; 3.0, K_2HPO_4; 5.0, $MgSO_4.7H_2O$; 0.2 and NaCl; 1.0, at 28ºC in a waterbath shaker with a shaking rate of 100 strokes/min. Samples from the cultures were taken at certain intervals and centrifuged at 5000 rpm for 20 minutes. Pullulan was precipitated from the supernatant using two volume of cold ethanol per volume of supernatant. The pullulan content of the precipitate was determined by enzymatic hydrolysis to maltotriose with pullulanase followed by determination of reducing sugar equivalents by using the dinitrosalisylic acid method. Obtained pullulan was characterized by FT-IR spectroscopy.

Conclusions

Among the examined isolates, a domestic pinkish strain; *A. pullulans* AZ-6 was found the best candidate for pullulan production. The maximum exopolysaccharide and pullulan concentrations were obtained as 17,60 and 17.56 g/L, respectively by using this strain. The FT-IR spectra of the exopolysaccharide produced by *A. pullulans* AZ-6 and of the standard sample were almost identical.

MULTIFUNCTIONAL EFFECTS OF VIABLE AND HEAT-KILLED LACTOBACILLUS PLANTARUM LN1 ISOLATED FROM KIMCHI

H.J. Jang[1], M.W. Song[1], J.H. Lee[1], H.D. Paik[1]
[1]Konkuk university, Department of Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea

Backgrounds

Recently, many investigators have studied heat-killed lactic acid bacteria (LAB) because heat-killed LAB are stored more effectively than viable LAB for long periods and are transported easily. Nonetheless, some researchers announced that heat-killed LAB are not probiotics regardless of functionality.

Objectives

We compared multifunctional effects of viable LAB and heat-killed LAB to determine whether these effects are as good in heat-killed LAB as viable LAB and to increase the use of the probiotics in industries via this study.

Methods

Lactobacillus plantarum Ln1 was incubated at 37°C for 15 h. Heat-killed LAB were prepared by heat-treatment at 80°C for 30 min. They were centrifuged, and the pellet was washed with 0.1% peptone water and resuspended. The antioxidant, anti-inflammatory, and anti-cancer effects of viable and heat-killed LAB were evaluated by a β-carotene bleaching assay, NO production in LPS-stimulated RAW 264.7 cells, and an MTT assay.

Conclusions

The antioxidant effect was better in heat-killed LAB 49.97% and 58.33% for viable and heat-killed LAB, respectively. NO production was reduced by treatment with *L. plantarum* Ln1 at 28.19 μmol compared to the control LPS-stimulated cells and untreated cells. MTT results of viable LAB were 68.63%, 89.05%, and 83.05%, and those of heat-killed LAB were 67.57%, 32.31%, and 20.85%, in HeLa, AGS, and HT-29 cells, respectively. Although MTT results are better for viable cells than heat-killed LAB, heat-killed LAB seem to have an anti-cancer effects. Thus, our findings about heat-killed LAB may provide useful information to the probiotics industry.

PROBIOTIC PROPERTIES OF SACCHAROMYCES CEREVISIAE ISOLATED FROM TRADITIONAL FERMENTED FOODS WITH A CHOLESTEROL-LOWERING EFFECT

J.Y. Hong[1], S.H. Son[1], S.H. Yi[2], N.K. Lee[1], S.P. Hong[2], J.M. Park[3], H.D. Paik[1]
[1]Konkuk university, Department of Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea
[2]Korea Food Research Institute, Department of Strategic Food Research, Seongnam, Republic of Korea
[3]Korean Culture Center of Microorganisms, Korean Culture Center of Microorganisms, Seoul, Republic of Korea

Backgrounds

Probiotics are defined as live micro-organisms that confer a health benefit on the host. Probiotic yeast *Saccharomyces cerevisiae* has been extensively studied in terms of its ability to limit inflammation and infection in the gastrointestinal tract. In recent studies, the ability of probiotic strains to hydrolyze bile salts has often been included among the criteria for probiotic-strain selection. Bile salts play an important role in the digestion of lipids in vertebrates and are synthesized and conjugated to either glycine or taurine in the liver.

Objectives

The present work was conducted to obtain information about the probiotic properties and functional materials of 3 strains of *S. cerevisiae* (KCCM 200280, 200281, and 200284) isolated from Korean pickled cucumbers.

Methods

Strains (KCCM 200280, 200281, and 200284) showed a good survival rate in artificial gastric acid and bile acid (>89%). In addition, enzymatic activity was assessed using the API kit, and beneficial enzymatic activities were detected. The *S. cerevisiae* strains showed strong attachment, 8.3%, 20.9%, and 16.4%, respectively, to intestinal HT-29 cells. Deconjugation of bile salts and precipitation of soluble cholesterol by *S. cerevisiae* in the bile salt-YM medium were measured. In the medium containing taurocholate (TCA) and glycocholate (GCA), all *S. cerevisiae* strains showed strong resistance to bile salts (>87%).

Conclusions

Therefore, these results suggest that *Saccharomyces cerevisiae* is applicable as a probiotic having a cholesterol-lowering effect.

THE EFFECT OF FERMENTED PARSLEY ROOTS JUICE VS. SODIUM NITRITE ON MINCED PORK SHELF-LIFE

C. Papuc[1], G. Stefan[1], V. Nicorescu[1], C. Predescu[1], I. Nicorescu[2], C. Petrescu[3]
[1]University of Agronomic Sciences and Veterinary Medicine of Bucharest,
Faculty of Veterinary Medicine, Bucharest, Romania
[2]Institute of Hygiene and Veterinary Public Health, Food Microbiology, Bucharest, Romania
[3]Scientica Foundation, Scientica, Bucharest, Romania

Backgrounds

In response to consumers' demand for natural preservatives, vegetable juices rich in natural nitrites may be an alternative to sodium nitrite.

Objectives

The objective of this study was to evaluate the effects of natural nitrites from parsley (*Petroselinum crispum*) roots fermented juice (NPFJ) on minced pork (MP) subject to refrigeration, comparatively to sodium nitrite (SN).

Methods

MP was treated with NPFJ in relation of 0, 50, 100, 150 ppm nitrite, and with SN in the same relations. Treated MP was refrigerated at 4ºC for 12 days. Microbiological parameters (total viable count (TVC), coliform bacteria (CB), *Enterobacteriaceae*, and *E coli*) and physico-chemical parameters (pH, volatile basic nitrogen (VBN) and thiobarbituric acid reactive substances (TBARS)) were determined every two days. NPFJ had similar effects on MP shelf-life, comparatively with SN at the same concentration. The best results were found in MP treated with NPFJ 150 ppm; the microbial counts varied in days 0-12 in the relations: TVC 5.4-5.6 log cfu/g, CB 2.1-3.2 log cfu/g, *Enterobacteriaceae* 2.1-2.7 log cfu/g, and *E. coli* <1 log cfu/g. For the physico-chemical parameters, the variations found were in the relations: pH 5.85-6.39, VBN 17.83-24.69 mg N/100 g, and TBARS 0.25-0.47 mg MDA/kg.

Conclusions

Natural nitrites from parsley roots fermented juice are highly effective in preserving minced pork and show potential to be used as preservatives in meat industry. This work was carried out through *Partnerships in priority areas* Program – PN II, implemented with the support of MEN – UEFISCDI (Romania), project nr. 149/2014.

FEMS7-1838
Food Microbiology - Part III

INFLUENCE OF OSMOTIC PRESSURE ON THE GROWTH OF S. CEREVISIAE IN THE MERLOT VARIETY

I. Pardo[1], L. Polo[1], L. Andrés[1], C. Berbegal[1], S. Ferrer[1]
[1]ERI BioTecMed, ENOLAB, Burjassot, Spain

Backgrounds

The climate change effect leads to a rapid growth of the grapevine and an imbalance in grape maturation. In a normal ripening period, sugars accumulate at an adequate level, maintaining the acidic structure and resulting in a balanced wine. An excessive concentration of sugar can delay the start or arrest alcoholic fermentation, due to the high osmotic pressure. Therefore, yeasts are not able to perform the fermentation because the high concentrations of sugar slow the osmotic processes of cell membranes and may decrease their growth.

Objectives

Studying the behaviour of 14 native *Saccharomyces cerevisiae* strains - previously isolated from ecological Merlot industrial vinifications - versus different concentrations of sugar.

Methods

A natural industrial Merlot grape must was added with glucose and fructose (50%/50%) to reach 22, 24 and 25° Brix. Growth kinetics, glucose/fructose consumption, and ethanol, glycerol and acetic acid production along alcoholic fermentation were monitored.

Conclusions

An increase of sugar content reduces the maximum biomass, the growth rate of yeasts, or both parameters. Moreover, the higher initial sugar concentration is (glucose and fructose), the higher ethanol, glycerol and acetic acid concentrations are produced. These increases, nevertheless, are not proportional to the amount of initial sugar. The most sensitive strains to high sugar concentrations are 2e and 2g, since they yield the lowest values of maximum biomass, growth rates or both, and the most resistant strains are 7a, 7d, 7e and 10b.

FEMS7-0766
Food Microbiology - Part III

THE CHANGE OF MICROBIAL FLORA BY STARCH GRANULES AND ISOLATION OF RAW STARCH-DEGRADING MICROORGANISMS IN BOVINE RUMEN FLUID

C.S. Park[1], D.H. Jung[1], Y.J. Eeom[1], G.Y. Kim[1]
[1]Kyung Hee University, Food Science and Biotechnology, Yongin, Republic of Korea

Backgrounds

Granular starches are found in a number of plants and the most common carbohydrate in human and animal diets. In general, they are incompletely digested due to their size and molecular conformation.

Objectives

The objectives in this study is to observe the change of microbial flora in rumen fluid of *Bos taurus coreanae* by starch granules and to isolate starch granule-degrading microorganisms.

Methods

The change of microbial flora in rumen fluid of Korea bovine, *Bos taurus coreanae* was analyzed by metagenomics analysis using starch granules composed of 70% amylopectin and 30% amylose. From the starch granule-containing media, several strong starch granule-degrading microorganisms were isolated and identified in anaerobic growth condition. The utilization profile of various resistance starches by isolated *Bifidobacterium choerinum* was compared with the human intestinal amylolytic anaerobes.

Conclusions

Even though the major microbial strain in rumen fluid was *Succiniclasticum* sp., *Streptococcus* sp. was firstly thrived followed by *Lactobacillus* sp. in starch granule-containing media. Besides, the presence of *Bifidobacterium* sp. was continuously observed. Several strong starch granule-degrading microorganisms were identified and isolated. These strains were *Bifidobacterium pseudolongum* and *B. choerinum.* Particularly, both microorganisms were strongly attached to starch granule, and also exhibited resistance starch-hydrolyzing activities. In fact, *B. choerinum* showed a fast hydrolyzing ability towards different type of raw and resistant starches by degrading 80% of substrates within 5 hours. These results suggest that *Bifidobacterium* sp. is one of the main granular starch degrader in rumen microbial flora and could be further studied as a probiotic candidate.

FEMS7-0649
Food Microbiology - Part III

PROFILE AND CHARACTERISTICS OF LACTIC ACID BACTERIA AND BACTERIOPHAGE DURING KIMCHI FERMENTATION

J.H. Park[1], Y.D. Lee[2], W.J. Park[1], G.Y. Lim[1]
[1]Gachon University, Department of Food Science and Biotechnology, Seongnam, Republic of Korea
[2]Seowon University, Department of Food Science and Engineering, Cheongju, Republic of Korea

Backgrounds

Many foods have been fermented based on lactic acid bacteria.

Objectives

Objective of the present study was to investigate lactic acid bacteria (LAB) and bacteriophage of succession.

Methods

The fermentation on kimchi was divided into 7℃ and 20℃. As fermentation started at 7℃ and 20℃, the proportion of LAB increased and amount of virus-like particle (VLP) changed.

Conclusions

According to the fermentation temperature, the quantitative change of bacteriophage showed at different time. As a result of microbial analysis using pyrosequencing at the change of VLP, change of the dominant LAB in each period was shown. *Leuconostoc* was the dominant species in the initial and middle stage of fermentation, and *Lactobacillus* in the late stage of fermentation at 7℃. *Weissella* did not show after the initial stage of fermentation at 7℃. *Lactobacillus* was the dominant species on the 2 day fermentation at 20℃. Total 17 Bacteriophages were isolated from 7℃ fermentation. Bacteriophages showed changes with the succession of LAB. In morphological analysis, *Weissella cibaria* bacteriophages were belonged to *Podoviridae* family. *Leuconostoc lactis* and *Leuconostoc citreum* bacteriophages were belonged to *Myoviriade* family. Selected 6 strain bacteriophages were stable in the acidic condition. Especially, φ1D.4.1 decreased only by 5.7 log PFU/ml at pH 2 for 30 minutes. Therefore, bacteriophage with high acid tolerance might be involved in the succession of LAB during natural fermentation of kimchi.

FEMS7-0650
Food Microbiology - Part III

CHARACTERIZATION AND GENOME SEQUENCE ANALYSIS OF BECP4 PHAGE FOR SHIGA TOXIN PRODUCING E. COLI

J.H. Park[1], Y.D. Lee[2], M. Kim[2], S.C. Cho[2], G.Y. Lim[1]
[1]Gachon University, Department of Food Science and Biotechnology, Seongnam, Republic of Korea
[2]Seowon University, Deaprtment of Food Science and Engineering, Cheongju, Republic of Korea

Backgrounds

Shiga toxin producing *E. coli* (STEC) have also been reported to contaminate fresh produce, leading to a high risk of infection in vulnerable populations such as children and the elderly. Recently, phages have been extensively studied and have been used for a variety of practical applications such as for biocontrol of STEC.

Objectives

In this study, BECP4 phage was isolated from bovine fecal samples, and analyzed for various characteristics and genome sequence.

Methods

BECP4 phage was analyzed for genome information and characterized biochemically.

Conclusions

Morphological analysis showed that BECP4 phage belonged to the family *Myoviridae*. The genomic sequence of BECP4 phage was comprised of circular double-stranded DNA and was 138,462 bp, with a G+C content of 43.65%. The genome showed 212 putative ORFs, and the 6 tRNAs were identified. In stability, BECP4 phage was susceptible to temperatures above 70℃. However, its stability was reduced to 3-4 log PFU/ml after 60 min in 70% ethanol. The host spectrum using 34 STEC strains demonstrated that the BECP4 phage was able to lyse 19 STEC strains.
Thus, *Myoviridae* BECP4 phage with high stability might serve as effective biocontrol agents to simultaneously reduce STEC in food and remove STEC from biofilms.

FEMS7-0206
Food Microbiology - Part III

TEMPERATURE PRECONDITIONING AFFECTS MICROBIAL COMMUNITY DYNAMICS OF POSTHARVEST CHERRY TOMATOES (LYCOPERSICUM ESCULENTUM VAR. CERASIFORME) DURING REFRIGERATION STORAGE

K.M. Park[1], M.C. Jeong[2], M. Koo[1,2]
[1]Korea University of Science and Technology, Food Biotechnology, Daejon, Republic of Korea
[2]Korea Food Research Institute, Food Storage and Distribution, Gyeonggi-do, Republic of Korea

Backgrounds

Microbial community structure of fruit and vegetable are strongly influenced by environmental conditions such as temperature. Many research focused on the microbiological and sensory quality changes and overall diversity and composition of bacterial communities by environmental conditions are poorly understood.

Objectives

The objectives were (1) to investigate microbial community variation by temperature preconditioning and (2) to determine the relationship between spoilage bacteria development and temperature preconditioning during storage.

Methods

After harvest, fruit temperature(FT) by preconditioning were controlled in 4 group: FT-5(immediately stored at 5℃); FT-10(10℃); FT-20(20℃); and FT-30(30℃) , after that, stored at 5 ℃. Microbial community analysis was performed by MALDI-TOF MS and VITEX 2 compact.

Conclusions

The communities on each preconditioned fruit were significantly distinct. After preconditioning treatment, bacterial composition consisted of 19 different genera and 52% of total bacterial isolates belonged to *Staphylococcus xylosus*, 14% to *Bacillus pumilus* and 8% to *Pantoea agglomerans*. The most abundant strains of FT-5 and FT-10 identified as *Bacillus pumilus*. In contrast, *Staphylococcus xylosus* were found with abundance above 60% in FT-20 and FT-30. At the end of refrigeration storage, bacterial diversity dramatically decreased to 9 genera and most strains belonged to vegetable spoilage bacteria. *Pseudomonas fluorescens* on FT-5 and FT-10 showed high abundance and *Rahnella aquatilis* was dominated in FT-20 and FT-30. We found that temperature preconditioning after harvest had a considerable impact on the microbial community. These observations will provide new sight to enhance microbiological safety of cherry tomato or to prolong postharvest shelf life based on microbial community-environmental condition relationships.

PRESERVATION OF A SMEAR SURFACE-RIPENED CHEESE ECOSYSTEM BY FREEZING AND FREEZE-DRYING: A PROOF OF CONCEPT

W. Cao[1], F. Irlinger[1], T. Cattenoz[1], M.N. Leclercq-Perlat[1], S. Passot[1], F. Fonseca[1]
[1]UMR GMPA- AgroParisTech- INRA, Université Paris-Saclay, Thiverval-Grignon, France

Backgrounds

The preservation of microbial resources of interest for cheese making and obtained from traditional technological uses (whey, indigenous microbial flora, wooden Gerles), appears as an important issue to safeguard the overall biodiversity of microbial cheese communities. Many protocols have been developed for long-term and stable storage of axenic cultures, while few preservation methodologies have been described for microbial consortia.

Objectives

The objective of this work was to develop preservation methods to stabilize entire microbial cheese communities without multiplication or isolation.

Methods

A simplified microbial community, composed of 9 micro-organisms and capable of reproducing the complex metabolic pattern of cheese maturation was used. Three independent cheese productions were performed. Stabilization conditions were applied, including formulation and different operating conditions of freezing, freeze-drying and storage. The survival of each micro-organism of the cheese consortia was quantified by microbiological counts in selective media at days 1 and 21 of the ripening and after freezing, freeze-drying and storage of cheese samples. Physical characterization was performed by measuring water activity and water content of stabilized samples. In order to better understand the mechanisms underlying preservation, thermal events such as the glass transition temperatures of cheeses were identified by differential scanning calorimetry.

Conclusions

This work made it possible a better knowledge of the resistance to stabilization processes of each micro-organism within the consortium. Moreover, a cheese production was successfully carried out by using the best stabilized cheeses for inoculation, showing that it is possible to preserve and then re-use the whole of a microbial community of interest.

Food Microbiology - Part III

INHIBITION OF PENICILLIUM BY LACTOBACILLUS SPP. ISOLATED FROM MILK.

J. Pereira[1], E. Antonio Rios[1], J. Angel Santos Buelga[1], G.L. María Luisa[1], L.D. Teresa María[1]
[1]Universidad de León, 1Department of Food Hygiene and Food Technology- Veterinary, León, Spain

Backgrounds

In order to control spoilage and toxigenic fungi in cheese, chemical preservatives are commonly used. Within the biocontrol techniques, which are highly valued today, lactic acid bacteria (LAB) are being investigated. In an earlier study by the authors, 93 strains of LAB with antagonistic capacity against *Penicillium commune* (M35, CECT 20940) and *Penicillium nordicum* (M32, CECT 20939) (strains of cheese origin) were isolated. After confirming the antagonistic capacity, 57 strains were selected, 34 showed the greatest capacity (with inhibition halos of 8-12 mm). In another study by the authors, 5 strains were identified, where 2 represented *Lactobacillus casei*, and the rest were *L. parabuchneri*, *L. rhamnosus* and *L. plantarum*.

Objectives

The aim of this study is to identify the 29 remaining strains and analyze their activity against another 5 strains of *Penicillium* (4 *Penicillium commune* and 1 *Penicillium verrucosum*).

Methods

The identification was carried out with a sequencing of DNA 16 S technique. The studies on *Penicillium* inhibition were carried out with a "spot on the lawn" plate technique.

Conclusions

Up to now, it was possible to identify 23 of the 29 strains. The species identified were: *Lactobacillus paracasei* (32.1%), *Lactobacillus casei* (25%), *Lactobacillus plantarum* (17.9%), *Lactobacillus parabuchneri* (7,1%), *Lactobacillus brevis* (3.6%), *Lactobacillus zeae* (3.6%) and *Lactobacillus fermentum* (3.6%). According to the antifungal capacity results against *Penicillium* strains, *Lactobacillus casei* was the species that revealed greater inhibition capacity.

FEMS7-1158
Food Microbiology - Part III

NATURAL ANTIMICROBIALS AND HIGH PRESSURE TREATMENTS ON THE INACTIVATION OF LISTERIA MONOCYTOGENES AND THE CHARACTERISTICS OF SLICED DRY-CURED HAM

A. Pérez-Baltar[1], A. Serrano[1], R. Montiel[1], D. Bravo[1], M. Medina[1]
[1]Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria, Food Technology, Madrid, Spain

Backgrounds

Listeria monocytogenes is a bacterial pathogen able to grow under different stress conditions (refrigeration temperatures, low pH or high levels of NaCl) and commonly found in the food industries, including tools and equipment. Combined inactivation treatments provide greater protection against this pathogen, improving the safety of ready-to-eat (RTE) meat products.

Objectives

The effect of high pressure processing (HPP) combined with enterocin and thymol on *L. monocytogenes*, total viable counts and the physicochemical, rheological and colour characteristics of sliced dry-cured ham was investigated.

Methods

A four-strain cocktail of *L. monocytogenes* was used to inoculate sliced dry-cured ham at 10^6 cfu/g. Enterocin extract and thymol were added to dry-cured ham slices at 1054 AU/g and 1.25 mg/g, respectively. Samples were pressurized at 450 MPa for 10 min and stored at 4 and 12 °C during 30 d. *L. monocytogenes* and total viable counts were performed at 1, 7, 15 and 30 d. Likewise, pH, water activity (a_w), colour and texture were determined at 1, 15 and 30 d in non-inoculated samples.

Conclusions

Enterocin exhibited a strong antimicrobial effect against *L. monocytogenes* in dry-cured ham, whereas a regrowth was registered from day 15 onwards. 450 MPa or thymol showed low activity against the pathogen. Combined treatment of enterocin and HPP exhibited a synergistic bactericidal effect during 30 d at 4 and 12 ºC, and could be a useful technology to avoid the growth of *L. monocytogenes* in case of contamination during the processing. Concerning physicochemical, rheological and colour characteristics, slight modifications were detected throughout the storage.

FEMS7-1170
Food Microbiology - Part III

HIGH PRESSURE TREATMENTS ON THE INACTIVATION OF LISTERIA MONOCYTOGENES AND EFFECT ON THE PHYSICOCHEMICAL CHARACTERISTICS OF DEBONED DRY-CURED HAM

R. Montiel[1], A. Pérez-Baltar[1], A. Serrano[1], M. Medina[1]
[1]Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria, Food Technology, Madrid, Spain

Backgrounds

Dry-cured ham can be contaminated with *Listeria monocytogenes* during the industrial processing, especially during deboning, slicing, packaging and other handling processes, which has become in a great concern for the manufacturers. Therefore, additional hurdles are needed to reduce or eliminate the presence of such pathogen in this processed ready-to-eat (RTE) meat product.

Objectives

The aim of this work was to investigate the effect of high pressure processing (HPP) on *L. monocytogenes* and the physicochemical characteristics of deboned dry-cured ham.

Methods

A four-strain cocktail of *L. monocytogenes* was inoculated in the external and internal side of deboned dry-cured hams at 10^{5-6} cfu. Hams were vacuum-packaged and pressurized at 450 and 600 MPa for 10 and 5 min, respectively, and stored under strict refrigeration temperatures (4 °C) and temperature abuse conditions (12 °C) during 60 d. Inoculated areas were taken from each ham at 1, 30 and 60 d to perform *L. monocytogenes* counts. Non-inoculated samples were taken at each sampling time for the determination of pH, water activity (a_w), moisture content, sodium chloride and nitrites content.

Conclusions

Pressurization at 600 MPa significantly reduced *L. monocytogenes* population in the internal side of dry-cured ham. The low water content in the external side protected the pathogen against HPP immediately after treatments, although *L. monocytogenes* counts significantly diminished during 60 d of storage at 4 and 12 ºC compared to non-treated samples. Regarding physicochemical characteristics, slight modifications in pH, a_w, moisture content, sodium chloride and nitrites content were recorded throughout the storage.

FEMS7-2852
Food Microbiology - Part III

BIOGENIC AMINE PRODUCTION IN A COLLECTION OF LACTIC ACID BACTERIA ISOLATED FROM GOAT MILK

A. Picon[1], P. Gaya[1], C. Escudero[1], C. Sánchez[1], M. Nuñez[1]
[1]INIA, Food Technology, Madrid, Spain

Backgrounds

Biogenic amines (BA) are low molecular weight organic bases that may cause food poisoning episodes. In fermented foods, the availability of substrates and the appropriate conditions for bacterial growth and decarboxylase activities cause their biosynthesis and accumulation. The most important BA in fermented foods are tyramine, histamine, putrescine and cadaverine, respectively produced from tyrosine, histidine, ornithine and lysine.

Objectives

To investigate the production of BA in a collection of 298 lactic acid bacteria isolated from goat milk.

Methods

BA production was evaluated in the decarboxylase agar medium (Bover-Cid and Holzapfel, 1999) after incubation at 30-37°C for 4 days. From isolates showing darkening or change in colour, total genomic DNA was extracted and PCR amplification with specific PCR primers for decarboxylase structural genes was performed (De las Rivas et al., 2005). Confirmation of BA production was performed by HPLC.

Conclusions

Darkening or change in colour in the decarboxylase agar medium with one or several precursor amino acids was recorded for 46 *Enterococcus*, 12 *Lactobacillus*, 10 *Lactococcus*, 5 *Leuconostoc*, 2 *Carnobacterium* and 2 *Weissella* isolates. Only the tyrosine decarboxylase gene could be amplified, from 46 *Enterococcus* isolates, the two *Carnobacterium* isolates and one *Lactobacillus* isolate. Tyramine production was confirmed by HPLC for all those 49 isolates.

FEMS7-2819
Food Microbiology - Part III

CHARACTERIZATION AND OPTIMIZATION OF TECHNOLOGICAL PROCESSES FOR THE PREPARATION OF ASTURIAN SAUSAGE THROUGH THE USE OF METAGENOMICS

N. Prado[1], M. Sampayo[1], P. González[1], J. Díaz[1]
[1]ASINCAR, Laboratorio e I+D+i, Noreña, Spain

Backgrounds

The manufacture of Asturian Sausage requires a fermentative process followed by a stage of maturation to attain its typical sensorial properties. Traditionally, microorganisms present in the meat or as well as those coming from activities like manipulation or industrial environment, are responsible of the fermentative processes. The problem is that not all the microorganisms present in the raw materials contribute to a good fermentation processes and sometimes they are responsible of product spoilage.

Objectives

Main goal is the use of sequencing techniques, Metagenomics, with the aim of improving the elaboration process of Asturian Sausage.

Methods

Metagenomics is a new scientific field that allows the analysis of a large number of nucleic acid fragments from a sample as well as the identification of which microbial species are present and in which relative percentage. This technique has advantages in comparison to conventional microbiological analysis techniques since it allows the identification of any microorganisms, including non-cultivable ones, and the determination of the phylogenetic relationships between them.Using Metagenomics we will be able to analyze the microorganisms responsible of the technological processes that take place during the elaboration of the fermented raw-cured sausage.

Conclusions

The determination of microbial ecology through the different production stages of the Asturian Sausage has allowed to obtain complete information about the fermentation process. This will allow the design of specific strategies to improve food safety as well as the development of new product processes.

ANTIOXIDANT AND ANTIMICROBIAL ACTIVITY OF DIFFERENT BLACK GRAPE POMACE EXTRACTS RICH IN POLYPHENOLS

C. Predescu[1], I. Nicorescu[2], G. Stefan[1], V. Nicorescu[1], A.E. Rus[3], C. Petcu[1], C. Papuc[1]
[1]University of Agronomic Sciences and Veterinary Medicine of Bucharest, Faculty of Veterinary Medicine, Bucharest, Romania
[2]Institute of Hygiene and Veterinary Public Health, Food Microbiology, Bucharest, Romania
[3]Banat's University of Agricultural Sciences and Veterinary Medicine of Timisoara, Food Science, Timisoara, Romania

Backgrounds

The pomace which results after obtaining the wine can be used as a source of antioxidants such as polyphenols.

Objectives

The aim of the study was to determine the antioxidant activity (AOxA) and antimicrobial activity (AMA) of polyphenols from black "Feteasca neagra" grape pomace (BGP) extracted in ethanol, methanol, acetone, chloroform, and water at room temperature for 12 hours.

Methods

Total polyphenolic content (TPC) was determined with Folin-Ciocalteu reagent and expressed as mg gallic acid equivalents (GAE)/100 mL, while total flavonoid content (TFC) was determined with sodium nitrite, aluminium chloride and sodium hydroxide and expressed as mg catechin equivalents (CE)/100 mL. AOxA was evaluated by DPPH scavenging activity, Fe(III) reducing power, and Fe(II) chelating capacity. The AMA of BGP polyphenolic extracts was determined using agar disk-diffusion method against *Staphylococcus aureus*, *Staphylococcus epidermidis* and *Enterococcus faecalis*. The highest TPC and TFC values were found in the ethanolic extract (210.85 mg GAE/100 mL and 119.27 mg CE/100 mL, respectively). Methanolic and ethanolic extracts showed important values for DPPH scavenging activity and Fe(III) reducing power, while ethanolic and acetone extracts presented the highest values regarding Fe(II) chelating activity. Polyphenols extracted in methanol and acetone showed significant AMA, but polyphenols extracted in ethanol showed maximum inhibition zones against all the microorganisms tested; chloroform and aqueous extracts showed less AMAs.

Conclusions

Black grape pomace represents an important source of polyphenols with antioxidant and antimicrobial activity. This work was carried out through Partnerships in priority areas Program-PN II, implemented with the support of MEN-UEFISCDI (Romania), project nr. 149/2014.

Food Microbiology - Part III

CONTRIBUTION OF VEGETABLES AND AGRICULTURAL ENVIRONMENTS TO THE SPREAD OF SHIGATOXIN 2 PHAGES AND THE EMERGENCE OF NEW SHIGATOXIN PRODUCING STRAINS.

P. Quirós[1], *M. Muniesa*[1]
[1]*Universidad de Barcelona, Genetics- microbiology and stadistics, Barcelona, Spain*

Backgrounds

There is a global tendency to eat a healthy diet rich in uncooked fresh vegetables, although consumption of raw products poses a risk of contamination by pathogens. Shiga toxin-producing *Escherichia coli* (STEC) are foodborne pathogens associated with serious human disease. Its principal virulence factor is Shiga toxin (Stx), whose genes are in the genomes of temperate bacteriophages (Stx phages). A relevant number of STEC recent outbreaks are linked to vegetable consumption, as the one in Germany in May 2011. It is unknown the real risk of Stx transduction causing the emergence of new STEC strains in vegetables, particularly when consumed little or no cooked.

Objectives

To evaluate different types of vegetables and agricultural soils for the occurrence, persistence and infectivity of Stx phages and to evaluate *stx* transduction and generation of STEC in these matrices.

Methods

A total of 90 samples (lettuce, cucumbers, spinach, lentil sprouts and soils) were used as matrices. The occurrence of infectious Stx1 and Stx2 phages in these matrices and their persistence at storage temperature (4 and 23ºC) was evaluated. Labelled Stx phages were used to generate *E. coli* lysogens in these matrices.

Conclusions

There is a greater occurrence of Stx2 phages (23.3 % samples) than Stx1 phages (5% samples), particularly in soil. Many Stx phages detected were infectious and persist more than 10 days at storage temperatures. Transduction and generation of STEC lysogens was observed in all matrices. Horizontal transfer of *stx* mediated by Stx phages may give rise to the emergence of new pathogens in vegetable matrices.

Food Microbiology - Part III

EVALUATION OF FRESH SWEETS WITH STAPHYLOCOCCUS AUREUS ENTEROTOXIN GENES A AND B IN KURDISTAN PROVINCE

B. Rahimian Zarif[1], *T. zabihollahi*[1]
[1]*Department of biology - sanandaj branch - Islamic Azad University - sanandaj - Iran, Biology, sanandaj, Iran*

Backgrounds

the main causes of food poisoning in the world are Enterotoxins A and B of *Staphylococcus aureus*. Approximately 20 to 55 percent of healthy adults are infected with this pathogen. Transmission of enterotoxin producer *Staphylococcus aureus* in fresh sweets, through contaminated dairy products or manufacturers, has increased the risk of food poisoning.

Objectives

the aim of the present study was to determine the prevalence of enterotoxin genes (sea) A and (seb) B between *S. aureus* strains isolated from products in several cities of Kurdistan province in 2015**.**

Methods

In cross-sectional study, 43 samples of fresh sweets were collected randomly of 8 cities in Kurdistan province based on the instructions of the Institute of Standard and Industrial Research of Iran and microbiology tests, the presence of *Staphylococcus aureus*, has been evaluated and distribution of sea and seb genes in isolates has been determined by PCR method.

Conclusions

The results have shown that percentage of contaminated fresh sweets with *Staphylococcus* was more than 6.97%. The frequency of enterotoxin sea and seb genes has been evaluated in samples. The contaminated samples with *Staphylococcus aureus* (2.32%) were able to producing enterotoxin A, and non of them were not able to producing enterotoxin B**.** Overall, the results have shown, there is the possibility of contamination fresh sweets with *Staphylococcus* and food poisoning. Pasteurization of dairy products, continuous microbial control fresh sweets and screening of food producer can reduce the risk of staphylococcal food poisoning**.**

Food Microbiology - Part III

CHARACTERISATION OF MULTIDRUG-RESISTANT DIARRHEAGENIC E. COLI FROM BOVINE DAIRY FARMING IN "CASTILLA Y LEON" (SPAIN)

E.A. Rios[1], J. Ramos Pereira[1], J.A. Santos[1], A. Otero[1], J.M. Rodríguez-Calleja[1]
[1]University of León, Department of Food Hygiene and Food Technology, Leon, Spain

Backgrounds

Several studies have showed an increase of multidrug-resistant *E. coli* as a raising concern for public health.

Objectives

This study was undertaken to carry out the characterisation of diarrheagenic *E. coli* obtained from dairy farms placed in the northwest of "Castilla y León" (Spain).

Methods

Fifty-six *E. coli* strains isolated from raw cow's milk (30) and dairy cattle farm environments (26; faeces, water, feed, air and handlers) were tested for biochemical phenotype, genetic profile and susceptibility to 22 antibacterial substances.

Conclusions

Thirty-three (59%) strains were PCR positive for the intimin gene (*eae*), negative for *stx*1 and *stx*2 genes, and lacking pEAF (*bfp*A-), thus considered atypical EPEC (aEPEC). Other virulence factors investigated were *espA*, *espB*, *tir* and *ehxA*. A high frequency (85%) of the tested aEPEC carried all these virulence genes but *ehxA* and only three strains showed these four genes. Nine (28%) aEPEC strains showed antibiotic resistance and six isolates were resistant to three or more antibiotics including ampicillin, cephalothin, cefotaxime, streptomycin, tetracycline, trimethoprim-sulphamethoxazole, sulfonamides, chloramphenicol, and amoxicillin-clavulanic acid.STEC strains (41%), bearing *stx* genes (predominantly *stx*1c), showed also other virulence factors (*hlyA*, *tia* and *subAB*). A high number (52%) of STEC strains exhibited antimicrobial resistance, among which 10 showed multiple resistance with streptomycin/gentamicin/chloramphenicol (4 strains) and ampicillin/cephalothin (4 strains) the most frequent antibiotics included in the resistance profiles. Overall, this study provides further evidence that cow's milk and farm environment are potential sources of both STEC and aEPEC bearing virulence genes and multiple antibiotic resistances which raises concerns for public health through the potential resistance dissemination along food chain.

Food Microbiology - Part III

THE USE OF PEPTIDOGLYCAN HYDROLASES IN FOOD PACKAGING BIOFILMS

T. Robles[1], *M. Quirasco*[1]
[1]*Universidad Nacional Autónoma de México, Faculty of Chemistry, Ciudad de Mexico, Mexico*

Backgrounds

E. faecalis strain F isolated from a Mexican cheese has shown extracellular lytic activity against gram positive and gram negative bacteria such as *S. aureus, Listeria monocytogenes, Micrococcus lysodeikticus, Salmonella enterica* Typhimurium and *Yersinia enterocolitica.* Bacteriolytic activity is associated to different enzymes with N-acetylglucosaminidase activity against bacterial peptidoglycan.

Objectives

The aim of this project was to produce a biofilm with peptidoglycan hydrolases immobilized by entrapment retaining antimicrobial activity against foodborne pathogens.

Methods

To achieve this goal, several mixtures of corn starch with glycerol as plasticizer were tested (thickness, solubility, elongation at break, tensile strength and water vapor permeability). As antimicrobial agents an extract with high concentration of the enzymes produced by *E. faecalis* strain F was immobilized and, lysozyme was tested as well. In the first formulation, the supernatant (previously neutralized) lyophilized was added to the support prior drying; and in the latter, lysozyme was directly added to the cold starch mixture. The catalytic activity of N—acetylglucosaminidase was detected by the hydrolysis of 4-Nitrophenyl N-acetyl-β-D-glucosaminide.

Conclusions

As a result, the film made with 5% (w/v) corn starch and 0.3 (w/w starch) glycerol had the best performance as support for immobilization.
Total activity was determined before and after immobilization and enzyme stability was assessed as well. The free enzyme showed 55% of activity at 4°C, which is important due to the intended use of the film at refrigeration temperature.

DEFINITION OF SAMPLING PROCEDURES FOR COLLECTIVE-EATING ESTABLISHMENTS BASED ON THE DISTRIBUTION OF ENVIRONMENTAL MICROBIOLOGICAL CONTAMINATION ON FOOD HANDLERS, UTENSILS AND SURFACES

D. Rodriguez-Lazaro[1], M. Hernandez[2], J.C. Ortiz[3], G. Fongaro[4], A. Valero[5]
[1]University of Burgos, Biotechnology and Food Science, 9001, Spain
[2]ITACyL, Laboratory of Molecular Biology and Microbiology, Valladolid, Spain
[3]Ayuntamiento de Madrid, Food Hygiene, Madird, Spain
[4]UFSC,
Laboratório de Virologia Aplicada- Departamento de Microbiologia- Imunologia e Parasitologia-, Florianópolis, Brazil
[5]University of Cordoba, Department of Food Science and Technology-, Cordoba, Spain

Backgrounds

Environmental sampling has been identified as an effective procedure to verify correct implementation of food safety control systems in catering establishments. At the same time characterization of microbial distribution of environmental contamination could potentially address effective fit-for-purpose sampling procedures.

Objectives

The study aimed at evaluating the microbiological contamination on food handlers, food-contact utensils and handlers'-contact utensils during food preparation for collective meals in Spain, as well as to determine contamination routes and their relationships between microbial indicators (aerobic mesophilic bacteria, *Enterobacteriaceae*, *Escherichia coli* and *Staphylococcus aureus*). Further, characterization of statistical distributions of microbial contamination and suggestion of sampling procedures were also performed.

Methods

1,202 environmental samples from three types of food catering establishments located in Madrid, Spain were monitored for presence of mesophilic bacteria, *Enterobacteriaceae*, *Staphylococcus aureus* and *Escherichia coli*. Samples corresponded to food-contact utensils, handlers'-contact utensils and food handlers, using 3M™ Petrifilm™ count plates. Contamination routes were identified through the calculation of Spearman correlation coefficients. Further, characterization of statistical distributions of microbial contamination and suggestion of sampling procedures were also performed.

Conclusions

53.0% of the samples were positive for at least one of the bacterial group studied and 328 (27.1%) with 1-15 CFU/plate. *Enterobacteriaceae, E. coli* and *S. aureus* were present in 62.1%, 7.5% and 26.6%, respectively of the food handlers' samples. Contamination routes from food handlers to handlers'-utensils was identified in a bidirectional way, being it subsequently spread to utensils in contact with foods. The microbial distribution affected significantly the number of samples needed to detect positives.

Food Microbiology - Part III

ADAPTATION OF LISTERIA MONOCYTOGENES TO SEVERAL FOOD-GRADE BIOCIDES

C. Rodríguez-Melcón[1], *R. Capita*[1], *C. Alonso-Calleja*[1]
[1]*Universidad de León, Food Hygiene and Technology, León, Spain*

Backgrounds

Biocides are compounds commonly used in the food system to reduce or eliminate both pathogenic and spoilage microorganisms. An increase in biocide tolerance is an important public health issue, as it might be expected to contribute to the increased persistence of pathogens in the food chain.

Objectives

The objective of this study was to determine whether *Listeria monocytogenes* can adapt to growth in increasing concentrations of several biocides commonly used in food processing facilities.

Methods

Four *L. monocytogenes* strains (serotypes 1/2a, 1/2b, 4a and 4b) were tested. The minimum inhibitory concentration (MIC) values of sodium hypochlorite (SHY), peracetic acid (PAA) and benzalkonium chloride (BZK) were established using a microdilution broth method in accordance with the CLSI Standard.

Conclusions

The MIC values (ppm) for *L. monocytogenes* cells ranged from 3,500 to 3,750 (SHY), 1,000 to 1,050 (PAA), and 1.0 to 2.0 (BZK). The cultures exhibited an acquired tolerance to such biocides, especially to SHY and BZK. The maximum concentrations (ppm) of biocides that allowed bacterial growth after several passages through gradually higher concentrations of such compounds ranged from 3,935 to 5,906 (BZK), 750 to 1,125 (PAA), and 1.7 to 8.5 (BZK). The highest adaptive tolerance was showed by *L. monocytogenes* 4a (SHY), 1/2a and 4b (BZK). It is suggested that sub-lethal exposure to food-grade biocides represents a risk for the development of adaptation of *L. monocytogenes* to such compounds. The importance of maintaining higher than MICs of biocides during sanitizing procedures to fight foodborne infections by *L. monocytogenes* is highlighted.

FEMS7-2861
Food Microbiology - Part III

EFFECT OF SEVERAL CONCENTRATIONS OF BIOCIDES ON THE ARCHITECTURE AND VIABILITY OF THE BIOFILMS FORMED BY LISTERIA MONOCYTOGENES

C. Rodríguez-Melcón[1], *C. Alonso-Calleja*[1], *F. Riesco-Peláez*[1], *R. Capita*[1]
[1]*Universidad de León, Food Hygiene and Technology, León, Spain*

Backgrounds

There are a number of circumstances where concentrations of biocides may be at sub-minimum inhibitory concentrations (sub-MICs). A better understanding of the phenomenon of biofilm may assist in the development of control strategies.

Objectives

The effect of sodium hypochlorite (SHY) and benzalkonium chloride (BZK) at different concentrations (0.5MIC, 1MIC, and 1.5MIC) upon the architecture and viability of the biofilms formed by *L. monocytogenes* (strains 2, 6, 7 and 12) was investigated.

Methods

Biofilm images were examined through confocal laser scanning microscopy (CLSM) after staining with SYTO9 and propidium iodide.

Conclusions

Biovolume (mean ± STD in the observation field -14,161 μm^2-) of the biofilms formed in the absence of biocides (control) ranged between 103.928,27 ± 6.730,16 μm^3 (strain 12) and 276.030,94 ± 42.291,89 μm^3 (strain 2). The presence of 0.5MIC of BZK during biofilm formation process increased ($P < 0.05$) the biofilm-forming ability of strains 6, 7 and 12. In contrast, at 1MIC or 1.5MIC, biocides reduced substantially ($P < 0.001$) the ability of *L. monocytogenes* to produce biofilm (biovolume between 28.40 ± 12.40 μm^3 and 266.32 ± 77.24 μm^3). The largest percentages (values higher than 95%) of live (green stained) cells ($P < 0.05$) were observed in biofilms grown in absence of biocides or in presence of 0.5MIC of biocides. In presence of 1MIC or 1.5MIC of biocides, percentages of dead (red) cells ranged between 32.60 ± 21.36% and 87.89 ± 10.29%. The findings of the present study suggest that the use of biocides at sub-inhibitory concentrations could represent a public health risk.

MODELLING AFLATOXIN CONTAMINATION IN DRY-CURED HAM BY APPLYING DATA MINING

B. Peromingo[1], D. Caballero[1], A. Alía[1], V. Bernáldez[1], E. Bermúdez[1], A. Rodríguez[1]
[1]Meat and Meat Products Research Institute, Animal Production and Food science, Cáceres, Spain

Backgrounds

Aspergillus flavus and *Aspergillus parasiticus* are mould species producers of aflatoxins (AFs) and may grow on dry-cured ham during the ripening process. AFs production is mainly influenced by environmental factors, especially water activity (a_w) and temperature (T). Data mining is an emerging technique in modelling which allows predicting data by exploring and analysing large volumes of data.

Objectives

The objective of this study was to predict AFs produced by *A. flavus* and *A. parasiticus* in a dry-cured ham matrix using predictive data mining.

Methods

Lineal model was used to calculate lag phases and growth rates and AFs amounts were quantified by uHPLC–MS/MS. Multiple Linear Regression (MLR) was used for deductive tasks. For predicting AFs, the application of MLR on data mining method is accurate to predict the minimum a_w and T values from which the strains begin to produce AFs (R^2 for AFB_1 and AFG_1 were 0.86 and 0.84, respectively) and the first day the toxin can be synthetised (R^2 for AFB_1 and AFG_1 were 0.88 and 0.87 respectively).

Conclusions

Thus data mining allows determining AFs contamination in dry-cured ham. This predictive model is important in developing prevention strategies to control AFs in dry-cured ham and avoid risks associated with this mycotoxin to consumer´s health.

GENOTYPING OF ENTEROTOXIC STAPHYLOCOCCUS AUREUS ISOLATED FROM RAW COW'S MILK AND CHEESES IN POLAND

W. Korpysa-Dzirba[1], J. Rola[1], A. Czubkowska[1]
[1]National Veterinary Research Institute, Department of Hygiene of Food of Animal Origin, Pulawy, Poland

Backgrounds

In the recent years, the market of raw milk cheeses is growing as such products are considered to be ecological, tasty and they do not have unnecessary additives. Milk without heat treatment used for production of raw milk cheeses may be contaminated by *S. aureus*. Enterotoxic strains of these bacteria can induce the symptoms of staphylococcal food poisoning (SFP).

Objectives

The aim of this study was to detect enterotoxic *S. aureus* recovered from raw cow's milk and estimate their sequence types (ST's).

Methods

Samples of raw cow's milk and cheeses were collected in dairy farms located in the eastern part of Poland. Detection of staphylococcal enterotoxins (SE's) genes and the markers responsible for methicillin resistance were done using multiplex PCRs. The enterotoxic isolates were analysed by MLST technique.

Conclusions

Eleven of 24 (45.8%) and 14 of 29 (48.3%) isolates recovered from raw cow's milk and cheeses, respectively, harboured the SE genes. The combination of *sed*, *ser* and *sej* markers was most often detected (52%), followed by *sep* and a combination of *seg* and *sei* (both 28.0%). Fifteen (60.0%) isolates had more than one SE gene. One (3.4%) *S. aureus* isolated from cheese was methicillin resistant. The sequence types (ST) 97 was often found, however other and some new ST were also identified. These results indicate that the enterotoxic CPS can be often found in raw cow's milk and cheeses and therefore may pose a risk of food intoxication. Estimation of sequence types enables to understand the ways of spreading of the isolates.

FEMS7-1747
Food Microbiology - Part III

ASSESSMENT OF HYGIENIC QUALITY OF RAW GOAT MILK IN POLAND

A. Czubkowska[1], J. Rola[1], W. Korpysa-Dzirba[1]
[1]National Veterinary Research Institute, Department of Hygiene of Food of Animal Origin, Pulawy, Poland

Backgrounds

The consumption of goat milk and goat milk products has been growing. Goat milk is attractive for consumers due to enhanced nutritional properties and lower allergenic potential in comparison to cow milk. The data on the hygienic quality of goat milk in Poland is limited.

Objectives

The aim of the study was to assess the hygienic quality of raw goat milk.

Methods

A total of 78 samples of raw goat bulk-tank milk from 30 different dairy farms in Poland were collected in 2016. Quality of the samples was determined in relation to the number of *E. coli*, *Enterobacteriaceae*, coagulase-positive staphylococci, total bacteria count and somatic cells count. The analysis were performed according to the standard ISO methods. Furthermore the presence of antimicrobial residues was examined using Delvotest SP NT.

Conclusions

The number of *E. coli* in raw milk samples was determined at an average level of $1.9x10^1$ cfu/ml, *Enterobacteriaceae* - $2,0x10^5$ cfu/ml, coagulase-positive staphylococci - $4.7x10^3$ cfu/ml. The average number of microorganisms in raw milk was $1.0x10^7$ cfu/ml, and the percentage of sample contamination >1500000 cfu/ml accounted for 38.5%. The average of somatic cell count in samples of raw milk was 1 566 000 cells/ml. Antimicrobial residues were detected in 7.8% samples of raw goat's milk. The obtained results indicate that some results of total plate count in raw goat milk exceed the hygiene criterium listed in Commision Regulation 853/2004 and antimicrobial residues are present in milk samples.

FEMS7-1359
Food Microbiology - Part III

IS THE DISTRIBUTION OF LISTERIA SPP. ISOLATED FROM ALL-NATURAL, MIXED SPECIES, PASTURED-RAISED BROILER FARMS RELATED TO DIFFERENTIAL GROWTH?

A. Locatelli[1], M.J. Rothrock - Jr.[1]
[1]USDA-ARS, US National Poultry Research Center, Athens, USA

Backgrounds

Listeria spp. represent an important foodborne pathogen, but relatively little is known about its environmental prevalence on poultry farms. Considering the environmental exposure inherent with pasture-raised production systems, these types of alternative poultry management systems represent an ideal setting to determine environmental *Listeria* spp. diversity and prevalence.

Objectives

Initial surveys of the isolate datasets revealed that across the farms samples *L. innocua* (59%) was found predominantly in feces and soil samples followed by *L. monocytogenes* (33%) and *L. welshimeri* (2%). Based on theses observations, we wanted to evaluate whether the distribution of *Listeria* species evidenced in broiler farms could results from a differential growth in liquid media.

Methods

Four *Listeria* strains isolated from soil were selected including one of each *L. monocytogenes* serogroups and one of *L. innocua*. These strains were inoculated either separately or in mixed culture in Tripticase Soy Broth (TSB) and University of Vermont (UVM) modified *Listeria* enrichment broth at 10^2 and 10^5 cells per ml and incubated for 24-48 hrs at 3 temperatures (20, 30, 42˚C).

Conclusions

Overall, the inoculum concentration and the liquid media have a significant effect on *Listeria* growth at all temperatures. No significant differences were observed between the growths of the three *L. monocytogenes* strains. In UVM media, a significantly shorter lag phase was observed for *L. innocua* compared to *L. monocytogenes* strains for both inoculum concentrations. This difference in the growth dynamic between may help to explain the *Listeria* species recovered from these broiler farms.

Food Microbiology - Part III

FLUORESCENT LABELING OF BIFIDOBACTERIUM ANIMALIS SUBSP. LACTIS TO DECIPHER THE FUNCTIONAL ROLE OF ITS EXOPOLYSACCHARIDE COVER

N. Castro-Bravo[1], C. Hidalgo-Cantabrana[1], A. Margolles[1], P. Ruas-Madiedo[1]
[1]IPLA-CSIC, Microbiology and Biochemistry of Dairy Products, Villaviciosa-Asturias, Spain

Backgrounds

The exopolysaccharide (EPS) layer covering the surface of different bacteria, including *Bifidobacterium animalis* subsp. *lactis*, has been associated with the beneficial properties attributable to the producing bacterium. Indeed, EPS are one of the microbial associated molecular patterns that initiate the interaction with the host.

Objectives

Our aim was to obtain different EPS-producing *B. animalis* subsp. *lactis* variants, harboring plasmids with genes coding for fluorescent proteins, to study the role of EPS on the adherence of the producing strain.

Methods

One chromosomally stable EPS-producing variant (S89L strain) was obtained by means of a double crossover marker-less strategy. In the type strain DSM10140 a gene was replaced with another containing a nonsynonymous mutation associated with the ropy phenotype, yielding S89L. Besides, the type DSM10140 strain and the ropy S89L variant were labeled with two plasmids containing genes for mCherry or the green fluorescent proteins, thus yielding four fluorescent strains. These strains were used to check their adhesion to the human intestinal cell line HT29 as well as their capability to form biofilms in different abiotic surfaces (gold, polystyrene and glass) using different methodologies (real time monitoring and end-point crystal-violet staining).

Conclusions

This is the first report on the construction of fluorescent labeled *B. animalis* subsp. *lactis* strains; the qualitative and quantitative fluorescence analyses showed that the ropy S89L strain displayed a reduced capability to adhere to the intestinal epithelial monolayer and to form biofilms under abiotic surfaces. These results underline the usefulness of fluorescent labeling to elucidate the biological properties of bifidobacterial EPS.

FEMS7-2506
Food Microbiology - Part III

MICROBIAL DIVERSITY IN TRADITIONAL RAW EWE'S MILK SERPA CHEESE

G.D.S. Maria Teresa P.[1], M.J. Benito[2], M.D.G. Córdoba[2], C. Egas[3], S. Ruiz-Moyano[2]
[1]Instituto Politécnico de Beja, Escola Superior Agrária de Beja, Beja, Portugal
[2]Instituto Universitario de Investigación en Recursos Agrarios INURA- Universidad de Extremadura, Producción Animal y Ciencia de los Alimentos, Badajoz, Spain
[3]Biocant Park, UCBiotech-CNC, Cantanhede, Portugal

Backgrounds

Serpa is an artisanal ripened Portuguese cheese granted the Protected Designation of Origin (PDO) label. The absence of any standardisation for the thermal process and starter microorganisms means that its quality and characteristics depend mainly on the endogenous flora. Most of the microflora present in raw milk cheese are lactic acid bacteria (LAB), but spoilage and pathogens bacteria may be present too, and this raises the potential of public health risks. Hence, controlling the microbial communities during the production is the main factor to ensure food safety and the sensorial properties of the final product.

Objectives

The aim was to study the fortuitous flora in Serpa cheese to control the microbial communities during its production.

Methods

Microbial diversity of Serpa cheeses from PDO and non-PDO registered industries were evaluated by culture-dependent and independent-methods.

Conclusions

Both approaches demonstrated that microflora mainly corresponded to LAB and to a lesser extent, enterobacteria. The main species identified by conventional 16S rRNA gene sequencing were *Lactobacillus paracasei/casei* in cheese from PDO industries; whereas in non-PDO *Lactobacillus brevis* was highlighted. However, the results obtained by high throughput sequencing analysis showed that although LAB were the main microbial group, *Lactococcus* genus contributing to ~40-60% of the population, followed by *Leuconostoc* and *Lactobacillus.* Among Enterobacteriaceae species identified, *Hafnia alvei* was presented at ~20-30% in all samples, however, *Escherichia coli* was also detected in non-PDO registered industries.

These results suggest the application of an autochthonous starter culture, formed by *Lactococcus* and *Lactobacillus* species, to control the microbial communities during Serpa cheese production.

Food Microbiology - Part III

MICROBIAL DYNAMIC DURING THE SUN-DRYING PROCESS OF FIGS (FICUS CARICA L.) CV. 'CUELLO DAMA BLANCO'

M.D.C. Villalobos[1], M.J. Serradilla[2], S. Ruiz-Moyano[1], A. Martín[1], M.D.G. Córdoba[1]
[1]Instituto Universitario de Investigación en Recursos Agrarios INURA- Universidad de Extremadura, Producción Animal y Ciencia de los Alimentos, Badajoz, Spain
[2]InstitutoTecnológico Agroalimentario de Extremadura INTAEX-CICYTEX, Área de Vegetales, Badajoz, Spain

Backgrounds

The consumption of both fresh and dried figs (*Ficus carica* L.) has recently increased due to their excellent sensorial and nutritional characteristics. Figs are distinguished by their perishability, mainly caused by the microbiological spoilage. The sun-drying process, due to its severe lack of control, can lead to diverse problems such as the fungal growth and subsequent mycotoxin production.

Objectives

The present work studies the microbial population of figs cv.'Cuello Dama Blanco' throughout sun-drying process.

Methods

The population of bacteria, yeasts and moulds were studied at fresh stage as well as in figs undergone a sun-drying process during a period of 15 days. Microorganisms were isolated and identified by sequence of the16S rRNA gene for bacteria and ITS region for fungi.

Conclusions

The results showed that fresh figs revealed a higher microbial population than sun-dried figs. At earlier dried fig developmental stages, microbiological populations were mainly dominated by the bacteria species *Pseudomonas gessardii* followed by *Pantoea agglomerans*, while among fungal population highlighted the yeasts species *Aureobasidium pullulans* followed by *Cryptococcus adeliensis, Hanseniaspora uvarum* and *Torulaspora delbrueckii* and a wide diversity of moulds such as *Cladosporium cladosporioides, Alternaria alternata, Cladosporium macrocarpum, Penicillium corylophilum* and *Penicillium brevicompactum*. Notwithstanding, with the sun-drying treatment, bacteria and yeasts disappeared and moulds were clearly the main microbial group with variation in the species identified. In addition to the species previously mentioned on fresh figs, other species such as *Aspergillus fumigates, Penicillium citrinum* and *Penicillum purpurogenum* were also found on sun-dried figs, while *Alternaria alternata* and *Cladosporium macrocarpum* were not detected.

COMPARATIVE GENOMICS AND TRANSCRIPTOMICS OF THIOL-RELEASE PATHWAY GENES IN WINE YEASTS AT FERMENTATION CONDITIONS

J. Ruiz[1], I. Belda[1], C. Barbosa[2], E. Navascués[3], D. Marquina[1], A. Mendes-Ferreira[2], A. Santos[1]
[1]Faculty of Biology- UCM, Microbiololgy, Madrid, Spain
[2]BioISI - Biosystems & Integrative Sciences Institute Universidade de Trás-os-Montes e Alto Douro, Escola de Ciências da Vida e Ambiente, Vila Real, Portugal
[3]Agrovin- S.A., Research & Development, Ciudad Real, Spain

Backgrounds

Varietal thiols (4-mercapto-4-methylpentane-2-one (4-MMP) and 3-mercapto-hexanol (3-MH)) play a key role in the characteristic passion-fruit aroma of some white grape varieties, however they are often present as non-volatile, odourless, conjugated forms in grape juice. Yeasts uptake the cysteinylated precursors (cys-4MSP and cys-3SH) through the general oligopeptide transporter (*GAP1*) and latter cleavage them by the action of β-lyase enzymes (*IRC7)*, releasing the correspondent volatile thiols. Nitrogen Catabolite Repression (NCR) regulates both genes, resulting in a low thiol release in most *Saccharomyces cerevisiae* strains.

Objectives

This work aims to evaluate the influence of nitrogen availability on the expression of thiols release-related genes (mainly *GAP1* as transporter and *IRC7* as β-lyase) in *S. cerevisiae* strains and of the correspondent orthologous genes in *Torulaspora delbrueckii* strains (non-conventional yeast of enological interest).

Methods

Fermentation assays were performed in synthetic grape juice under two nitrogen condition, low (LN) and high concentration (HN). Yeast growth and nutrient consumption were monitored throughout fermentations. RNA samples were obtained at 24h (nitrogen depletion in LN) and 96h (nitrogen starvation in LN) for *IRC7* and *GAP1* expression analysis by qRT-PCR.

Conclusions

Intraspecific differences were found within the *S. cerevisiae* strains regarding *IRC7* and *GAP1*expression levels irrespective of the nitrogen condition. Also, *T. delbrueckii* showed notable physiological differences from *S. cerevisiae* strains in both nitrogen assays. Our results, suggest that in *T. delbrueckii* both genes are differentially regulated by nitrogen, which is line with the increased volatile thiol release previously observed in natural must fermentations under non-limiting nitrogen conditions.

EIIANTR PLAYS A KEY ROLE IN SALMONELLA FITNESS AND VIRULENCE VIA 1,2-PROPANEDIOL METABOLISM

S. Ryu[1], *W. Yoo*[1], *H. Yoon*[2]
[1]*Seoul National University, Department of Agricultural Biotechnology, Seoul, Republic of Korea*
[2]*Ajou University, Department of Molecular Science and Technology, Suwon, Republic of Korea*

Backgrounds

The nitrogen-metabolic phosphotransferase system (PTS^{Ntr}) consists of EI^{Ntr}, NPr, and $EIIA^{Ntr}$ (encoded by *ptsP*, *ptsO*, and *ptsN* respectively). Due to the location of *ptsO* and *ptsN* downstream of *rpoN* in the same operon, this system has been postulated to be involved in nitrogen metabolism. However, a specific substrate transferred by PTS^{Ntr} is yet to be determined. Instead, a number of studies demonstrate that PTS^{Ntr} exerts multifaceted roles as a regulatory system in diverse bacteria.

Objectives

In order to understand roles of PTS^{Ntr} in *Salmonella enterica* serovar Typhimurium, bacterial transcriptome of a Δ*ptsN* strain was analyzed.

Methods

S. Typhimurium SL1344 and its isogenic mutant strain, Δ*ptsN*, were subjected to RNA sequencing. The results of transcriptome analysis were evaluated using qRT-PCR, Western-blot analysis, and Invasion assay. Total RNAs were isolated from *Salmonella* strains at mid-log phase in LB medium. RNA sequencing was performed using the Illumina GAII (Illumina).

Conclusions

$EIIA^{Ntr}$ positively regulated the expression of genes involved in Vitamin B_{12} synthesis and 1,2-propanediol metabolism, whereas negatively controlled the expression of *Salmonella* pathogenicity island 1 (SPI-1), which is required for bacterial invasion into host cells. In accordance with this observation, *Salmonella* lacking $EIIA^{Ntr}$ was more competent to invade host cells than wild-type *Salmonella* when supplemented with 1,2-propanediol as carbon and energy sources. These results suggest that *Salmonella* exploits $EIIA^{Ntr}$ as a key player to modulate proliferation and invasion in the host intestine.

Food Microbiology - Part III

EFFECT OF THE PH ON THE ANTIVIRAL ACTIVITY OF THE (-)-EPIGALLOCATECHIN GALLATE

G. Sánchez[1], . Walter Randazzo[2], I. Falcó[2], L. Gómez-Mascaraque[1], A. López-Rubio[1], R. Aznar[2]
[1]Instituto de Agroquímica y Tecnología de los Alimentos,
Tecnologías de Conservación y Seguridad Alimentaria, Paterna, Spain
[2]University of Valencia, MIcrobiology and Ecology, Paterna, Spain

Backgrounds

Epigallocatechin gallate (EGCG), a flavonoid from green tea, is said to have extensive antimicrobial activity in a wide range of food spoilage or pathogenic fungi, yeast and bacteria.

Objectives

In this work, the antiviral activity of EGCG was assessed against hepatitis A virus (HAV) and murine norovirus (MNV), a human norovirus surrogate, at different temperatures, contact times and pH conditions.

Methods

Antiviral activity of EGCG was evaluated by cell-culture methods, viability RT-qPCR and RT-qPCR at different exposure times at 4, 25 and 37 °C. In order to elucidate the antiviral effect of green tea catechins and their derivatives, EGCG solutions (2.5 mg/mL) were prepared in PBS at the different pHs and analysed through HPLC-MS.

Conclusions

EGCG was effective in reducing the titers of HAV and MNV in a dose-dependent manner at neutral pH and 25 and 37 ºC, while no effect was reported at 4 ºC. Furthermore, results also revealed that EGCG was effective inactivating MNV and HAV at neutral and alkaline pH but was ineffective at pH 5.5. Results from cell-culture and viability RT-qPCR assays indicated no differences and therefore it suggests that EGCG did not dramatically affect the viral capsid, which instead might suffer subtle alterations of proteins. Moreover, HPLC/MS analysis of catechin solutions at different pHs indicated that antiviral activity was most likely due to catechin derivatives rather than EGCG itself, given the evolution of these compounds at the various pH conditions tested. These findings suggest that green tea catechins have the potential to be used as natural antimicrobials to control enteric virus contamination.

Food Microbiology - Part III

VIABILITY RT-QPCR FOR ASSESSING ENTERIC VIRUS INFECTIVITY IN SHELLFISH

G. Sánchez[1], W. Randazzo[2], F. Le Guyader[3], R. Aznar[2]
[1]Instituto de Agroquímica y Tecnología de los Alimentos, Tecnologías de Conservación y Seguridad Alimentaria, Paterna, Spain
[2]University of Valencia, Microbiology and Ecology, Paterna, Spain
[3]IFREMER, Laboratoire de Microbiologie, Nantes, France

Backgrounds

The incidence of human noroviruses (NoVs) and hepatitis A virus (HAV) outbreaks due to contaminated food or water shows a rising trend in the last years. Since enteric virus detection is based on RT-qPCR, differentiation between infectious and inactivated enteric viruses is a major challenge to stablish the real health risk associated to contaminated food.

Objectives

To explore the potential of new intercalating dyes to differentiate between infectious and thermally inactivated NoVs and HAV suspensions using the RT-qPCR assay proposed in the ISO 15216 and to assess its applicability in shellfish samples.

Methods

Initially, PMA and PEMAX (GenIUL), and PMAxx (Biotium) at a final concentration of 50 µM were compared by treating infectious and thermally-treated (99 ºC for 5 min) NoVs (GI and GII) and HAV suspensions in PBS. Then, mussels (*Mytilus galloprovincialis*) and oysters (*Crassostrea gigas*) concentrates were prepared according to ISO 15216. After the PMAxx pretreatment, the RNA was extracted and quantified by RT-qPCR. Additionally, bio-accumulated and naturally contaminated oysters were analysed to verify the pretreatment performance.

Conclusions

PMAxx performed better than PMA and PEMAX since it removed the RT-qPCR signal from thermally inactivated NoVs and HAV. In shellfish, pretreatment with 50 µM PMAxx and 0.5% Triton X-100 completely removed the RT-qPCR signal from thermally inactivated HAV and NoV GII, but not from NoV GI. On bio-accumulated oysters, this pretreatment totally removed the signal of both thermally inactivated NoVs.

According to the results, the PMAxx-Triton pretreatment successfully discriminates between infectious and thermally inactivated enteric viruses, in shellfish, and it can be easily incorporated to the ISO procedure for virus detection (ISO 15216).

Food Microbiology - Part III

LACTOBACILLI ENUMERATION AND BIOCHEMICAL IDENTIFICATION OF ISOLATES OF TOP YOGURT BRANDS

G. Satchanska[1], N. Dimov[1], V. Ahad[1], A. Doycheva[1], D. Ilin[1]
[1]New Bulgarian University, Natural Sciences, Sofia, Bulgaria

Backgrounds

Lactic acid bacteria are pronounced probiotics. They strongly improve the human immune system and produce beneficial for the human health vitamins. Lactobacilli shows strong bactericidal and antifungal activity. Due to synthesis of many enzymes involved in degradation of toxic substances yogurt is known as a food favourable to higher longevity.

Objectives

Six top brands of 3.6 % cow yogurt available at the bulgarian market were examined.

Methods

Lactobacilli count was enumerated in 1 g yogurt *via* the Koch's method. Incubation was performed on MRS media at 45^{o} C for 24 h. Lactobacilli were isolated on enriched with skim milk MRS agar. API 50 CH kit with 50 different metabolites: glycerol, erythrol, D-and L-arabinose, D-ribose, D- and L-xylose, D-adonitol, methyl-beta-D-xylopiranoside, D-galactose, D-glucose, D-fructose, D-mannose, D-sorbose, L-rhamnose, dulcitol, inositol, D-mannitol, D-sorbitol, methyl-alpha D-mannopyranoside, methyl-alpha D-glucopyranoside, N-acetylglucosamin, amygdalin, arbutin, esculin/ferric citrate, salicin, D-cellobiose, D-maltose, D-lactose, D-melibiose, D-saccharose, D-trehalose, inulin, D-melizitose, D-rafinose, starch, glycogen, xylitol, gentiobiose, D-turanose, D-lyxose, D-tagatose, D- and L-fucose, D- and L-arabitol, potassium guconate, potassium 2-ketoguconate, potassium 5-ketoguconate ribose was used for examining the isolates' biochemical activity.

Conclusions

Our results revealed the following number of lactobacilli per gram yogurt: Elena yogurt - 0,7x10^{6}, Vereia yogurt – 2.6x10^{6}, Na baba yogurt - 3.4x10^{6}, Rodopeia yogurt - 4x10^{6}, Parshevitza yogurt - 2.8x10^{7}, LB yogurt - 7.1x10. All examined samples covered the EU standard except one sample, which was close to standard. Isolated lactobacilli were identified as *Lactobacillus bulgaricus* ssp. *delbrueckii* being positive in degradation of only 4 out of 50 metabolites: D-glucose, D-fructose, D-mannose and D-lactose.

Food Microbiology - Part III

QUALITATIVE AND QUANTITATIVE CHARACTERISTIC OF YEASTS DURING SAUERKRAUT FERMENTATION OF DIFFERENT VARIETIES

P. Satora[1], M. Skotniczny[1], S. Strnad[1], M. Cioch[1]
[1]University of Agriculture in Krakow,
Department of Fermentation Technology and Technical Microbiology, Kraków, Poland

Backgrounds

Sauerkraut is the most important vegetable silage produced in Europe. It is obtained traditionally by spontaneous fermentation of cabbage with indigenous microbiota mainly lactic acid bacteria but also yeasts and fungi. The quality of sauerkraut depends mainly on microbiota present on the leaves surface of raw cabbage. The correct sequence of microorganisms is essential in achieving a stable product with flavor and aroma typical of sauerkraut.

Objectives

The aim of this study was to characterize biodiversity of yeasts present during fermentation of 8 varieties of cabbages.

Methods

Yeast were enumerated using WL Nutrient Agar with Chloramphenicol. Isolates were identified and classified by PCR-RAPD and –RFLP methods. PCR products of the 5.8S ITS domain of selected isolates per distinct RFLP pattern were gel purified (QIAquick PCR purification kit; QIAGEN), and both DNA strands were directly sequenced (Macrogen; http://www.macrogen.com). BLAST searches were performed with the NCBI/GenBank database, and the ClustalX software (http://www-igbmc.u-strasbg.fr/BioInfo) was used to construct multiple-sequence alignments.

Conclusions

The yeasts were present only during first three days of fermentation. Kamienna Glowa cabbage were characterized by the highest level of yeasts ($2{,}98 \cdot 10^3$ CFU/g), the lowest – Cabton (4 CFU/g). From the beginning of fermentation the amount of yeasts gradually decreased. 73 isolates were used for PCR-RAPD analysis. 25 different patterns were found. *Pichia* genus representatives, mainly *Pichia membranifaciens* predominated among isolates, with lower amounts of *Candida*, *Geotrichum* and *Rhodotorula* strains.

This research was funded by Polish National Science Center as a part of the project no. DEC-2014/15/B/NZ9/04527.

FEMS7-2108
Food Microbiology - Part III

ELECTRONIC MICROSCOPY BRINGS NEW KNOWLEDGE ON THERMORESISTANCE OF CLOSTRIDIAL ENDOSPORES WHEN HURDLE TECHNOLOGY IS COMBINED TO THERMAL TREATMENTS

T. Savard[1], J. Barrette[1], M.R. Zareifard[1], S. Grabowski[1], D. Chabot[2]
[1]Food Research and Development Centre, Agriculture and Agri-Food Canada, St-Hyacinthe, Canada
[2]Ottawa Research and Development Centre, Agriculture and Agri-Food Canada, Ottawa, Canada

Backgrounds

Hurdle technologies which mean a combination of treatments to enhance food safety are nowadays largely used by food processors. Scientists have validated multiple mild combinations to control the most common food-borne pathogens, *Listeria, Salmonella* and *Escherichia* while *Clostridium botulinum* has been almost forgotten since it requests drastic thermal treatments.

Objectives

However, harsh treatments affect quality and nutritional value of canned foods. The goal of this study was to decrease the intensity of thermal treatments by combining other hurdles like organic acids.

Methods

An experimental design has been developed to verify the effects of selected processing parameters (pH, acidulants, vegetables, and temperature) on the thermal resistance (D and z-values) of *Clostridium sporogenes* PA3679, *Clostridium botulinum* 62-a, PC0101AJ0 and 13983B and scanning/transmission electronic microscopy has been used to measure changes on spore's components.

Conclusions

The results indicate that a very mild acidification from natural pH (5.8) to pH of 4.8 with organic acids ensure a significant reduction of D-value for all tested species. However, those results also show a significant discrepancy between the measured thermal resistance of the strains and the expected ones as 6 log of *C. botulinum* were totally destroyed at 108°C in 30 sec. in acidified beans. With the help of electronic microscopy, it appears that the core, the protein coat, the cortex and other components are affected differently by thermal treatments combined with organic acids. This study brings therefore, a significant new knowledge to control the safety of food and may help to reduce harsh treatments in the canning industry.

FEMS7-2016
Food Microbiology - Part III

MICROBIOLOGICAL EVALUATION OF GROUND BEEF MARKETED IN BUTCHER SHOPS SUPERMARKETS IN THE SOUTHERN REGION OF CUIABA-MT

M.H. Scabora[1], C.C.P. Barros[2], A.T.D.S. Faustino[1], E.D.A. Silva[1], K.R. Rosa[3], P.A. Testa[1]
[1]Faculdade de Tecnologia SENAI Mato Grosso, Educação, Cuiabá - Mato Grosso, Brazil
[2]FATEC SENAI MT, Educcation, Cuiabá, Brazil
[3]Instituto Federal de Educação- Ciência e Tecnologia de Mato Grosso, Tecnologia de Alimentos, Instituto Federal de Educação- Ciência e Tecnologia de Mato Grosso-, Brazil

Backgrounds

Fresh ground meat usually has a higher microbial count than whole pieces, because there is greater contact due to its processing, contributing to the development of microorganisms.

Objectives

The objective of this study was to evaluate the microbiological and physico-chemical quality of the ground beef sold in supermarket butchers in the southern region of Cuiabá-MT.

Methods

Six supermarkets (A, B, C, D, E, and F) were selected in the southern region of the city of Cuiabá - MT, where a sample was collected from each point, and the analyzes were carried out in triplicate. The samples had the average weight of 250 g, and these were already milled on the tray of the butcher's shop, as soon as the supermarkets opened. They were packed in a thermal box to maintain the temperature and characteristics of the product. The temperature of the samples was measured using a digital spit thermometer (-50 ºC to +300 ºC), shortly after purchase. Microbiological and physico-chemical analyzes were carried out as soon as the samples arrived at the Laboratory of Food Microbiology and Physical Chemistry of the SENAI Mato Grosso Technology College.

Conclusions

Taking into account the results obtained, it is possible to conclude that, in relation to the microbiological quality, all the analyzed samples do not comply with the current legislation RDC 12 of 2001. There is a need to intensify the inspection with the objective of improving sanitary education and the awareness of the Manipulators at the butcher and supermarket managers.

THE HONEY FROM APIS MELLIFERA SSP. SICILIANA TO TACKLE LISTERIA MONOCYTOGENES ISOLATED FROM FOOD

D. Schillaci[1], M.G. Cusimano[1], S. Migliore[2], S. Sapienza[1], V. Arizza[1], M. Vitale[2]
[1]University of Palermo, STEBICEF, Palermo, Italy
[2]Istituto Zooprofilattico Sperimentale Sicilia, A. Mirri, Palermo, Italy

Backgrounds

Listeria monocytogenes is an important foodborne pathogen and its growth as biofilm, intrinsically resistant to several antimicrobial treatments and sanitization procedures, is cause of contamination and environmental persistence in the food industry.

Objectives

To find alternative treatments to the use of antibiotics and disinfectants on farms and industrial setting, we evaluated the efficacy of honey (thistle flowers) from the *Apis mellifera* ssp. *siciliana* on the growth and persistence as a sessile community (biofilm) of some isolates of *L.monocytogenes*.

Methods

The ability to grow as biofilms of twenty-five *L. monocytogenes* isolated, supplied by the Italian Reference Laboratory (IRL), was assessed by using flat-bottom 96-wells plates at 37°C in TSB medium added with 2% glucose and staining the biomass with crystal-violet 0.1%. The ability to produce biofilms ranged from a higher value of optical density (OD) at 600 nm of 0.888 to a lower of 0.148. Antimicrobial properties of *siciliana* bee honey were assessed on isolates and reference strains of *L. monocytogenes*. All tested isolates were susceptible to honey at least to MIC values at the maximum screening concentration of 50% w/v. However MIC values of 30 (% w/v) of honey were obtained for some strains. The anti-biofilm properties of honey were assessed at a concentration of 50% w/v against the best biofilm producers strains (OD ranging from 0.888 to 0.593) and we found inhibition percentages ranging from 73 to 55.5.

Conclusions

The obtained data are promising because indicate a way to replace or reduce conventional disinfectants or antibiotics from food processing facilities.

FEMS7-0058
Food Microbiology - Part III

EFFECTS OF GAMMA IRRADIATION ON COLOR AND MICROBIAL LOAD OF SAFFRON FROM DIFFERENT AREAS OF IRAN

M. Seyhoon[1], M. Barzegar[2], M.A. Sahari[3], G. Khoshpouri[1]
[1]NSTRI, Research School of Radiation Applications, Tehran, Iran
[2]Tarbiat Modares University,
Department of Food Science and TechnologyResearch School of Radiation Applications, Tehran, Iran
[3]Tarbiat Modares University, Department of Food Science and Technology, Tehran, Iran

Backgrounds

Saffron (Crocus sativus L.), from the Iridaceae family, is the world·s most expensive spice. Gamma irradiation is a technique which uses are gradually increasing worldwide, with positive effects on preventing decay by sterilizing the microorganisms and by improving the safety without compromising the nutritional properties and sensory quality of the foods.

Objectives

In this research the effects of gamma irradiation on microbial load, shelf life and some other characteristics of Iranian native saffron from defferent regions of Khorasan province were studied.

Methods

Saffron samples were collected from 3 regions of Khorasan - Iran including Ghaenat, kalat and Torbate heydariyeh and packaged in poly-ethylene bags. The samples were irradiated at doses of 0.0, 1.0, 2.0, 3.0, 4.0, 5.0 and 6.0 kGy then stored at room temperature for 60 days. Chemical characteristics such as colour indices a *, b *, L by Hunter lab and the microbial load were investigated.

Conclusions

Changes in colour indices showed direct relation with the intensity of irradiation dose. The color intensity was increased by increasing doses and it was maintained after 2 months storage in Ghaenat samples. In addition with increasing irradiation dose the amounts of ΔEh were little in Ghaenat samples

The un-irradiated saffron samples showed vast amounts of microbial contamination. After 4 kGy radiation spore forming bacteria was removed completely and aerobic mesophyll, *Enterobacteriaceae*, *coliforms* and fungi counts were decreased, significantly ($p<0.05$). The lowest microbial load was belonged to Ghaenat, kalat and Torbate Heydariyeh regions, respectively. *E.coli* was observed in no samples.

Generally, in all samples from 3 regions, by considering the changes in color parameters and decreasing microbial load the dose of irradiation 4 kGy was the optimum and suggested dose.

UN-SHIELDING EXTRACELLULAR MATRIX OF BIOFILM FORMING BACTERIA PROVIDES NOVEL MEAN TO IMPROVE DAIRY PRODUCTS MICROBIAL QUALITY

M. Shemesh[1], N. Ben-Ishay[1,2], D. Inbar[1,3], R. Reifen[2], D. Steinberg[3]
[1]Agricultural Research Organization ARO The Volcani Center, Food Quality and Safety, Rishon LeZion, Israel
[2]The Hebrew University- The Robert H. Smith Faculty of Agriculture- Food and Environment, Biochemistry- Food Science and Nutrition, Rehovot, Israel
[3]The Hebrew University-Hadassah, Institute of Dental Sciences, Jerusalem, Israel

Backgrounds

Microbial damages caused by biofilm-forming bacteria in the dairy industry are a fundamental threat to safety and quality of milk products. *Bacillus* species, which are major contaminants of dairy products, can form structured multicellular communities known as biofilms on contact surfaces as well as within the milk products themselves.

Objectives

We investigate the role of the extracellular matrix of *Bacillus subtilis* produced through biofilm formation in bacterial survival during milk processing. Furthermore, we develop novel approach of mitigating biofilm formation within milk towards improving dairy products quality and safety.

Methods

Using molecular genetics and food microbiology methodology, we found that the extracellular matrix produced by *B. subtilis* during biofilm formation within milk have a major role in bacterial survival during the milk processing. Noticeably, the mutant strains unable of matrix production were found to be hypersensitive to milk processing procedures such as heat pasteurization. This finding indicates that extracellular polymeric substances serve as a protecting material for biofilm forming bacteria and by un-shielding this protective structure would lead to increasing sensitivity of bacterial cells to stressful environments encounter during milk processing. Therefore, we further aimed to mitigate biofilm formation using the ability of divalent ions such as Mg^{2+} and Ca^{2+} of blocking matrix production by *Bacillus* species. Thus, our further observations indicate about hypersensitivity of bacterial cells, in the presence of these divalent ions, to heat pasteurization undertaken during milk processing.

Conclusions

We suggest that un-shielding biofilm forming bacteria from the extracellular matrix may provide novel mean to improve dairy products microbial quality.

FEMS7-2623
Food Microbiology - Part III

ANTIFUNGAL ACTIVITY OF PLANT EXTRACTS FAMILY OF LAMIACEAE LINDL

O. Shemshura[1], *A. Sadanov*[1], *N. Bekmakhanova*[1], *S. Aitkeldieva*[1], *K. Iskandarova*[1]
[1]*Institute of Microbiology and Virology, Department of Education and Science, Almaty, Kazakhstan*

Backgrounds

At present intensive development of research of green technologies to produce antifungal agents on the basis of green plants, or aqueous (organic) extracts. Plant species of the family *Lamiaceae Lindl*. have a wide range of biologically active substances and have great potential as a basis for the creation of biological products for plant protection.

Objectives

Investigation of antifungal activity of the extracts of plants of the family *Lamiaceae Lindl*. against pathogens of fungal diseases of soybeans and tomatoes. Identify of biologically active components.

Methods

The objects of study were phytopathogens *Fusarium oxysporum*, *Alternaria alternata*, *Aspergillus niger*, isolated from infected soybean plants and tomatoes and ethanol extracts of the plant species: *Monarda citriodora*; *Hyssopus officinalis*; *Satureja hortensis*; *Ocimum basilicum* of the family *Lamiaceae Lindl*. Antifungal activity of the ethanol extracts was determined by agar diffusion method. Biologically active components in the extracts were detected by biochemical methods.

Conclusions

All studied extracts inhibited the growth of the pathogenic fungus *Alternaria alternata*, zones of inhibition of growth was between 18 to 24 mm, depending the species of plant. The growth of *Fusarium oxysporum* was inhibited by *Monarda citriodora* and *Ocimum basilicum* (the inhibition halo of the pathogen were 14 mm). In the *Hyssopus officinalis* extract were found components - analogs of ciklopenine and verrukozine. In the extracts of the *Monarda citriodora* and *Ocimum basilicum* detected benzoic acid. In the extract of *Satureja hortensis* is found protocatechuic acid. The results can be used in the development and application of green technologies to protect plants from fungal infections.

FEMS7-2634
Food Microbiology - Part III

EFFECT OF ARACHIDONIC ACID OF THE FUNGUS MORTIERELLA SP. ON THE SYNTHESIS OF MYCOTOXINS BY FUNGI OF THE GENUS FUSARIUM, ALTERNARIA AND BOTRYTIS

O. Shemshura[1], A. Sadanov[1], N. Bekmakhanova[1], G. Mombekova[1]
[1]Institute of Microbiology and Virology, Department of Education and Science, Almaty, Kazakhstan

Backgrounds

In recent years, promising is the use of arachidonic acid from fungi of the genus Mortierella as an inducer of plant resistance to phytopathogenic fungi. Preparations of this type are of low toxicity to a useful fauna on the effectiveness of action on the phytopathogens are not inferior to the nature of the chemical fungicides and lower cost and low consumption rates make them the use of ecologically beneficial. Investigation of the mechanism of action of arachidonic acid on the phytopathogenic fungi is of great interest.

Objectives

to investigate the influence of arachidonic acid on the synthesis of mycotoxins by phytopathogenic fungi

Methods

Effect of arachidonic acid of the fungus Mortierella sp. the change in the qualitative composition of mycotoxins extracts phytopathogenic fungi of the genus Fusarium, Alternaria, Botrytis was investigated by the biochemical method

Conclusions

It has been established that arachidonic acid, isolated from of the fungus Mortierella sp. affects synthesis of toxic metabolites by pathogenic fungi genera Alternaria, Fusarium, Botrytis. Thus, the phytopathogenic fungi unable to synthesize some mycotoxins if the arachidonic acid included into the culture medium. On the medium without arachidonic acid (control), the synthesis of these mycotoxins is detected. For example, the fungus Fusarium oxysporum has lost the ability to synthesize verrukofortin and rukofortin; fungus Alternaria alternata is not able to synthesize fellutanin, rukofortin and regulozuvin; Botrytis cinerea has lost the ability to synthesize regulozuvin B verrukofortin and verrukozin.

HELICOBACTER PYLORI INFECTION IN MOTHERS MODIFIES FECAL MICROBIOTA IN THEIR NEWBORNS ACCORDING TO THE MODE OF DELIVERY

H. Shin[1], C. Hernandez[2], P. Troncoso[2], M. Ortiz[2], M. Vera[2], G.M. Dominguez-Bello[3], P.R. Harris[2]
[1]Sejong University, Food Science and Biotechnology, Seoul, Republic of Korea
[2]Pontificia Universidad Católica de Chile School of Medicine,
Pediatric Gastroenterology and Nutrition, Santiago, Chile
[3]New York University School of Medicine, Medicine, New York, USA

Backgrounds

Interactions of resident intestinal microbes with the mucosal surface play important roles in normal intestinal development. Long-standing infections such as gastric *H. pylori* modify the gastric microbiota and might modify fecal microbiota composition.

Objectives

To evaluate the fecal microbiota of mother-child pairs and its relation to *H. pylori* status.

Methods

A total of 22 mother-child pairs were recruited and we took one stool sample of the mothers before hospital discharge and one stool sample of the newborns at home (15 days old). Maternal *H. pylori* status was evaluated by antigen detection. The V4 region of the 16S rRNA gene was sequenced using Illumina MiSeq platform. Sequences were analyzed using the QIIME pipeline.

Conclusions

Fifty percentage of mothers (11/22) have positive *H. pylori* status. Thirteen babies were vaginally delivered and 9 were born by C-section. All babies were fully breastfed. *H. pylori* was not detected in the feces of newborns. The analyses showed that there were differences in the structure of the microbiota by maternal *H. pylori* status only in infant feces born vaginally (PERMANOVA, p=0.01). Although with similar bacterial alpha diversity level, infants born vaginally to *H. pylori*-infected mothers had higher abundance of *Enterobacteriaceae* and *Veilonella* (LEfSe analysis, LDA>3.0-fold). Maternal *H. pylori* status affects the fecal microbiota composition in babies born by vaginal delivery, but not in babies born by C-section. The results suggest that the effect of the maternal *H. pylori* on the infant fecal microbiota is mediated by the acquired vaginal microbiota at birth.

Food Microbiology - Part III

CASE STUDY OF SHELF LIFE OF SWEET-POTATO KING'S CAKE

L. Silva[1], M. Sale Gomes[1], F. Martins[2], A.M. Cavaco[3], M.D. Antunes[4], M.L. Faleiro[5]
[1]Duas Siglas, Research, Faro, Portugal
[2]FILIPE MARTINS-GESTÃO DE NEGÓCIOS- UNIPESSOAL LDA, Bakery, Olhão, Portugal
[3]Universidade do Algarve, Center for Electronics- Optoelectronics and Telecommunications, Faro, Portugal
[4]Universidade do Algarve, MeditBio- Centro para os Recursos Biológicos e Alimentos Mediterrânicos, Faro, Portugal
[5]Universidade do Algarve, Center for Biomedical Research, Faro, Portugal

Backgrounds

The shelf life of a food product is dictated by the time interval during which maintains its organoleptic properties. These properties can be lost due to several factors including the action of spoilage microorganisms and alteration of physico-chemical characteristics. Moreover the growth of foodborne pathogens must be limited assuring food safety to consumers.

Objectives

In this study, the quality of sweet-potato king's cake over storage at two different temperatures (room temperature ~24 ºC and 4 ºC) during 43 days was determined.

Methods

The pH value, texture, water activity and sugar concentration (glucose, fructose and sucrose) were evaluated. The microbial counts included aerobic mesophilic microorganisms, molds and yeasts, and *Enterobacteriaceae*. For the first 14 days, in a weekly basis, a sensory analysis was also conducted with a taste panel representative of the common consumer.

Conclusions

Results showed that there were no significant differences between the two storage temperatures after 14 days for all tested parameters. Through the remaining days it was observed a tendency to dryness by increasing texture and decreasing of water activity values. In terms of microbiological quality the mesophilic microorganisms, *Enterobacteriaceae* and molds and yeasts after 14 days of storage were within acceptable levels. However, at 28 days for cakes stored at room temperature microbial growth was detected. In conclusion, the limit interval ("best before") for consuming this type of cake should be considered the 14 days after baking.

FEMS7-2198
Food Microbiology - Part III

THE IMPACT OF POTASSIUM METABISULFITE AND ELECTROMAGNETIC IRRADIATION ON LACTOBACILLUS PARACASEI SPP. PARACASEI AT DIFFERENT PHS OF GROWTH MEDIA

D. Soghomonyan[1], A. Trchounian[2]
[1]Yerevan State University- Research Institute of Biology, Biochemistry- Microbiology and Biotechnology, Yerevan, Armenia
[2]Yerevan State University, Biochemistry- Microbiology and Biotechnology, Yerevan, Armenia

Backgrounds

Certain strains of lactic acid bacteria (LAB) could contaminate wines and are known as wine spoilage bacteria. Optimal pH for growth of LAB is 6.5, but the most wines having a pH between 2.9 and 3.9. Probably the combined effects of wine preservative potassium metabisulfite ($K_2S_2O_5$) and electromagnetic irradiation (EMI) could suppress growth of LAB.

Objectives

The aim of this study was to investigate the combined effects of low intensity high frequency EMI (after 1 h irradiation) at 51.8 and 53 GHz frequencies (the flux capacity of 0.06 mW/cm^2), and different concentrations (30 and 300 mg/l) of $K_2S_2O_5$ on growth and survival of *Lactobacillus paracasei spp. paracasei* at pH 6.5 and 3.7.

Methods

For revealing these effects,the growth specific rate (μ) and colony forming units (CFU) number were determined for irradiated and non irradiated bacteria.

Conclusions

Revealed, that at pH 6.5, 300 mg/ l $K_2S_2O_5$ decreased μ ~1.5 and CFU in ~1.25 fold, and combination with EMI at both frequencies suppressed μ ~2 and 2.4 and CFU ~1.5 and 1.7 fold, respectively, while 30 mg/l had no suppressive effect on the growth of bacteria. The effects were stronger at pH 3.7: 300 mg/ l $K_2S_2O_5$ totally suppressed μ and CFU of irradiated and non-irradiated cells. The 30 mg/l $K_2S_2O_5$ decreased μ ~2.2 and CFU 10^2 fold and the combination with EMI at both frequencies decreased μ ~3.4 and CFU 10^3 times compared with non-irradiated samples.

It is assumed that low pH conditions and EMI enhanced the antibacterial effects of $K_2S_2O_5$ on LAB.

A REDUCTION IN LACTOSE IN PROBIOTIC YOGURT USING LACTOBACILLUS PLANTARUM LN4 WITH HIGH B-GALACTOSIDASE ACTIVITY

S.H. Son[1], H.L. Jeon[1], S.J. Yang[1], N.K. Lee[1], H.D. Paik[1]
[1]Konkuk University, Department of Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea

Backgrounds

Kimchi is a Korean traditional fermented vegetable dish, one of the healthiest foods in the world. Kimchi contains many lactic acid bacteria producing enzymes that can help lactose intolerant patients. β-Galactosidase, one of useful enzymes hydrolyzes lactose to galactose and glucose.

Objectives

The aim of this study was to isolate potential probiotic strains from kimchi that show probiotic properties and high β-galctosidase activity and reduce lactose content of yogurt.

Methods

A potential probiotic strain was isolated from kimchi using *Lactobacillus* selective agar. Among isolates from kimchi, *Lactobacillus plantarum* Ln4 had high acid tolerance (pH 2.5 with 0.3% pepsin, 3 h) and bile salt tolerance (0.3% oxgall, 24 h). *L*. *plantarum* Ln4 produced a useful enzyme according to the API zym kit and showed high capacity for adhesion to human colon adenocarcinoma cell line HT-29. *L*. *plantarum* Ln4 was sensitive to a commercial antibiotic according to a paper disc diffusion method. β-Galactosidase activity of *L*. *plantarum* Ln4 was evaluated using ortho-nitrophenyl-β-galactosidase (ONPG) and the result was 3,320.99 Miller units. Probiotic yogurt containing *L*. *plantarum* Ln4 showed reduced lactose contents as compared with commercial yogurt.

Conclusions

Therefore, *L*. *plantarum* Ln4 isolated from kimchi has probiotic properties and high β-galactosidase activity and can be used as a probiotic starter culture in the dairy industry.

AN ANTIDIABETIC EFFECT OF NOVEL PROBIOTIC LACTOBACILLUS STRAINS ISOLATED FROM KIMCHI

S.H. Son[1], H.L. Jeon[1], S.J. Yang[1], N.K. Lee[1], H.D. Paik[1]
[1]Konkuk University, Department of Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea

Backgrounds

Kimchi is made of various vegetables such as cabbage, salt-fermented seafood, and red pepper, and is a Korean fermented food containing various lactic acid bacteria. Isolates from kimchi have probiotic characteristics and functional properties such as antioxidant and antidiabetic effects.

Objectives

The aim of the study was to screen *Lactobacillus* strains isolated from kimchi to identify those with probiotic properties and an antidiabetic effect.

Methods

Twenty *Lactoabacillus* strains were isolated from kimchi using *Lactobacillus* selective agar. Among the 20 *Lactobacillus* strains, 4 showed high resistance to acid (pH 2.5 with 0.3% pepsin, 3 h) and basic conditions (0.3% oxgall, 24 h). Enzymatic activities of 4 *Lactobacillus* strains were not indicative of a harmful enzyme according to the API zym kit. The 4 *Lactobacillus* strains had high capacity for adhesion to HT-29 cells and were sensitive to commercial antibiotics such as ampicillin, tetracycline, chloramphenicol, and doxycycline according to a paper disc diffusion method. The 4 *Lactobacillus* strains were identified as *Lactobacillus plantarum* Lb41, and *L. brevis* B151, G1, and KU15006. Among the 4 probiotic strains, a cell-free supernatant and intact cells of *L*. *brevis* G1 had the highest α-glucosidase-inhibitory activity: 24.14% and 11.18%, respectively. *L*. *brevis* KU15006 isolated from kimchi had a strong antidiabetic effect.

Conclusions

Therefore *L*. *brevis* KU15006 may help diabetes patients undergoing antidiabetic treatment.

MOLECULAR TYPING OF LISTERIA MONOCYTOGENES ISOLATED FROM FOOD OF ANIMAL ORIGIN

M. Sosnowski[1], B. Lachtara[2], K. Wieczorek[1], J. Osek[1]
[1]National Veterinary Research Institute, Department of Hygiene of Food of Animal Origin, Pulawy, Poland
[2]National Veterinary Research Institute, Department of Hygiene of Animal Origin, Pulawy, Poland

Backgrounds

Pulsed-Field Gel Electrophoresis (PFGE) subtyping analysis is one of the most important molecular method for the characterization of *Listeria monocytogenes*, an important epidemiologically foodborne pathogen.

Objectives

The aim of the study was genotypic characterization of *L. monocytogenes* isolated from food of animal origin in various part of Poland in years 2013 – 2016.

Methods

A total of 130 strains tested were classified into serogroups 1/2a, 1/2b, 1/2c and 4b, which are most commonly associated with human infections. The PFGE method with two digested enzyme *Asc*I and *Apa*I was applied to generate combined dendrograms and to assess a degree of genetic relatedness using 95% of similarity in different serogroups.

Conclusions

In each serogroup the following number of PFGE profiles were specified: 18, 16, 7 and 36 in 1/2a, 12/b, 1/2c and 4b serogroups, respectively. The highest diversity was observed in group 1/2b, where 11 profiles (68.8%) were represented by only one strain. The most genetic relatedness was demonstrated in 1/2c serogroup, where 30 out of 33 strains (90.1%) belonged to 4 pulsotypes with 3 to 17 strains. Most of the strains clustered into individual patterns were originated from different food products and were isolated in different part of Poland at various times.
A high genetic diversity among *L. monocytogenes* strains of 1/2a, 1/2b and 4b serogroups was showed. However, a significant degree of relatedness in 1/2c was observed.

Food Microbiology - Part III

DISTRIBUTION OF LISTERIA MONOCYTOGENES SEROGRUPS AMONG DIFFERENT FOOD CATEGORIES AND ENVIRONMENTAL SAMPLES IN POLAND

K. Wieczorek[1], M. Sosnowski[1], B. Lachtara[1], J. Osek[1]
[1]National Veterinary Research Institute, Department of Hygiene of Food of Animal Origin, Pulawy, Poland

Backgrounds

Listeriosis caused by *L. monocytogenes* is one of the most common food-borne illness with the high mortality rate. These ubiquitous bacteria may be found in various foods matrices: such as ready to eat food (RTE), fish and meat.

Objectives

The aim of this study was to assess the prevalence of four serogroups: IIa, IIb, IIIc and IVb, responsible for most cases of human listeriosis, among *L. monocytogenes* from various food and environmental samples.

Methods

A total of 596 *L. monocytogenes* strains were examined. The isolates were originated from 7 food categories: meat, fish, cheese, processed meat, delicatessen food, swab from processing plants and others. Multiplex PCR was performed to determine serogroups.

Conclusions

It was found that serogroup IIa was the most prevalent (n=280, 47.0%) followed by serogrup IVb (n=136, 22.8%), IIc (n=100, 16.8%) and IIb (n=80, 13.4%). Additionally, serogroup IIa dominated in fish (85.7%) and cheese products (84.6%). In remaining food categories incidence of this serogroup ranged from 42.1% (processed meat) to 55.0% (swab). On the other hand, the least marked serogroup IIb was not found in fish and in other categories was presented at the level from 4.3% (meat) to 37.5% (others).

This data gave evidence that serogrups of *L. monocytogenes* associated with human listeriosis may be present in wide range of food categories and suggest that this pathogen may represent a potential threat to public health.
Funded by KNOW (Leading National Research Centre) Scientific Consortium "Healthy Animal - Safe Food", decision of Ministry of Science and Higher Education No. 05-1/KNOW2/2015.

Food Microbiology - Part III

THE EFFECT OF REPLACING SYNTHETIC PRESERVATIVES WITH NATURAL ONES ON FRANKFURTERS' SHELF-LIFE

G. Stefan[1], C. Predescu[1], C. Papuc[1], I. Gajaila[1], V. Nicorescu[1], A.E. Rus[2]
[1]University of Agronomic Sciences and Veterinary Medicine of Bucharest, Faculty of Veterinary Medicine, Bucharest, Romania
[2]Banat's University of Agricultural Sciences and Veterinary Medicine of Timisoara, Food Science, Timisoara, Romania

Backgrounds

Plant polyphenols and fermented juices rich in nitrite may be used as preservatives in meat industry.

Objectives

The aim of this study was to evaluate the effects of replacing ascorbate (AS) with hawthorn (*Crataegus monogyna*) polyphenols (HP) and synthetic nitrite (SN) with parsley (*Petroselinum crispum*) roots fermented juice nitrite (PRFJN), in different concentrations and relations, in unsmoked frankfurters.

Methods

The antioxidants and nitrite were used according to the following scheme: (1)50 ppm AS and 50 ppm PRFJN, (2)50 ppm HP and 50 ppm PRFJN, (3)0 ppm antioxidant and 50 ppm PRFJN, (4)25 ppm AS and 25 ppm PRFJN, (5)25 ppm HP and 25 ppm PRFJN, (6)0 ppm antioxidant and 25 ppm PRFJN, and (7)50 ppm AS and 50 ppm SN, as control. pH, thiobarbituric acid reactive substances (TBARS), cure efficiency, residual nitrite, total viable counts (TVC), *Enterobacteriaceae (EB)*, *Escherichia coli* and coliform bacteria (CB) were determined at 3-day intervals for 15 days. During storage, comparatively with (7), the best physico-chemical parameters were found for 1, 4, and 5 lots, and the best microbiological parameters for 1, 2, and 3 lots. For 1, 2, and 3 lots, the TVC, EB, *E. coli* and CB values were lower than the values found in the lots 4, 5, 6, and 7.

Conclusions

Replacement of AS with HP and SN with PRFJN was able to improve frankfurters shelf-life. This work was carried out through *Partnerships in priority areas* Program – PN II, implemented with the support of MEN – UEFISCDI (Romania), project nr. 149/2014.

THE INFLUENCE OF DIFFERENT NITROGEN AND TEMPERATURE CONDITIONS ON MIXED CULTURE FERMENTATION BETWEEN S. UVARUM, S. EUBAYANUS STRAINS AND S. CEREVISIAE STRAIN

Y. Su[1], C. Lopes[2], A. Querol[1], J.M. Guillamón[1]
[1]Instituto de Agroquímica y Tecnología de los Alimentos, Departamento de Biotecnología de los Alimentos, Valencia, Spain
[2]Instituto de Investigación y Desarrollo en Ingeniería de Procesos, Biotecnología y Energías Alternativas, Buenos Aires, Argentina

Backgrounds

S. eubayanus and *S. uvarum* are two cryotolerant yeast species which are closely related with cider, beer and wine industry.

Objectives

We would like to explore phenotypically nitrogen requirement of different strains of *S. eubayanus* and *S. uvarum* species, and conduct competition fermentation with *S. cerevisiae*.

Methods

Nitrogen requirement was monitored by their growth and fermentation ability at different nitrogen concentrations. Subsequently, one low nitrogen demand strain of each species was chosen and competition fermentation was carried out with *S. cerevisiae* respectively under different nitrogen and temperature conditions.

Conclusions

In general, *S. eubayanus* strains used in our study have a lower nitrogen demand than *S. uvarum* strains. For the competition fermentation with *S. cerevisiae*, at low temperature (12°C), *S. cerevisiae* is not able to outweigh neither *S. eubayanus* nor *S. uvarum*, regardless of nitrogen concentration. On the contrary, *S. cerevisiae* completely out competed both non-*cerevisiae* species at high temperature fermentation (28°C), regardless of nitrogen concentration. At an intermediate temperature (20°C), in nitrogen limited condition, the maximum population of each species in the mixed culture was similar, however in non-limiting nitrogen condition, the percentage of *S. cerevisiae* in the mixed culture was higher than the other two species. Therefore, the competition experiments clearly evidenced that low temperature and low nitrogen concentration condition increase the competitiveness of the non-*cerevisiae* species. This result is of paramount importance for the industrial use of these alternative yeast species because of some traits of interest as lower ethanol yield and higher glycerol and aroma production.

Food Microbiology - Part III

INTERCELLULAR PRODUCTION OF HYDROGEN PEROXIDE AS A PREVENTION TO SALMONELLA PROLIFERATION

G. Sutton[1], *M. Marvasi*[1]
[1]*Middlesex University, Natural Sciences, London, United Kingdom*

Backgrounds

Due to an increase in produce associated gastroenteritis, it is becoming clearer that we know little about the ecology of human pathogens in vegetables. Research has shown that *Salmonella* (14028) can grow in numbers up to 10^5 CFU/fruit compared with the initial inoculum. It was also found that Piccolo tomatoes were less conductive to *Salmonella* than larger cultivars.

Objectives

We hypothesise that cherry tomatoes naturally produce higher levels of H_2O_2 in their intercellular fluid than larger tomatoes.

Methods

Around 100 cells of *Salmonella* were inoculated in wounds of both Piccolo and Alicante cultivars. *Salmonella* proliferation was measured after a week of incubation by plating on Xylose lysine deoxycholate agar (XLD agar). To test H_2O_2 levels a novel method was used. Pieces of the pericarp (from both cultivars) totalling 2g were subjected to a pressured vacuum to infiltrate distilled water into the intercellular space. The pieces were then spun in a centrifuge to extract all fluid from the intercellular space. Samples were de-proteinised using 10kD spin columns. A fluorometric assay was used to test the concentration of H_2O_2. Multiple biological and technical replicas were carried out.

Conclusions

The increase of *Salmonella* from one week of initial incubation was up to 3.6 log,(CFU)/tomato in Alicante cultivar (SE=0.09), and 2.6 log,(CFU)/tomato in the cherry cultivar (SE=0.21). The difference in *Salmonella* proliferation was significant (α=0.05). The cherry tomatoes showed an average of 0.76nmol/ml of H_2O_2 whereas the Alicante cultivar showed an average of 0.46nmol/ml. The difference in H_2O_2 concentration between the tomato cultivars was significant. We speculate that *oxyR* gene in *Salmonella* activates the regulation of H_2O_2 inducible genes in tomatoes.

IDENTIFICATION OF HEALTHY AND TECHNOLOGICALLY HAZARDOUS ASAIA SPP., ISOLATED FROM FOOD PRODUCTS AND PRODUCTION ENVIRONMENT, USING GENOTYPIC AND PHENOTYPIC METHODS

E. Svirakova[1], J. Kyznar[1], S. Purkrtova[2], R. Karpiskova[3], M. Jelinkova[4], J. Felsberg[4], I. Nemeckova[5]
[1]University of Chemistry and Technology Prague, Department of Food Preservation, Prague 6, Czech Republic
[2]University of Chemistry and Technology Prague, Department of Biochemistry and Microbiology, Prague 6, Czech Republic
[3]Veterinary Research Institute, Department of Bacteriology, Brno, Czech Republic
[4]The Czech Academy of Sciences, Institute of Microbiology of the CAS, Prague 4, Czech Republic
[5]Dairy Research Institute, Department of Technology and Microbiology, Prague 6, Czech Republic

Backgrounds

Bacteria from the *Asaia* genus represent technologically hazardous bacteria contaminating food products and processing environment due to worldwide globalization. *Asaia bogorensis* and *Asaia lannensis* are opportunistic pathogens causing serious nosocomial infection in immunocompromised individuals.

Objectives

The aim of this work is the identification and characterization of *Asaia* spp., isolated from food products and production environment, using genotypic and phenotypic methods.

Methods

The 16S rRNA gene sequencing and the MALDI-TOF MS methods were used for identification of tested *Asaia* spp. on the species level. The ERIC-PCR method was used for verification of its applicability for isolates. The optical microscopy method, the agar plate method, the densitometric method and the disk diffusion method were used for estimation of *Asaia* spp. characteristics.

Conclusions

Using the MALDI-TOF MS method, the database of main protein spectra for *Asaia krungthepensis* CCM 7333, *Asaia lannensis* BCC 15734 and *Asaia siamensis* CCM 7132 was created. All unknown isolates were identified as *Asaia lannensis* using the MALDI-TOF MS method at the highly probable species identification level. Likewise, these isolates were identified as *Asaia lannensis* using the 16S rRNA gene sequencing method; the consensus of obtained *Asaia lannensis* gene sequences with similar presented in available databases was minimally 99 %.The obtained results could be useful for effective assurance of health safety and quality of food products using modern identification methods providing quick, damning and reliable results. This work was supported by the Ministry of Agriculture of the Czech Republic, by the National Agency for Agriculture Research, by the project QK1710156 (2017−2021, MZE/QK).

EARLY BLOWING IN RAW GOATS' MILK CHEESE: ENTEROBACTERIACEAE LEVELS AND EYES FORMATION DURING CHEESE RIPENING.

R. Tabla[1], A. Gómez[1], A. Simancas[2], I. Roa[1], F. Molina[2]
[1]CICYTEX-INTAEX, Dairy products, Badajoz, Spain
[2]Universidad de Extremadura, Bioquímica- Biología Molecular y Genética, Badajoz, Spain

Backgrounds

Enterobacteriaceae activity can influence cheese ripening; it may even be responsible for some specific characteristics of artisanal cheeses. Some specific characteristics of artisanal cheeses, such as higher proteolysis and lipolisis, have been correlated with *Enterobacteriaceae* activity. However, gas production capability of many *Enterobacteriaceae* can lead to early blowing in cheese, especially when initial population is high.

Objectives

The aim of this work was to study early blowing in raw goats' milk cheese, eye formation during ripening and its relationship with *Enterobacteriaceae* population.

Methods

Two different batches of cheese from raw goats' milk produced according to the PDO "Ibores" regulation (OJEU, 2004) were selected. One of them showed early blowing and the other was a typical one. Cheeses were cut in half at 7 and 60 days of ripening. The inner surface was digitalized using a densitometer (Bio–Rad GS800) and analysed using Fiji software. If present, mechanical holes were visually identified and erased. Additionally, *Enterobacteriaceae* levels and total mesophilic aerobic bateria were determined at 0, 7, 15, 30 and 60 days of ripening.

Conclusions

Although initial levels were similar for both batches, microbial growth was more intense in cheese with early blowing defect. Moreover, their ripening conditions were not able to inhibit *Enterobacteriaceae* growth. Most of the eyes in cheese were small sized and were formed during the first week of ripening. However, in defective cheese, big fissures appeared by the end of ripening.

FEMS7-2768
Food Microbiology - Part III

PHENOLIC ANTIOXIDANT MOBILIZATION IN BLACK GRAPE, APPLE AND DRAGON FRUIT RESIDUES BY ENZYMATIC TREATMENT USING A CELLULOLYTIC COCKTAIL FROM RHIZOMUCOR MIEHEI

C. Zambrano[1], F. Kovács[1], A. Kotogán[1], T. Papp[1,2], K.C. Mondal[3], F. Hargitai[1], C. Vágvölgyi[1], J. Krisch[4], M. Takó[1]
[1]University of Szeged, Department of Microbiology, Szeged, Hungary
[2]University of Szeged, HAS-USZ "Momentum" Fungal Pathogenicity Mechanisms Research Group, Szeged, Hungary
[3]Vidyasagar University, Department of Microbiology, Midnapore, India
[4]University of Szeged, Institute of Food Engineering, Szeged, Hungary

Backgrounds

There is growing interest for application of phenolic antioxidants as additives in functional foods. Therefore, the bioprocesses able to produce bioactive phenolics from natural sources have significant attention in the food industry. Many fruit residues contain such phytochemicals, but most of them are in glycosidic form having reduced bioavailability. However, it is known that the carbohydrate-cleaving enzymes can release polyphenols from their glycosides.

Objectives

In our previous experiments, a cellulolytic cocktail with high beta-glucosidase activity was produced from *Rhizomucor miehei* on wheat bran. Moreover, we proved that the beta-glucosidase of the fungus can increase the amounts of free phenolic antioxidants in sour cherry pomace. Here we applied this cellulase mix to enrich phenolic antioxidants from black grape, apple and dragon fruit residues.

Methods

Oven dried and lyophilized samples were mixed with *R. miehei* cellulase cocktail with or without addition of commercial *Aspergillus niger* pectinase. The reaction mixtures were incubated at 50°C for 5 or 24h under constant stirring, then, total phenolic content and antioxidant activity were analyzed in the clear supernatant.

Conclusions

Total phenolic content of the samples generally increased during the enzymatic treatment; however, its rate was different in each type of fruits, and depended on the drying method used for pomace pretreatment as well. In most samples, the antioxidant activity exhibited correlation with the total phenolic content. Addition of pectinase also supported the content of free antioxidative phenolics, which can be further improved by prolonging the incubation time to 24h. This research was supported by the NKFIH PD 112234 and GINOP-2.2.1-15-2016-00006.

FEMS7-0488
Food Microbiology - Part III

DETECTION AND IDENTIFICATION OF MYCOBACTERIA IN FOODS OF ANIMAL ORIGIN FROM SUPERMARKETS

M. Tello[1], E. Molina[1], N. Elguezabal[1], M. Serrano[1], R.A. Juste[2], J.M. Garrido[1], I.A. Sevilla[1]
[1]NEIKER - Tecnalia, Sanidad Animal, Derio, Spain
[2]SERIDA, Managing Director, Villaviciosa, Spain

Backgrounds

The genus *Mycobacterium* includes worldwide distributed obligate and opportunistic pathogens able to infect humans, livestock and wild animals. Mycobacteria are highly resistant to heat treatments and other adverse situations. Therefore, the consumption of contaminated livestock products could represent a route of mycobacteria transmission and pose a risk to human health.

Objectives

To study the exposure level to mycobacteria through the consumption of livestock products available in supermarkets using microbiological and molecular biology techniques.

Methods

Five supermarkets belonging to important chains were selected. 138 samples of dairy products and 119 samples of meat products were purchased at two different time points in order to analyse two independent batches of most of the products under study. All samples were submitted to several mycobacterial culture protocols and to a tetraplex (Real-time) PCR able to detect the genus *Mycobacterium*, *M*. *avium* and *M*. *tuberculosis* complex. Further identification was performed using additional molecular methods.

Conclusions

M. avium subsp. *hominissuis* (2), *M. avium* subsp. *avium* (1) and *M. fortuitum* (1) were isolated from one dairy (infant formula) and 3 meat products, respectively. Mycobacterial DNA (*M. avium*, *M. tuberculosis* complex and other mycobacteria) was detected in 15.22% of dairy products and 1.68% of meat products. Even if mycobacteria isolation and DNA detection was scattered, obtained results indicate that some contact with mycobacteria could occur through the consumption of these products. Thus, performing a thorough evaluation of the risk posed by the entry of these microbes into the food chain could be of great interest.

Food Microbiology - Part III

CONJUGATED LINOLEIC ACID PRODUCTION OF PROPIONIC ACID BACTERIA ISOLATED FROM MIHALIC CHEESE

G. Tirpanci Sivri[1], *O. Oksuz*[1]
[1]*Namık Kemal University, Food Engineering Department, Tekirdağ, Turkey*

Backgrounds

Mihaliç Cheese, a traditional cheese of Turkey, has some characteristic properties because of Propionic Acid Bacteria (PAB). It is known that *Propionibacterium* spp. are capable of producing conjugated linoleic acid (CLA) which has attracted much attention since it has been associated with potential anti-carcinogenic, anti-adipogenic, anti-atherosclerotic and anti-diabetogenic activities.

Objectives

The aim of this study was to evaluate the CLA isomerization capacity of PAB isolated from a traditional cheese.

Methods

Propionibacterium spp. were isolated from Mihaliç cheese provided from 10 different local producers. Isolates have been identified by using Bruker Microflex MALDI-TOF-MS. *Propionibacterium freudenreichii* ssp. shermanii and *Propionibacterium freudenreichii* ssp. freudenreichii were dominant isolates. They were tested for their ability to produce CLA from free linoleic acid in skim-milk medium at 30 °C for 72 hours under anaerobic conditions.

Conclusions

CLA formation after incubation was determined by GC-MS. CLA isomers, c9,t11-C18:2 and t10,c12-C18:2 as abundant isomers, were also determined. The yield was calculated as the ratio of total CLA content and the amount of free linoleic acid. The production of CLA by Propionic acid bacteria offers a possible mechanism for some health-enhancing properties and provides new opportunities for the development of functional foods.

FEMS7-1009
Food Microbiology - Part III

DETERMINATION OF ANTIMICROBIAL ACTIVITIES OF HAWTHORN (CRATAEGUS MONOGYNA) FRUIT AND SEED IN METHANOL EXTRACT

D.D. Altan[1], T. Gumus[1], G. Tirpanci Sivri[1]
[1]Namık Kemal University, Food Engineering Department, Tekirdağ, Turkey

Backgrounds

Hawthorn belongs to the tribe *Crataegeae* and member of the *Rosaceae* family that native to the Mediterranean region, including north Africa, Europe and Asia. It is reported that 21 *Crataegus* species have been identified in Turkey. *Crataegus monogyna* is one of the most common species. *Crataegus* commonly is known as hawthorn and stated with different names, including *"yemişen, ekşi muşmula, aluç, kuş yemişi" in different regions of Turkey. Crataegus* species have been used since ancient times, traditionally. Scientific evidence has demonstrated that *Crataegus* species have high antioxidant activity due to the presence of different bioactive compounds, such as flavonoids, vitamin C, organic acids, minerals.

Objectives

The purpose of this study was to evaluate the antimicrobial activities of Hawthorn fruit and seeds extract in methanol.

Methods

In this study, antimicrobial activity against five bacterial species (*Escherichia coli* O157:H7 ATCC 33150, *Staphylococcus aureus* ATCC 25923, *Listeria monocytogenes* ATCC 7644, *Salmonella* Enteretidis ATCC 13076, *Vibrio parahaelmolyticus* ATCC 17802) using the disc diffusion method of methanol extracts were determined.

Conclusions

Extracts of hawthorn fruit and seeds showed antimicrobial activity against tested reference bacteria with a different zone diameter (7.44-14.40 mm). Seed extracts exhibited the highest antimicrobial activity against *Listeria monocytogenes* (9.16 mm), while fruit extract exhibited strong antimicrobial activity against *Vibrio parahaelmolyticus* (14.40 mm). It was understood that hawthorn fruit and seeds extracts have had potential to be utilized as antimicrobial agent.

EARLY TRANSCRIPTIONAL RESPONSE TO BIOTIC STRESS IN MIXED STARTER FERMENTATIONS INVOLVING SACCHAROMYCES CEREVISIAE AND TORULASPORA DELBRUECKII

J. Tronchoni[1], J.A. Curiel[1], P. Morales[1], R. Torres-Pérez[1], R. Gonzalez[1]
[1]ICVV CSIC-Universidad de La Rioja-Gobierno de La Rioja, Enologia, Logroño, Spain

Backgrounds

Advances in microbial wine biotechnology have led to the recent commercialization of several non-*Saccharomyces* starter cultures. These are intended to be used in either simultaneous or sequential inoculation with *Saccharomyces cerevisiae*.

Objectives

We analysed the transcriptional response to co-cultivation of *S. cerevisiae* and *Torulaspora delbrueckii*. The study is focused in the initial stages of wine fermentation with the goal of better understand the microbial interactions that can be stablished during wine fermentation with mixed-starters.

Methods

Fermentations were carried out in bioreactors using synthetic grape must to mimic industrial conditions. Experiments were carried out in triplicate for fermentation kinetics, CO_2 performance and RNAseq analysis.

Conclusions

Both species showed a clear response to the presence of each other, even though the portion of the genome showing altered transcriptional levels was relatively small. Changes in the transcription pattern suggested a stimulation of metabolic activity and growth, as a consequence of the presence of competitors in the same medium. The response of *S. cerevisiae* seems to take place earlier, as compared to *T. delbrueckii*. Enhanced glycolytic activity of the mixed culture was confirmed by the CO_2 production profile during these early stages of fermentation. Interestingly, *HSP12* expression appeared induced by co-cultivation for both of *S. cerevisiae* and *Torulaspora delbrueckii* in the two time points studied. This might be related with a recently described role of Hsp12 in intercellular communication in yeast. Expression of *S. cerevisiae PAU* genes was also stimulated in mixed cultures.

Acknowledgments: MINECO (AGL2015-63629-R,RTC-2014-2186-2); EU (7FP-IRSES-GA612441); (JdC- JA.Curiel).

Food Microbiology - Part III

CONTROL OF BIOFILMS FORMED BY LISTERIA MONOCYTOGENES ISOLATED IN BRAZILIAN TILAPIA-PROCESSING FACILITIES USING ENVIRONMENTAL-FRIENDLY ALTERNATIVES

D. Vázquez-Sánchez[1], J. Antunes Galvão[1], A. Kato[1], E. Micotti Gloria[1], M. Oetterer[1]
[1]University Of Sao Paulo / Luiz de Queiroz College of Agriculture, Agri-Food Industry- Food and Nutrition, Piracicaba, Brazil

Backgrounds

New factors that can increase the prevalence of bacterial pathogens have been recently introduced by the massive production of tilapia filets in Brazil.

Objectives

The aims of this study were to assess the biofilm-forming ability of *Listeria monocytogenes* isolated in Brazilian tilapia-processing plants and determine their resistance to chemical disinfectants and environmental-friendly alternatives.

Methods

Biofilms of eight *L. monocytogenes* strains (including ATCC 15313) formed on polystyrene and stainless steel surfaces for 5, 24 and 48 h at 25°C were examined. The effectiveness of sodium hypochlorite, peracetic acid, and eleven essential oils (*Cordia verbenacea, Corymbia citriodora, Cymbopogon winterianus, Eucalyptus camaldulensis, Eucalyptus staigeriana, Eucalyptus urograndis, Lippia sidoides, Melaleuca alternifolia, Melaleuca leucadendron, Pimenta pseudochariophyllus, Thymus vulgaris*) were determined against planktonic cells and 24-h-old biofilms in terms of minimal inhibitory concentration and logarithmic reduction in the number of viable biofilm cells per square centimeter.

Conclusions

A positive correlation (with $P<0.01$) between the native surface of strains and their ability to form biofilms on polystyrene and stainless steel was found at each time. L2 and L8 strains showed the highest biofilm-forming ability in stainless steel and polystyrene, respectively. In contrast, ATCC 15313 had the lowest. Peracetic acid and *Lippia sidoides* oil were the most effective disinfectants against planktonic cells and biofilms formed by L2 and L8, followed by *Thymus vulgaris*, *Pimenta pseudochariophyllus* and sodium hypochlorite. Therefore, *Lippia sidoides* oil can be considered as an effective disinfectant to control the proliferation of *Listeria monocytogenes* in fish-processing facilities and an environmental-friendly alternative to reduce the current pollution caused by chemicals.

Food Microbiology - Part III

ENVIRONMENTAL-FRIENDLY ALTERNATIVES TO CONTROL BIOFILMS OF COAGULASE-POSITIVE STAPHYLOCOCCUS AUREUS ISOLATED IN BRAZILIAN TILAPIA-PROCESSING FACILITIES

D. Vázquez-Sánchez[1], J. Antunes Galvão[1], M. Rodrigues Mazine[1], E. Micotti Gloria[1], M. Oetterer[1]
[1]University Of Sao Paulo / Luiz de Queiroz College of Agriculture, Agri-Food Industry- Food and Nutrition, Piracicaba, Brazil

Backgrounds

Mass production of tilapia filets in Brazil have included new factors that can enhance the prevalence of pathogens in tilapia-processing plants.

Objectives

This study aimed to determine the biofilm-forming ability of coagulase-positive *Staphylococcus aureus* isolated in Brazilian tilapia-processing plants and their resistance to chemical and environmental-friendly disinfectants.

Methods

Biofilms formed by ten strains (including ATCC 6538) on polystyrene and stainless steel were analyzed after 5, 24 and 48 h at 25°C. The efficacy of sodium hypochlorite, peracetic acid, and essential oils of *Cordia verbenacea, Corymbia citriodora, Cymbopogon winterianus, Eucalyptus camaldulensis, Eucalyptus staigeriana, Eucalyptus urograndis, Lippia sidoides, Melaleuca alternifolia, Melaleuca leucadendron, Pimenta pseudochariophyllus* and *Thymus vulgaris* were determined against planktonic cells and 24-h-old biofilms in terms of minimal inhibitory concentration and logarithmic reduction of viable biofilm cells per cm^2.

Conclusions

The native surface of strains and their ability to form biofilms on polystyrene and stainless steel was positively correlated (with $P<0.01$) at each time. S8 and S10 strains showed the highest biofilm-forming ability in stainless steel and polystyrene, respectively. ATCC 6538 had a similar biofilm formation in both surfaces, being intermediate in comparison with the other strains. *Lippia sidoides*, *Thymus vulgaris* and *Pimenta pseudochariophyllus* oils were significantly ($P<0.05$) more effective against planktonic cells of S8 and S10 than peracetic acid and sodium hypochlorite. Meanwhile, *Lippia sidoides*, *Thymus vulgaris* and peracetic acid showed a significantly ($P<0.05$) higher effectiveness against biofilms than *Pimenta pseudochariophyllus* and sodium hypochlorite. Therefore, *Lippia sidoides* and *Thymus vulgaris* oils represent an effective and environmental-friendly alternative to control the spread of *S. aureus* in fish-processing facilities.

RISK ESTIMATES ACCORDING TO THE ORIGIN, FOOD MATRIX, SEROTYPE AND ANTIMICROBIAL RESISTANCE OF LISTERIA MONOCYTOGENES STRAINS ISOLATED IN SANTIAGO, CHILE.

M. Vidal[1], D. Rivera[2], L. Lapierre[3], R. Vidal[4]
[1]Secretaria Regional Ministerial de Salud Region Metropolitana, Laboratorio de Salud Pública Ambiental y Laboral, Santiago, Chile
[2]Universidad Andrés Bello, Escuela de Medicina Veterinaria, Santiago, Chile
[3]Universidad de Chile, Facultad de Ciencias Veterinarias y Pecuarias, Santiago, Chile
[4]Universidad de Chile, Facultad de Medicina, Santiago, Chile

Backgrounds

Listeria monocytogenes is a ubiquitous bacterium widely distributed in nature, being the etiological agent of listeriosis, usually caused by eating food contaminated or by direct contact with infected animals. Listeriosis has a high case-fatality rate in susceptible groups, such as pregnant women, children and the elderly. There are not previous reports of antimicrobial resistance in isolates from food in Chile.

Objectives

Determine the risk associated to food types, origin, serotype and antimicrobial resistance phenotype in *L. monocytogenes* strains.

Methods

The study includes 222 isolates of *L. monocytogenes*. 182 isolates from different food types and 40 from clinical specimens. The antimicrobials tested were: ciprofloxacin, gentamicin, sulfamethoxazole-trimethoprim, erythromycin, cephalothin, ampicillin, penicillin-G and tetracycline. The Kirby Bauer (KB) test to evaluate phenotypical antibiotic sensitivity was used. Minimum inhibitory concentration (MIC), "gold standard" quantitative test, also was performed. A chi-squared test to determine the association between antimicrobial resistance, food matrix, origin and serotype of *L. monocytogenes* strains, was applied.

Conclusions

45 out of 222 (20.3%) strains showed different antimicrobials resistance profile. Most of them showed resistance to a single drug (58%). Clustering analysis shows five groups, in which was possible to distinguish three resistance profiles-origin associations; (i) only livestock origin strains, (ii) includes strains of human origin and (iii) was a mixture of clinical and food strains. There was no single profile of multidrug resistance, whether associated to food type or specific serotypes. Our analysis only established relationships (p=0.05) between strains from food matrix and antimicrobial resistance, mainly raw meat and fish.

FEMS7-2545
Food Microbiology - Part III

THE EXPRESSION OF THE CHITINOLYTIC SYSTEM OF LISTERIA MONOCYTOGENES IS SUBJECT TO DIFFERENT REGULATION DEPENDING ON CARBON SOURCE UTILISATION INCLUDING CELLOBIOSE AND GLUCOSE

M. Villoria Recio[1], *M. Halberg Larsen*[1], *H. Ingmer*[1]
[1]*Food safety and zoonosis, Veterinary disease biology, Frederiksberg C- københavn, Denmark*

Backgrounds

Listeria monocytogenes is a food-borne pathogenic bacterium which can cause fatal infections. Outside the host, this bacterium inhabits terrestrial and marine environments where chitin polymer is abundantly found and it serves as carbon and nitrogen source to chitinolytic bacteria. In *L. monocytogenes*, the chitinolytic system comprises two chitinases, ChiA and ChiB and a lytic polysaccharide monooxygenase (LPMO10). The chitinases are expressed during growth in soil supporting their role in environmental survival. Despite the absence of chitin in mammalian hosts, the chitinolytic system is also important for infection. The regulation of chitinases is complex and includes several central regulators, namely PrfA, σB, agr and Hfq.

Objectives

The objective of our study is investigating the regulatory mechanisms and induction cues of the chitinolytic system in order to better understand its role in the different life modes of *Listeria*. Specifically, the role of different carbon sources on the expression of the chitinolytic system was studied and related to virulence.

Methods

The expression of *chiA*, *chiB*, *Lm*LPMO10 and *actA* was measured quantitatively by qRT-PCR upon addition of chitin, glucose and cellobiose to wildtype cells and mutants lacking the chitinases or *prfA*. Bacterial cells were grown in microtiter wells and growth was followed by OD measurements.

Conclusions

Chitin is a strong inducer of the *chiB* gene in a low-carbon content medium. Whilst glucose can only support *chiB* induction in stationary phase in a chemically defined media, this study reveals that the addition of cellobiose reverts this effect and gives a new insight on the regulation of the chitinases.

Food Microbiology - Part III

MILKING MACHINE BIOFILMS: BACTERIAL COMMUNITY COMPOSITION AND PREVALENCE OF ANTIBIOTIC RESISTANCE

M. Weber[1], B. Goepfert[1], M. Savin[1], S. Tueffers[1], A. Lipski[1]
[1]Food and Nutrition Science, Food Microbiology and Hygienics, Bonn, Germany

Backgrounds

Biofilms on milking machines are a source of contamination of raw milk and its products. They can facilitate the transmission of mastitis pathogens within herds and the dissemination of antibiotic resistances.

Objectives

Due to the close contact of bacterial cells within a biofilm, we analyzed the bacterial community composition of biofilms and the relation between the density of bacterial populations and the abundance of antibiotic resistance genes to reveal the impact of biofilms on horizontal gene transfer.

Methods

Swab samples of different parts of the milking machine of a dairy farm were investigated by culture-dependent and -independent methods. Spots in the milking system with enhanced microbial colonization were identified by colony counting on selective and non-selective media. The fraction of antibiotic resistant cells was quantified on media containing different β-lactams and tetracycline. Direct DNA extracts were obtained from each swab sample and used to create clone libraries of 16S rRNA genes. Isolates as well as clone sequences were identified by 16S rRNA sequencing to assess the bacterial diversity and to identify dominating bacterial groups and antibiotic resistant isolates. The DNA extracts were screened for different groups of antibiotic resistance genes by RT-qPCR.

Conclusions

Different parts of the milking machine displayed high biofilm cell density. A high bacterial diversity, also of antibiotic resistant strains, was detected for several bacterial phyla. Different antibiotic resistance genes were quantified by RT-qPCR and correlated with bacterial densities at the sampling points.
The impact of bacterial cell density on the abundance of resistant cells and resistance genes was discussed.

IMPACT OF PECTIC OLIGOSACCHARIDES FROM APPLE POMACE ON THE ADHESION OF LACTIC ACID BACTERIA, PATHOGENS AND FAECAL BACTERIA TO THE CACO-2 CELLS

A. Wilkowska[1], A. Nowak[2], I. Motyl[2]
[1]Institute of Fermentation Technology and Microbiology, Biotechnology and Food Sciences, Łódź, Poland
[2]Institute of Fermentation Technology and Microbiology,
Faculty of Biotechnology and Food Sciences- Lodz University of Technology, Łódź, Poland

Backgrounds

Pectin-derived oligosaccharides (POs) are promising candidates for new-generation prebiotics.

Objectives

The aim of the study was to examine the POs from apple pomace (AP), as potential source of prebiotics, in terms of the impact of its presence on the adhesion of lactic acid bacteria, faecal bacteria (isolated from the cow faeces) and selected pathogens to the intestinal epithelial cells.

Methods

The potential of AP as a raw material for POs production by means of enzymatic and mild acid hydrolysis was evaluated. Oligosaccharides with different degrees of polymerization (DP) were assessed using high performance anion exchange chromatography. Adhesion test for lactic acid bacteria, faecal bacteria and pathogenes was performed using Caco-2 cells.

Conclusions

The strongest stimulation of adhesion results were noted in the presence of P2 preparation. Its composition contained oligosaccharides with a DP of 1-10, but the content of oligosaccharides with DP 7-10 were twice higher than in the P1 preparation. Hydrolysate number 3 (P3) contained only oligosaccharides of DP 1-4. Our results indicate that the obtained POs oligosaccharides affects the adhesion of lactic acid bacteria, but the phenomenon strongly depends on the strain. Faecal bacteria and tested pathogens show much weaker adhesion to the intestinal cells in the presence of tested oligosaccharides. These results indicate that the apple pomace hydrolysates can be used as prebiotics for human and animals, because they stimulate bowel colonisation with lactic acid bacteria and inhibit the development of infections caused by pathogens.

INFLUENCE OF SORBIC ACID AND SODIUM PYROSULFITE ON THE PRODUCTION OF VOLATILE PHENOLS BY BRETTANOMYCES/DEKKERA BRUXELLENSIS IN BLUEBERRY WINE

A. Wilkowska[1]
[1]*Institute of Fermentation Technology and Microbiology, Biotechnology and Food Sciences, Łódź, Poland*

Backgrounds

Brettanomyces/Dekkera bruxellensis is considered to be a major cause of wine spoilage due to the production of off-flavors such as vinyl- and ethylphenols, N-heterocyclic compounds, acetic acid and biogenic amines. 4-ethyl-phenol and 4-ethyl-guaiacol are the most abundant off-flavors produced by this yeast responsible for a sensory defect known as 'Brett character' associated with aromas of barnyard, wet animal and horse-sweat.

Objectives

The aim of this study was to evaluate the volatile phenols produced by *B. bruxellensis* under a range of growth-limiting conditions.

Methods

The yeasts were cultured in a blueberry wine containing different quantities of growth inhibitors such as ethanol, SO_2 (sodium pyrosulfite) and sorbic acid. The formation of 4-ethylphenol and 4-ethyl-guaiacol was periodically monitored by SPME-GC/MS. The wine color was analyzed using CR-5 Chroma Meter (Konica Minolta). Hue angle, Chroma and total color difference were calculated from Hunter L, a and b values.

Conclusions

Comparing samples supplemented with sorbic acid (100-500 mg/L), the additional use of 35 mg/L of total sulfur dioxide significantly reduced the synthesis of volatile phenols: by 2-57% in wine containing 5% (v/v) of ethanol, and by 3-67% in 12% (v/v) wine. A dose of 100 mg/L of sorbic acid in combination with 100 mg/L of sulfur dioxide exerted an inhibitory effect on the production of volatile phenols in undiluted blueberry must. The results of this study suggest possible ways of controlling *B. bruxellensis* in wineries.

DEVELOPMENT OF SPECIES-SPECIFIC PRIMERS FOR THE RAPID DETECTION OF THE 1, 3-PENTADIENE DEBARYOMYCES HANSENII PRODUCERS STRAINS

P. Wrent[1], E.M. Rivas[2], E. Gil de Prado[2], M.J. Valderrama[2], J.M. Peinado[2], M.I. de Silóniz[2]
[1]Univeridad Complutense de Madrid, Microbiology III, Madrid, Spain
[2]Universidad Complutense de Madrid, Microbiology III, Madrid, Spain

Backgrounds

In order to prevent microbial spoilage, preservatives such as sorbic acid or its salts, are added to foods. It has been confirmed that some strains belonging to the *D. hansenii* species are capable of spoiling foods by decarboxilation of sorbate and subsequent production of 1, 3-pentadiene. The volatile 1,3 pentadiene compound, produces a petroleum-, hydrocarbon-like unpleasant off-odour. Single nucleotide polymorphism of *PAD1* and *FDC1* genes are essential for the decarboxylation of phenylacrilic acids in *S. cerevisae*. However, there is a lack of an affordable and rapid method for the detection of 1,3 pentadiene producer strains.

Objectives

To developed a specific PCR assay for the rapid detection of 1,3 pentadiene *Debaryomyces hansenii* producer strains based in a putative *FDC1* homologues region present in this yeast species.

Methods

About 100 strains, most of them belonging to *D. hansenii* species, were used in this work from different Type Culture Collections or isolated in our laboratory. Some of them from 1,3-pentadiene spoiled foods. For the primer design we used a putative *FDC1* homologue region present in *D. hansenii* whose sequence was obtained from NCBI.

Conclusions

For first time to our knowledge, we describe in this work the *D. hansenii DhFDC* region, a putatively homologue sequence of the *S. cerevisiae FCD1/YDR539W* gene. The *DhFDC* region presents an identity of 66% with the *FDC1* gen of *S. cerevisiae* and is located in close proximity (528bp) to *DhPAD* gen, but with an opposite reading frame. The DhFDC region was a good marker of D. hansenii 1,3 pentadiene producer strains.

[3]University of Foggia, Department of the Science of Agriculture- Food and Environment, Foggia, Italy
[4]Instituto de Agroquímica y Tecnología de Alimentos IATA-CSIC, Biotechnology, Paterna- Valencia, Spain

Backgrounds

Kefir is a health-promoting beverage that is produced by milk fermentation with a consortium of bacteria and yeasts. The development of cereal-based products is of particular interest to elude milk intolerances of sensitive consumers. Among the various techniques for VOC analysis, Proton Transfer Reaction - Time of Flight - Mass Spectrometry (PTR-ToF-MS) offers an on-line determination during fermentation, with rapid and direct measurements that led to highly informative analytical output.

Objectives

On-line monitoring of VOC associated with the headspace i) of classical kefir and ii) of three kefir-like cereal-based beverages using PTR-ToF-MS.

Methods

A commercial PTR-ToF-MS 8000 apparatus from Ionicon Analytik GmbH (Innsbruck, Austria) was used to analyse the headspace of milk, barley, corn and oat beverages fermented with two commercial kefir starter cultures. The ionization conditions in the drift tube were 110 °C, 2.30 mbar and 550 V. The vials with fermenting matrices were sampled in an automated fashion using an autosampler. All data detected and recorded by the PTR-TOF-MS were processed and analysed using MATLAB and in-house developed scripts written in the R programming language.

Conclusions

To our knowledge, this is the first report on the study of VOC associated with the kefir headspace using PTR-ToF-MS, the on-line monitoring of VOC released during kefir fermentation and the detection of VOC associated with the headspaces of kefir-like cereal-based beverages. This information can be useful to better understanding the kefir fermentation process, to enhance sensorial quality of the products, and to select candidate VOC biomarkers for the selection of new starter cultures.

EVALUATION OF SPOILAGE INDEX FOR ANIMAL FEED UNDER DIFFERENT STORAGE CONDITIONS

K. Yi[1], S. Cho[2], S. Kang[1], D.W. Kim[3], Y.J. Choi[1], C.D. Jeong[4], S.S. Lee[4], S.K. Kim[1]
[1]Konkuk University, Department of Animal Science and Technology, Seoul, Republic of Korea
[2]Chonbuk National University, Department of Animal Science, Jeonju, Republic of Korea
[3]RDA, National Institute of Animal Science, Wanju, Republic of Korea
[4]Sunchon National University, Department of Animal Science and Technology, Suncheon, Republic of Korea

Backgrounds

Prevention of spoilage in animal feed is crucial for animal and human health. However, there is little knowledge about spoilage index for feed. Spoilage of feed can be occurred within its shelf life depending on its storage conditions. Once feed is spoiled, various toxic compounds are generated and affect animal nutrition and performance with economic loss.

Objectives

Temperature, humidity and moisture contents are important environmental factors and they can influence spoilage of feed during storage. Occurrence of unexpected microbial growth and consequent production of organic acids can be recognized as indicators for progression of spoilage. The present study was conducted to evaluate relationships between those environmental factors and spoilage indicators.

Methods

Fractional factorial experimental design with three factors and their three levels was performed. For factors (levels), temperature (factor A; 23, 30, 37°C), humidity (factor B; <30, 55, >90%) and moisture content (factor C; 12, 24, 36%) were employed and 15 runs Box-Behnken design was constructed. Animal feed consisted of corn (29.4%), wheat bran (69.6%) and soybean meal (1.0%) was stored in designed storage conditions for two weeks. For analysis, microbial enumeration, water activity and organic acid production were performed. Response surface model between environmental factors and spoilage indicators was estimated to evaluate spoilage index.

Conclusions

In occurrence of unexpected microbial growth, significant linear and quadratic effects were found at moisture ($p<0.05$). Significant interaction between humidity and moisture was detected ($p<0.05$). It was found that humidity and moisture showed significant linear effect on water activity of feed ($p<0.05$). In organic acid production, significant linear effect of moisture on lactic and acetic acids was observed ($p<0.05$). Significant interaction between temperature and moisture was shownin lactic acid production ($p<0.05$).

TRANSCRIPTOMIC ANALYSIS OF THE HEAT STRESS RESPONSE FOR A COMMERCIAL BAKER'S YEAST SACCAROMYCES CEREVISIAE

R. Yilmaz[1], V. Purutcuoglu Gazi[2], D. Varol[3]
[1]Hacettepe University, Food Engineering Department, Ankara, Turkey
[2]Middle East Technical University, Statistical Department, Ankara, Turkey
[3]Middle East Technical University, Department of Statistics, Ankara, Turkey

Backgrounds

Saccharomyces cerevisiae constantly faces changes even harsh environments such as high temperature threaten their survival, at least, prevents them from performing optimally. It is exposed to various stresses during its propagation and industrial application. We described the global gene expression profile responses to heat stress, including heat shock and temperature shift for the yeast from local company.

Objectives

The aim of this study is to explore the effects of heat stresses on global gene expression profiles and to identify the candidate genes for the heat stress response in *Saccharomyces cerevisiae* by using microarray technology.

Methods

These yeast cells were grown at 30°C to obtain initial cultures. These initial culture cells were transferred to 25°C for 6 hours and then 37°C for 1 hour in order to apply the heat shock treatment. The same strategy was performed for the application of temperature-shift treatment. Then the DNA microarray analysis was used to examine the mechanism of the heat stress response of the *S. cerevisiae*. Here, the data from all hybridizations and array normalization were analyzed using the GeneSpringGX 12.1 (Agilent) and the R 2.15.2 program language. In the analysis, all required statistical methods were performed comparatively. For the normalization step, among alternatives, the RMA results were used. To determine differentially expressed genes under heat stress treatments, the fold-change and the hypothesis testing approaches were executed under various cut-off values via different multiple testing procedures. Then up/down regulated probes were functionally categorized via the PAMSAM clustering.

Conclusions

The transcriptome changes under the heat shock and temperature-shift stress treatments show that the number of differentially up-regulated genes among the heat shock proteins and transcription factors changed significantly and the change in temperature is one of the important environmental conditions affecting propagation and industrial application of baker's yeast. This study statistically analyzes this affect via one-channel microarray data.

OUTER MEMBRANE VESICLE TRANSLOCATES SALMONELLA PATHOGENICITY ISLAND PROTEINS IN SALMONELLA ENTERICA SEROVAR TYPHIMURIUM

S. Kim[1], S.Y. Hwang[1], S.I. Kim[1], H. Yoon[1]
[1]Ajou University, Department of Molecular Science Technology, Suwon, Republic of Korea

Backgrounds

Salmonella enterica serovar Typhimurium is a primary cause of enteric diseases and has acquired a variety of virulence factors during its evolution into a pathogen. Secreted virulence factors interact with commensal flora and host cells and enable *Salmonella* to survive and thrive in hostile environments. Outer membrane vesicles (OMVs) released from many Gram-negative bacteria function as a delivery vehicle for complex molecules, including virulence factors.

Objectives

In order to understand the roles of OMV in virulence regulation of *Salmonella*, a proteomic analysis was conducted on OMVs from *S. enterica* serovar Typhimurium ATCC 14028.

Methods

S. Typhimurium OMVs were harvested under two different conditions mimicking the infection environments and were subjected to LC-MS/MS analysis. The results of proteome analysis were evaluated using western-blot analysis and fluorescence microscopy.

Conclusions

Proteomic profiling on *Salmonella* OMVs revealed that multiple virulence effectors produced from *Salmonella* pathogenicity islands (SPIs) were associated with OMVs. SPI effectors have been known to be secreted by type 3 secretion systems (T3SSs). OMV-mediated secretion of SPI proteins was verified using western blotting in a mutant lacking SPI-1/SPI-2 T3SSs and flagella system. OMVs possessing SPI-1 effectors, when treated to epithelial cells, increased the amount of F-actin contents in the host cell membrane. Considering the role of OMVs as a long distance delivery vehicle without bacterial interactions with host cells, secretion of effectors via OMVs shed light on a new virulence strategy in *Salmonella* infection. This study was supported by a grant 14162MFD972 from Ministry of Food and Drug Safety in 2017.

Food Microbiology - Part III

RESPONSE SURFACE METHODOLOGY FOR ANTIBACTERIAL EFFECTS OF 3 NATURAL PRESERVATIVES AGAINST LISTERIA MONOCYTOGENES ON FRESH LETTUCE

H.H. Yu[1], M.W. Song[1], N.K. Lee[1], H.D. Paik[1]
[1]Konkuk University, Department of Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea

Backgrounds

Listeria monocytogenes is one of significant foodborne pathogens widely distributed in foods including vegetables. Therefore, the fresh-cut vegetable industry is searching for a preservative that kills food-poisoning bacteria and is safe for humans.

Objectives

The objective of this study was to develop a 3-dimensional response surface model for inactivation of *L. monocytogenes* on fresh lettuce by means of 3 natural preservatives, grapefruit seed extract (GSE), cinnamaldehyde (CA), and nisin at 4°C.

Methods

Following a central composite design, lettuce was inoculated with a cocktail of 3 strains of *L. monocytogenes* (ATCC 15313, H7962 serotype 4, and Scott A NADC 2045 4b) and treated with an antibacterial solution including GSE (0.64 to 7.36 ppm), CA (1.6 to 18.4 ppm), and nisin (0.48 to 5.5 ppm). Lettuce was stored at 4°C for 12 h. Surviving *L. monocytogenes* cells were enumerated on Oxford listeria selective agar after incubation at 37°C for 24 h.

Conclusions

Nisin alone reduced *L. monocytogenes* by 2 $\log(N/N_0)$. GSE and CA alone showed a low antibacterial effect that reduced *L. monocytogenes* by ~1 $\log(N/N_0)$. Nevertheless, while keeping CA at 10 ppm, nisin 6 ppm and GSE 8 ppm reduced *L. monocytogenes* by approximately 4 $\log(N/N_0)$. While keeping GSE at 4 ppm, nisin 6 ppm and CA 20 ppm reduced *L. monocytogenes* by approximately 4 $\log(N/N_0)$ on lettuce. Therefore, the combination GSE 5–6 ppm, CA 15–20 ppm, and nisin 5.5–6 ppm is an effective antibacterial solution against *L. monocytogenes* on fresh lettuce.

FEMS7-0795
Food Microbiology - Part III

OPTIMIZATION OF THE ANTIBACTERIAL EFFECTS OF GRAPEFRUIT SEED EXTRACT, CINNAMALDEHYDE AND NISIN AGAINST SALMONELLA SPP. ON FRESH LETTUCE

H.H. Yu[1], M.W. Song[1], N.K. Lee[1], H.D. Paik[1]
[1]Konkuk University, Department of Food Science and Biotechnology of Animal Resources, Seoul, Republic of Korea

Backgrounds

Contamination with *Salmonella* spp. has often been implicated in foodborne illness outbreaks associated with consumption of fruits and vegetables including apples, tomatoes, lettuce, and parsley. Therefore, manufacturers of fresh-cut vegetables have become interested in developing a food preservative that can reduce pathogens such as *Salmonella* spp. in fresh produce and is safe for humans.

Objectives

The aim of this study was to evaluate the effects of 3 natural preservatives, grapefruit seed extract (GSE), cinnamaldehyde (CA), and nisin, against *Salmonella* spp. on fresh lettuce using the response surface methodology.

Methods

Following a central composite design, lettuce was inoculated with a cocktail of *S*. Typhimurium and *S*. Enteritidis and a combined antibacterial solution including GSE (0.049 to 0.301 mg/ml), CA (0.032 to 0.368 mg/ml), and nisin (0.016 to 0.184 mg/ml). The lettuce was stored at 4°C for 24 h. Surviving *Salmonella* spp. cells were enumerated on Salmonella-Shigella (SS) agar after incubation at 37°C for 24 h.

Conclusions

In this model, while keeping nisin constant at 0.1 mg/ml, GSE and CA reduced *Salmonella* spp. counts by approximately 2 $\log(N/N_0)$. Nisin was not effective against gram-negative bacteria. Nevertheless, while keeping CA constant at 0.2 mg/ml, GSE and nisin reduced *Salmonella* spp. counts by approximately 2 $\log(N/N_0)$. Therefore, the combination GSE 0.25–0.3 mg/ml, CA 0.25–0.35 mg/ml, and nisin 0.1–0.15 mg/ml is an effective antibacterial solution against *Salmonella* spp. on fresh lettuce.

METAGENOMIC ANALYSIS REVEALS SEASONAL FEATURES OF WILD LETTUCE IN SOUTH KOREA

Y.C. Yu[1], S.J. Yum[1], D.Y. Jeon[1], H.G. Jeong[1]
[1]Chungnam national university, Food Science and Technology, Daejeon, Republic of Korea

Backgrounds

Lettuce(*Lactuca sativa*) is the most popular vegetables in the world and also largely consumed in South Korea. Pathogens in microbiota of lettuce can be more harmful because lettuce is commonly eaten without cooking.

Objectives

This study was conducted to reveal the microbiota of wild lettuce in South Korea and compare the difference of the seasonal microbiota having potential pathogens.

Methods

We collected lettuces(n=30) from five different sites in South Korea in April and July. 16S universal primer that was constructed to avoid chloroplast's 16S rRNA gene was used to amplify the 16S rRNA gene that targeted on V5-V6 region. Amplicon sequencing was performed using the Illumina Miseq™ platform under manufacturer's instructions.

Conclusions

After trimming and qualifying of raw sequences, the average 74,543 reads were analyzed per each sample. In April group, Proteobacteria was the predominant phylum, however, Fimicutes was more abundant in July. Among dominant genera (a proportion over 5% at least one sample), *Exiguobacterium* was the dominant genus in both April and July. *Pantoea* known as including potential pathogenic species was the most dominant in April, whereas *Enterobacter* was second dominant genus in July. In most of the sites, there are potential pathogenic genera such as *Bacillus*, *Staphylococcus*, including pathogenic species. In a PCoA result, there are compartmented clusters between April and July. In order to confirm the potential pathogens in microbiota of wild lettuce, further study using more samples collected in various location is necessary.

Food Microbiology - Part III

PREVALENCE AND VIRULENCE MARKERS OF YERSINIA ENTEROCOLITICA IN MEAT

A. Zadernowska[1], W. Chajecka-Wierzchowska[1]
[1]University of Warmia and Mazury in Olsztyn, Chair of Industrial and Food Microbiology, Olsztyn, Poland

Backgrounds

According to annual reports of the European Food Safety Authority, *Yersinia enterocolitica* is third most common enteropathogen responsible for food poisoning. Meat is regarded as the main source of these infections.

Objectives

The aim of the study was to analyse the incidence of *Y. enterocolitica* in raw meat and to determine the incidence of selected factors of virulence of the bacteria. A total of 254 samples were obtained from several local markets in Olsztyn, Poland. Samples were consisted in poultry meat, beef meat, pork meat, minced pork and beef meat, minced poultry meat.

Methods

All the samples were kept at 4°C during transport and during storage before analysis. The analysis was done according to PN-EN ISO 10273:2003 within 4 hours after purchase. Genomic DNA isolation was performed with the Genomic Mini kit (A&A Biotechnology, Gdynia, Poland) according to the manufacturer's instructions. Triplex PCR was carried out to amplify three *Y. enterocolitica* genes: *ail, ystA* and *ystB*.

Conclusions

Yersinia enterocolitica were found in poultry meat (2), pork (3) and minced pork and beef (2). All of the strains of *Y. enterocolitica* were classified as biotype 1A, none of them had the gene *yst*A responsible for the production of enterotoxin YstA or the gene *ai*l responsible for the production of adhesin Ail. The gene *yst*B, responsible for the production of enterotoxin Ystb, was found in 5 out of 7 strains.

Food Microbiology - Part III

LAMP AND RAPIDCHEK SELECT FOR THE RAPID AND SENSITIVE DETECTION OF SALMONELLA SPP. IN MEAT

A. Zadernowska[1], *W. Chajecka-Wierzchowska*[1]
[1]*University of Warmia and Mazury in Olsztyn, Chair of Industrial and Food Microbiology, Olsztyn, Poland*

Backgrounds

Meeting the food safety standards and complying with risk management in the food chain makes it necessary to develop new, rapid and reliable methods for identification of microbiological hazards. LAMP (Loop-mediated isothermal amplification), developed by Notomi *et al.* in 2000, can specifically, sensitively and rapidly amplify nucleic acids utilizing a DNA polymerase enzyme with high strand displacement activity and two pairs of primers recognizing six independent sequences of a target gene under isothermal conditions. RapidChek Select is immunochemical-based method with application of phage as a selective agent for Salmonella. Phage attack cross reactive bacteria preventing them from causing a false positive reaction in the assay.

Objectives

The objective of the studies was to investigate the potential for detection of *Salmonella* in chicken meat with alternative methods: LAMP (Loop-Mediated Isothermal Amplification) and RapidChek Select (immunoassay method based on the lateral flow technology) and to compare the results with the findings obtained with the reference method ISO 6579.

Methods

Meat samples were purchased from a retail market in Olsztyn (northeast Poland). Portions of meat (25g) were artificially contaminated with *Salmonella* and/or another *Enterobacteriaceae* bacteria cells on three levels and were tested by three methods.

Conclusions

The sensitivity of the alternative method was 100% and the specificity was 100%. Both the application of the LAMP and RapidChek Select tests allow for a substantial reduction of waiting time for the results, which is particularly important for analyses of raw materials and products with a short shelf-life.

AFLP CHARACTERIZATION OF MICROORGANISMS FOR A RAPID AND ACCURATE IDENTIFICATION IN WINE AND OTHER FOOD INDUSTRIES

D. García Martínez[1], O. Zafra[1], J. Calzada[1], E. Pérez Lago[1], R. Francisco[1], I. Baselga[1], C. Santos[1]
[1]Universidad Francisco de Vitoria, Experimental Sciences, Pozuelo de Alarcón Madrid, Spain

Backgrounds

Winemaking is a natural fermentation process driven by microorganisms present in the grape skin and in the environment. Nowadays, there is a great interest in the study of microorganisms involved in fermentation due to the influence they have in organoleptic properties. Our group carried out the analysis, by the AFLP technique, of 1200 yeasts randomly isolated from 17 vineyards to create a database that includes the species and strain specific alleles amplified with two selected pairs of primers. In this study, yeasts were isolated from musts that belong to Ribera de Duero PDO in Spain.

Objectives

Currently our group tends to improve the database and our efforts are focused in samples isolated of different PDO in order to contrast yeast, grapes, *terroir*…

Methods

We have chosen La Mancha PDO and musts from different white grape strains have been analyzed. The isolated yeasts have been characterized by ITS-RFLP and AFLP analysis. Fermentation experiments are in progress with selected strains with the aim to analyze the produced aromatic compounds and hence link microbiology with flavor.
Also, we are working in setting up the method to differentiate edible mushroom strains in order to keep a record and provide genetic tools that warrant integrity of strains

Conclusions

AFLP analysis has been proved to be an accurate method to differentiate wild yeasts allowing subsequent characterization of specific strains in fermentation processes in order to determine their oenological properties. The technique is now being tested in edible mushrooms in which the setting up is different and results are preliminary

Food Microbiology - Part III

BACTERIAL DIVERSITY OF HIGH BACTERIAL COUNT RAW COWS´ MILK FROM THE BULK TANK OF DIFFERENT DAIRY FARMS IN GERMANY

J. Zimmermann[1], *A. Lipski*[1]
[1]*Institute of Nutrition and Food Science, Food Microbiology and Hygiene, Bonn, Germany*

Backgrounds

The bacterial load of raw milk directly affects quality and shelf life of the processed milk and dairy products. Psychrotrophic bacteria pose a serious problem because they are able to grow rapidly under cold storage and contribute to spoilage by proteolytic or lipolytic activity.

Objectives

We characterized the dominating contaminants from 38 raw milk samples with high microbial load (>100.000 cfu/mL) from different dairy farms and determined their diversity.

Methods

Total bacterial counts were determined as colony forming units at 30°C or 10°C. Numbers and percentages of colonies with different morphologies were determined, in order to calculate the bacterial diversity and to isolate and identify dominating species. Additionally, diversity was determined by culture-independent analyses of 16S rRNA sequences from DNA extracts. Bacterial diversity of raw milk samples was calculated with Shannon-Weaver and Shannon-Evenness indices.

Conclusions

Results of the culture-dependent and –independent approach revealed two different groups of raw milk samples: Samples with low diversity and dominating bacterial taxa and samples with higher diversity and without dominating bacterial taxa. The dominating taxa of the first group were identified as Gammaproteobacteria and Firmicutes, respectively. The psychrophilic Gammaproteobacteria showed spoilage potential by lipolytic or proteolytic activity at 10°C and/or 4°C and were able to grow rapidly under cold conditions. The mesophilic species of the phylum Firmicutes were identified as potentially pathogenic bacteria, known to cause mastitis in dairy cows. In this study, we demonstrated that both groups, psychrophilic and mesophilic bacteria, are able to represent the dominating contaminant in raw cows´ milk from bulk tanks.

DETECTION OF INTESTINAL PARASITES WITH CONVENTIONAL AND MOLECULAR METHODS IN FOLLOW-UP HIV/AIDS CASES

Ö. Akgül[1], B. Sapmaz[2], Ö.F. Karasakal[1], H. Kırkoyun Uysal[3], Y.A. Öner[3]
[1]Üsküdar University, Vocational School of Health Services, İstanbul, Turkey
[2]Nisantasi University, Vocational School, Istanbul, Turkey
[3]Istanbul University Istanbul Medical Faculty, Medical Microbiology, Istanbul, Turkey

Backgrounds

In people living with HIV, several complaints related to the gastrointestinal system, mainly diarrhea can be determined.

Objectives

We tried to examine the existence of *Giardia* spp., *Blastocystis* spp., *Entamoeba histolytica*, *Dientamoeba* spp. and *Cryptosporidium* spp. in stool samples.

Methods

In our study, we aimed to detect the existence of intestinal parasites with conventional methods based on microscopy and with molecular methods based on multiplex-PCR in 90 ART naive or ART adherent HIV/AIDS cases.

Conclusions

An overall prevalence of 36.7% at least one intestinal parasitic infections was recorded and the prevalence of this infection was due to *Blastocystis* spp. (22.2%), followed by *Dientamoeba* spp. (13.3%), *Entamoeba histolytica* (4.4%), *Cryptosporidium* spp. (3.3%), *Giardia* spp. (2.2%) and multiple parasitic infections (7.7%). The type of sexual behaviors (especially homosexual intercourse) are related with the detection of intestinal parasites as statistically highly significant ($p<0.001$). The increase in CD4+ T lymphocyte counts was negatively associated ($p=0.062$) and the increase in viral load levels was positively associated ($p<0.001$) with intestinal parasite detection rates. A statistically significant difference was observed in the overall parasitic infection rate was higher in pre-ART participants than in on-ART participants ($p=0.002$) and was higher in participants with diarrhea than in on participants without diarrhea ($p=0.019$). Further studies using larger participants and based on the detection of more pathogens are needed to provide more insight into the true etiology of gastrointestinal complaints in HIV/AIDS cases.

ANTIMICROBIAL ACTIVITY OF SIX PLANTS SEEDS EXTRACTS ON URINARY PATHOGENIC BACTERIAL STRAIN

D. AL-Kurjiya[1]
[1]*research institute of the university of Bucharest-ICUB -faculty of biology, microbiology, bucharest, Romania*

Backgrounds

The purpose of this study was to investigate the antimicrobial activity of different plant extracts against urinary pathogenic strains.

Objectives

to examination the ability of vegetal extracts as antimicrobial activity on gram negative bacteria.

Methods

The urine samples were taken from pregnant women with different ages, who were suffering from urinary tract infections. A number of nine urinary pathogenic strains (3 *Escherichia coli*, 3 *Klebsiella spp*., 2 *Proteus spp.* and 1 *P. aeruginosa)* after isolation and identification depending upon cultural characteristics and biochemical tests results. The aqueous and alcoholic seeds extracts of sweet seeds, honey melon, cucumber, celery, sweet violet, cinnamon, with the following concentrations: 1%, 5% and 10% were tested. Bacterial suspensions of 0.5 MacFarland density were prepared and seeded on Muller Hinton media, followed by the distribution of filter paper discs previously saturated with watery and alcoholic plant extracts and dried at room temperature for 1 hour. The plates were incubated at 37C^{o} for 24 hours. Then the diameters of the growth inhibition zones were measured and average values were calculated when more than one strain of the same species was used.

Conclusions

This study demonstrates that the investigated seeds extracts could represent a viable alternative for the treatment of urinary tract infections, particularly taking into account the increasing incidence of antibiotic resistance among the etiological agents of these most frequent infectious diseases. Their antimicrobial efficiency in both aqueous and alcoholic extract form demonstrate the richness and active principles and the potential for multi-pharmacological actions, correlated with reduced side effects.

CELL ASSOCIATED AND SOLUBLE VIRULENCE FACTORS IN NON ALBICANS CANDIDA STRAINS ISOLATED FROM IMMUNOCOMPROMISED PATIENTS

D. AL-Kurjiya[1]
[1]*research institute of university of Bucharest -faculty of biology, microbiology, bucharest, Romania*

Backgrounds

to study the virulance factor of non- *albicans candida which are considered the main impotent reasons which responsible for pathogenicity*

Objectives

the purpose of this study is to establish the virulence phenotype of non -*albicans candida spp*. isolated from localized and systemic infections in immunocompromised patients.

Methods

a total of 37 non candida albicans spp strains i.e.,*C.glabrata*(10),*C.tropicalis* (7),*C.krusei*(6),*C.famata*(4),*C.parapsilosis* (4),*C.kefyr*(3)and *C.guilliermondi*(2)were isolated from various clinical specimens.the production of extracellular hydroponic enzymes was determined by using specific growth media i.e., gelatin agar(bovine serum albumin)(BSA) for protease (Prz) ,egg yolk agar for phospholipases(Pz) and blood agar for haemolysis(Hz),(the lowest the value ,the highest is the production of the respective virulence factor).the results were recorded semi quantitatively and expressed as ratio of the colony diameter to the diameter of the colony plus the precipitation/haemolysis zone .the fungal adherence to HeLa cells was assessed by Cravioto's adapted method. adherence indexes and pattern were established by microscopic evaluation .the biofilm formation was quantified by a modified violet crystal microtiter method,after 48h of incubation at 35Cº in Sabouraud dextrose broth supplement with 8%glucose,distributed in 96 multi well plates .the Candida albicans ATCC 10231 was used as reference.

Conclusions

the in vitro study of the virulence factors profiles in non -albicans candida spp strains isolated from different clinical infections is imperative for the understanding of their pathogenesis and correlation with certain infectious processes,aspect that could contribute to the proper the therapeutic management of fungal infectious .

INVESTIGATION OF ANTIMICROBIAL EFFECT OF EXTRACTS MAHONIA AQUIFOLIUM

A. Damjanović[1], J. Antic Stankovic[2], S. Mijatovic[2], G. Zdunić[3], Z. Juranic[1]
[1]Institute of Oncology and Radiology of Serbia, Department for Experimental Oncology, Belgrade, Serbia
[2]Faculty of Pharmacy University of Belgrade, Departmet of Microbiology and Immunology, Belgrade, Serbia
[3]Department for Pharmaceutical Investigations and Development,
Institute for Medicinal Plant Research Dr. Josif Pančić, Belgrade, Serbia

Backgrounds

Mahonia aquifolium is one of the most abundant plants of the genus *Mahonia*, it belongs to the ornamental shrubs and is widespread in Europe and America. Preparations of this plant are used in traditional medicine, for the treatment of inflammatory conditions of the skin. It is believed that the berberine and the barberine type alkaloids are main holders of activity of the plants of this genus.

Objectives

The aim of the study was to investigate the effect of water and ethanol extracts of *M. aquifolium,* on the the survival of various ATCC strains of microorganisms (*S. aureus*, *S. mutans*, *B. subtilis*, *E. coli*, *K. pneumoniae*, *C. albicans*).

Methods

The effect of the extracts on the production of biofilm and glycocalyx, was determined after treatment of *S. aureus* with sub-inhibitory concentrations of extracts. Also, it was examined the influence of the extracts on the activity of antibiotics (amoxicillin, cephalexin, ceftriaxone, erythromycin, tetracycline, chloramphenicol, gentamicin, bacitracin) on the growth of *S. aureus* and antimycotics (nystatin and voriconazole) on the growth of *C. albicans*.

Conclusions

Obtained results showed that ethanol extract has better antimicrobial effect, in comparison with aqueous extract. Both extracts moderately reduce the production of virulence factors and show anadditive effect with tested antibiotics and antmycotics, on the tested strains of microorganism

AUGMENTATION OF THE HYDROLYSIS OF DIETARY GLUCOSYLCERAMIDE IN THE LARGE INTESTINE BY A NEWLY BACTERIUM ISOLATED FROM CANINE FECES

N. Asanuma[1]
[1]*Meiji University, Life Science, Kawasaki, Japan*

Backgrounds

Ceramides and sphingoids are known to play various roles as second messengers in many aspects of cell regulation, including cell growth, cell differentiation, autophagy, and apoptosis. The major sphingolipids included in plant food are glucosylceramide (GluCer). However, dietary GluCer is barely hydrolyzed to ceramide in the intestinal tract, and most of GluCer is exerted in feces.

Objectives

Thus, we examined the method to enhance GluCer hydrolysis in the large intestine by intestinal bacteria.

Methods

A novel anaerobic bacterium having high ability to hydrolyze plant GluCer was isolated from canine feces, and designated *Bacterium_A*. To use this isolate as a probiotic, freeze-dried cells were administered to mice.

Conclusions

The 16S rRNA gene sequence analysis indicated that *Bacterium_A* was a member of the *Clostridium coccoides* rRNA group of organisms, but the divergence to other bacteria was more than 5 %. Oral administration of *Bacterium_A* cells to mice for 4 weeks had no effects on feed intake, body weight gain, appearance, or behavior. These results suggest that *Bacterium_A* is not acutely toxic to mice. When a low level of purified GluCer was fed to mice, some amount of GluCer was exerted in feces, indicating that even extracted or free GluCer is not completely hydrolyzed in the digestive tract. GluCer excretion by mice fed apple powder was similar to that with purified GluCer. Irrespective of the state of GluCer, administration of freeze-dried *Bacterium_A* cells significantly decreased the amount of GluCer recovered in feces, suggesting that GluCer is hydrolyzed by *Bacterium_A* mainly in the large intestine.

ANTITUBERCULAR POTENCY OF 1, 3, 5, 6 AND 7 SUBSTITUTED 4-HYDROXYQUINOLIN-2(1H)-ONES

M. Bidart de Macedo[1], A. Peixoto[2], L. Verschaeve[3], P. Cos[1], G. Caljon[1], L. Maes[1], P. Delputte[1], J. Košmrlj[4], D. Cappoen[1]
[1]University of Antwerp, Department of Pharmaceutical Sciences, Wilrijk - Antwerp, Belgium
[2]Institut de Pharmacologie et de Biologie Structurale, Département Mécanismes Moléculaires des Infections Mycobactériennes, Toulouse, France
[3]University of Antwerp, Department of Biomedical Sciences, Wilrijk - Antwerp, Belgium
[4]University of Ljubljana, Department of Chemistry and Biochemistry, Ljubljana, Slovenia

Backgrounds

Approximately 2 billion people are infected with *Mycobacterium tuberculosis* and are hence at risk of developing active tuberculosis. There are several problems associated with the currently available treatment: nonadherence, potential side effects, and drug resistance. As a result, new treatments for tuberculosis are urgently needed. The search of newer antitubercular drugs led to the identification of several quinoline-based antituberculosis agents.

Objectives

The objective of this work was to search from the hydroxyquinolin-2(1*H*)-ones, a group of pharmacological active compounds with diverse antifungal and antibacterial activity, a candidate a new antituberculosis agent.

Methods

A library of 54-membered of substituted 4-hydroxyquinolin-2(1*H*)-ones and related compounds was designed, scored *in-silico* for drug likeness using the FAF-Drugs3 tool and subsequently synthesized. The minimal inhibitory concentration (MIC) was evaluated by serial dilution method, using a luminescent reporter strain *Mycobacterium tuberculosis* H37Ra^{lux} that harbors the pSMT1 plasmid carrying the *lux*AB genes from *Vibrio harveyi*. The *in vitro* cytotoxicity of the selected compounds was evaluated against MRC-5 human lung fibroblast cell and the early signs of genotoxicity were evaluated by Vitotox™ assay.

Conclusions

In this investigation, we have observed the antimycobacterial potency of a small library of 4-hydroxy-2(1*H*)-quinolones and structural related compounds. Derivatives carrying a 3-phenyl substituent were favored exhibiting low MIC and no signs of cytotoxicity or genotoxicity. Although the activity was not in the same order as the first line antituberculosis drugs, the library proved that the 4-hydroxy-2(1*H*)-quinolone can be altered by structural modification and change in substituents of the heterocyclic scaffold, representing, hence, an interesting group of antitubercular compounds.

USE OF SACCHAROMYCES CEREVISIAE AND TRICODERMA VIRIDAE FOR LOW COST POULTRY FEED PRODUCTION IN BANGLADESH

A. Biswas[1], K. Kazi[2], H. Qurashi[3]
[1]Sunchon National University, Animal Science and Technology, Suncheon, Republic of Korea
[2]Bangladesh Agricultural Research Council, Krishi Gobesona Foundation, Dhaka, Bangladesh
[3]Chittagong Veterinary and Animal Sciences University, Animal Science and Nutrition, Chittagong, Bangladesh

Backgrounds

Low cost poultry feed ingredients like maize, wheat, rice polish, rubber seed contain low protein. Also, rice polish contain high fiber, so use of those ingredients in poultry ration is limited.

Objectives

This experiment was conducted to increase protein and vitamin level and decrease fiber level of locally available feed ingredients to formulate a low cost poultry feed.

Methods

Selected feed ingredients were mixed separately with *Saccharomyces cerevisiae* and *Tricoderma viridae* in a different combination. From fermented ingredient, samples were collected at 48 hours interval for crude protein, crude fiber estimation. Estimation of Vitamin A, D, K and toxicity level of fermented feed were done by UHPLC. On the basis of highest protein and lowest fiber containing ingredients, a low cost ration was formulated and an on-station also two on-farm trials on broiler were performed.

Conclusions

Crude protein content of these ingredient was increased from 9% to 12% for maize, 11% to 13% for rice polish, 11% to 14.5% for wheat and 17% to 20% for rubber seed. Treated rice polish was found to decrease crude fiber from 18% to 12%. Significantly higher carcass quality, feed conversion ratio (FCR) were ($p<0.01$) observed in treatments diet fed bird and no toxin was observed in fermented feed. In the on-station trial, cost of treatment feed was about 2.6 BDT/kg less compared to control feed and profit margin was 39.3 BDT/bird higher for treatment group bird compare to control. In case of on-farm trial, the average cost of treatment feed was 29.2 BDT/kg which was 1.8 BDT/kg less compared to control and profit margin was calculated to be 20.15 BDT/bird higher for treatment group bird compare to control.

IMPROVING THE IN VITRO MODELS OF GASTROINTESTINAL DIGESTION: THE ROLE OF THE ORAL MICROBIOME

M. Calatayud[1], C. Xiong[2], K. Francesconi[2], G. Du Laing[3], T. Van de Wiele[1]
[1]Ghent University, Center for Microbial Ecology and Technology CMET, Ghent, Belgium
[2]University of Graz, Institute of Chemistry, Graz, Austria
[3]Ghent University, Department of Applied Analytical and Physical Chemistry, Ghent, Belgium

Backgrounds

The oral cavity contains a vast diversity of microorganisms. The alimentary bolus, composed by chewed food and saliva, reaches the stomach and small intestine, where different food components are digested and released for further absorption. Despite the relevance of the microbiome to the human physiology, little is known about the effect of microorganisms in the estimation of oral bioaccessibility (fraction of a specific compound released from its matrix during digestion) of drugs, toxicants or food compounds.

Objectives

Assess the effect of the oral microbiome into the *in vitro* bioaccessibility and intestinal transport of an environmental pollutant (arsenic).

Methods

An *in vitro* model with four stages (oral, gastric, small intestinal and colonic) was applied to rice, mussels and nori seaweed. Oral reactors were inoculated with salivary samples from healthy donors and colon reactors were inoculated with a fecal inoculum from the same donors. Oral reactors without the addition of saliva were run in parallel. After each digestion step, samples were centrifuged and filtered, and arsenic content was analyzed in supernatants. The supernatants from the small intestine and colon digestion were applied to a co-culture model of Caco-2 and HT29-MTX cells in Transwells® and arsenic transport and cellular uptake were assessed.

Conclusions

The presence of oral microbiota (saliva) in the *in vitro* model affected significantly the bioaccessibility of arsenic in a food-dependent way. The oral microorganisms increased the cellular uptake of the environmental pollutant in all the conditions. The current standardized *in vitro* methods for evaluating bioaccessibility are lacking a key element in the digestion process (oral and gut microorganisms), which could affect the *in vitro/in vivo* correlations. The combination of *in vitro* digestion models, including microbial metabolic potency, with models of the gut epithelium, can offer a more accurate prediction of As bioavailability, and in a broader context, environmental pollutants, drugs or food compounds.

EXTENSIVE RECOMBINATION FOLLOWED BY ALMOST STRICT CLONALITY IN THE EMERGENCE OF THE MYCOBACTERIUM TUBERCULOSIS COMPLEX

A. Chiner-Oms[1], L. Sanchez-Busó[2], J. Corander[3], S. Gagneux[4], F. González-Candelas[1], S. Harris[2], I. Comas[5]
[1]FISABIO-Universitat de Valencia, Unidad Mixta Infección y Salud, Valencia, Spain
[2]Wellcome Trust Sanger Institute, Pathogen Genomics, Hinxton, United Kingdom
[3]University of Oslo, Department of Biostatistics, Oslo, Norway
[4]Swiss Tropical and Public Health Institute, Medical Parasitology and Infection Biology, Basel, Switzerland
[5]Biomedicine Institute of Valencia, Tuberculosis Genomics Unit, Valencia, Spain

Backgrounds

The role of recombination in the evolution of the *Mycobacterium tuberculosis* complex (MTBC) is debated. MTBC has been usually regarded as essentially clonal. The availability of hundreds of MTBC clinical strains as well as some of close relatives such as *M. canetti* provides the opportunity of analysing the microevolutionary events that led to the emergence of the tuberculosis bacillus.

Objectives

To analyse the role of recombination in the evolution of MTBC, firstly in shaping its current diversity, and secondly to characterise the ancestor of the MTBC just before its transition to the successful pathogen we know today.

Methods

Firstly, we checked for recombination events that occurred after the MTBC ancestor split from *M. canetti*. We analysed ~1600 representative strains of the global genetic diversity of the MTBC. All the analytical approaches used agreed in assigning a minimal role to recombination in the recent evolution of the MTBC. Also, when checking for recombination signal between *M. canetti* and MTBC strains no ongoing recombination was found.

Secondly, we searched for ancient recombination events. We found 67 recombination events between the branch leading to the MTBC ancestor and *M. canetti* branches. Genes in these regions were enriched for functions involved in symbiotic interactions inside a host cell.

Conclusions

From our results, recombination seems to have played a relevant role in the early speciation events and in the emergence of the MTBC. However, once the MTBC ancestor diverged into the current diversity, recombination has no longer been detected.

CARBAPENEM-RESISTANT KLEBSIELLA PNEUMONIAE INFECTIONS: RISK FACTORS AND 30-DAY MORTALITY IN HOSPITALIZED PATIENTS FROM A KPC ENDEMIC REGION.

A.V. Cienfuegos[1], P. Sierra Viana[2], C. Restrepo Castro[2], F. Ramirez Brinez[2], G. Roncancio Villamil[3], H. del Corral Londoño[1], J.N. Jimenez Quiceno[1]
[1]Universidad de Antioquia, Antioquia, Medellin, Colombia
[2]IPS Universitaria Clínica León XIII, Antioquia, Medellín, Colombia
[3]Clínica CardioVID, Antioquia, Medellin, Colombia

Backgrounds

Carbapenem-resistant-*K.pneumoniae* (CRK) has become a worldwide threat due to its rapid spread and limited therapeutic options.

Objectives

The aim of this study is to identify risk factors and to determine 30-day-mortality in CRK infections.

Methods

A cohort enrolling all patients infected by *K.pneumoniae* in one hospital (700-beds) from Medellín-Colombia during 2014-2015 was analyzed. Clinical information was retrieved from charts. Risk factors were identified by a case-control analysis; cases were defined as patients infected by CRK and controls as patients infected by carbapenem-susceptible-*K.pneumoniae* (CSK). Analyses were done using logistic regression. To determine 30-day-mortality a survival analysis was performed. Models were fitted using a generalized-gamma and Weibull distributions because of non-proportionality of risks

Conclusions

In total 338 patients were enrolled, 49 (14.5%) infected by CRK and 289 (85.5%) infected by CSK. Most patients were male (58.5%) and adults (median=67-years IQR=51-76). Factors associated to CRK adjusted for time-at-risk were previous use of meropenem (OR=7.04, 95%CI=3.20-15.30), ciprofloxacin (OR=2.71, 95%CI=1.21-6.07) and urinary catheter (OR=2.35, 95%CI=1.16-4.77). Overall 30-day-mortality was 13.9% (n=47); 11 deaths occurred among CRK-infected-patients (22.5%) and 36 among CSK (12.5%)(p=0.062). Death incidence rate was 0.007 per person-days. In the bivariate analyses, age >67-years (HR=2.11, 95%CI=1.16-3.84) and Charlson index (HR=1.17, 95%CI=1.04-1.32), but not CRK-infection (HR=1.46 95%CI=0.74-2.88) were associate with higher mortality. In the multivariate analysis only Charlson index remained associated to 30-day-mortality. Previous use of carbapenems and ciprofloxacin in the last six months and urinary catheter play an important role in CRK-infection. Although death proportion was higher among CRK infected patients, comorbidities were the main risk for 30-day-mortality.

[2]Federal University of Viçosa, 36570 000 MG, Brazil
[3]Faculty of Medicine
[4]Federal University of Ouro Preto, MG, Brazil
[5]Department of microbiology
[6]Department of Food Engineering
[7]Department of Health and Nutrition

Background: Human milk (HM) is a complete food in terms of nutrition, immune precursors and microbial content, necessary to the newborn's (NB) development. Pasteurization is applied to HM deposited in the banks, eliminating most of the endogenous microorganisms.

Objective:To identify the prevalent culturable lactic acid bacteria (LAB) in colostrum, transition and mature HM and to verify their potential as probiotic.
Methods: Milk Samples from 14 nursing mothers were plated in Rogosa and modified MRS agar media. A total of 320 colonies were picked from the highest dilutions and coccus or bacillus, Gram positive, negative for gelatinase or beta hemolysis were evaluated for resistance to artificial gastric juice (AGJ), bile salts (BS), sensitivity to antibiotics (AS), growth in the presence of human blood serum (HBS) and antagonism to pathogens.

Results:The majority of strains were beta-hemolytic (297) and the final 23 isolates were identified as Enterococcus faecalis (E. faecalis) (11), Staphylococcus epidermidis (S. epidermidis) (9), S. lugdunensis (3). The species resisted well to the AGJ and to BS, antagonized indicator pathogens, grow moderately in the presence of HBS and the sensitivity to antibiotics was variable.

Conclusion: It is the first time that culturable LAB strains from HM were systematically isolated from mothers along their nursing period, E faecalis identifed as prevalent at different stages of lactation and probiotic characteristics evaluated. However the ecological function of the prevalence of such strains in the onset of the intestinal colonization of the NB deserves further investigation.

SYNERGISTIC ACTIVITY OF MICAFUNGIN PLUS VORICONAZOLE AGAINST MULTIDRUG-RESISTANT CANDIDA AURIS: CANDIDEMIA

H. Fakhim[1], A. Chowdhary[2], J. Meis[3], V. Afsane[4], H. Badali[5]
[1]Mazandaran University of Medical Sciences, Department of Medical Mycology and Parasitology-, Tabriz, Iran
[2]University of Delhi,
Department of Medical Microbiology- Division of Mycology- Vallabhbhai Patel Chest Institute, Delhi, India
[3]- Canisius Wihelmina Hospital CWZ, Department of Medical Microbiology and Infectious Diseases, Nijmegen, Netherlands Antilles
[4]Mazandaran University of Medical Sciences, Department of Medical Mycology and Parasitology, Sari, Iran
[5]Mazandaran University of Medical Sciences- Sari- Iran,
Department of Medical Mycology and Parasitology, Sari, Iran

Backgrounds

Blood stream infections due to *Candida auris* is related to a high mortality rate, treatment failure, and resistant to fluconazole, voriconazole, amphotericin B, and caspofungin. Thus, the precise identification of agents and *in vitro* antifungal susceptibility testing is highly recommended. Novel therapeutic strategies, such as combination therapy, are essential for increasing the efficacy and reducing the toxicity of antifungal agents.

Objectives

We investigated the *in vitro* combination of micafungin plus voriconazole against multidrug-resistant *C. auris* as agents of candidemia.

Methods

A total of ten clinical isolates were obtained from tertiary care hospitals in Delhi, North India. Isolate identities were performed based on conventional methods and MALDI-TOF MS. The interactions of micafungin with voriconazole were investigated using a microdilution checkerboard technique in 96-well microtitre plates. The range of the concentration depended on the MIC results for each isolate; the maximum concentration was twofold the MIC and then serial diluted. Data obtained by visual reading were further analyzed using the fractional inhibitory concentration index (FICI).

Conclusions

Results revealed that MICs range for voriconazole and micafungin were 0.5-8 and 0.25–8 mg/L, respectively. The checkerboard analysis revealed that the combination of micafungin with voriconazole exhibited synergistic activity against all 10 multidrug-resistant *C. auris* isolates (FICI range: 0.15-0.5). Overall, no antagonistic effects were observed in this experiments.
Remarkably, the majority of isolates were resistant to fluconazole and unsuccessful treatment of *C. auris* infections with fluconazole, voriconazole, amphotericin B, caspofungin, and anidulafungin has been already on recorded. Further, interaction between micafungin with voriconazole exhibited synergistic activity against multidrug-resistant *C. auris* isolates. It seems that lower concentrations of drugs cause fewer side-effects and improve the treatment outcomes. However, *in vivo* studies with suitable animal models of *C. auris* infection is highly recomended.

1Department of Medical Mycology and Parasitology /Invasive Fungi Research Centre IFRC- School of Medicine-, Sari, Iran

Backgrounds

ATTAF-1 and ATTAF-2 are triazole alcohol-derived analogues, containing (2,4-dichlorophenyl)-1,2,4-triazole-thiol moiety being developed for the treatment of invasive *Candida* infection. ATTAF-1 and ATTAF-2 have demonsrrated potent *in vitro* activitiy against a broad range of *Candida* species. Herein, we have evaluated the *in vivo* efficacy of ATTAF-1 and ATTAF-2 against *Candida albicans* strains in an invasive candidiasis murine model.

Objectives

We have evaluated the *in vivo* efficacy of ATTAF-1 and ATTAF-2 against *Candida albicans* strains in an invasive candidiasis murine model.

Methods

Female 4-5 weeks old CD1 (ICR) mice were used. A clinical isolate of *C. albicans*, obtained from blood culture, was used in this experiment. The day of infection, mice were challenged i.v. with 1×10^6 CFU/animal of *C. albicans* into the lateral tail vein. Groups consisting of 15 immunocompetent mice were administered ATTAF-1, ATTAF-2, and fluconazole (3.5 and 35 mg/kg/day) intraperitoneally, once daily for 5 days. The efficacy of therapy was evaluated through survival time, the fungal tissue burden and histopathological studies. Data analysis was performed by using GraphPad Prism software.

Conclusions

Mortality was significantly delayed in mice that were administered ATTAF-1 and ATTAF-2 at a dose of 35 mg/kg compared with that in the fluconazole 35 mg/kg and control mice. Fungal burden was 4.8 ± 0.36 log mean CFU/g of kidney for control mice and 2.8 ± 0.31, 2.8 ± 0.31, and 3.4 ± 0.31 for mice treated with ATTAF-1, ATTAF-2, and fluconazole (35 mg/kg), respectively.Potential therapeutic dose of ATTAF-1 and ATTAF-2 (35 mg/kg) were effective in treating invasive candidasis caused by *C.albicans* in mice. Further studies with more isolates of Fluconazole-Susceptible and -Resistant *Candida* Species representing a wider range of MICs should be carried out to assess whether there is any relationship between MIC values and ATTAF-1 and ATTAF-2 efficacy.

FIRMICUTES WITH LPS-OUTER MEMBRANES: IMPLICATIONS FOR THE EVOLUTION OF CELL ENVELOPES IN BACTERIA

S. Gribaldo[1]
[1]*Pasteur, Microbiology, Paris, France*

Backgrounds

The bacterial envelope is one of the oldest and most essential cellular components. However, one of the major unanswered questions in Evolutionary Biology is why there are two substantially different cell envelope architectures, Gram-positive (monoderm) and Gram-negative (diderm), and how such dramatic transition occurred in Bacteria.
The Firmicutes represent the textbook examples of classical Gram-positive cell envelope architecture. Surprisingly, two lineages within the Firmicutes -the Negativicutes and the Halanaerobiales- display typical diderm cell envelopes with an outer membrane containing lipopolysaccharide, constituting an evolutionary conundrum.

Objectives

Our objectives were:
to clarify the evolutionary relationships among the Negativicutes and the Halanaerobiales within the Firmicutes.
to use genomic information to provide functional inference on key OM systems in these two diderm Firmicutes lineages.
to understand the evolutionary relationships of the OM of Negativicutes and Halanaerobiales with the other diderm bacterial phyla.

Methods

We carried our an exhaustive phylogenomic analysis on hundreds of complete genomes from Firmicutes and representative of major bacterial phyla. These data were confirmed and extended by experimental characterisation of the cell envelope of a diderm Firmicute.

Conclusions

Together, our results support the hypothesis that the LPS-OMs of Negativicutes and Halanaerobiales are remnants of an ancient diderm cell envelope that was present in the ancestor of the Firmicutes, and that the monoderm phenotype in this phylum is a derived character that arose multiple times independently through OM loss.
Diderm Firmicutes represent promising new experimental models to study the evolution and function of both monoderm and diderm bacterial cell envelopes.

IMPROVING AMINOGLYCOSIDES ANTIBIOTICS ACTIVITY BY LIPOSOMAL FORMULATIONS: FORMULATIONS CHARACTERIZATION/ ANTIBACTERIAL STUDIES

M. Halwani[1]
[1]*King Abdullah International Medical Research Center, Nanomedicine, Riyadh, Saudi Arabia*

Backgrounds

Aminoglycoside antibiotics remain among significant antibiotics families who's still fighting microorganisms until nowadays, though, pathogenic microorganisms never settle the battle yet. Pathogenic microorganisms have used various resistance's mechanisms to avoid aminoglycoside antibiotics' kill including modifying bacterial cell membrane permeability, promoting efflux pumps, inactivating antibiotics binding sites, and producing bacterial biofilms. Nevertheless, the uncontrolled usage of these antibiotics frequently associated with adverse side effects which occurs on treated patients as general cytotoxicity or particular nephrotoxicity and ototoxicity. All above render aminoglycosides antibiotics use to be hazardous. Liposomes drug delivery systems were used for decades to improve drugs activity and reduce toxicity.

Objectives

This communication is about presenting the experience of a decade in encapsulating different aminoglycoside antibiotics inside different liposomal formulations.

Methods

Basically, Amikacin, gentamicin, and tobramycin were chosen individually in several studies to compare free forms of these antibiotics versus encapsulated forms within liposomal formulations. In addition, tobramycin was further enhanced to eradicate biofilm bacteria by co-encapsulation with bismuth-ethanedithiol in liposomal formulation. Gentamicin was also enhanced in same manner with gallium metal. Neutral and negative charged liposomes have been used recently to increase the encapsulation efficiency of gentamicin antibiotic and their antibacterial activities were assessed.

Conclusions

In conclusion, liposomal formulations as drug delivery systems apparently it can be one of the promising choices to lead pharmaceutical approach for developing conventional antibiotics such as aminoglycoside antibiotics.

VALUE OF MATRIX-ASSISTED LASER DESORPTION IONIZATION-TIME OF FLIGHT FOR ROUTINE IDENTIFICATION OF VIRIDANS GROUP STREPTOCOCCI

G. Hasçelik[1], O. Altay[2], N. Karacan[3], M. Özdal Salar[3], H.K. Müstak[3]
[1]Hacettepe University Faculty of Medicine, Ankara, Turkey
[2]Hacettepe University Faculty of Medicine, Department of Medical Microbiology, Ankara, Turkey
[3]Ankara University Faculty of Veterinary Medicine, Department of Microbiology, Ankara, Turkey

Backgrounds

Phenotypic tests do not always unequivocally identify some species viridans group streptococci (VGS). In the last couple of decades, molecular methods have enabled more accurate genotypic identification of bacteria. In recent years, the matrix-assisted laser desorption/ionization-time of flight mass spectrometry (MALDI-TOF MS) technique has emerged as an alternative for clinical microbiology laboratories for the identification of a wide range of bacteria and fungi.

Objectives

This study assesses the ability of MALDI Biotyper to identify VGS isolates using 16S rDNA sequence analysis.

Methods

All the 94 clinical isolates of VGS were identified by conventional microbiological methods and then by MALDI Biotyper (Bruker Daltonics, Germany). The spectra were analysed by using the Flex Control 3.0 software and MALDI Biotyper 3.1 database library. 16S rRNA gene sequencing was used as a reference method for species identification.

Results: MALDI Biotyper accurately identified 78.7%(n:74) of the isolates to species level. Only one of the 94 isolates was misidentified as *S. pneumoniae* by the MALDI Biotyper system .
Maldi Biotyper (n=30; 21 S. oralis and 9 S. mitis) were able to distinguish S. mitis/oralis. 16S rDNA analysis failed to identify three strains and named these as S. mitis/S.oralis.

Conclusions

MALDI-TOF appeared to be a rapid and reliable alternative for identification of VGS strains to group level, but was not able to discriminate closely related species of certain groups.

IS THERE ANY CORRELATION BETWEEN BIOFILM PRODUCTION AND ANTIBIOTIC SUSCEPTIBILITY TESTS OF BURKHOLDERIA SPECIES ISOLATED FROM CYSTIC FIBROSIS AND NON-CYSTIC FIBROSIS PATIENTS?

O. Altay[1], G. Hascelik[1], B. Sener[1]
[1]Hacettepe University- Faculty of Medicine, Department of Microbiology, Ankara, Turkey

Backgrounds

Biofilm formation is an important virulence factor of various types of bacteria. Biofilm matrix provides a protective shield against the host immune system, besides it forms a physical barrier to the penetration of antibiotics.

Objectives

The aim of this study was to compare the biofilm formation of *Burkholderia* spp. strains isolated from CF and non-CF patients and to evaluate the correlation between *biofilm production* and antibiotic resistance.

Methods

A total of 36 *Burkholderia* spp. (15 CF, 13 non-CF and 8 control strains [LMG 1222, LMG 21824, LMG 16654, LMG 18829, LMG 18157, LMG 16775, LMG 13010 and LMG 1883]) isolates were analyzed. All the *Burkholderia* spp. were identified by conventional methods and MALDI-TOF-MS method (Bruker-Biotyper, USA). Biofilm formation was determined by using crystal violet microtiter plate assay. Antibiotic susceptibilities of ceftazidim, meropenem and trimethoprim/sulfamethoxazole (TMP-SXT) were determined by disc diffusion method according to CLSI guidelines.

Results: Among the 28 *Burkholderia* spp. isolates, biofilm production was determined in 78.5% (22/28) of the test isolates. No significant difference was detected among the biofilm positivity rates between CF (80%, 12/15) and non-CF (76.9%, 10/13) *Burkholderia* isolates. Rates of resistance to ceftazidime were 36.7% and 61.5%; to meropenem were 53.3% and 15.9%; to TMP-SXT were 0% and 15.9%, respectively, in CF and non-CF isolates.

Conclusions

No significant correlation between *biofilm production* and antibiotic resistance were detected. *Burkholderia* spp. exhibits significant susceptibility to TMP-SXT. Higher meropenem resistance in CF patients might be attributed to the expression of the specific efflux pump in the CF context.

SEROTYPE DISTRUBITION IN TRANSPOSON CARRYING MULTI-DRUG RESISTANT STREPTOCOCCUS PNEUMONIAE AMONG INVASIVE AND NON-INVASIVE ISOLATES

F.N. Akdogan Kittana[1], I.B. Kaya[2], G. Hascelik[1], S. Saricam[2], N. Gurler[3], K.S. Diker[2]
[1]University of Hacettepe Faculty of Medicine, Department of Medical Microbiology, Ankara, Turkey
[2]University of Ankara Faculty of Veterinary Medicine, Department of Microbiology, Ankara, Turkey
[3]University of Istanbul Faculty of Medicine, Department of Medical Microbiology, Istanbul, Turkey

Backgrounds

Streptococcus pneumoniae infections are challenging since pneumococci have more than 90 serotypes and its emergence of resistant strains has increased. The widespread dissemination of antibiotic resistance among pneumococci is associated with horizontal gene transfer (HGT) with mobile genetic elements like transposons. Transposons cause higher risk of treatment failure in pneumococcal infections.

Objectives

The aim of this study was to detect serotype distribution and transposons of multi-drug resistant invasive and non-invasive pneumococcal isolates.

Methods

Sixty-four invasive and 43 non-invasive isolates were included. For serogrouping and serotyping of the isolates, latex particule agglutination and Quellung reaction were performed, respectively. The resistance genes (*erm*A, *erm*B, *mef*E, *mef*I, *tet*M, *tet*O, *aph*A-III and *cat*pC194) and Tn916 transposons specific genes (*int*, *xis*, *tnp*A and *tnp*R) were investigated by *in*-house PCR with spesific primers. The results were compared with already known transposons.

Conclusions

Serotype 19F and 19A were first and second commonly observed in invasive (40.6% and 15.62%) and non-invasive (39.5% and 6.98%) isolates, respectively. Majority of the pneumococci (88.2%) carries Tn*916* family's transposons. Most commonly detected transposon was Tn*2010* (37.2%). Transposon Tn6002 (28.12% and 13.95%) and Tn3872 (15.62% and 20.9%) were detected in invasive and non-invasive isolates, respectively. Serotype distribution and transposon types have no statistically significant difference between invasive and non-invasive isolates. The 13 and 23 valent pneumococcal vaccine covered the studied isolates. Since serotype distribution and transposons of *S.pneumoniae* isolates may change in time naturally, close monitoring is essential.

FREQUENCY AND ANTIMICROBIAL SENSITIVITY OF ESCHERICHIA COLI 0157:H7 IN HEALTHY FARM/ABATTOIR/POULTRY WORKERS OF PESHAWAR, PAKISTAN

A. Jan[1], J. Ahmed[1], S. Mumtaz[2]
[1]Institute of Basic Medical Sciences- Khyber Medical University, Microbiology, Peshawar, Pakistan
[2]Khyber Medical College, Pathology, Peshawar, Pakistan

Backgrounds

Escherichia coli O157:H7 causes severe food-borne diseases transferred through milk, beef, and mutton. It mainly causes diseases in people taking these foods and milk coming from animals and poultry.

Objectives

This study was conducted to determine whether this organism is transferred through healthy humans associated with animals and poultry to the community. Therefore zoonosis through *Escherichia coli* O157:H7 was determined in healthy farm, abattoir and poultry workers in Peshawar.

Methods

The data were collected through standardized questionnaire in which questions were based on the hygiene practice, work duration, exposure to unprescribed antibiotics and disease history. A total of 200 samples were collected were collected including swabs from hands and mouth and from surfaces frequently used to work and stool sample, out of which 50(25%) samples were taken each from farm, poultry and abattoir workers while the rest of 50 (25%) samples were taken from the regular visitors of the sites. Stool and swab samples were collected from healthy workers.

Conclusions

Prevalence of *E. coli* O157:H7 was calculated as 23(11.5%) isolates recovered from farm workers, 21(10.5%) from abattoir workers, 20(10%) from poultry workers and 19 (9.5%) from visitors of these areas. The overall prevalence calculated was 41.5 per hundred persons. The organism was resistant to Vancomycin and sensitive to Ciprofloxacin. Four primers were used but amplification was observed on primers for Shiga toxin 3 and 4.

The organism is highly prevalent in farm and abattoir workers and they are considered to be active carriers of E. coli O157:H7.

AN ESSENTIAL ROLE FOR TAGLN2 IN PHAGOCYTOSIS OF LIPOPOLYSACCHARIDE-ACTIVATED MACROPHAGES

C.D. Jun[1]
[1]Gwangju Institute of Science and Technology, School of Life Sciences, Gwangju, Republic of Korea

Backgrounds

Bacterial infection is a common cause of sepsis and sepsis-associated organ failure, which cause high morbidity and mortality. Macrophages are the first line of host defense against pathogens and phagocytosis is one of the most important initial immune responses. The polymerization actin cytoskeleton mediates protrusions or ruffling of the macrophage membrane that can internalize target pathogens. In this process, a large number of actin-regulatory proteins are participating in actin remodeling. However, the molecular machineries that account for the enhanced ability of phagocytosis in activated macrophages as compared to resting macrophages are relatively unknown.

Objectives

We investigated the role of TAGLN2, a 22-kDa actin-binding protein, in Toll-like receptor (TLR)-stimulated phagocytosis.

Methods

TAGLN2 expression level was examined using reverse transcriptase quantitative polymerase chain reaction, and Western blotting. To examined whether function of TAGLN2 is related with the receptor-mediated phagocytosis, we utilized macrophages obtained from TAGLN2-deficient (*TAGLN2*$^{-/-}$) mice. For ex vivo and in vivo phagocytosis, we used E.coli and Salmonella and phagocytic activity was determined by flow cytometry and confocal real-time live imaging using confocal microscopy.

Conclusions

Here, we demonstrate TAGLN2 was greatly induced in macrophages in response to lipopolysaccharide (LPS), a ligand for TLR4, partly via the NF-κB pathway. TAGLN2-deficient macrophages (*TAGLN2*$^{-/-}$) showed defective phagocytic functions of IgM- and IgG-coated sheep red blood cells as well as bacteria. Cell signaling pathways involved in actin rearrangement—PI3 kinase/AKT and Ras-ERK—were also down-regulated in LPS-stimulated TAGLN2-deficient macrophages. Moreover, *TAGLN2*$^{-/-}$ mice showed higher mortality after bacterial infection than wild-type littermates. Thus, current results provide a novel function of TAGLN2 as a molecular armament required for host defense.

INVESTIGATING THE EFFICACY OF DISINFECTANTS BEING USED IN A HOSPITAL AGAINST SOME NOSOCOMIAL INFECTION CAUSING BACTERIA

Ç. Yavaş[1], F. Kaynak Onurdağ[2]
[1]Trakya University Institute of Health Sciences, Department of Basic Pharmaceutical Sciences, Edirne, Turkey
[2]Trakya University Faculty of Pharmacy, Department of Pharmaceutical Microbiology, Edirne, Turkey

Backgrounds

Hospital infections are severe infections with high mortality and morbidity. However, they are preventable infections when appropriate precautions are taken. Disinfectant activity tests are applied with standard bacterial strains and bacterial strains isolated from hospital environments may have different sensitivities than their standard counterparts.

Objectives

In our study, it was aimed to determine the efficacy of the disinfectants used in Trakya University Hospital to the bacteria isolated from the same hospital.

Methods

Twenty-five *Acinetobacter baumannii* (resistant to ciprofloxacin, gentamicin, meropenem, imipenem and ceftazidime), 14 *Klebsiella pneumoniae* (ESBL), 15 *Staphylococcus aureus* (MRSA) and 14 *Enterococcus faecalis* (VRE) isolates were included in the study. Susceptibilities were tested through the guidelines of CLSI M100-S25.

OPASTER®, SEKUSEPT®, MOONCID® PULVEREX, INCIDIN® Foam, ANIOS® Aniospray Quick, ANIOS® Aniosrub, OXY®, OXY®-WC-Bath, EXPÜR® and PENTAX® were tested with the applied ways in the hospital in clean and dirty conditions through TS EN 1040/1999 guidelines by qualitative suspension test.

Conclusions

As a result; all bacteria were observed to be susceptible to Incidin®Foam, Anios®Aniospray, Anios®Aniosrub, Oxy® ve Oxy®WC-Bath in all conditions and to be susceptible to Opaster® in hospital conditions. However, resistant isolates were observed to Ekusept®, Expür® and Pentax®.

Three disinfectants do not have efficacy to the isolates and this may lead to a spread in the hospital infections which also cannot be treated. As a result, we recommend that these disinfectants should not be used in our hospital and disinfectant efficacy tests should be applied to the drug resistant isolates in the hospitals regularly.

IN VITRO SUSCEPTIBILITY PATTERNS OF CLINICALLY IMPORTANT TRICHOPHYTON AND EPIDERMOPHYTON SPECIES AGAINST NINE ANTIFUNGAL DRUGS

S. Khodavaisy[1], H. Badali[2], H. Fakhim[2]
[1]Tehran University of Medical Sciences, Department of Medical Mycology and Parasitology, Tehran, Iran
[2]Mazandaran University of Medical Sciences,
Department of Medical Mycology and Parasitology/Invasive Fungi Research Center IFRC- School of Medicine, sari, Iran

Backgrounds

Despite the common, worldwide, occurrence of dermatophytes, little information is available regarding susceptibility profiles against currently available and novel antifungal agents.

Objectives

In the present investigation, we evaluated the in vitro antifungal susceptibilities of nine antifungal agents, viz. amphotericin B, fluconazole, itraconazole, voriconazole, isavuconazole, posaconazole, terbinafine, anidulafungin and caspofungin against sixty-eight clinical Trichophyton species and Epidermophyton floccosum.

Methods

A collection of sixty-eight clinical Trichophyton species and Epidermophyton floccosum were previously identified and verified to the species level by sequencing the internal transcribed spacer (ITS) regions of rDNA. MICs of amphotericin B, fluconazole, itraconazole, voriconazole, posaconazole, isavuconazole, terbinafine and MECs of caspofungin and anidulafungin were performed based on CLSI M38-A2.

Conclusions

The resulting MIC90s of all strains were, in increasing order, as follows: terbinafine (0.063 mg l1); posaconazole (1 mg l1); isavuconazole and anidulafungin (2 mg l1); itraconazole, voriconazole, amphotericin B, and caspofungin (4 mg l1) and fluconazole (>64 mg l1). These results confirm that terbinafine is an excellent agent for treatment of dermatophytosis due to T. rubrum, T. mentagrophytes, T. verrucosum, T. schoenleinii and E. floccosum. In addition, the new azoles POS and ISA are potentially useful antifungals to treat dermatophytosis. However, the clinical effectiveness of these novel antifungals remains to be determined.

MOLECULAR CHARACTERIZATION OF HIGHLY SUSCEPTIBLE CANDIDA AFRICANA FROM VULVOVAGINAL CANDIDIASIS

S. Khodavaisy[1], *H. Badali*[2], *S. Mohsenii*[3], *S. Olia*[4]
[1]*Tehran University of Medical Sciences, Department of Medical Mycology and Parasitology, Tehran, Iran*
[2]*Mazandaran University of Medical Sciences, Department of Medical Parasitology and Mycology, Sari, Iran*
[3]*Sari Branch-, Department of Microbiology, Sari, Iran*
[4]*Gazvin University of Medical Sciences, Department of Medical Mycology and Parasitology, Gazvin, Iran*

Backgrounds

Phylogenetic studies highlight Candida africana as an atypical variant within Candida albicans species complex which is dominantly recovered from vaginal specimens.

Objectives

This study aimed to characterize *C. africana* isolates from patients with vulvovaginal candidiasis (VVC) by molecular methods and in vitro susceptibilities.

Methods

One hundred and fifty-six (48.44 %) Candida strains were collected from 322 patients diagnosed with VVC. Of these, 114 (73.07 %) were germ tube positive and presented green color on the chromogenic medium, thus classified as *C. albicans* species complex.

Conclusions

One hundred and nine (95.61 %) out of 114 isolates were identified as *C. albicans*, while five (4.38 %) isolates were identical with C. africana based on hwp1 PCR. C. africana appeared to be highly susceptible to the tested antifungals. In conclusion, among the *C. albicans* species complex, *C. albicans* predominantly and *C. africana* rarely occur in vaginal mucosa. Due to limited information on molecular epidemiology of this novel yeast, more studies using molecular methods are needed to elucidate the interand intraspecific genomic variations of *C. africana* isolates.

CORALMYCINS A AND B, NEW POTENT ANTI-GRAM NEGATIVE COMPOUNDS FROM THE MYXOBACTERIA CORALLOCOCCUS CORALLOIDES M23

W.G. Kim[1], Y.J. Kim[1], H.J. Kim[1], K. Cho[2], H. Koshino[3]
[1]Korea Research Institute of Bioscience & Biotechnology, Superbacteria Research Center, Daejeon, Republic of Korea
[2]Hoseo University, Department of Biotechnology, Asan, Republic of Korea
[3]RIKEN, Center for Sustainable Resource Science, Wako, Japan

Backgrounds

Recently, infections caused by MDR Gram-negative bacteria have become a growing problem. There is an urgent need for new agents to treat infections caused by Gram-negative bacteria resistant to currently available agents.

Objectives

Myxobacteria are a group of Gram-negative bacteria that produce a diverse range of bioactive secondary metabolites. Myxobacteria have received attention as a source of novel anti-infective natural products. Our objective is to search for anti-Gram-negative metabolites from Korean myxobacteria.

Methods

We report the producing strain, fermentation, isolation, structural determination, and antibacterial activities of potent anti-Gram negative compounds.

Conclusions

Two new potent anti-Gram negative compounds, coralmycins A (**1**) and B (**2**), were isolated from cultures of the myxobacteria *Corallococcus coralloides* M23, together with another derivative (**3**) that was identified as the very recently reported cystobactamid 919-2. Their structures including the relative stereochemistry were elucidated by interpretation of spectroscopic, optical rotation, and CD data. The relative stereochemistry of **3** was revised to *"S*R*"* by NMR analysis. The antibacterial activity of **1** was most potent against Gram-negative pathogens, including *Escherichia coli*, *Pseudomonas aeruginosa*, *Acinetobacter baumanii*, and *Klebsiella pneumoniae*, with MICs of 0.1–4 μg/mL; these MICs were 4–10 and 40–100 times stronger than the antibacterial activities of **3** and **2**, respectively. Thus, these data indicated that the β-methoxyasparagine unit and the hydroxy group of the benzoic acid unit were critical for antibacterial activity. Coralmycin A has great potential for treatment of multidrug-resistant bacteria, including Gram-negative bacteria.

SYNERGISTIC EFFICACY OF SODIUM NEW HOUTTUYFONATE IN COMBINATION WITH BERBERINE AGAINST METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS

X. Li[1], C. Li[1], X. Lu[1], J. Pang[1], X. You[1], X. Yang[1]
[1]Chinese Academy of Medical Sciences & Peking Union Medical College, Institute of Medicinal Biotechnology, Beijing, China

Backgrounds

Staphylococcus aureus is a normal colonizing species in the human anterior nares and causes a wide variety of diseases. It is notorious for its ability to become resistant to antibiotics, thus limiting treatment options. Plants have provided us with a good source of antimicrobial agents and are candidates as new antibiotic substances.

Objectives

We evaluated two natural compounds, sodium new houttuyfonate (SNH) and berberine, for their in vitro efficacy against Methicillin-Resistant *Staphylococcus aureus* (MRSA).

Methods

A total of 162 *S. aureus* clinical isolates were collected from hospitals in Beijing, China, from 2009-2013. MRSA isolates were identified and screened by VITEK 2-COMPACT system, MIC of Oxacillin, and a multiplex polymerase chain reaction (PCR) targeting the 16S ribosomal RNA (rRNA) and mecA. MIC and checkerboard assay were performed to test antibacterial activity of SNH and berberine individually or in combination, respectively. Time killing analysis was performed to characterize the kill kinetics of SNH and berberine both alone and in combination against selected clinical isolates and well characterized control strains.

Conclusions

SNH inhibited all test strains with minimum inhibitory concentrations (MICs) ranging from 16 to 64 µg/mL in susceptibility tests, while 32-512 µg/mL for berberine alone. SNH and berebreine inhibited bacterial growth in a concentration-dependent manner in time-kill analysis, and showed significant synergistic effects against *S. aureus* Mu50, ATCC 43300, ATCC33591 and clinical isolated 8-50. Our findings suggest that the combination of two natural compounds, SNH and berberine, is a promising candidate for anti-MRSA drug development.

‘CREDIBLE’ – A CRE-MEDIATED DOUBLE REPORTER SYSTEM TO STUDY PENETRATION OF PHYSIOLOGICAL BARRIERS BY CELL-PENETRATING EFFECTOR PROTEINS

M.L. Lubos[1], T. Danyukova[2], B. Skryabin[3], C. Geyer[4], M.A. Schmidt[1], C. Rüter[1]
[1]Institute of Infectiology, Center for Molecular Biology of Inflammation, Münster, Germany
[2]Center for Obstetrics and Pediatrics, Department of Pediatrics, Hamburg, Germany
[3]TRAnsgenic animal and genetic engineering Models TRAM, Medical Faculty, Münster, Germany
[4]IZKF Core Unit "Preclinical Imaging eXperts" PIX, Institute of Clinical Radiology, Münster, Germany

Backgrounds

Previous studies identified the effector protein YopM of *Yersinia enterocolitica* as a novel bacterial cell-penetrating effector (CPE). The two N-terminal α-Helices (2αH) of YopM mediate translocation across the host cell plasma membrane independently of *Yersinia*’s type three secretion system (T3SS) and intracellular delivery of molecular cargos like GFP.

Objectives

In order to further study and characterise the mechanisms of cell penetration by CPEs and further cell-penetrating peptides (CPPs) *in vivo*, we have generated a Cre-mediated double reporter (‘CREDIBLE’) system. Transgenic mice harbouring the ‘CREDIBLE’ construct, express two reporter genes, namely near-infrared fluorescent protein (iRFP) and luciferase upon Cre/loxP-recombination.

Methods

The ‘CREDIBLE’ system is functional and both reporters are expressed upon recombination *in vitro*. Furthermore, crossing transgenic mice with mice expressing Cre-recombinase leads to recombination events, indicating the functionality of the system *in vivo*.

To analyse the distribution of CPP/CPEs *in vivo*, we have constructed different CPP-Cre fusion proteins, including 2aH-Cre. The recombinant proteins will be administered to the transgenic mice via different routes and their distribution can be analysed in real time by non-invasive live optical imaging.

Conclusions

Additionally, the ‘CREDIBLE’ system can be applied in a variety of studies using drug delivery systems like exosomes or targeted drug delivery to characterise their efficacy and distribution *in vivo*. Furthermore, the ‘CREDIBLE’ system can be used to monitor bacterial or viral infections *in vivo* and, in particular, to gain a more detailed insight into the role and function of various virulence factors during infection (e.g. secreted bacterial effector proteins, outer membrane vesicles).

ONE DAY-OLD CHICKS AS A SOURCE OF ANTIMICROBIAL RESISTANT BACTERIA FOR COMMERCIAL LAYING HENS FARMS

M.A. Moreno[1], M. Ugarte[2], C. Bárcena[2], M. García[2], F. Esperón[3], J.L. Tadeo[4], L. Domínguez[2]
[1]Universidad Complutense de Madrid, Departamento de Sanidad Animal, Madrid, Spain
[2]Universidad Complutense de Madrid, Centro de Vigilancia Sanitaria Veterinaria, Madrid, Spain
[3]Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria, Centro de Investigación en Sanidad Animal, Valdeolmos, Spain
[4]Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria, Departamento de Medio Ambiente, Madrid, Spain

Backgrounds

Some antimicrobial resistant (AR) *Salmonella* spp. are detected on the national Spanish monitoring programmes in laying hens (LH) in spite of the few antimicrobials authorized for LH in Spain. Testing of AR on *Escherichia coli* from LH is not mandatory at European level but it is clear that AR on *E. coli* should be not lower than that on *Salmonella* spp., having besides a higher prevalence. Accordingly, *E. coli* is a good model for testing sources of AR bacteria in commercial LH farms.

Objectives

To test if AR *E. coli* isolates are introduced into a commercial LH farm by one day-old chicks and to follow its dynamics until entering table egg production.

Methods

Three batches of one day-old chicks from different hatcheries purchased by a commercial LH farm were sampled three times: when arriving to the farm (samples from 15 transport boxes) , at two weeks of age (samples from 10 manure belts) and some days before change to the laying house (18 weeks). Samples where pooled, diluted with peptone water and spread onto MacConkey agar plates (incubation at 37 ºC for 20-24 h). Ten presumptive *E. coli* colonies per sampling where picked, identified by PCR and AR determined using EUVSEC plates (Sensititre ®) containing 14 antimicrobials.

Conclusions

There are clear differences on AR *E. coli* (multiresistance patterns and resistance frequencies) between one day-old chicks batches from different suppliers; nevertheless, these indicators of AR tend to down at the end of the growing phase.

3-D CELL CULTURE METHODS TO ACHIEVE ANTI-CANCER DRUG

F.S. Mousavi[1], R. Heidarifar[2], H. Jamshidi[3], A. Daemi[1]
[1]Urmia Branch -Islamic Azad Univercity, Biotechnology, Urmia, Iran
[2]shahid beheshti university, medical school, teheran, Iran
[3]kermanshah university, medical school, kermanshah, Iran

Backgrounds

Many animal cells can be propagated outside the animal body. The isolated cells from the tissues and organs of animals may be at the right temperature in a medium containing nutrients and growth factors to grow into plastic containers. Cultured organs, tissues and cells of organisms in vitro cell culture is called two different applications in different branches of biological sciences

Objectives

Recent studies have demonstrated the potential of utilizing 3D cell culture models in drug discovery programs; however, it is evident that further research is required for the development of more complex models that incorporate the majority of the cellular and physical properties of a tumor.

Methods

The methods for culturing cells in 3D utilizing lrECM as a subtrate involves seeding a single cell suspension either on top of matrices (3D ‘on top’ assay) or mixed into lrECM (3D ‘embedded’ assay), which promotes the formation of cells into 3D structures in a time-dependent manner . LrECM is not the only biologically relevant matrix available for 3D cell culture. Collagen I has also been utilized as a substrate for culturing tumor cells in 3D systems.

Conclusions

A clearer understanding of the complex mechanisms influencing the mode of action and efficacy of cancer therapeutics is essential to move closer towards the goal of eradicating cancer cells in the patient. Research into new 3D tumor models that more closely represent the tumor microenvironment in systems that are scalable to meet the requirements of screening practices is underway, with notable progress published recently

INTERFERENCES IN CLINICAL DIAGNOSIS CAUSED BY THE PRESENCE OF INFECTIOUS BACTERIOPHAGES IN THE HUMAN BODY

B.J. Maryury[1], F. Navarro[2], M. Muniesa[1]
[1]Universitat de Barcelona, Genetic- Microbiology and Statistics, BARCELONA, Spain
[2]Hospital de la Santa Creu i Sant Pau- Institut d'Investigació Biomèdica Sant Pau, Service of Microbiology, Barcelona, Spain

Backgrounds

Bacteriophages have re-emerged as powerful regulators of the bacterial populations in natural ecosystems. As in natural environments, phages invade the human body and they are the most numerous group of virus in human viromes of healthy individuals. This is revealed in recent metagenomic studies, despite the presence of phages in human bodies was described decades ago. The influence of the presence of phages in humans has yet to be evaluated, but it could be envisaged a clear influence in the regulation of bacterial populations, that might have later an impact in human health.

Objectives

To explore the presence of phages in clinical samples and to evaluate how these phages could interfere in clinical diagnosis.

Methods

Clinical samples (blood, ascitic, urine, cerebrospinal fluid and serum) were evaluated for the presence of infectious bacteriophages able to propagate and lyse *E. coli* and *Pseudomonas* host strains. The presence of phage particles was confirmed by electron microscopy.

Conclusions

Infectious tailed phages were detected in >46% ascitic and urine samples. The presence of phages was shown to hinder bacterial isolation in some of these samples, either by preventing the confluent bacterial growth required for an antibiogram assay, by reducing the bacterial growth in liquid enrichment or by killing the bacteria present in a sample, confounding the diagnostic. The presence of phages in human samples, most of the times not considered, can influence and bias the results of microbiological and molecular results, suggesting that more attention should be paid to their interference.

THE ROLE OF MAGNETOSOMES ON THE TOLERANCE TO HEAVY METALS IN MAGNETOTACTIC BACTERIA

D. Muñoz-Rodríguez[1], L. Marcano[2], R. Martín-Rodríguez[3], A. García Prieto[4,5], J. Alonso[2,5], M.L. Fdez-Gubieda[2,5], A. Muela[1,5]

[4]Universidad del País Vasco UPV/EHU, Física Aplicada I, Leioa, Spain
[5]BCMaterials, Building No.500- Parque Tecnológico de Zamudio, Derio, Spain

Backgrounds

Magnetotactic bacteria are a group of aquatic prokaryotes capable of navigating along the Earth´s magnetic field lines thanks to the production of internal magnetic nanoparticles called magnetosomes. These nanoparticles, whose synthesis is genetically controlled, are the subject of intensive research because of their well-defined magnetic properties, becoming really useful in biotechnological applications (1). Currently, the generally accepted role of magnetosomes is based on magnetoaerotaxis hypothesis: these magnetosomes favour the alignment of the bacteria with the geomagnetic field lines, allowing them move in a chemical redox gradient in a more efficient way within the water column (2). However, it is still not clear if the magnetic navigation is the only purpose of producing such organelles.

Objectives

In the present work, we explore a new possible role of magnetosomes as `protective shields´ against metal stress induced by the presence of heavy metals.

Methods

With this aim we have determined the resistance profiles to several transition metals (Co, Mn, Ni, Zn and Cu) in *Magnetospirillum gryphiswaldense* MSR-1, either when bacteria present magnetosomes or not. We have observed that the tolerance to the different metals is significantly higher (up to six-fold higher in Mn) when the bacteria present magnetosomes. Moreover, we have proved by magnetic and structural characterization techniques the incorporation of some of these elements into the magnetosome structure.

Conclusions

The incorporation of metals other than Fe into the magnetosome structure opens up the possibility of using magnetotactic bacteria as a tool in bioremediation applications such as biomagnetic recovery of metals from raw sewage (3).

[2]BCMaterials, No.500 Building- Parque Tecnológico de Zamudio, Derio, Spain
[3]Universidad del País Vasco, Electricidad y Electrónica, Leioa, Spain
[4]Universidad del País Vasco, SGIker Medidas Magnéticas, Leioa, Spain
[5]Universidad del País Vasco, Física Aplicada II, Leioa, Spain

Backgrounds

Magnetotactic bacteria are ubiquitous aquatic prokaryotes able to synthesize intracellular membrane-bound magnetite or greigite nanoparticles called magnetosomes (1). Currently, the magnetosomes provoke great attention thanks to several outstanding physical and magnetic properties (uniform morphology, thermally stable magnetic moment, high biocompatibility), that make possible their use in biomedical applications, such as magnetic resonance imaging or magnetic hyperthermia for cancer treatment. Based on the higher sensitivity of cancerous cells to temperature increase compared to healthy tissue (2), the hyperthermia treatment makes use of the heat-releasing power of magnetic nanoparticles when exposed to an alternating magnetic field (AMF) to produce cell death. Indeed, magnetosomes hold high potential for hyperthermia applications, since they have shown very promising heating capacity (3).

Objectives

In the present work, the efficiency of magnetosomes as heat generators and their impact on cell viability has been checked on murine macrophage cells in *in vitro* tests.

Methods

Our results clearly indicate that the hyperthermia treatment causes both cell death and inhibition of cell proliferation. Specifically, only 36% of the treated macrophages remained alive 2 h after alternating magnetic field exposure, and 24 h later the percentage fell to 22%.

Conclusions

This reduction confirms the suitability of the magnetosomes as efficient heat nanogenerators in hyperthermia treatments.

GFP-BINDING APTAMER - A TOOL FOR RECOMBINANT PROTEINS PURIFICATION

K. Muszynska[1], E. Kowalska[1], F. Bartnicki[1], M. Bodaszewska-Lubas[1], W. Strzalka[1]
[1]Jagiellonian University, Plant Biotechnology, Krakow, Poland

Backgrounds

Green Fluorescent Protein (GFP) is often used as a tag of cellular proteins. It is very useful in a broad range of studies including detection and enumeration of bacteria, monitoring of microorganisms survival, gene expression and protein localisation. Despite the fact that GFP is a very powerful tool for prokaryote and eukaryote cells studies, the purification of GFP-tagged proteins from such material is limited to anti-GFP antibodies or other conventional chromatography methods.

Objectives

Due to popularity of GFP in cell biology research, the aim of the study was to develop a DNA aptamer, which could be used for the purification of GFP-tagged proteins from microbial, plant and animal cells.

Methods

The selection of the DNA aptamer was performed by the SELEX method (Systematic Evolution of Ligands by Exponential Enrichment). GFP used in selection process was overexpressed and purified from *E.coli* BL21 strain. After the sixth round of selection the pool of ssDNA molecules was cloned and sequenced. The specificity of single aptamers was analyzed with the help of quantitative real-time PCR. Among the tested sequences, the aptamer characterized by the best binding to GFP was identified. The specificity of this aptamer was verified using the pull-down assay.

Conclusions

The results of study suggest that the developed aptamer might serve as a new tool for the purification of GFP-tagged proteins. Further research on the selected aptamer may expand variations of implements for protein purification.

PHARMACOLOGICAL ACTIVITY AND MECHANISM OF ACTION FOR SOME VEGETAL COMMERCIAL OILS ON ANTIBIOTIC RESISTANT AND BIOFILM FORMING MICROORGANISMS

H. Najee[1], C. Kamerzan[2], V. Lazar[3]
[1]Bucharest university-Faculty of Biology, Botany-Microbiology, Bucharest, Romania
[2]Research Institute of the University of Bucharest-ICUB, Microbiology, Bucharest, Romania
[3]Research Institute of the University of Bucharest-ICUB, Botany-Microbiology, Bucharest, Romania

Backgrounds

Discovering new antibacterial strategies represents a real scientific challenge, due to the antimicrobial resistance growing problem (among the eight top health global problems till 2020). Our aim was to assess the anti-pathogenic activity of the extracts from *Nigella sativa, Thymus vulgaris* and *Syzygium aromaticum* mixture (M-ST), *Origanum vulgare* and *Olea europaea* commercial oils, and to propose a mechanism of action for the tested extracts

Objectives

To investigate the biological activity of some medicinal plants extracts and essential oils on antibiotic resistant microbial strains and biofilm forming microorganisms

Methods

The clinical isolates were identified (by Vitek method) and characterized for their antibiotic resistance profile (by disc diffusion method). A set of 43 strains, belonging to four representative microbial species were studied*: Pseudomonas aeruginosa*, *Escherichia coli*, *Staphylococcus aureus* and *Candida albicans*. The antimicrobial activity of the commercial extracts was assessed by using the binary serial dilution method, the concentrations ranges being oil specific. Two other techniques were used, i.e. the crystal violet staining for the anti-biofilm activity and flow cytometry, for identifying the mechanism of action for the tested extracts (cell coatings permeation, or efflux pumps inhibition).

Conclusions

Our results proved that the tested oils are valuable alternatives for the development of novel anti-pathogenic strategies. Future tests will be made for comparative analysis of the effect exhibited by commercial *vs* freshly extracted fatty and essential oils.

ANTIMICROBIAL PROPERTIES OF POLYPHENOL EXTRACTS FROM TWO AUTOCHTHONOUS BEAN LANDRACES OF THE CAMPANIA REGION, SOUTHERN ITALY, BEFORE AND AFTER COOKING

F. Nazzaro[1], M.N. Ombra[1], A. d'Acierno[1], R. Coppola[2], M. Zaccardelli[3], C. Pane[3], P. Spigno[4], R. Riccardi[4], F. Fratianni[1]

[3]CREA, CREA, Pontecagnano SA, Italy
[4]Cooperativa ARCA 2010, Cooperativa ARCA 2010, Acerra NA, Italy

Backgrounds

Common beans (*Phaseolus vulgaris*) represent a worthy supply of essential nutrients and phenolic compounds with resourceful health benefits. However, the biochemical and structural changes resulting from cooking processes, can, in a certain sense, alter or diminish some of such advantages.

Objectives

Polyphenol-rich extracts of two indigenous landraces of *Phaseolus vulgaris*, “Nero di Frigento” and “Nero di Acerra”, cultivated in the Campania region, Southern Italy, were analyzed, before and after cooking of beans, to determine their potential antimicrobial activity.

Methods

Antimicrobial activity was evaluated through the inhibition halo test using two pathogen strains, S*taphylococcus aureus* and *Pseudomonas aeruginosa.*

Conclusions

Polyphenolic extracts of the uncooked “Nero di Frigento” beans showed antimicrobial activity against *Ps. aeruginosa*, and a halo of 18.3 mm of diameter was visualized using 5 µg of the extract. The activity was even higher using the same amount of extract after cooking, with the formation of a halo of 25 mm in diameter. Polyphenols of uncooked “Nero di Acerra” beans were inactive against *Ps. aeruginosa.* Such activity was observed after cooking, and 5 µg of such extract produced zones of inhibition of about 9.67 mm. Polyphenols of cooked “Nero di Acerra” were also active against *St.aureus*, at 5 µg. Results seem interesting considering, for example, the fate of polyphenols in the gut and how they can affect the survival of pathogens or probiotics. Further research is underway to understand the influence of individual polyphenols, before and after cooking of beans, on different helpful and pathogen bacteria.
Unknowledgment: The work was supported by "SALVE" and "AGRIGENET" projects, PSR 2007-2013, Campania region

ANTIMICROBIAL ACTIVITY OF POLYPHENOLS EXTRACTED BY TWO DIFFERENT EVOOS OF THE IRPINIAN PROVINCE, IN SOUTHERN ITALY

F. Nazzaro[1], A. d'Acierno[1], R. Cozzolino[1], A. Martignetti[1], R. Coppola[2], F. Fratianni[1]
[1]Istituto di Scienze dell'Alimentazione - CNR, DiSBA-CNR, Avellino, Italy
[2]DiAAA, DiAAA-University of Molise, Campobasso, Italy

Backgrounds

Extra virgin olive oil (EVOO), the most valuable olive oil category, is greatly appraised around the world for its healthy properties, chiefly due to the presence of monounsaturated fatty acid and antioxidant compounds (polyphenols, tocopherols, etc). In recent times, phenolic compounds present in olive oil stimulated scientific attention due to their beneficial functional and nutritional effects including antioxidant and antimicrobial activities. Production of EVOO represents an important element for the economy of Province of Irpinia in the Campania region, Southern Italy.

Objectives

Our study aimed to evaluate the antimicrobial properties of total polyphenols of EVOOs “Ravece” and “Ruveia”, both cultivated in the village of Montella of Irpinia province.

Methods

Polyphenols from EVOOs "Ravece" and "Ruveia" were obtained following the method of Bayram et al (2012).Total polyphenols were determined (Singleton and Rossi 1965). The antimicrobial activity was evaluated using 4.9 µg of polyphenol extracts of Ravece and Ruveia, as a zone of inhibition, against the human harmful and foodborne pathogens *Bacillus cereus*, *Staphylococcus aureus and Escherichia coli*.

Conclusions

Both extracts were effective in inhibiting the growth of *E. coli* and *B. cereus*. Despite higher content in the total polyphenols, sample "Ruveia" did not give a corresponding greater antimicrobial activity, normalizing the test in terms of GAE polyphenols amount, against the pathogens, respect to "Ravece". However, polyphenols of "Ruveia" but not those of "Ravece" showed activity against the methicillin-resistant strain of *S. aureus*.
Further studies will try to evaluate the influence of individual polyphenols present in the EVOOs on the activity *versus* different pathogens.

INVESTIGATING THE EFFECT OF EFFLUX PUMP INHIBITORS TO CIPROFLOXACIN EFFICACY IN CLINICAL ISOLATES OF ACINETOBACTER SPP.

U. Kayiş[1], S. Ökten[2]
[1]Trakya University Institute of Health Sciences, Department of Basic Pharmaceutical Sciences, Edirne, Turkey
[2]Trakya University Faculty of Pharmacy, Department of Pharmaceutical Microbiology, Edirne, Turkey

Backgrounds

Drug resistance has been a great problem for the treatment of infections. The most realistic approach in recent years is researching the inhibition of resistance and enlightening the inhibition mechanisms rather than synthesizing new compounds.

Objectives

In this study, it is aimed to determine i) the effect of PAβN, CCCP and NMP on MIC of ciprofloxacin, ii) to obtain the ideal inhibitor concentration that eliminates the ciprofloxacin resistance.

Methods

Sixty-seven ciprofloxacin resistant *Acinetobacter baumannii* isolated from Trakya University Hospital were included in the study. Ciprofloxacin susceptibility was investigated for these isolates in absence and presence of PAβN, CCCP and NMP. Antimicrobial susceptibility testing was done by microdilution method through the guidelines of CLSI M100-S25. Thirty-two isolates determined to have 4 or more fold decrease in ciprofloxacin MIC values in the presence of the inhibitors, were included in checker board assay.

Conclusions

In the presence of 25mg/L PAßN, CCCP and NMP; 32.83%, 61.50% and 32.30% of the isolates were detected to be susceptible to ciprofloxacin, respectively. In the presence of 100mg/L PAßN, CCCP and NMP; 40.30%, 100% and 61.50% of the isolates were detected to be susceptible to ciprofloxacin, respectively. FIC indexes and inhibitor concentrations that inhibit ciprofloxacin resistance were calculated according to the checker board assay results. The effect of the combinations was reported as synergic or additive.

THROMBOCIDIN DERIVATIVES AND THEIR ACTIVITY ON THE BACILLUS SUBTILIS CELL ENVELOPE

S. Omardien[1], H. van Veen[2], L. Hamoen[1], J.W. Drijfhout[3], S.A.J. Zaat[4]
[1]University of Amsterdam, Swammerdam Institute for Life Sciences, Amsterdam, The Netherlands
[2]Academic Medical Centre AMC, Central Electron-Microscopy, Amsterdam, The Netherlands
[3]Leiden University Medical Center LUMC, Immunohematology and Blood Transfusion, Leiden, The Netherlands
[4]Academic Medical Centre AMC, Medical Microbiology, Amsterdam, The Netherlands

Backgrounds

Cationic antimicrobial peptides (CAMP) have been proposed as an antibiotic candidate, but presently the mode of action of many antimicrobial peptides to cause bacterial cell death remains abstruse.

Objectives

In this study two CAMPs, TC-19 and TC-84, were characterized by determining their effect on vegetative cells and spores of gram-positive bacteria, using *Bacillus subtilis* strain 168 as a model organism. TC-19 and TC-84 are derivatives of thrombocidins, the major CAMPs of human blood platelets.

Methods

Transcriptomic analysis using microarrays was employed to observe the response of the bacterium to sublethal concentrations. Transmission electron microscopy was used to observe cell envelope deformities. Laurdan was employed to observe changes in membrane fluidity. *Bacillus subtilis* mutant strains expressing proteins fused to the green fluorescent protein (GFP) were examined for delocalization of proteins involved in essential cellular processes. Alexa Fluor® 488 labelled TC-84 was used to evaluate the binding site of this peptide to vegetative cells and spores. Real-time microscopy was employed to determine spore germination or outgrowth inhibition.

Conclusions

The transcriptomic and microscopy results show that TC-19 and TC-84 are bactericidal by targeting the *B. subtilis* cell envelope. The distortion leads to changes in the fluidity of the membrane, causing the delocalization of essential proteins. TC-19 and TC-84 targets the cytoplasmic membrane of germinated spores preventing outgrowth.

COEVOLUTION BIOMARKERS AND HUMAN SUSCEPTIBILITY TO GASTRIC CANCER IN A POPULATION OF THE COLOMBIAN ANDES

V. Pabon Figueroa[1], A. Angulo[1], J.C. Caguazango[2], A. PAZOS[2]
[1]University of Nariño, Centro de Estudios en Salud CESUN, Pasto, Colombia
[2]University of Nariño, Biology, Pasto, Colombia

Backgrounds

Helicobacter pylori infection is the main risk factor for the development of gastric cancer (GC), however, the prevalence of infection does not predict the incidence of the disease, so it is necessary to understand the host-bacteria relationship as a key factor in gastric etiopathogenesis. In Colombian populations it has been previously identified that the disruption of coevolution of the human-*H.pylori* genome is associated with a greater severity of gastric lesions.

Objectives

To analyze the association between human-*H. pylori* coevolution, human genetic susceptibility to GC and gastric disease in a population of the Andes of Colombia (Túquerres-Nariño).

Methods

We included 82 patients with analysis of human and bacterial ancestry. The genotypes of gene polymorphisms of cytokine IL1β (-511 C/T), IL10 (-819C/T), (-1082 G/A) and TNFα (-308 G/A) were determined by PCR-RFLPs technique and IL1-RN * 2 by standard PCR. We used the logistic regression model to establish the possible association between different biomarkers in the function of gastric lesions.

Conclusions

In the high-risk GC population studied, 70% of patients were carriers of the risk alleles -511T(76%), -819T(81%) and 1082A(54%). This high frequency of risk alleles could predispose individuals as a complementary risk factor to *H. pylori* infection for GC development. The disruption of human-H. pylori coevolution was associated with the presence of atrophic gastric lesions, which could explain the high incidence of GC in the population of the Colombian Andes (OR=5.25, 95% CI: 1.52 -18,10). No association was found between biomarkers of genetic susceptibility to GC (cytokine polymorphisms) and disruption of human-*H. pylori* coevolution.

PERFORMANCE OF LINE PROBE ASSAY FOR DETECTION OF MDR-TB ON RT-PCR POSITIVE SPUTUM SAMPLES

M.S. Park[1], D.H. KIm[1], Y.M. Kim[1], S.H. Kim[1]
[1]Korea National Institute of Health, TB and respiratory infections, Cheongju, Republic of Korea

Backgrounds

Rapid, accurate diagnosis of drug resistant-TB is critical for timely initiation of treatment and control of disease. Line probe assays (LPAs) were endorsed by the WHO for molecular detection of drug resistance. But application of LPAs to sputum samples is still limited on smear-positive samples.

Objectives

In this study, we evaluate the diagnostic performance of genotype MTBDRplus v1.0 on three commercial RT-PCR kits, GeneXpert MTB/RIF, Anyplex MTB/NTM, and Genedia MTB/NTM, positive samples.

Methods

A total of 678 consecutive specimens were tested with RT-PCR kits and positive samples on either NAATs were subjected to the MTBDRplus. The results of RT-PCR kits were divided into 2 group; low and high bacteria load by CT values and performance characteristic of MTBDRplus was assessed to the MGIT 960 drug susceptibility test.

Conclusions

Of 678 samples, 53.5% MTB isolates were grown in MGIT 960, of which 82.7% were RT-PCR positive, of which 56.5% were interpretable by MTBDRplus. When put the low CT group from RT-PCR as the criteria for application of MTBDRplus, 167 of Xpert, 155 of Seegene, 146 of Genedia positive samples were interpretable by MTBDRplus compared with 127 of smear-positive specimens. The sensitivities of MTBDRplus for the detection of isoniazid and rifampicin resistant from all group were 100%, respectively, and the specificities were comparable across all systems. These findings suggest that put the CT values of RT-PCR as a criteria for application of MTBDRplus, not only accuracy but also affordable sample numbers were increased compared with acid fast staining.

THE ARCHAEAL DIVERSITY IN HUMAN BODY

M.R. Pausan[1], K. Koskinen[1], M. Beck[2], A.K. Perras[1,2], E. Jantscher-Krenn[3], R. Krause[1], C. Moissl-Eichinger[1]
[1]Medical University of Graz, Internal Medicine, Graz, Austria
[2]University of Regensburg, Microbiology and Archaea, Regensburg, Germany
[3]Medical University of Graz, Obstetrics and Gynecology, Graz, Austria

Backgrounds

Trillions of microbes live in and on the human body, forming the human microbiota. These complex communities contain taxa from all three domains of life (Bacteria, Eukarya and Archaea) as well as viruses. These microorganisms function like an “invisible organ” by helping in energy harvest and storage, contributing to metabolic functions, protecting humans against pathogens, and educating the immune system. Most studies target the predominant bacterial community of this “invisible organ” and the (so far detected) not-pathogenic archaeal community and its diversity remains largely hidden. Since archaea have been associated mainly with the human gut and oral microbiome, little is known about the presence and diversity of archaea in other body sites.

Objectives

In this study, we aim to explore the archaeal diversity and presence in different body sites of the human body (e.g. nose, lung, vagina, appendix, and oral).

Methods

The study is based on a NGS approach, by amplifying the archaeal 16S rRNA with specific primers and analyzing the results through dada2 pipeline and R.

Conclusions

The archaeal diversity within the human body is higher than it was expected and is not only composed of archaea from Euryarchaeota phylum, but also Thaumarchaeota and Woesearchaeota. Furthermore, the methanogenic archaea that are mainly associated with the gut and oral microbiome are rather present in other body sites as well like the human nose and in the lung. This indicates that the archaea as bacteria are present in different body sites and are not restricted to a specific body site.

DESIGN, SYNTHESIS AND IN VITRO AND IN VIVO ACTIVITY OF FUROXAN DERIVATIVES AGAINST MYCOBACTERIUM TUBERCULOSIS

F. Pavan[1], P. Souza[2], L. Marino[2], C. Ribeiro[2], G. Fernades[2], M.C. Chung[2], R. Fruttero[3], J. Santos[2]
[1], Araraquara, Brazil
[2]UNESP, Biological Sciences, Araraquara, Brazil
[3]Università degli Studi di Torino, 3Dipartimento di Scienza e Tecnologia del Farmaco, Turin, Italy

Backgrounds

Tuberculosis (TB) remains a serious health problem responsible to cause millions of deaths annually. As many others infectious diseases, no or few drugs were developed after the gold age (until 60´s).

Objectives

Design, synthesize and evaluate *in vitro* and *in vivo* a novel series of hybrid furoxan derivatives against *Mycobacterium tuberculosis* (Mtb).

Methods

In vitro – Determination of minimal inhibitory concentration (MIC_{90}) against clinical isolates (susceptible and resistant) was performed by Resazurin Microtiter Assay (REMA) and cytotoxicity assay (IC_{50}) on MRC-5 and J774A.1 cells; activity against non-replicant bacteria by LORA (Low Oxygen Recovery Assay); mutagenicity was performed by AMES test; time-kill curve was performed by 20 days of incubation; stability study was performed by HPLC and finally, microarray to determine the mechanism of action. *In vivo* – Oral bioavailabity for pharmacokinetic (PK) screening and infection/treatment were performed by BALB/c mice.

Conclusions

A library of forty compounds were synthesized and tested against Mtb and cytotoxicity. Of those, we chose the best compound to proceed further studies, the compound 14c ((E)-4-(4-((2-isonicotinoylhydrazono)methyl)phenoxy)-3-(phenylsulfonyl)-1,2,5-oxadiazole 2-oxide. 14c compound showed good activity against non-replicant bacteria and all clinical resistant isolates. Not mutagenic. Bactericidal pharmacodinamic. Showed to be stable at pH 7.0 and 5.0 and seems to inhibit protein synthesis as mechanism of action. *In vivo* showed good PK and after 20 days of treatment with 200 mg/kg of body weigh sterilizing effect. Based on these results we are performing others further studies but we are able to conclude 14c as promising new class against TB.

REPURPOSING CLINICALLY APPROVED CEPHALOSPORINS FOR TUBERCULOSIS THERAPY

S. Ramon Garcia[1], R. González del Río[2], A. Santos Villarejo[2], G. Sweet[3], F. Cunningham[2], D. Barros[2], L. Ballell[2], A. Mendoza-Losana[2], S. Ferrer-Bazaga[2], C. Thompson[3]
[1]University of Zaragoza, Department of Microbiology, Zaragoza, Spain
[2]GlaxoSmithKline - Diseases of the Developing World, TB DPU, Tres Cantos, Spain
[3]University of British Columbia, Department of Microbiology, Vancouver, Canada

Backgrounds

While modern cephalosporins developed for broad spectrum antibacterial activities have never been pursued for tuberculosis (TB) therapy, we explored their potential repositioning as new anti-TB drugs.

Objectives

We previously demonstrated that combinatorial drug therapy might be employed to increase the efficacies of available antibiotics, allowing them to be repurposed for TB therapy within synergistic combinations [doi: 10.1128/AAC.00474-11]. Rifampicin, the cornerstone drug for TB therapy, is not administered at its optimal clinical dose due to long-established toxicity concerns. If the anti-mycobacterial activity of rifampicin could be increased, TB therapy could be shortened, thus reducing the rate of transmission and the emergence of drug resistance.

Methods

We screened an in-house library of ca. 600 commercially available antibiotics, and found that (i) cephalosporins had strong synergies with rifampicin and ethambutol, a first-line anti-TB drug (4- to 64-fold more active in combination than either drug alone); (ii) common chemical patterns required for single drug activity against *Mtb* were identified using structure-activity relationships (SAR) studies; (iii) synergy was observed even under intracellular growth conditions where beta-lactams typically have limited activities; (iv) cephalosporins and rifampicin were synergistic but limited synergy was observed with rifapentine or rifabutin; (v) Clavulanate was a key synergistic partner in triple combinations, together with cephalosporins rescued the activity of rifampicin against a rifampicin resistant strain; (vi) uptake experiments demonstrated that synergy was not due exclusively to increased rifampicin accumulation within the mycobacterial cells, and; (vii) cephalosporins were also synergistic with new anti-TB drugs such as bedaquiline and delamanid.

Conclusions

We identified first generation cephalosporins having clinically relevant inhibitory concentrations, both alone and in synergistic drug combinations. Cephalosporins are orally bioavailable with good safety profiles; together with their anti-mycobacterial activities reported here, it suggests that they could be repurposed within new combinatorial TB therapies.

ASSESSMENT OF NULL MUTATIONS IN GSTT1 AND GSTM1, TLR 2 POLYMORPHISM (ARG677TRP) AND EFFICACY OF COMMONLY PREVAILING ERADICATION THERAPIES IN HELICOBACTER PYLORI INFECTED PATIENTS OF PAKISTAN

F. Rashid[1], H. Noor[2], M. Ali[2], R. Kamran[3], A. Yameen[4], T. Ahmad[4], F. Rasheed[5]
[1], Islamabad, Pakistan
[2]Pakistan Institute of Medical Sciences, Department of Gastroenterology, Islamabad, Pakistan
[3]Pakistan Institute of Medical Sciences, Microbiology, Islamabad, Pakistan
[4]Pakistan Institute of Nuclear Science and Technology, Delta V Mass Spectrometer Lab, Islamabad, Pakistan
[5]Nuclear Medicine Oncology & Radiotherapy Institute, BreathMAT Lab, Islamabad, Pakistan

Backgrounds
The prevalence of H. pylori, its associated risk factors and efficacy of eradication therapies against it, varies widely in different geographical regions. In the developing countries H. pylori infection is more prevalent. Therefore, assessment of efficacy of prevailing eradication therapies as well as mutations is essential to decrease the epidemiology. Up till now, no study has been carried out to determine the association of TLR 2 (Arg677Trp) polymorphism as well as GSTT1 and GSTM1 polymorphism with H. pylori and gastro-duodenal diseases as genetic risk factor.
Objectives
To determine the prevalence and association of TLR-2 and GST genes polymorphism with H. Pylori infection along with efficacy and side effects of prevailing treatment therapies in the local population suffering from gastro-duodenal diseases.
Methods
A total of 159 patients were enrolled to determine the prevalence and effectiveness of first line eradication therapies namely standard triple therapy and sequential therapy as well as second line eradication therapies which included levofloxacin based triple therapy and moxifloxacin based triple therapy. The status of H. pylori infection in patients was determined by 13C Urea Breath Test. Also, 130 individuals (59 H. pylori infected and 71 H. pylori non-infected) were enrolled separately for PCR based detection of polymorphism in TLR-2 Arg677Trp (C2029T), GSST-1 and GSTM1 genes.
Results
The prevalence of H. pylori was found 72.3% in symptomatic population. The eradication rates for standard triple therapy, sequential therapy levofloxacin based therapy and moxifloxacin based therapy were 66.7%, 62.9%, 30.8% and 14.3% respectively. No association was found between SNP in TLR-2 Arg677Trp (C2029T) and null mutations in GSST-1 genes with H. pylori infection ($p>0.05$).
Conclusions
The prevalence of H. pylori infection was very high in Pakistani population with gastro-duodenal diseases. The resistance to prevailing first line and second line eradication therapies was also found very high in our region. Furthermore, gastro-duodenal disorders were not found associated with GSTM1 and GSTT1 null mutations as well as TLR-2 (Arg677Trp) polymorphism.

THE EFFECT OF RUMEN BACTERIA FROM SHEEP ADAPTED TO A TANNINIFEROUS DIET ON IN-VITRO FERMENTATION PARAMETERS OF PISTACHIO HULL BY-PRODUCT USING BOVINE INOCULUM

Y. Babaei[1], Y. Rouzbehan[1], D. Alipour[2]
[1]Tarbiat Modares University, Department of Animal Science, Tehran, Iran
[2]Faculty of Agriculture- Bu-Ali Sina University-, Department of Animal Science, Hamedan, Iran

Backgrounds

Backgrounds: Drought climatic conditions have led to a scarcity of ruminant feeds in many countries. The use of agricultural by-products such as pistachio hulls (PH) could be an alternative to conventional feeds in overcoming this problem. The major limitation of using these by-products is the presence of high levels of tannins which have a negative effect on ruminal fermentation parameters. Mature Taleshi sheep that consume tannin rich feeds such as oak leaves appear to have ruminal bacteria with defensive mechanisms against these polyphenols.

Objectives

Objectives: The capability of ruminal isolated tannin degrading bacteria from these animals (i.e., Taleshi sheep) to ferment a tanniniferous by-products (i.e., pistachio hulls) incubated with rumen fluid from Holstein dairy cows was assessed. Six Gram positive cocci were isolated from the rumen of the Taleshi sheep and their 16s rRNA gene sequences showed them to be closely related to *Streptococcus gallolyticus*.

Methods

Methods: In three runs of in vitro gas production (GP), the effect of two of these isolates incubated with buffered ruminal fluid of Holstein cow and PH was evaluated. The GP was recorded from 1 to 96 hours of incubation. Incubating either of the isolates with PH caused a significantly higher in vitro gas production, in vitro organic matter disappearance, metabolisable energy and volatile fatty acids than those without isolate.

Conclusions

Conclusions: The improvement in the ruminal parameters when either of the isolates was used suggested the possible presence of isolated tannin-degrading bacteria (*Streptococcus gallolyticus* sp.).

[3]Faculty of Pharmacy- Ahvaz Jundishapur University of Medical Sciences- Ahvaz- Iran, Medicinal Chemistry-, Ahvaz, Iran
[4]Agricultural and Natural Resources Center- Ahvaz- Iran, Agricultural and Natural Resources Center, Ahvaz, Iran

Backgrounds

Leishmaniasis is a major health problem global and affects millions of people especially in developing countries. Science, there is no immunoprophylaxis (vaccination) accessible for Leishmania infections and commercial drugs are unsatisfactory. .

Objectives

The objective of the present survey was to state the antileishmanial activity of two herbal medicine (*Satureja khuzestanica* leaf and *Heracleum persicum* fruit) extracts were evaluated against *Leishmania major* and *Leishmania infantum* using colorimetric MTT (2-(4,5-dimethyl-2-thiazolyl)-3,5-diphenyl-2H-tetrazolium bromide) assay and compared to the Glucantime as a reference.

Methods

The leaves extracts of selected plants were obtained by maceration. The *in vitro* assays were carried out on *Leishmania major* and *Leishmania infantum* using colorimetric MTT assay in comparison with Glucantime. The concentration-response curves tested extracts and glucantime solutions were designed and IC_{50} values were located.

Conclusions

Anti-Leishmina effects of *Satureja khuzestanica* and *Heracleum persicum* on *L. major* and *L. infantum* promastigote were revealed with 50% inhibitory concentration (IC50) values of 4.8 and 7.5 mg ml^{-1} for *Satureja khuzestanica*, 29.3 and 14.7 mg ml^{-1} for *Heracleum persicum*. In the comparison with the standard drug, glucantime, which had IC50 value of 40.2 mg ml^{-1} for *L.major* and 18.5 mg ml^{-1} for *L. infantum* promastigote after 72 hours incubation, respectively. ***Conclusions:*** These results revealed that compounds from *Satureja khuzestanica* and *Heracleum persicum* have anti-leishmania properties that necessary to survey the effects of these extracts on leishmania genus in animal models in future.
Keywords: Antileishmanial activity, *Leishmania major*, *Leishmania infantum*, Glucantime, Promastigote, MTT assay.

SELECTION OF BACTERIA FOR INDUCING TOLERANCE TO SALINITY AND TEMPERATURE STRESS IN TOMATO PLANTS

M.K. Sang[1], S.J. Yoo[1], J. Song[1], H.Y. Weon[1]
[1]National Academy of Agricultural Science, Agricultural Microbiology, Wanju-gun, Republic of Korea

Backgrounds

Abiotic stress such as salinity and temperature stresses are severe environmental constraint to agricultural productivity. Plant growth-promoting rhizobacteria(PGPR) could play an important role in alleviation of abiotic stress as well as biotic stress in plants.

Objectives

We investigated effects of bacterial strains on inducing tolerance to abiotic stress including salinity, high and low temperature in tomato plants.

Methods

To do this, we isolated 1,944 bacterial strains from rhizo- and endosphere of tomato plants in various regions in South Korea, and tested bacterial characters related to plant growth promotion including production of phosphate solubilization and indole-acetic acid (IAA), and activity of 1-aminocyclopropane-1-carboxylate (ACC) deaminase; bacterial adaptability to salinity(-70, -500, and -1000kPa salt solution) and temperature conditions(10, 25, and 40^{o}C). Through these in vitro assays, we pre-screened 46 strains, sequentially, tested plant trials in a greenhouse.

Conclusions

After challenging salinity or temperature stress to plants treated with bacterial suspension, we evaluated plant growth and selected four strains as potential agents to help plant tolerate abiotic stress including both high salinity and high/low temperature stress. We will investigate how the strains could interact with plants and alleviate abiotic stress by induced tolerance in tomato plants.

AEROGELS OF ENZYMATICALLY OXIDIZED GALACTOMANNANS FROM LEGUMINOUS PLANTS: VERSATILE ANTIMICROBIAL RELEASE SYSTEMS

T. Silvetti[1], P. Campia[2], L. Merlini[3], M. Brasca[1], Y. Galante[3]
[1]Institute of Sciences of Food Production ISPA-CNR, Italian National Research Council CNR, Milan, Italy
[2]Department of Agricultural and Environmental Sciences Production- Landscape- Agroenergy, University of Milan, Milan, Italy
[3]Institute of Chemistry of Molecular Recognition ICRM, Italian National Research Council CNR, Milan, Italy

Backgrounds

Thanks to their biodegradability and biocompatibility and their porous structure, polysaccharides nanostructured aerogels provide high added-value materials suitable to be loaded with active principles. In this study, new aerogels were obtained from enzymatic-oxidization of galactomannans (GM) extracted from the leguminous plants fenugreek, sesbania and guar. TEMPO-mediated, laccase oxidation of GM in aqueous solution caused a viscosity increase up to fifteen-fold, generating elastic and stable hydrogels, which, upon lyophilization, were converted into water-insoluble aerogels, capable of uptaking water or solvents several times their own original weight.

Objectives

The purpose of this work was to evaluate the efficiency of GM-based aerogels for the release of antimicrobial compounds in active form.

Methods

Antimicrobial actives used in the food (nisin, lysozyme), medical (polymyxin B) and industrial (5-chloro-2-methyl-4-isothiazolin-3-one/2-methyl-4-isothiazolin-3-one (CIT/MIT)) fields were absorbed into the aerogels from aqueous solutions. Repeated water rinsing, dry blotting and re-lyophilization of the hydrogels were performed to generate “loaded” aerogels. The release of the incorporated actives against *Pseudomonas aeruginosa, Serratia marcescens, Escherichia coli, Salmonella* Typhimurium, *Halvia alvei* and *Enterobacter cloacae* (polymyxin B) and *P. aeruginosa, E. coli, Staphylococcus aureus*, *Saccharomyces* spp., *Pichia* spp. and *Penicillium* spp. (CIT/MIT), *Clostridium tyrobutyricum* and *Enterococcus faecalis* (nisin), and *C. tyrobutyricum* (lysozyme) was monitored through biochemical, microbiological and spectrophotometric assays.

Conclusions

The actives released from GM-aerogels were able to control microbial growth *in vitro*, even in the presence of a relatively high cell concentration thus these biomaterials might represent innovative and versatile and sustainable carrier systems of active principles for food, biomedical and industrial applications.

ABCS OF A NOVEL ANTIMICROBIAL AGENT: ANTIBACTERIAL ACTIVITY, BACTERIAL "BACKTALK" AND COMPARATIVE CYTOTOXICITY

L. Tonoyan[1], G.T.A. Fleming[1], P.H. Mc Cay[1], V. O'Flaherty[1]
[1]National University of Ireland- Galway, Microbiology, Galway, Ireland

Backgrounds

In the context of growing antibiotic resistance, alternative therapies are urgently required. Peroxidase-catalysed systems produce effective antimicrobial agents, but have drawbacks associated with enzyme stability. Here, we report a novel and highly efficient biocidal complex (BC), generated by enzyme-free reaction between hydrogen peroxide and two oxidizable substrates (iodide and thiocyanate).

Objectives

This study aimed to evaluate the antibacterial properties, the potential for induction of resistance and cross-resistance, and to investigate the potential cytotoxicity of BC.

Methods

Micro-dilution and time-kill assays were used to determine minimum inhibitory, bactericidal concentrations and killing kinetics of BC. Mono- and dual-species biofilms were established in modified Robbin's devices and the biofilm eradication concentrations of BC were defined. Multi-passage studies were performed in the presence of sub-inhibitory concentrations of BC to select for resistance, whereas, chemostats were used to investigate bacterial adaptation to BC and resistance to levofloxacin under nutrient limiting environment. MTT, haemoglobin release and comet assays were used for the evaluation of cytotoxicity, haemolytic activity and genotoxicity.

Conclusions

BC was a potent bactericidal agent, causing rapid death of pathogenic bacteria in planktonic and biofilm forms. Bacteria exposed to BC failed to develop resistance after serial passages. Furthermore, chemostats operated with BC-selection pressure yielded population with no altered susceptibility towards BC and levofloxacin, revealing that BC usage was not promoting tolerance to itself and cross-resistance to antibiotics. Cytotoxicity studies indicated non-selective cytotoxic (yet biocompatible), dose-dependent haemolytic and non-genotoxic profile of BC. Thus, it may be used to treat infection sites and to decontaminate surfaces.

THE PESTICIDE BEHAVIOR AND AZOLE RESISTANCE DEVELOPMENT IN RICE PADDY FIELDS

A. Vaezi[1], *H. Badali*[1], *H. Fakhim*[1]
[1]*mazandaran university of medical sciences, Medical Mycology and Parasitology, sari, Iran*

Backgrounds

Trend of azole resistance in *Aspergillus fumigatus* in different continents is important to conduct surveillance studies to prevent and control aspergillosis and antifungal stewardship. Tricyclazole is an agrochemical fungicide belonging to the class of triazole, commonly used in paddy rice fields in Asian countries which inhibits the pentaketide (DHN) and branch pathways of melanin synthesis in *Pyricularia oryzae*. Although emerging azole resistance contributes to treatment failures is unknown, triazole fungicide use in agriculture has been linked to this phenomenon in Europe.

Objectives

We aimed to study the current status of azole resistance *A. fumigatus* obtained from paddy fields with exposure to tricyclazole.

Methods

A total of 108 soil sampling were collected from four different locations of paddy fields in Mazandaran, 31 (28.7 %) of soil samples harbored *A. fumigatus*. 11 of 31 *A. fumigatus* isolates grew on SDA supplemented with itraconazole or voriconazole at 48 °C. The isolates were confirmed by partial sequencing of the β-tubulin gene. In vitro antifungal susceptibility tests of 11 isolates were performed against seven antifungal agents based on CLSI guideline (M38-A2).

Conclusions

Posaconazole and voriconazole were 2 log ^{2}-dilution steps and 3 log ^{2}-dilution steps less active than luliconazole and lanoconazole, respectively. The highest MICs in increasing order were constantly found with luliconazole, lanoconazole, posaconazole, caspofungin and amphotericin B. Only two *A. fumigatus* isolates harboured TR34/L98H variant. In contrast, TR46/Y121F/T289A and other point mutations were not detected in the *CYP51A* promoter region. In this study, one might conclude that tricyclazole, with different mechanism of action against medical azoles, induce azole resistance in *A. fumigatus* isolates. Further knowledge about the role of tricyclazole on the azole resistance development is required, in order to avoid a highly dangerous pesticide selection pressure that would enhance the risk of azole resistance.

POTENTIAL OF USING HISTIDINE KINASE INHIBITORS AGAINST COLISTIN-RESISTANT KLEBSIELLA PNEUMONIAE

N. Velikova[1]
[1]*Wageningen University, Animal Sciences, Wageningen, Netherlands Antilles*

Backgrounds

Antimicrobial resistance in general, and colistin resistance in particular, requires the urgent development of novel approaches to fight resistant pathogens. Bacterial two-component systems have been linked to colistin resistance in *Klebsiella pneumoniae*. Here, we report the potential to use recently discovered bacterial histidine kinase inhibitors against colistin-resistant *K. pneumoniae* and the other ESKAPE pathogens.

Objectives

The objectives of the presented work were to study the synergistic effect of histidine kinase inhibitors and colistin *in vitro* and *in vivo*.

Methods

Microdilution assays to determine fractional inhibitory concentrations
G. mellonella larvae as an infection model to study the synergistic effect in vivo

Conclusions

Research in progress

MOLECULAR CHARACTERIZATION FOR ESBL GENES OF E.COLI ISOLATES FROM LIVESTOCK ANIMALS IN ITALY REVEALS HIGH PREVALENCE OF TEM AND LOW PREVALENCE OF CTX-MI GENES

S. Migliore[1], B. Amato[2], M. La Giglia[1], C. Piraino[3], M. Goria[4], V. Di Marco Lo Presti[2], M. Vitale[5]
[1]Istituto Zooprofilattico Sperimentale della Sicilia, Molecular Biology, Palermo, Italy
[2]Istituto Zooprofilattico Sperimentale della Sicilia, Area barcellona P.G., Palermo, Italy
[3]Istituto Zooprofilattico Sperimentale della Sicilia, Diagnostica Specialistica, Palermo, Italy
[4]Istituto Zooprofilattico Sperimentale of Piedmont, Molecular Biology, Turin, Italy
[5]Zooprofilattico Sperimentale della Sicilia, Molecular Biology, Palermo, Italy

Backgrounds

Pathogenic strains of *Escherichia coli* (*E. coli*) are classified as: enterotoxigenic *E. coli* (ETEC); enteroinvasive (EIEC), enteropathogenic (EPEC) and enterohemorrhagic (EHEC). These groups differ in their epidemiology and pathogenesis and their O:H serotypes. The presence and diffusion of antibiotic resistance such as extended spectrum of beta lactamases (ESBL) is a growing problem for several gram-negative bacteria. The first plasmid-mediated ß-lactamase was described in the early 1960s from a single strain of *E. coli* isolated from a patient named Temoniera in Greece (TEM). TEM-1 gene is now found in many different species of the family *Enterobacteriaceae*

Objectives

The aim of the study was the analysis of virulent genes and ESBL genes in *E .coli* strains isolated from livestock animals. A total of 36 isolates from cattle and pigs were analyzed.

Methods

Genetic analysis were performed by multiplex PCRs. Two PCRs target the genes *aggR, aap, aatA, astA, pet, shf , irp2, set1A* and *eae.* Other two Multiplex PCRs target genes encoding ß-lactamases: TEM, OXA, SHV, CTX-M, CMY and DHA type β-lactamases.

Conclusions

On a total of 30 *E.coli* isolates from livestock 20 resulted positive for TEM only. 5 resulted positive for both TEM and CTX- MI and 11 were completely negative for ESBL genes. Interestingly the different prevalence was probably related to farm management since higher prevalence of virulence and ESBL genes was present in intensive farming in contrast to extensive and traditional farm management.

Acknowledgement: The research is supported by grant CCM2015AMR of Italian Ministry of Health

EFFICIENT REMOVAL OF BISPHENOL A AND DICLOFENAC BY LACCASE FROM PLEUROTUS OSTREATUS

K. Wlizło[1], *J. Polak*[1], *A. Jarosz-Wilkołazka*[1]
[1]*Maria Curie-Skłodowska University, Department of Biochemistry, Lublin, Poland*

Backgrounds

The problem encounters by the modern biotechnology is the bioremediation of wastewaters contaminated by commonly used compounds, such as bisphenol A (BPA), used in the plastic industry, and diclofenac (DCF), popular anti-inflammatory pharmaceutical. Considering an endocrine disrupting activity of BPA and a negative effect of DCF on water organisms, the degradation of those compounds has become an important and extensively studied issue. There are some papers indicating the possibility of BPA and DCF degradation by microorganisms such as *Bacillus amyloliquefaciens*, *Pseudomonas aeruginosa* or ammonia oxidizing bacteria, however, the application of ligninolytic fungal enzymes such as laccase may provide even higher efficiency of this process.

Objectives

The aim of presented work was to determine the ability of laccase from *Pleurotus ostreatus* to the degradation of bisphenol A and diclofenac by the enzyme with or without addition of specific mediators increasing the efficiency of the reaction.

Methods

Purified laccase from *P. ostreatus* was incubated with BPA or DCF with or without addition of TEMPO or ABTS used as mediator. The transformation process was analyzed using high performance liquid chromatography (HPLC).

Conclusions

Laccase from *P. ostreatus* was an efficient biocatalyst during BPA non-mediated degradation, whereas degradation of DCF was more efficient in the presence of mediators. However, the addition of mediators had an impact on different products formation during degradation process, which will be further studied by the ecotoxicity evaluation using *Vibrio fisheri*.

This work was partially supported by National Science Centre (2015/17/N/NZ9/03647).

IDENTIFICATION OF ANTIBACTERIAL COMPOUNDS IN PROPOLIS AND MECHANISTIC INSIGHT INTO ITS BACTERICIDAL ACTION

Y. Yoshimasu[1,2], T. Ikeda[3], N. Sakai[4], A. Yagi[4], Y. Morinaga[2], S. Furukawa[2], R. Nakao[1]
[1]National Institute of Infectious Diseases, Bacteriology I, Shinjuku, Japan
[2]Nihon University, Food Bioscience and Biotechnology, Fujisawa, Japan
[3]Sojo University, Pharmaceutical Sciences, Kumamoto, Japan
[4]Olympus Corporation,
Micro System Technology Department- Medical Elemental Technology Development Division, Hachioji, Japan

Backgrounds

Propolis, a bee product, exhibits biological activities including antimicrobial action, and has been widely used as a folk medicine against infectious diseases. However, the reason for propolis's prophylactic/therapeutic potential against infectious diseases remains obscure.

Objectives

We sought to reveal the mechanism by which propolis attacks pathogen, and identify antibacterial compounds in propolis.

Methods

The antibacterial mechanism of propolis against *Porphyromonas gingivalis* or *Escherichia coli* was investigated by comprehensive approaches, including spatial/temporal analysis using high-speed atomic force microscopy (HS-AFM) with nanometer resolution, and a fluorescence-based membrane potential assay using flow cytometry. Antibacterial compounds were isolated from ethanol-extracted propolis. Fractions from the purification were subjected to a growth inhibition assay using *P. gingivalis*, to assess their antibacterial activities.

Conclusions

HS-AFM analysis showed that propolis immediately triggered development of aberrant membrane blebs, followed by bleb-bleb fusion events on the cell surface of *P. gingivalis*. We found that propolis induced biphasic membrane perturbation against *E. coli* cells, i.e., low propolis concentrations depolarized membranes and high propolis concentrations hyperpolarized membranes and led to loss of membrane integrity. Furthermore, we identified at least three antibacterial compounds in propolis with low cytotoxicity to human oral epithelial cells. It is notable that a pentacyclic triterpenoid of plant origin, ursolic acid, showed the highest lipophilic properties and strongest antibacterial effect (MIC: 31.25 μM) of the three antibacterial compounds identified in the present study. We therefore suggest that propolis is an exquisite membrane-targeting antibacterial agent with prophylactic/therapeutic applicability against periodontitis and other bacterial infectious diseases.

A NEW METHOD OF DNA ISOLATION FROM SPUTUM SAMPLES FOR DIAGNOSIS OF TUBERCULOSIS WITHOUT ANY LABORATORY INSTRUMENTS

E. Ağel[1], H. Sağcan[2]
[1]TUBİTAK Marmara Research Center, Food Institute, Kocaeli, Turkey
[2]Istanbul University, Molecular Biology and Genetic, Istanbul, Turkey

Backgrounds

DNA isolation from difficult specimens is an important point in the detection of many pathogens and bacteria. Today, many DNA isolation methods have complex processing steps and require laboratory devices. Therefore, a simply DNA isolation method that can be used not only in laboratory but also in the field is required.

Objectives

The aim of this study is development of a simple and effective method for homogenization of sputum samples and isolation of DNA without any laboratory instruments.

Methods

Homogenization was carried out in 5% trypsin solution at room temperature for 30 min. Before DNA isolation, samples were contaminated with 10^1 to 10^5 cfu/mL *M. tuberculosis.* After homogenization, samples were passed through the silica solid phase column. Before using, columns were conditioned with chemical treatment in order to better retention of DNA. After passing sample through the column, column was washed with 80% isopropyl alcohol(10 mL). In order to remove alcohol, column was dried. Finally, DNA in the column was eluted with 10 mM TE solution(2 mL).

Conclusions

Trypsin homogenization method is found more successful and simpler than other methods in the previous studies. Studying in room temperature is the additional advantage of this method.

Five different DNA isolation methods have been compared and it has been reported that QIAGEN Qiamp is the most successful method. In the developed new method, 10^2 cfu/mL concentrations can be detected, so the method is as successful as the Qiagen. The most important point of this method is isolation of DNA without using any complex devices.

CAPILLARY CYTOMETRY, A NEW APPROACH TO VALIDATE THE ANTIMICROBIAL EFFICIENCY OF ISOLATOR DISINFECTION.

G. CARRE[1], C. MULLER[2], J.P. GIES[1], J. DUBOIS[3], P. URRUTTI[4], F. GUERRIN[3], P. ANDRE[1]
[1]Université de Strasbourg, Laboratoire de Biophotonique et pharmacologie UMR 7213, ILLKIRCH, France
[2]Université de Strasbourg, Institut Pluridisciplinaire Hubert Curien- UMR 7178, Strasbourg, France
[3]Groupe ARECO, Innovation, GRASSE, France
[4]OSMOSE, Recherche et développement, ROQUEFORT LES PINS, France

Backgrounds

In the pharmaceutical industry, the use of isolator technology increases in a significant way. Hydrogen peroxide vapor (HPV) is the most commonly gas used to disinfect isolators.

Objectives

The disinfection efficiency is determined by biological indicators (BIs) *i.e.* a coupon inoculated with 10^6 spores of *Geobacillus stearothermophilus*. According to the ISO 14161 norm, a 7 days period of incubation at 56°C in tryptic soy broth is recommended before declaring a BI positive (incomplete spore disinfection) or negative (complete spore inactivation).

To determine more rapidly this effectiveness, a capillary cytometry technic was optimized.**Methods**

Membrane integrity, regarded as a reflection of cell viability, is monitored by a live/dead kit (Invitrogen, L13152). By setting an arbitrary threshold to 2.10^5 events/mL, it is possible to predict 24hrs later, with a 100% efficiency, that the broth medium will be positive (cloudy) 7 days later. In the same manner a value under 4.10^4 events/mL will predict over 98% that the broth will remain sterile. If the value is between, a further incubation of 24hrs is required and a 48hrs later value over 2.10^5 events/mL, indicates that the broth medium will be positive (cloudy) 7 days later.

Conclusions

Thus, thanks to our original capillary cytometry technic, we now can determine the presence/absence of surviving cells and thereby determine the efficiency of isolator disinfection in a 24-48hrs time period instead of 7 days.

NEW TOOLS AND DATA PROCESSING PROCEDURES FOR QUICK METAPROTEOMICS

J. Armengaud[1], M. Charlotte[1], M. Guylaine[1], S. Gérard[1], A.B. Béatrice[1], P. Olivier[1]
[1]CEA, DRF-ibitecS-SPI-Li2D, Bagnols-sur-Cèze, France

Backgrounds

Metaproteomics allows i) establishing an inventory of organisms present in a sample, even for a complex microbiota, and ii) documenting new insights into functional pathways and interactions between microorganisms. Combining this approach with metagenomics is crucial for in-depth exploration of microbiomes.

Objectives

Our long-term goal is simplifying metaproteomics data acquisition and data treatment for being able to explore any microbiota in a few hours even without sequencing data. Here, we propose a lab-assembled microbiota reference for evaluating data processing procedures for metaproteomics. We also designed a new bioinformatics pipeline for quick analysis of samples.

Methods

We assembled an artificial microbiota reference comprising 24 bacterial species covering 20 genera and 5 phyla. The proteins from this standard were extracted and tryptic peptides were generated. We acquired several metaproteomics dataset by recording high quality tandem mass spectra on this peptide pool using a tandem mass spectrometer incorporating an ultra-high-field orbitrap analyzer. Typically, a set of 117,703 spectra have been recorded over a 3h run, allowing identification and characterization of the 24 bacteria. Important functional information can be extracted from these data with the detection of 4,371 candidate proteins. Furthermore, we exemplified the possible applications of this procedure to decipher the microbiota (bacteria, archaea, fungi, and microalgae) of diverse environmental samples: wall deposits, biofilms, soils, and feces.

Conclusions

Based on this reference dataset, we propose an innovative data processing procedure for minimizing false-positive identification of organisms, and performing species-resolved metaproteomics with the most appropriate pan-proteomics database.

MULTILOCUS VARIABLE-NUMBER TANDEM REPEAT TYPING OF MYCOBACTERIUM KANSASII

Z. Bakula[1], A. Brzostek[2], A. Podpora[1], P. Parniewski[2], J. Dziadek[2], T. Jagielski[1]
[1]University of Warsaw- Faculty of Biology,
Department of Applied Microbiology- Institute of Microbiology, Warsaw, Poland
[2]Polish Academy of Sciences,
Mycobacterium Genetics and Physiology Unit- Institute of Medical Biology, Łódź, Poland

Backgrounds

Mycobacterium kansasii is one of the most virulent nontuberculous mycobacteria (NTM). It is also one of the six most commonly isolated NTM species around the world. The observed genetic homogeneity of *M. kansasii* strains results in poorly understood epidemiology of infections due to this pathogen.

Objectives

The aim of this study was to search the genome of *M. kansasii* for tandem repeat sequences, similar to variable number tandem repeat (VNTR) sequences in *M. tuberculosis* allowing for intraspecies differentiation/species fingerprinting.

Methods

The *M. kansasii* genome (GenBank, NCBI, Reference Sequence: NC_022663.1) was screened for the occurrence of TR loci with the Vector NTI Software (Thermo Fisher Scientific, Waltham, MA, USA). Primers were designed to anneal to the flanking region of TRs utilizing same software as for the TR screening. PCR protocols were tested on a collection of 15 strains representing six *M. kansasii* subtypes (I-VI) as well as 90 *M. kansasii* clinical strains isolated from Polish respiratory patients between 2000 and 2015.

Conclusions

A total of 17 potential VNTR loci with high variability in the number of TRs were identified among strains of *M. kansasii* subtypes. Additionally, six of the tested VNTRs (1, 2, 7, 15, 17, 20) showed variation among *M. kansasii* clinical strains (all of type I). In summary, the newly designed VNTR-based typing method of *M. kansasii* appears to be a promising tool for *M. kansasii* fingerprinting and thus may help to better explore the transmission routes of *M. kansasii* infections.

NOVEL PHYLOGENETIC MARKERS FOR COST-EFFICIENT AND ACCURATE TYPING OF PROTOTHECA MICROALGAE

Z. Bakula[1], Ś. Marcin[1], P. Siedlecki[2], J. Gawor[3], R. Gromadka[3], T. Jagielski[1]
[1]University of Warsaw - Faculty of Biology, Department of Applied Microbiology, Warszawa, Poland
[2]University of Warsaw - Faculty of Biology, Department of Systems Biology, Warszawa, Poland
[3]Institute of Biochemistry and Biophysics, DNA Sequencing and Oligonucleotides Synthesis Unit, Warsaw, Poland

Backgrounds

The genus *Prototheca* comprises unicellular, achlorophyllous, yeast-like algae widely distributed in the environment. Four out of seven currently postulated species are pathogenic to humans and animals, being the causative agents of protothecosis.

State-of-the-art methods of *Prototheca* spp. identification and discrimination include microscopic assessment of cell morphology, evaluation of carbohydrate and alcohol assimilation patterns, and three PCR based methods, which focus on analysis of rDNA operon. The molecular identification methods have been designed for identification of *P. blaschkeae*, *P. zopfii* gen. 1, and *P. zopfii* gen. 2 and are not suited for differentiation of other postulated species.

Moreover, our studies have shown (not published) that each *Prototheca* species has multiple divergent copies of rDNA operon in its genome. This poses technical problems for analysis of PCR products and sequencing.

Objectives

The study aims at proposing an accurate, easy-to-use, quick, and cheap method for differentiation of all *Prototheca* species currently known as an alternative approach to current typing methods.

Methods

Based on whole genome sequencing of reference strains of eight *Prototheca* species (genotypes) (not published) eight draft genomes were assembled, for which genes were predicted *in silico*. Cross-examination of the drafts revealed a total of 187 genes that were shared by all eight strains. Of these genes, two single-copy genes were selected based on their discriminative power in phylogenetic analyses. For these genes primer pairs were designed, PCR products amplified and sequenced.

Conclusions

Two new PCR-sequencing assays based on single-copy genes, i.e. *CYTB* and *EF1α*, are proposed. These two phylogenetic markers enable distinction of all seven known species, offering a useful tool in the identification algorithm of *Prototheca* algae.

The study was financed by the National Science Centre grants «PRELUDIUM» (2013/09/N/NZ2/00248) and «SONATA» (2014/15/D/NZ7/01797).

DE NOVO ASSEMBLY OF MICROBIAL GENOMES FROM HUMAN GUT METAGENOMES USING BARCODED SHORT READ SEQUENCES

A. Bishara[1], E. Tkachenko[2], E. Moss[2], T. Andermann[2], J. Kang[2], S. Batzoglou[1], A. Bhatt[2]
[1]Stanford University, Computer Science, Stanford, USA
[2]Stanford University, Genetics, Stanford, USA

Backgrounds

Assembling genomes and defining strain-level architecture within complex microbial communities are challenging with current shotgun sequencing approaches. Existing methodologies do not capture structural differences between closely related co-occurring strains such as those arising from horizontal gene transfer and insertion sequence mobilization. Recent techniques partition large DNA molecules, then barcode short fragments derived from them, to produce short-read sequences containing long-range information. These techniques combine high nucleotide accuracy and low input mass requirements with the capacity to resolve repeated sequences within metagenomes.

Objectives

We present a novel application of short-read barcoding techniques to metagenomic samples, and Athena, an assembler that uses these barcodes to produce improved metagenomic assemblies.

Methods

We compare our approach utilizing the 10x Genomics Gemcode platform against conventional shotgun sequencing techniques in a mock bacterial mixture and a clinical gut microbiome time series. Athena assemblies are validated with Sanger sequencing. In addition, we perform RNA sequencing to investigate transcriptional effects of newly assembled sequences.

Conclusions

In the mock bacterial mixture, we successfully assemble and genomically place multiple copies of the highly conserved 16S/23S ribosomal RNA operon, which is present in a single disconnected copy in the conventional assembly. In the clinical time series, we significantly improve draft completeness, uncover strains of Bacteroides caccae differing in the positions of transposon integration, and find the abundance of these strains to fluctuate widely over the course of treatment. RNA sequencing reveals overexpression of antibiotic resistance genes coinciding with both antibiotic administration and the appearance of proximal transposons harboring a putative bacterial promoter.

MONITORING THE RESPONSE OF STAPHYLOCOCCUS AUREUS TO ANTIMICROBIAL PLANT PHENOLICS BY MULTIPARAMETER FLOW CYTOMETRY

L. Bouarab Chibane[1], *P. Degraeve*[1], *N. Oulahal*[1]
[1]*Université Claude Bernard Lyon1, Genie Biologique, Bourg en Bresse, France*

Backgrounds

Screening of antibacterial biomolecules is still primarily assessed at the population or colony level. However, it is accepted that a bacterial cells population exposed to a stress can cause the appearance of different cell populations including sub lethally compromised cells which could be defined as viable but non culturable (VBNC). Recent advances in flow cytometry namely in multi parameter flow cytometry (MP-FCM) provide the opportunity to obtain high-speed information at real time on damage at single-cell level.

Objectives

The aim of this study was to examine the possibility to corroborate MP-FCM analysis with additional techniques (culturable cells enumeration, effect on liposomes as biophysical membrane models) to elucidate the mechanism of action of plant phenolics active against *Staphylococcus aureus*.

Methods

Fluorescent probes such as propidium iodide, Syto9®, Bis (1,3-dibutylbarbituric acid) and 5(6)-Carboxyfluorescein diacetate were analyzed by flow cytometry to examine vital functions like the membrane integrity, the membrane potential and metabolic activity of *S. aureus* cells exposed to various antimicrobial plant phenolics (5,7-dihydroxy-4-phenylcoumarin, isobutyl-4-hydroxybenzoate, epigallocatechin gallate and 5,8-dihydroxy-1,4-naphtoquinone).

Conclusions

Comparison of MP-FCM analyses with culturable cells enumeration and observation of the effect on liposomes integrity of various plant phenolics revealed that while compounds such as 5,7-dihydroxy-4-phenylcoumarin and isobutyl-4-hydroxybenzoate were bactericidal, they neither affected the integrity of the membrane of *S. aureus* cells, nor the integrity of liposomes.

IMPLEMENTATION OF AN AUTOLYSIS SYSTEM AS A TOOL FOR FUNCTIONAL METAGENOMICS ANALYSIS

J. Cárcel Márquez[1], E.M. Camacho Fernández[1], A. Flores Díaz[1], E. Santero Saturino[1]
[1]Centro Andaluz de Biología del Desarrollo/CSIC/Universidad Pablo de Olavide/Junta de Andalucía, Departamento de Biología Molecular e Ingeniería Bioquímica, Sevilla, Spain

Backgrounds

Functional metagenomic allows for the identification of novel activities of interest present in uncultured microorganisms. Unfortunately, this strategy is limited, among other factors, by the accessibility of the heterologous enzyme to the substrate. For intracellular activities, the substrate must enter the bacterial cell to allow detection, while for extracellular activities the host must be able to secrete the enzyme to the growth medium. This way the efficiency of the screening could be limited.

Objectives

The main purpose of this work is to develop an autolysis system that, in response to an inducer, lysates bacteria releasing their content into the growth medium. This system must also permit survival of a proportion of the bacterial population to allow the recovery of positive clones

Methods

We have implemented an inducible autolysis system previously developed in our laboratory. It is based in the lysis operon of lambda phage and responds to anhydrotetracycline as an inducer. We have demonstrated that the autolysis system allows detection of intracellular activities and the recovery of positive clones. Subsequently we carried out a screening for cellullase activity in the presence or absence of the autolysis system to compare the efficiency of cellulose activity detection

Conclusions

We have demonstrated that the autolysis system is necessary for the detection of intracellular activities. Additionally, the system improves detection of positive clones for cellullase activity. In all cases, the lysis system allows recovery and subsequent confirmation of positive clones. In summary, our system is an effective tool to improve functional metagenomic analysis.

WHOLE GENOME SEQUENCE OF NOCARDIA CERRADOENSIS STRAIN CNM 20130759, ISOLATED FROM HUMAN IN A PRIMARY CUTANEOUS INFECTION

G. Carrasco[1], S. Monzón[2], N. Garrido[1], P. Jiménez[3], I. Cuesta[2], M.J. Medina-Pascual[1], J.A. Sáez-Nieto[1], S. Valdezate[1]
[1]National Centre of Microbiology / Institute of Health Carlos III, Taxonomic Reference and Research Laboratory, Majadahonda Madrid, Spain
[2]National Centre of Microbiology / Institute of Health Carlos III, Bioinformatics Department, Majadahonda Madrid, Spain
[3]National Centre of Microbiology / Institute of Health Carlos III, Genomic Department, Majadahonda Madrid, Spain

Backgrounds

Nocardia cerradoensis is an unusual member of the *Nocardia nova* complex and the only available draft genome belongs to an environmental strain.

Objectives

First whole genome sequencing (WGS) of a clinical *N. cerradoensis* strain, isolated from an immunosuppressed 52-year-old woman with internal infection after infiltration.

Methods

The *de novo* draft genome sequencing was performed on the Illumina® NextSeq 500 sequencing system using the fragment library generated by the Nextera. After correction (fastQC v0.11.3) and removing adapter (Trimmomatric v0.36), sequence was processed and assembled using SPAdes (vs3.8.0). Later, the QUAST quality control was applied. 16S rRNA, *gyrB*, MLSA pattern (16S-*gyrB*-*hsp65*-*secA1*) were determined by PCR.

Conclusions

N. cerradoensis strains CNM20130759 showed a genome size of 8,9 Mb, including 972 contigs (120 contigs ≥ 1000 bp; minimum, 222 bp; maximum, 1035523bp; N50, 394,043bp) and a GC-content of 67.74%. No CRISPR repeats were founded. The housekeeping and intrinsic genes (*gyrB, rpoA, rpoB, secA, hsp65*, *folP, trpB, cobQ, soda, sodC, inhA, nrdF, nrdB, nrdE, nrdH, …)*, resistance and virulence genes (ATP-binding cassette, *ddpA*, fibronectin-binding protein, sortase A, ESC-1, serine protase, *tlyC*, *katA, katE* and *katG, murA, Int-Tn, stp, tetR,* NCRCNM_01157, NCRCNM_01690*, bmrR, yfmO, mdtG, ermY, qacA, drrA, surG, mdtL, bcr, marR, mmr,*…) were identified. The characteristics genes of nearby genus as *Mycobacterium* (Insertion elements IS6110 and IS5376, universal stress protein Rv2005c, KsdD-like Rv0785, sensor TcrY, multidrug efflux Rv0194, Rv1459c …) were also found. MLST is a good approach for identification, but WGS became the definitive tool for the identification and the understanding of the virulence of *N. cerradoensis.*

COLD ATMOSPHERIC PLASMA AS A DECONTAMINANT OF MYCOPLASMA-INFECTED CELLS.

Y. Chalenko[1], E. Sysolyatina[1], I. Rakovskaya[2], M. Vasiliev[3], O. Petrov[4], V. Fortov[5], S. Ermolaeva[1]
[1]Gamaleya Research Center of Epidemiology and Microbiology, laboratory of ecology pathogens, Moscow, Russia
[2]Gamaleya Research Center of Epidemiology and Microbiology, laboratory of mycoplasma, Moscow, Russia
[3]Joined Institute of High Temperatures, laboratory of dusty plasma, Moscow, Russia
[4]Joined Institute of High Temperatures, laboratory of low-temperature plasma, Moscow, Russia
[5]Joined Institute of High Temperatures, High Temperatures RAS, Moscow, Russia

Backgrounds

Mycoplasma spp. are the smallest bacteria lacking the cell wall [1]. Many species represent a serious problem for industrial biotechnology being common contaminants of cell lines [1]. Cold atmospheric plasma (CAP) is a flow of partly ionized gas that has an ambient temperature. CAP has unspecific bactericidal activity due to charged particles, active oxygen and nitrogen species and UV [2].

Objectives

To establish a bactericidal effect of cold atmospheric plasma on *Mycoplasma hominis.*

Methods

To investigate a direct effect, *M. hominis* plated on agar or HEp-2 cells infected with 10^7 CFU ml^{-1}*M. hominis* were treated with CAP, described previously [2], for 2 or 5 min. Survivors were counted in 72 h.For an indirect plasma effect investigation the cultural medium DMEM was treated with plasma for 5 min and then added to infected cells. *M. hominis* survivors were plated on agar and counted in 72 h.

Conclusions

M. hominis showed an outstanding CAP resistance in comparison with other bacteria [2,3]. 5-minutes direct plasma treatment of infected cells reduced the amount of mycoplasmas twice, but had a toxic effect on HEp-2 cells. Indirect treatment was not toxic for cells and caused 10 fold drop of bacteria load. Thus, CAP treatment of cultural medium might be useful for decontamination of cell lines infected with *Mycoplasma* spp.

[2]FISABIO Public Health, Department of Genomics and Health, Valencia, Spain
[3]Instituto de Salud Carlos III, Centro Nacional de Microbiología, Madrid, Spain
[4]CIBER, Epidemiology and Public Health, Madrid, Spain

Backgrounds

The identification of fungal presence in human samples have traditionally relied on disease symptoms, laboratory identification and biochemical tests. Although these methods are still fundamental, there is an increasing move towards molecular diagnosis. Since the spread of Next Generation Sequencing (NGS) technologies, researchers have been on the hunt for reliable DNA barcode markers capable to describe Prokaryota and Eukaryota taxonomy. Specifically, for fungal samples, the Internal Transcribed Spacer (ITS) between 18S and 28S ribosomal genes has been the best candidate barcode marker so far, but still there is no consensus about the most suitable pair of primers targeting this region.

Objectives

The efficiency and specificity of a renowned pair of primers targeting the ITS1 region have here determined and an optimization protocol is proposed for Illumina MiSeq sequencing platform.

Methods

A mock community of 6 different fungal species causing human diseases has here tested checking for the influence of starting DNA amount and their relative dominance. Besides, the primers specificity was tested.

Conclusions

The use of tested primers, although statistical analysis of sequences distribution revealed some biases due to PCR and library preparation, faithfully reflects the initial proportion of the species. Besides, we observed no unspecific amplification of control human DNA. Finally, the results confirm the reliability of tested primers targeting ITS1 for fungi detection and characterization by PCR reaction, library preparation and Illumina based sequencing for clinical molecular diagnosis.

BIOGENIC SELENIUM NANOPARTICLES: A NOVEL STRATEGY TO FACE ANTIBIOTIC RESISTANCE?

E. Cremonini[1], *M.M. Lleo*[1]
[1]*University of Verona, Diagnostic and Public Health, Verona, Italy*

Backgrounds

Tailored metal nanoparticles with desired physico-chemical properties have been proposed as a new line in the battle against antibiotic-resistant microorganisms.

Objectives

In this study, biogenic Selenium Nanoparticles (SeNPs) have been tested as an alternative therapy for antibiotic resistant bacteria.

Methods

The strain *Stenotrophomonas maltophilia* SeITE02 was used to produce biogenic NPs. The antibacterial activity of SeNPs was tested against several clinical strains from *Pseudomonas aeruginosa*, *Stenotrophomonas maltophilia*, *Achromobacter xylosoxidans*, *Staphylococcus haemolyticus* and *Staphylococcus aureus*. MICs of SeNPs and antibiotics were determined according to the CLSI broth microdilution method. The NPs inhibitory and disruptive biofilm activity was determined by Crystal Violet staining and conventional plating. Bioiflm biomass was determined also by observation at fluorescence microscope.

Conclusions

SeNPs demonstrated antibacterial activity with low MIC values (8-16 µg/ml) against some of the tested strains and proved capable of inhibiting the synthesis of biofilm and disaggregating the polysaccharide matrix at concentrations ranging between 50 and 100 µg/ml. The quantification of culturable cells points out the antibiofilm potential of the SeNPs causing a 2-8 $\log_{10}$ CFU/ml reduction. Experiments to test the possible synergistic antibiofilm activity of SeNPs and antibiotics are still ongoing.
Biogenic SeNPs showed a good antibiofilm and antibacterial activity with low MICs value for a number of clinical isolates. SeNPs can be considered biocompatible structures that could be administered, either alone or in combination with antibiotics, in new therapeutic strategies to inhibit the growth of resistant pathogens or to facilitate the penetration of microbial biofilms.

New Methods and Techniques

A NOVEL NUCLEIC-ACID BASED BIOSENSOR FOR VIBRIO SPP. DETECTION IN AQUATIC ENVIRONMENTS

E. Da-silva[1], J. Baudart[2], L. Barthelmebs[1]
[1]Université de Perpignan Via Domitia, Laboratoire Biocapteurs Analyses Environnement, Perpignan, France
[2]Sorbonne Universités- UPMC Univ. Paris 06- USR 3579, LBBM- Observatoire Océanologique, Banyuls-sur-Mer, France

Backgrounds

The water resource is regularly monitored for its bacteriological quality through the detection of fecal indicator bacteria, such as *Escherichia coli*, using culture-based methods. Nevertheless, non fecal pathogens are widely distributed in aquatic environment, and due to environmental stresses, may enter into a viable but non culturable state becoming non detectable by cultivation. Nucleic acid-based biosensors are innovative analytical tools allowing a rapid detection of bacteria and present several advantages. These devices are cost-effective, robust, sensitive, specific, quantitative and do not required genes amplification.

Objectives

In the present study, a novel nucleic acid-based biosensor was developed for the monitoring of *Vibrio* spp., including well-known pathogenic species.

Methods

This biosensor was based on a sandwich hybridization assay in which nucleic acid target (RNA) was bound between an immobilized capture probe and a labeled signal probe. The hybridization was then revealed by an enzymatic system, leading to a signal proportional to the entrapped target.

Conclusions

In a first step, probes were validated using synthetic targets and detection limit was determined as 100 pM. In a second step, specificity was checked by using RNA extracted from a panel of 31 environmental bacterial strains. The biosensor allowed a good discrimination between the *Vibrio* and the non-*Vibrio* strains and detection limit of 5 $ng.\mu L^{-1}$ of total RNA was obtained. Finally, the device was successfully applied to the analysis of spiked and natural environmental samples.
In order to develop miniaturized devices that could be directly implemented on site, transfer towards an electrochemical detection is in progress.

THE OCCURRENCE AND ASSOCIATION OF FUSARIUM SPECIES AND THEIR EMERGING MYCOTOXINS IN WHEAT, MAIZE AND LEEK

M. Decleer[1], A. Rajkovic[1], K. Audenaert[2], S. De Saeger[3]
[1]Ghent University, Department of Food Safety and Food Quality, Gent, Belgium
[2]Ghent University, Department of Applied biosciences, Gent, Belgium
[3]Ghent University, Department of Bioanalysis, Gent, Belgium

Backgrounds

The emerging *Fusarium* mycotoxins are a class of compounds that are attracting increasing interest due to their presence in high concentrations in many food products and their potential toxicity towards animals and humans.

Objectives

The objectives of this research were (i) to evaluate the natural occurrence of beauvericin (BEA) and enniatins A, A1, B and B1 (ENNs) in wheat and maize collected from trial fields in Flanders, Belgium, (ii) to estimate a possible correlation between fungal colonization by *Fusarium* species and accumulation of BEA and ENNs and (iii) to characterize the production of BEA, ENNs and moniliformin (MON) by *Fusarium* isolates in an interaction with leek.

Methods

704 wheat and maize samples were collected during the harvest of 2015 and 2016 and analysed for BEA and ENNS by LC-MS/MS according to Decleer et al. (2016). Leek plants infected with *F. avenaceum* were analyzed for BEA, ENNs and MON with an UPLC–MS/MS method developed and validated in the framework of this study. To assess the link between *Fusarium* species and their mycotoxin production, Q-PCR was used to measure the presence of *Fusarium* species.

Conclusions

The results indicated that all wheat samples were contaminated with at least one of the emerging mycotoxins with BEA, ENN B and ENN B1 as the most abundant mycotoxins in Belgian maize and wheat samples. Since the incidence and concentrations of the artificially inoculated leek plants were low, we assume that these mycotoxins are most likely not involved in the interaction of *F. avenaceum* with its host leek.

New Methods and Techniques

INFLUENCE OF CEREULIDE ON THE MITOCHONDRIAL FUNCTION OF CACO-2 AND HEPG2 CELLS USING EXTRACELLULAR FLUX ANALYSIS

M. Decleer[1], S. De Saeger[2], A. Rajkovic[1]
[1]Ghent University, Department of Food Safety and Food Quality, Gent, Belgium
[2]Ghent University, Department of Bioanalysis, Gent, Belgium

Backgrounds

Cereulide (CER) is a lipophilic cyclododecadepsipeptide produced by Bacillus cereus. This toxin is known to induce food poisoning, sometimes related with liver failure and even fatal outcome. In contrast with doses associated with food poisoning, recent prevalence data demonstrated relatively low concentrations of cereulide in rice and pasta dishes. The effects of repeated exposure to low levels of cereulide is largely unknown and can lead to(sub)chronic harms.

Objectives

The goal was to provide insight into the impact of a continuous exposure of low doses of CER on metabolic responses of Caco-2 and HepG2 cells as models for intestinal and liver toxicity.

Methods

Caco-2 and HepG2 cells were exposed to food-relevant low concentrations of CER to investigate the effect of a longer exposure. To explore the mechanisms involved in the mitochondrial function, the Seahorse Bioscience XFe24 analyzer (Massachusetts, USA) was used in combination with well-established assays for mitochondrial activity (MTT) and changes in protein content (SRB (sulforhodamine B)). The effects of CER on the mitochondrial oxygen consumption rate (OCR) were assessed using the Seahorse Bioscience XF Cell Mito Stress Test assay kit. High-resolution mass spectrometry was used to unravel the metabolic profile of CER.

Conclusions

The three-day treatment with low concentrations of CER on mitochondrial respiration in Caco-2 cells showed perturbations in mitochondrial respiration at 0.125 ng/ml. These in vitro data suggest that repeated exposure of CER might injure intestinal cells even at relative low doses. Cereulide appear to be more toxic than other cyclodepsipeptide toxins with ionophoretic properties like valinomycin and beauvericin.

FILMARRAY GI® PANEL FOR DETECTION OF ENTERIC PATHOGENS IN STOOL SAMPLES IN CHILE

F. Mauricio[1], L. Yohanna[1], H. Juan[1], B. Pablo[1], G. Sebastian[1], S. Cynthia[1], F. Camila[1], T. Juan[1]
[1]Laboratorio de Biología Molecular, Clínica las Condes, Santiago, Chile

Backgrounds

Gastrointestinal infections remain a major public health problem worldwide and its diagnosis is one of the main challenges. In the last years, several molecular techniques for the detection of multiple pathogens have been developed, allowing to determine the etiology of infection. In 2014, the FDA released for clinical use the Filmarray GI® panel that allows detection of 23 pathogens (14 bacteria, virus 5 and 4 parasites) within an hour.

Objectives

To show and analyze the experience of Filmarray GI® panel in the Molecular Biology Laboratory of Clinica las Condes, Chile

Methods

A cross-sectional observational study that includes the results of 2127 stool samples tested by Filmarray GI® panel from January 2015 to January 2016.

Conclusions

Of the 2127 tests requested around one third were negative and positive samples with one to eight pathogens were detected. High prevalence of diarrheogenic *E. coli* and co-infections was observed. Implementation of a 24/7 molecular testing significantly decreased the average turn-around-time (TAT) of this panel from hours to 2.5 hours. This work presents the experience of using FilmArray GI® panel as a tool for diagnosis of gastrointestinal infections, which highlights the large number of positive samples for a microorganism and co-detection of enteric pathogens. The 24/7 service provided detection results to clinicians in a timely manner.

CONSTRUCTION OF A PROMOTER STRENGHT SCREENING VECTOR IN BACILLUS SUBTILIS BASED ON A GENE ENCODING A SUPERFOLDER GREEN FLUORESCENCE PROTEIN COMBINED WITH FACS

C. Gago Córdoba[1], *W. Meijer*[1]
[1]*Centro de Biología Molecular Severo Ochoa, Virología y Microbiologia, MADRID, Spain*

Backgrounds

Identification of promoters and determination of their strength and regulation is crucial for understanding the role of downstream-located genes. RNAseq or qPCR can identify and monitor promoter strength. However, these methods are time consuming, expensive and do not allow easy testing of the promoters in different settings. Systems based on reporter genes are generally used for these studies. Systems are based on lacZ fusions are laborious and provide only the mean expression profile of all cells within the population. GFP is an excellent reporter allowing rapid, reproducible analysis at single cell level. However, convenient systems for Bacillus subtilis are lacking, principally because most versions of the gfp protein variants do function well at 37 degrees.

Objectives

Developing a convenient promoter characterization system for B. subtilis using as reporter a superfolder GFP-encoding gene that is optimized for stable expression in B. subtilis.

Methods

PCR-based cloning was performed to construct a B. subtilis integration vector containing a special gfp reporter gene apt for promoter study analysis.

Conclusions

We have developed a B. subtilis integration vector containing a promoterless special gfp gene that has been improved in several ways for optimal use in B. subtilis and containing three unique restriction sites upstream of the RBS.

Variants of the system were constructed in which inducible promoters with different strengths were cloned in front of the reporter gene and these were used to prepare calibration profile to determine the relative strength of promoters of interest by FACS.

New Methods and Techniques

ASPERGILLUS FUMIGATUS ERG4B (AFU1G07140): A USEFUL TOOL FOR TYPING PURPOSES

R. Garcia-Rubio[1], *G. Santoni*[2], *M.C. Monteiro*[3], *G. Riaran-Moreno*[3], *L. Alcazar-Fuoli*[3], *E. Mellado*[3]
[1]*Spanish National Center for Microbiology, Mycology, Majadahonda Madrid, Spain*
[2]*Hospital Británico de Buenos Aires, Infectious Diseases Department, Buenos Aires, Argentina*
[3]*National Center for Microbiology, Mycology, Majadahonda Madrid, Spain*

Backgrounds

Aspergillus fumigatus is a saprotrophic mold responsible for invasive aspergillosis in immunocompromised hosts. Ergosterol is the main sterol of fungal membranes and the target of some antifungal agents. In *A. fumigatus* ergosterol pathway, some enzymes have two homologs such as the sterol C-24 reductase, encoded by *erg4A* and *erg4B*, which catalyze a final step of the ergosterol biosynthesis. Deletion of *erg4* in *Saccharomyces cerevisiae* and *Fusarium graminearum* changes their azole susceptibility profile.

Objectives

1.- To improve a genotyping method previously described (Garcia-Rubio et al., 2016) based on hypervariable tandem repeats within exons of surface protein coding genes (TRESP) by adding *A. fumigatus erg4B* sequencing information.

2.- To investigate whether differences in *erg4B* tandem repeats are related to the azole susceptibility profile of *A. fumigatus* strains.

Methods

One hundred and fifty *A. fumigatus* strains with clinical origin (105 azole susceptible and 45 azole resistant) were used in this study. They were previously characterized by PCR amplification and sequencing of three genes: Afu3g08990 (CSP), Afu2g05150 (MP2), and Afu6g14090 (CFEM). Afu1g07140 (*erg4B*) sequences were added for improving typing discrimination.

Conclusions

The TRESP typing discrimination power was improved when *erg4B* sequences were added as a typing target. So far no relation between the size of tandem repeat integrations and azole susceptibility profile was obtained. Further work with *erg4B* mutants will confirm its role in the ergosterol biosynthesis and its relation with azole susceptibility.

[3]Razi Vaccine and Serum Research Institute- Agricultural Research- Education and Extension Organi zation AREEO, Tuberculin, KARAJ, Iran

Backgrounds

Salmonella as a major food-borne disease has imposed significant public health and economic loss along the globe. Traditionally, serotyping has lots of shortcomings, on the other hand, results acquired by most of molecular typing methods aren't reproducible. Also these techniques should be able to determine the origin of a single globally distributed clonal lineage.

Objectives

To solve all mentioned problems related to conventional and molecular typing method, MLST scheme has been implemented as a generic, repeatable, robust and portable technique.

Methods

Having a previous history of clonal population structure among 76 *Salmonella* Enteritidis by using MLST technique, this study was designed to evaluate the discrimination ability of this method among different *Salmonalla* serotypes. 4 DNA templates belonging to 3 different serogroup D1, B and C1and One standard *salmonella* Enteritidis were exploited in this study. Three out of seven MLST house-keeping genes including hisD, thrA, sucA were considered to be amplified.

Conclusions

While we observed a clonal population group among our *Salmonella* Enteritidis isolates, we successfully differentiated 3 most frequent Iranian serotype including Enteritidis, Typhimurium and Infantis, in different clustal groups.
Generally, molecular typing methods are intended to tackle two different levels of epidemiological problems. In one hand localized outbreak of disease in a short period of time and on the other, relation between strains causing a disease in different geographic areas with a longer period. This study proves MLST method is a satisfactory platform to provide all these needs and can be regarded as a desirable prospective global typing strategy.

DEVELOPING MLVA TECHNIQUE AS A COMPROMISED APPROACH TOWARD MOLECULAR CHARACTERIZATION OF PASTEURELLA MULTOCIDA

R. Ghaderi[1], K. Tadayon[1], A. Jabbari[1], A. sanchooli[1], A. Arab[1], R. Banihashemi[1], M. SEKHAVATI[1]
[1]Razi Vaccine and Serum Research Institute- Agricultural Research- Education and Extension Organi zation AREEO, Aerobic Bacterial Vaccine, KARAJ, Iran

Backgrounds

Multi locus variable number tandem repeat analysis as a PCR-based technique scrutinizes short tandem repeats within amplified DNA. These tandem repeat units show frequent variation in the number of copies by slippage strand misalignment throughout DNA synthesis. Different numbers of tandem repeat units makes different fragment lengths in a way that each discrete sized fragment called as unique "allele" for the locus under study. Razi Vaccine and Serum Institute has a long history of production of vaccine against fowl cholera and Haemorrhagic septicemia using indigenous strains.

Objectives

In order to genetically characterize these vaccine strains, it was tried to set-up this technique over *Pasteurella multocida* while there had been no evidence of any similar attempts so far.

Methods

Employing Tandem Repeat Finder software, *Pasteurella multocida* strain PM70 as the main complete genome was gone under TRs investigation process. More over 9 other complete genome strains including: ATCC43137, HB01, OH4807, PMTB2.1, 3480, HB03, HN06, NC-006300-fna, and NC-016808-fna were compared by selected tandem repeats.

Conclusions

Three microsatellites markers with 6, 9 and 12 bp size were selected entitled VNTR6,VNTR9and VNTR12. Using Primer 3 software under NCBI website 3 pairs of primers were designed to incorporate Amplicons less than 800 bps in length encompassing the Tandem repeat region in the middle. Optimization process was done to harmonize all 3 amplification protocols. 2 vaccine strains and 4 field isolates were successfully gone under MLVA investigations. Our findings proved the feasibility of this technique that can be employed as an appropriate way to characterize *Pasteurella multocida* isolates.

NOVEL ISOLATION AND CULTURE APPROACHES TO IMPROVE THE RECOVERY OF LICHEN ASSOCIATED BACTERIA USING LICHENIC EXTRACTS

E. G Biosca[1], R. Flores[1,2,3], R. D Santander[1], J.L. Díez-Gil[4], E. Barreno[2,3]
[1]Universitat de Valencia, Microbiología y Ecología, Burjassot, Spain
[2]Instituto Cavanilles de Biodiversidad y Biología Evolutiva, Botánica, Burjassot, Spain
[3]Universitat de Valencia, Botánica, Burjassot, Spain
[4]Instituto de Investigación Sanitaria La Fe, Grupo RETRACAR, Valencia, Spain

Backgrounds

Lichens, commonly considered mutualisms between a mycobiont and one or more photobionts, are now recognized as multispecies symbiosis in which non-photosynthetic bacterial communities are stable, specific and structurally integrated partners. The diversity and functional roles of these symbiotic bacteria within the lichen have recently begun to be studied, but mainly by culture-independent approaches. This is because of difficulties in their isolation and culture on standard media that do not mimic lichen nutrients. Nevertheless, to culture as yet unculturable bacterial symbionts is essential to clarify their contribution to the lichen symbiosis, but also to explore their biotechnological potential and the description of new taxa.

Objectives

The objective was to improve the recovery of lichen associated bacteria by developing innovative isolation and culture approaches.

Methods

We evaluated the effect of thalli washing time, and different disinfection treatments and processing protocols, as well as newly developed growth media enriched with novel lichen extracts. Once optimized the methodology, it was applied for the isolation of bacteria from the lichens *Pseudevernia furfuracea*, *Ramalina farinacea* and *Parmotrema pseudotinctorum*.

Conclusions

The developed methodology allowed significant increases in the number and diversity of lichen associated culturable bacteria, which makes lichens an important source of new microorganisms. Further, it allowed the growth of previously uncultured lichen symbiotic bacteria. This methodology, which is patent granted (ES2575752, 2017), is also applicable to other microorganisms of these lichen species and others. (GV-PROMETEOII/2013/021 and UV-INV-AE 112-66196).

CIRCULAR DICHROISM SPECTROSCOPY REVEALS NEW POSSIBILITIES IN DETERMINATION OF STERIGMATOCYSTIN IN AQUEOUS SOLUTIONS

D. Jaksic Despot[1], M. Šegvić Klarić[2], I. Piantanida[3]
[1]Faculty of pharmacy and biochemistry, Department of microbiology, Zagreb, Croatia
[2]University of Zagreb- Faculty of pharmacy and biochemistry, Department of microbiology, Zagreb, Croatia
[3]Ruđer Bošković Institute,
Division of organic chemistry and biochemistry- Laboratory for biomolecular interactions and spectros copy, Zagreb, Croatia

Backgrounds

Sterigmatocystin (STC) is a mycotoxin produced by many fungal species, ubiquitous in working and living environment. STC exhibits hepatotoxic, nephrotoxic, mutagenic and carcinogenic effects representing a significant risk to human and animal health. LC-MS is the most commonly used technique for the STC detection. Possible complications like matrix effects on ionisation efficiency make use of isotopically labelled STC internal standard inevitable, in addition to laborious sample preparation. Circular dichroism (CD) spectroscopy is extensively used to study structural, kinetic and thermodynamic features of chiral molecules. Since STC is chiral molecule CD spectroscopy for its determination in various substrates is worth of exploring.

Objectives

The purpose of this study was to demonstrate CD spectroscopy application in the determination of STC in various aqueous matrices.

Methods

CD spectra of STC aqueous solutions were recorded by standard Jasco J810 setup in 1 cm quartz cuvette at various physicochemical conditions (temperature, organic solvents and salts addition).

Conclusions

STC forms aggregate in aqueous solutions, yielding strong CD signal in 300-400 nm range specific to STC, with the intensity up to 1000:1 compared to the baseline. The CD signal intensity is proportional to STC concentration within 10^{-7} M to 10^{-5} M range, and none of relevant species from food or environment (including structurally similar aflatoxin B1) does not interfere with this CD-signal. These facts strongly encourage an innovative approach to STC monitoring, which could result in a completely new analytical method for the specific determination of STC, as well as studying non-covalent interactions of STC with biomacromolecules.

GEXPLORE – A NOVEL GENOME-WIDE APPROACH FOR STUDYING HOST-PATHOGEN INTERACTIONS

S. Kambarev[1], V. Kalichuk[1], G. Béhar[1], B. Mouratou[1], L. Marsollier[2], S. Corvec[3], F. Pecorari[1]
[1]CRCINA- INSERM- CNRS- Université d'Angers- Université de Nantes- Nantes- France, Nuclear Oncology Research, Nantes, France
[2]CRCINA- INSERM- Université de Nantes- Université d'Angers- Angers- France, Avenir ATOMycA, Angers, France
[3]CRCINA- INSERM- CNRS- Université d'Angers- Université de Nantes- Nantes- France, Clinical and translational research in skin cancer, Nantes, France

Backgrounds

Display technologies such as Shotgun phage display and ANTIGENome have proven their potential for identification of bacterial adhesins and novel vaccine candidates. However, the coverage of their input genomic libraries is limited by the low-efficient bacterial transformation step.

Objectives

The aim of this work was the development of a completely *in vitro*, ribosome display-based approach for genome-wide identification of host-pathogen interactions without the need for transformation step.

Methods

Genomes of *Staphylococcus aureus*, *Streptococcus gallolyticus* and *Mycobacterium ulcerans* were used. DNA fragmentation (100-1000 bp) was performed with ultrasound. Whole-genome expression libraries were prepared using an alternative GC-based cloning strategy and PCR. Ribosome display selection was performed for 3-4 alternate rounds on plates/beads. Whole genomes, input genomic libraries and selection outputs were sequenced on Illumina MiSeq. In order to validate GeXplore, random genomic libraries of *S. aureus* were selected against human Fc fragment. Subsequently, libraries of *S. gallolyticus* and *M. ulcerans* were selected against patient-derived IgG/IgA preparations.

Conclusions

Completely *in vitro* preparation of genomic expression libraries was achieved with our alternative cloning strategy. Next-generation sequencing revealed high genomic library coverage which, interestingly, was directly proportional to the G+C content of the input genome. After three selection rounds the output consisted mainly of fragments, encoding the IgG-binding domains of the staphylococcal proteins Sbi and SpA. Thus, GeXplore showed high specificity on a genome-wide scale. Finally, we used our method to identify potentially immune-relevant proteins of *S. gallolyticus* and *M. ulcerans*. In conclusion, GeXplore has the potential to streamline the host-pathogen interactome analysis.

New Methods and Techniques

RAPID AND SIMPLE DETECTION OF LIPOPOLYSACCHARIDE IN DRINKING WATER USING SURFACE IMMOBILIZED POLYMYXIN B

H.J. Kang[1]
[1]*Korea University, School of Civil- Environmental and Architectural Engineering, Seoul, Republic of Korea*

Backgrounds

Lipopolysaccharide (LPS) is the main component of the cell walls of gram-negative bacteria and a potent initiator of inflammatory reactions in mammalians. It is necessary to monitor LPS in drinking water, because the lysis of gram-negative bacteria and LPS dispersion may result in various complications such as diarrhea, bleeding, fever, etc. These days the Limulus amoebocyte lysate (LAL) assay is the most popular, but the assay is not suitable to monitor LAL in drinking water containing high concentration of divalent cations. It is thus needed a new assay to be insensitive to the presence of divalent cations.

Objectives

Polymyxin B is produced by *Bacillus polymyxa* and attenuates gram-negative infections by binding to LPS. The binding is reported not to be strongly affected by divalent cations. The aim of this study was to develop a new method using polymyxin B to overcome the disadvantages of the LAL assay.

Methods

Polymyxin B is initially immobilized onto the surface of a 96-well plate using a silane coupling agent. Then, a water sample containing LPS and known amount of FITC-LPS were simultaneously added to the polymyxin B immobilized 96-well plate for competitive binding. Fluorescence intensity was analyzed using a multimode plate reader for assaying LPS in the sample.

Conclusions

The newly developed method was less sensitive to pH, temperature, and divalent cations than the LAL assay. Additionally, the method could detect LPS down to 0.07 EU/mL within 15 minutes. These results suggest that the method is efficient in monitoring LPS in drinking water.

INTRODUCTION OF CULTURE INDEPENDENT METHODS IN THE ROUTINE MONITORING OF MICROBIAL QUALITY OF DRINKING WATER

A. Knezev[1], M. Taucer-Kapteijn[1], E. Penders[1], S. Strating[1], D. Kloes[2], C. de Vries[2], R. Broks[3], R. Steen[1]
[1]Het Waterlaboratorium, Advice, Haarlem, The Netherlands
[2]Het Waterlaboratorium, Biology, Haarlem, The Netherlands
[3]Het Waterlaboratorium, Management, Haarlem, The Netherlands

Backgrounds

The majority of standard methods for microbiological control of drinking water is based on cultivation. Recent developments in microbiology provided a variety of molecular alternatives for the assessment of drinking water quality. Widespread use in research demonstrated the clear benefits of molecular methods. However, lack of a framework for the comparison of data gained by molecular, cultivation independent, techniques with data gained by standard, cultivation-based, techniques represents an important obstacle in the implementation of molecular methods in routine monitoring.

Objectives

Develop a framework for the comparison of molecular methods to cultivation based standards.

Methods

Alternatives for general (GMQ) and hygienic (HMQ) microbial water quality monitoring are discussed. For the GMQ flow-cytometry (FCM) and adenosine three-phosphate (ATP) concentration are compared to heterotrophic plate count (HPC). For HMQ, RNA based detection (RT-PCR) and MALDI-TOF based typing are compared to standard methods for *E.coli* and Enterococci.

Conclusions

Novel methods proved to be faster, highly sensitive and more specific than cultivation based standards. As a result, their application in practice improves operational efficiency and risk control. In spite of higher resolution, new methods also generate uncertainties related to limited information about physiological properties of newly described bacterial species and ecological fate of target components that are used in molecular methods. Wide application of new methods in routine monitoring is crucial to gain real life information, but risks related to uncertainties must be acknowledged and addressed in future scientific research.

TARGETED METAGENOMICS FOR ANALYSIS OF RESISTOMES (RESCAP1.0)

V. Lanza[1], F. Baquero[1], M. Jose Luis[2], R. Ramos-Ruiz[3], B. Gonzalez-Zorn[4], A. Andremont[5], A. Sanchez-Valenzuela[1], D. Ehrlich[6], S. Kennedy[6], E. Ruppe[6], W. van Schaik[7], R.J. Willems[7], F. de la Cruz[8], T.M. Coque[1]
[1]Hospital Universitario Ramón y Cajal University Hospital- Ramón y Cajal Health R, Servicio de Microbiología, Madrid, Spain
[2]CSIC, Centro Nacional de Biotecnologia, Madrid, Spain
[3]Parque Cientifico de Madrid, Unidad de Genómica, Madrid, Spain
[4]Universidad Complutense de Madrid, Facultad de Veterinaria, Madrid, Spain
[5]Hôpital Bichat, Bactériologie Laboratory, Paris, France
[6]Université Paris-Saclay, MGP MetaGénoPolis- INRA, Paris, France
[7]University Medical Center Utrecht, Medical Microbiology, Utrech, The Netherlands
[8]Universidad de Cantabria y IBBTEC, Biologia Molecular, Santander, Spain

Backgrounds

Antimicrobial resistance is considered a major Global Health challenge. The ensemble of antibiotic resistance genes in particular metagenomes constitutes a “resistome”. Methodological limitations of available high-throughput metagenomic technologies could have seriously influenced our perception about the size and diversity of different resistomes.

Objectives

To develop a targeted capture platform (TCP) for improving the quantitative and qualitative analysis of resistomes (ensemble of genes encoding antibiotic resistance and their precursors in metagenomes). To evaluate the pool of antimicrobial resistance genes (heavy metals, biocides) and plasmid markers (relaxases), relevant for the selection and transmissibility of antimicrobial resistance genes.

Methods

ResCap (a TCP based on NimbleGene-Roche technology), includes probes for 8,667 canonical genes (7,963 to antibiotics, 704 to metal & biocides), 76.000 genes homologous to the former ones (47,806 for antibiotics and 30,794 for biocide and metals) and 2,517 relaxase genes (plasmid markers). Comparison of ResCap with metagenomic shotgun sequencing (MSS) was performed using 17 fecal samples (9 humans, 8 swine).

Conclusions

ResCap significantly improves MSS to detect “gene abundance” (from 2.0% to 83.2%) and “gene diversity” (26 versus 14.9 genes per sample per million of reads, 300 fold by using ResCap), which were calculated using novel bioinformatic tools. New approaches are also provided to compare disparate resistomes. ResCap, the first TCP to analyse resistomes, clearly enhance the sensitivity and specificity of available metagenomic methods, provides the possibility to analyse other genes related to antimicrobial resistance and opens the possibility to accurately study other complex microbial systems.

DEVELOPMENT OF RECOMBINASE POLYMERASE AMPLIFICATION ASSAYS FOR DETECTION OF COXIELLA BURNETII

Y. Li[1], Q. Yin[2], Y. Qi[1], Y. Shao[1], J. Li[1], Y. Pan[1], S. LI[1], H. Chen[1], T. Xu[3], B. Yang[2], X. Luo[2]
[1]Huadong Research Institute for Medicine and Biotechniques, Medicine and Biotechniques, Nanjing, China
[2]China Pharmaceutical University, School of Pharmacy, Nanjing, China
[3]Nanjing Medical University, School of Basic Medical Sciences, Nanjing, China

Backgrounds

Coxiella burnetii is the causative agents of Q fever.Q fever is highly fatal and listed as a biological warfare agent. Because the clinical symptom of Q fever is not typical, the disease can be easily missed and misdiagnosed. Sensitive, specific and rapid diagnostic tests for the detection of Coxiella burnetii are necessary to accurately and promptly diagnose patients and ensure that they receive proper treatment.

Objectives

To develop recombinase polymerase amplification assays for detection of Coxiella burnetii

Methods

Recombinase polymerase amplification(RPA) assays using a lateral flow test (RPA-nfo) were developed targeting the 23SrRNA gene of Coxiella burnetii. A group of specific primers and probes with high amplification efficiency at 37°C was screened successfully, and the concentration of reverse primer and the probe was 5μM, respectively. Furthermore, the RPA-nfo reaction was completed in 20 minutes at 37°C followed by a 3-5 minutes incubation at room temperature for development of an immunochromatographic strip.

Conclusions

All the results showed that the constructed RPA detection system has good specificity for detection of Coxiella burnetii without cross-reaction with other viruses, and can detect Coxiella burnetii at levels comparable to that of the quantitative PCR method.The
constructed RPA detection system showed superior detection performance, which could provide technical support for Coxiella burnetii in site detection.

OPTICAL ELASTIC SCATTERING FOR LABEL-FREE IDENTIFICATION OF PATHOGENS

V. Genuer[1], D. Decq[1], J. Méteau[1], C. Belafdil[2], S. Benahmed[1], P.R. Marcoux[1], E. Schultz[1], O. Gal[2], M. Maurin[3]
[1]CEA, Division microTechnologies for Biology and Healthcare, 38054 Grenoble cedex 9, France
[2]CEA, DRT - LIST, 91191 Gif-sur-Yvette, France
[3]CHU Grenoble, Bacteriology Lab- CS10217, 38043 Grenoble cedex 9, France

Backgrounds

Screening *S. aureus* carriers on hospital admissions, especially before surgery, has been shown to reduce the occurrence rate of *S. aureus* infections. Given the large number of individuals requiring screening, rapid and cost-effective methods should be promoted. Chromogenic selective media such as ChromID *S. aureus* were introduced for this goal. They achieve the direct identification of *S. aureus* in one step, thus reducing workload and cost. However, they require a long incubation time (24h to 48h), and some confirmation tests in order to avoid false positive.

Objectives

We report here the ability of optical elastic scattering in discriminating *S. aureus* from other *staphylococci* at an early stage of growth (6h of incubation), directly on ChromID plate. Furthermore, it is compatible with any kind of confirmation tests as it is label-free, non-invasive and non-destructive.

Methods

Our instrument (called Microdiff) is based in Grenoble hospital and performs analyses of the scattering pattern (scatterogram) generated by a microcolony. A laser targets the microcolony to be identified and resulting photons are collected with a camera. Then pattern recognition algorithms yield in a few seconds the most probable identity for the probed microcolony.

Conclusions

A database of 4700 scatterograms over 34 strains was collected on microcolonies, at 6h of incubation on ChromID *S. aureus*. The obtained data were compared to a database so that machine learning can yield identification results. It gave a 91% discrimination rate between *S. aureus* and non-*aureus staphylococci*. As a comparison, color reading at 24h of incubation yields in average 93% of correct classification.

MALDI-TOF SPECTRA ANALYSIS FOR DETECTION OF VANCOMYCIN-RESISTANT ENTEROCOCCUS FAECIUM

A. Mazzariol[1], *L. Galia*[1], *S. Dal Cero*[1], *A. Bertoncelli*[1]
[1]*University of Verona, Diagnostic and Public Health, Verona, Italy*

Backgrounds

Active screening with rectal swabs is useful to detect carriage and contribute to prevention of Vancomycin-resistant enterococci (VRE) healthcare-acquired infections

Objectives

Identify by Maldi-TOF characteristic peak for vancomycin resistance in *Enterococcus faecium*, to minimize reporting time and isolate carriers/patients as soon as possible.

Methods

The study included 196 clinical isolates of *E. faecium,* 140 of them were glycopeptides resistant strains obtained from rectal swabs during screening, and 56 were glycopeptides susceptible isolated from blood culture and urine.

All isolates were identified by Maldi-TOF Vitek MS (bioMerièux) with an adjusted protein extraction protocol, starting from a 1.5 McF solution and using 70% formic acid and equal volume of pure acetonitrile, to ncrease the Maldi-tof performance in the identification of *E. feciucm*

Vancomycin resistance determinants (*vanA, vanB, vanC*) were detected by PCR. All-resistant strains carried vanA, while susceptible strains didn't show any resistance determinant.

Good selected spectra of all strains were considered for analysis. Proteins common both susceptible and resistant strains and with a relative intensity lower than 0.03% were eliminated

We create a final super spectrum with all resistant strains that was compared with Enterococci database and identify the 7870 peak ± 4 Da that correlate with vancomycin resistance.

This peak was absent in all susceptible strains and present in 122 out 140 vancomycin-resistant showing a sensibility of 87% and a specificity of 100% in detecting vancomycin resistant strains**Conclusions**

The presence of the peak it will be useful in the rapid detection of vancomycin resistant clinical isolates.

THE LEVELS OF TRACE ELEMENTS AND OXIDATIVE/NITROSATIVE STRESS PARAMETERS IN PATIENTS WITH BRUCELLA MELITENSIS

M. Miraloglu[1], E. Belge Kurutas[2]
[1], Adana, Turkey
[2]Faculty of Medicine- Sutcu Imam University, Department of Medical Biochemistry, Kahramanmaras, Turkey

Backgrounds

This is the first report regarding to investigate the activities of erythrocyte catalase (CAT) and superoxide dismutase (SOD), levels of plasma malondialdehyde (MDA), nitic oxide (NO), 3-Nitrotyrosine (3-NTx) as oxidative /nnitrosative stress parameters and serum zinc (Zn), copper (Cu) and selenium (Se) concentrations as trace elements were measured in patients with brucella melintensis, and results were compared with those of healthy individuals.

Objectives

The investigation included 31 patient with Brucella melitensis (age: 32.3±3.2) and 26 healthy subjects (age: 33.2±4.9) as control group who were admitted to Department of Medical Microbiology, Faculty of Medicine, Cukurova University.

Methods

The activities of erythrocyte CAT and SOD, levels of plasma MDA were measured as spectrophotometric. The levels of NO and 3-NTx in plasma were measured by ELISA. Serum Zn, Cu and Se concentrations were measured with flame atomic absorption spectrometry.

Conclusions

The mean of erythrocyte CAT and SOD activities and serum Zn and Se concentrations were significantly lower among patients compared with controls ($p<0.001$). However levels of plasma MDA in patients were comparable to controls and the mean NO, 3-NTx and levels in patients were significantly higher than controls ($p>0.001$). A significant positive correlation was found between levels of plasma MDA, NO, 3-NTx and serum Cu concentrations in patients with Brucella melitensis. Decreased Zn and Se levels, antioxidant system insufficiency and increased levels of MDA NO, 3-NTx and Cu were shown in patients with Brucella melitensis. Supplementary trace element antioxidative process may increase scavenger enzyme activities and also clinical symptoms may be amelioration in these patients.

EFFECT OF THE YEAST COFLOCCULATION GENES FLO1, FLO5 AND FLO11 EXPRESSION ON THE YEAST-FILAMENTOUS FUNGUS CO-ADHESION IN A NOVEL IMMOBILIZATION METHOD, "YEASTS BIOCAPSULES"

J. Moreno García[1], F.J. Martín García[2], T. García Martínez[2], J.J. Moreno Vigara[3], J.C. García Mauricio[2], L.F. Bisson[4]
[1], Cordoba, Spain
[2]University of Córdoba, Microbiology, Córdoba, Spain
[3]University of Córdoba, Agricultural Chemistry, Córdoba, Spain
[4]University of California Davis, Viticulture and Enology, Davis, USA

Backgrounds

The use of immobilized systems for alcoholic fermentations offers many advantages over conventional free cell methods: facilitates higher cell densities, improves yield, allows the reutilization of the biocatalyst, among others. A novel method of yeast immobilization, called "yeasts biocapsules", has been developed in which yeast cells are attached to the hyphae of the fungus *Penicillium chrysogenum* forming a matrix in where substrates/products are easily diffused. Yeast cells and *P. chrysogenum* aggregate, or "coflocculate", to further form a biocapsule. Yeast genes *FLO1*, *FLO5* and *FLO11* have recently shown to be involved in the coflocculation process and may therefore be drivers of ecosystem organizational patterns.

Objectives

The aim is to analyze the impact of the yeast genes *FLO1*, *FLO5* and *FLO11* on the biocapsule formation.

Methods

Biocapsules were made with strains *S. cerevisiae* BY4742 and FY23 with *FLO* genes deletion and overexpression, the later constructed using *ADH2* and *HSP30* promoters.

Conclusions

Significant differences were found in terms of % yeast immobilized, with FY23 FLO11-ADH2 showing the highest values. Flo11p is a cell surface glycoprotein required for formation of fibrous interconnections between cells. These results shed light on yeast genes that influence yeast-fungus co-immobilization and might lead to an improvement of biocapsule yeast immobilization efficiency and further extend the field of application for this new system.

EDEN: EVOLUTIONARY DYNAMICS WITHIN ENVIRONMENTS

P.C. Münch[1,2,3], *B. Stecher*[2,4], *A.C. McHardy*[1,3,5,6]
[1]*Helmholtz Centre for Infection Research, Computational Biology for Infection Research, Braunschweig, Germany*
[2]*Ludwig-Maximilian University of Munich, Max von Pettenkofer-Institute for Hygiene and Medical Microbiology, Munich, Germany*
[3]*German Centre for Infection Research DZIF, Partner Site Hanover-Brunswick, Brunswick, Germany*
[4]*German Centre for Infection Research DZIF, Partner Site LMU Munich, Munich, Germany*
[5]*Heinrich Heine University Dusseldorf, Cluster of Excellence on Plant Sciences, Dusseldorf, Germany*
[6]*Heinrich Heine University Dusseldorf, Department of Algorithmic Bioinformatics, Dusseldorf, Germany*

Backgrounds

Metagenomics revolutionized the field of microbial ecology, giving access to Gb-sized datasets of microbial communities under natural conditions. This enables fine-grained analyses of the functions of community members, studies of their association with phenotypes and environments, as well as of their microevolution and adaptation to changing environmental conditions.

Objectives

Phylogenetic methods for studying adaptation and evolutionary dynamics are not able to cope with big data. Calculating the dN/dS ratio for the large-scale sequence data sets that are being generated in metagenomics and comparative microbial genomics is very challenging, due excessive run times of current methods.

Methods

EDEN is the first software for the rapid detection of protein families and regions under positive selection, as well as their associated biological processes, from meta- and pangenome data. It provides an interactive result visualization for detailed comparative analyses. EDEN is available as a Docker installation under the GPL 3.0 license, allowing its use on common operating systems, at http://www.github.com/hzi-bifo/eden

Conclusions

We applied EDEN to 66 samples of the HMP project from six body sites sampled from healthy individuals. Across all body sites, most protein families with significant signs of positive selection in comparison to all other protein families were annotated with transport and binding functions, suggesting the existence of a functional pan-selectome. We also used EDEN to characterize human gut metagenome samples. EDEN determined a significantly higher dN/dS ratio for the protein coding genes from lean individuals compared to overweight and obese individuals, suggestive of a higher functional diversity in the guts of lean individuals.

FEMS7-2680

A METHOD FOR THE IN SILICO DETECTION OF PLASMID FRAGMENTS IN ENVIRONMENTAL SAMPLES

P.C. Münch[1,2,3], *B. Stecher*[2,4], *A.C. McHardy*[1,3,5,6]
[1]*Helmholtz Centre for Infection Research, Computational Biology for Infection Research, Braunschweig, Germany*
[2]*Ludwig-Maximilian University of Munich, Max von Pettenkofer-Institute for Hygiene and Clinical Microbiology, Munich, Germany*
[3]*German Centre for Infection Research, Partner Site Hanover-Brunswick, Brunswick, Germany*
[4]*German Centre for Infection Research, Partner Site LMU Munich, Munich, Germany*
[5]*Heinrich Heine University Dusseldorf, Cluster of Excellence on Plant Sciences CEPLAS, Dusseldorf, Germany*
[6]*Heinrich Heine University Dusseldorf, Department of Algorithmic Bioinformatics, Dusseldorf, Germany*

Backgrounds

Conjugation, the interbacterial transmission of circular DNA, is an biologically important and highly efficient mechanism for the horizontal spread of genes, allowing cells to adapt to different environments i.e. antibiotic resistance. With the aid of metagenomics – the application of random shotgun sequencing to environmental samples – we have the possibility to sequence whole microbial communities including bacterial chromosomes and conjugative genetic elements i.e. plasmid sequences.

Objectives

Until now, the extraction of the plasmid content from a metagenomic sample requires segregation steps which are complex, costly and only applicable to new experiments. Here, we propose a new method for the *in silico* identification and extraction of plasmid fragments allowing to study plasmid diversity and may improve assembly strategies.

Methods

We compared predictive performance of various learning strategies such as random forest (RF), support vector machine (SVM), relevance vector machines (RVM) and logistic regression for the classification task. In each case, we built a classifier based on sequence properties and k-mer content. Plasmidminer is available under the GPL 3.0 license at http://www.github.com/hzi-bifo/plasmidminer

Conclusions

We developed a software tool for discrimination between plasmid-derived and chromosome-derived sequences called Plasmidminer. The algorithm reaches an classification AUC ROC score of 0.93 (+/- 0.01) based on 10-fold cross validation for the discrimination of *Escherichia coli* chromosomes and their plasmid sequences. We furthermore plan to train the classifier to cope with all genomes that are available at NCBI and to handle read and contig-sized sequence fragments.

THE FASTEST AVAILABLE METHOD TO DETECT SOMATIC COLIPHAGES, USED AS INDICATORS OF FECAL POLLUTION IN WATER AND FOOD

M. Muniesa[1], B. Elisenda[1], I. Lejla[1], P.B. Miriam[1], T. Daniel[1], L. Francisco[1], B. Anicet[1], J. Juan[1]
[1]Universitat de Barcelona, Genetic- Microbiology and Statistics, BARCELONA, Spain

Backgrounds

Somatic coliphages are indicators of fecal and viral pollution in water and food and one of the most reliable and cost effective methods. Several countries have already included them in their water management policies. Standardized methods (ISO, EPA) for their enumeration are available, but their implementation in routine laboratories will be favored if user-friendly commercial kits become available.

Objectives

Development of a new method to evaluate somatic coliphages, based in the use of a tailored *Escherichia coli* host strain that allows detection of <10 somatic coliphages in less than 3:00 h

Methods

The host strain *E. coli* WG5 was modified by replacing *uidB* and *uidC* genes encoding the transport of the glucuronic acid inside the cell, and overexpressing *uidA*, encoding the enzyme β-glucoronidase. Because the bacterial cell is unable to incorporate the substrate, the substrate only reaches the enzyme after the cellular lysis caused by phages. After phage-mediated lysis, the intracellular accumulated β-glucoronidase (overexpressed) release to the medium producing a change of color from yellow to dark blue.

Conclusions

The method is robust, sensitive (even less than 5 phages) and very fast. It requires only 1:30 h to detect 50 phages, and 2:15 h for 5 phages. The method is applicable to different types and volumes of environmental and food samples, liquid or solid. It can be also used for quantitative analysis applying the Most Probable Number (MPN). .

This is the fastest microbiological method detecting culturable fecal indicator microorganisms available so far.

New Methods and Techniques

NEW RAPID PCR PROTOCOL BASED ON HIGH-RESOLUTION MELTING ANALYSIS (HRMA) TO IDENTIFY SACCHAROMYCES CEREVISIAE AND OTHER SPECIES WITHIN ITS GENUS

C. Nadai[1], *B. Bovo*[1], *A. Giacomini*[1,2], *C. Viviana*[1,2]
[1]*University of Padova, DAFNAE, Legnaro, Italy*
[2]*University of Padova, CIRVE, Conegliano, Italy*

Backgrounds

Selection projects aiming at the identification of new *Saccharomyces* strains are always on going as the use of the suitable yeast can strongly improve fermented food production, particularly winemaking. They are mainly targeted on *S. cerevisiae*, but others species in the *Saccharomyces* genus are of interest. For this reason, more and more efficient molecular techniques for yeast identification able to accelerate yeast selection process are always needed. Among the *Saccharomyces* genus, four yeasts are widespread in natural environments: S*. cerevisiae*, *S. bayanus*, *S. kudriavzevii* and *S. paradoxus*. Therefore, among the *Saccharomyces* species, their discrimination is of great interest.

Objectives

The development of an assay that allowed an easy, rapid and simultaneous discrimination among the *Saccharomyces* species during yeast selection programs.

Methods

A two-step protocol is proposed. Firstly the *Saccharomyces* genus identification is achieved by multiplex PCR analysis. Then, the *Saccharomyces* species is determined by a new method based on HRMA.

Conclusions

For HRMA two primer pairs have been proposed. The first was able to achieve the simultaneous identification of the four widespread *Saccharomyces* species, the second was used for the unambiguous discrimination of *S. cerevisiae* within its taxonomical genus.

MCRAPD, POTENTIAL IMPORTANCE AND ITS POSITION IN THE TYPING OF BURKHOLDERIA MULTIVORANS AND BURKHOLDERIA CENOCEPACIA

L. Navrátilová[1], P. Jana[1], N. Radko[1], R. Vladislav[1]
[1]Palacký University Olomouc, Department of Microbiology, Olomouc, Czech Republic

Backgrounds

Typing techniques are extremely useful for nosocomial infection surveillance, their material and labour costs still limit their use to retrospective studies.

Objectives

We aimed to test the performance of techniques potentially useful for routine typing, namely the McRAPD.

Methods

48 bacterial isolates recovered from respiratory pathways from 19 patients with chronic pulmonary diseases from the Department of Respiratory Medicine and Department of Pediatrics, University Hospital Olomouc during the period from April 2012 to October 2016 and identified as *B. cenocepacia* or *B. multivorans* by MALDI-TOF MS. This set of isolates was expanded to include 3 epidemic strains of *B. multivorans* RAPD-III from University Hospital Olomouc, 3 reference strains from BCCM/LMG and the 4 strains of Motol University Hospital, which included the Czech and global epidemic strains. We used three RAPD primer AP-12, 270 and 272. For amplification was used LightCycler 96.

Conclusions

In *B. multivorans*, 4 patients were demonstrated to harbour a local hospital epidemic strain described earlier in patients under intensive care in our University Hospital, one of them had in addition another different strain. Whereas 3 patients had a unique strain. In *B. cenocepacia*, two patients had the Czech epidemic strain ST-32. All *B. cenocepacia* strains were different both from the global epidemic strain ET-12. All other strains were unique in individual patients.
McRAPD proved its applicability as rapid and economic strain typing technique. However, the universal applicability in different bacterial species makes this technique a promising screening tool for routine high-throughput epidemiological surveillance of infectious agents.

OPTIMIZATION OF THE METHOD FOR EVALUATION OF THE STRINGENT RESPONSE AMONG DIFFICULT TO CULTIVATION BACTERIAL SPECIES

D. Nowicki[1], M. Cashel[2], A. Szalewska-Palasz[1]
[1]University of Gdansk, Bacterial Molecular Genetic, Gdansk, Poland
[2]National Institute of Child Health and Human Development, Molecular Genetics, Bethesda, USA

Backgrounds

The nucleotide second messengers, guanosine tetra- and penta- phosphate [(p)ppGpp], are responsible for the global downregulation of transcription, translation, DNA replication, and growth rate that occurs during the stringent response. More recent studies suggest that (p)ppGpp is also an important effector in many life processes, including virulence, persister cell formation, and biofilm production as well as antibiotic resistance.

Objectives

The aim of this work was to optimize a method of (p)ppGpp alarmone level assessment for clinical isolates and environmental strains.

Methods

We adapted ^{32}P nucleotide labeling method and thin layer chromatography separation on PEI cellulose plates to assess (p)ppGpp cellular level in strains that are difficult to cultivate. Specified, strain dependent cultivation conditions are one of the most problematic steps in stringent response evaluation for many bacterial isolates. In the routinely used isotope labeling technique cells are grown in defined MOPS minimal medium to avoid influence of pH variation and salinity on TLC separation. Our assay is fitted for most of poorly culturable strains as *Enterococcus faecalis*, *Streptococcus epidermidis*, *Listeria monocytogenes*, *Shigella sonnei*, *Staphylococcus aureus*. The cultures are pre-grown overnight on defined medium plates and then are shifted to liquid medium for ^{32}P labeling for 30'. We used 96-well plate format to rapid and efficient determination of alarmone induction which makes this methods suitable also for screening tests in response to specific stress agents including antibiotics.

Conclusions

The presented method may be useful to assess the stringent control of metabolism in clinical isolates, environmental strains, or other slow growing bacteria.

New Methods and Techniques

ANTIBIOFILM ACTIVITY OF THE THIN ZINC OXIDE FILM FORMED BY ATOMIC LAYER DEPOSITION UNDER UV-A LIGHT

K.H. Park[1], M. Antoinette[1], G.D. Han[2], H.J. Kang[1], J.H. Shim[2], H.D. Park[1]
[1]Korea University, Civil- Environmental and Architectural Engineering, Seoul, Republic of Korea
[2]Korea University, Mechanical Engineering, Seoul, Republic of Korea

Backgrounds

Microorganisms tend to aggregate and adhere to a surface by forming biofilms. Because biofilm cells are embedded by extracellular polymeric substances secreted by themselves, they are less sensitive to antibiotics or antimicrobial agents than planktonic counterpart. Synthesis of a surface resistant to biofilm formation is an important issue, especially when a surface comes in contact with water. One approach for synthesizing an antibiofilm surface is to provide it ability to produce reactive oxygen species (ROS).

Objectives

To synthesize an antibiofilm surface, we formed zinc oxide (ZnO) thin films on glass slides by atomic layer deposition (ALD). Although ZnO nanoparticles are reported to produce ROS, it has not been verified whether ZnO films formed by ALD would produce ROS and, in turn, inhibit biofilm formation. Therefore, this study was aimed to quantify ROS production and evaluate antibiofilm activity by the ZnO film.

Methods

Nanostructures of the ZnO films were characterized by X-ray diffraction, atomic force microscopy, and field-emission scanning electron microscopy. Photocatalytic activities of the ZnO films were analyzed by measuring ROS including superoxide anion, hydroxyl radical, and singlet oxygen. *Staphylococcus aureus* biofilms were formed on the ZnO films in a drip-flow device. Antibiofilm activity was evaluated by confocal laser scanning microscopy.

Conclusions

The ZnO films consisted of closely packed nano-sized hexagonal wurtzite crystalline structures. Under UV-A light irradiation, they produced ROS actively, comparable to ZnO nanoparticles. More importantly, the ZnO films could reduce *S. aureus* biofilms more than half, suggesting that the ZnO thin films formed by ALD is an effective antibiofilm surfaces.

New Methods and Techniques

OPTIMAL RNA EXTRACTION METHOD FOR THE ANALYSIS OF BACTERIAL SMALL RNAS CONTAINED IN MEMBRANE VESICLES

C. Garcia-Bonillo[1], C. Perez-Cruz[1], E. Mercade[1]
[1]University of Barcelona, Department of Biology- Healthcare and the Environment, Barcelona, Spain

Backgrounds

Membrane vesicles (MVs) are released by many Gram-negative bacteria and *Pseudomonas aeruginosa* is one of them. Currently, the presence of *small* RNA (sRNAs) in MVs is being extensively analysed in eukaryotes but remains nearly unexplored in prokaryotes. The methodology of extraction of sRNAs may influence the results obtained in further studies.

Objectives

To determine the optimal RNA extraction method for the analysis of bacterial *s*RNAs contained in MVs in order to support future studies aimed at determining the biological roles of these sRNAs.

Methods

Three different RNA extraction methods were assayed: miRCURY™ RNA isolation kit – Cell & Plant content (EXIQON®), FastRNA™ SPIN Kit for Microbes (MP®) and miRNeasy Mini Kit (QIAGEN®). These kits were used to extract total RNA and, quality and purity of extracted RNA was determined by OD values, capillary electrophoresis and fluorimetry. The efficiency of extraction of *P. aeruginosa* PAO1 *s*RNAs (RsmZ, CrcZ and PhrS) was studied by RT-qPCR.

Conclusions

Results indicate that the kits EXIQON® and MP® extract more effectively the *small* RNAs fraction than QIAGEN®. EXIQON® is recommended to extract *small* RNAs from MVs because the obtained RNA profiles are cleaner, the protocol is easier to perform and the number of copies does not present significant differences with MP®. As the different RNA isolations methods give extensive variations in the sRNAs yields and patterns, it is crucial to select an RNA isolation approach depending on the research purpose.

EXPLODING AN INTERNAL BOMB. BACTERIAL TOXIN-ANTITOXIN SYSTEMS AS A TARGET FOR NOVEL ANTIMICROBIALS

M. Równicki[1,2], T. Pieńko[2,3], J.I. Castilo Silva[2,4], D. Bartosik[5], J. Trylska[2]
[1]College of Inter-Faculty Individual Studies in Mathematics and Natural Sciences, University of Warsaw, Warsaw, Poland
[2]Centre of New Technologies, University of Warsaw, Warsaw, Poland
[3]Faculty of Pharmacy with the Laboratory Medicine Division, Medical University of Warsaw, Warsaw, Poland
[4]Colegio "La Paz", A.C. La Paz S/N, Tijuana- B.C.-, Mexico
[5]Institute of Microbiology, University of Warsaw, Warsaw, Poland

Backgrounds

Insufficient progress in tackling antibiotic resistance has made the development of novel antimicrobial strategies a prime concern. The bacterial toxin–antitoxin systems (TAs) are modules that play a crucial role in bacterial persistence, pathogenicity and cell survival due to the presence of an "internal bomb" – toxin.

Objectives

In this study we investigated an artificial activation of TA using antisense peptide nucleic acid (PNA) oligomers. We targeted TA *mazEF* that was found ubiquitous in *Enterobacteriaceae*.

Methods

The secondary structure of mRNA antitoxin (*mazE*) was predicted using the RNAfold and Mfold software. On this basis, we selected specific regions as targets for antisense inhibition by complementary oligonucleotides. We synthesized PNA (anti-*mazE*) with the cell penetrating peptide $(KFF)_3K$ to assure the delivery of PNA through bacterial cell walls. To evaluate the antimicrobial effectiveness of such PNA we determined the minimal inhibitory concentration (MIC) for bacterial cultures of enteropathogenic *E. coli*. By performing quantitative reverse transcript (qRT)-PCR we examined the decay of *mazE* mRNA in viable bacterial cells after treatment with PNA at different concentrations. Additionally, we checked synergistic interactions between anti-*mazE* PNA and selected antibiotics (polymyxin B, trimethoprim, sulfamethoxazole) defining fractional inhibitory concentration (FIC). Moreover, we determined the population of persister cells after treatment with PNA and with PNA in combination with antibiotics.

Conclusions

Our findings showed that TA *mazEF* could become a novel target for developing antibacterial compounds. We believe that TAs should be investigated further as an effective antibacterial strategy against bacteria.

VITAMIN B12 AS A NOVEL CARRIER FOR ANTISENSE PEPTIDE NUCLEIC ACIDS TO BACTERIAL CELLS

M. Równicki[1,2], M. Wojciechowska[2], A. Wierzba[3], J. Czarnecki[4], D. Bartosik[4], D. Gryko[3], J. Trylska[2]
[1]College of Inter-Faculty Individual Studies in Mathematics and Natural Sciences, University of Warsaw, Warsaw, Poland
[2]Centre of New Technologies, University of Warsaw, Warsaw, Poland
[3]Institute of Organic Chemistry, Polish Academy of Sciences, Warsaw, Poland
[4]Institute of Microbiology, University of Warsaw, Warsaw, Poland

Backgrounds

The widespread emergence of bacterial resistance to known antibiotics creates a need to develop novel antibacterials. The use of short, modified oligonucleotides as inhibitors of bacterial transcription or translation seems a promising strategy. However, the main and yet unsolved problem precluding their use as antibiotics is that bacteria do not uptake synthetic oligonucleotides from the environment.

Objectives

We examined vitamin B12 (cobalamin) as a natural carrier for peptide nucleic acid (PNA) oligomers into Gram-negative *Escherichia coli* and *Salmonella* Typhimurium cells.

Methods

To provide a convenient system to monitor the effect of antisense PNA in *E. coli* and *S.* Typhimurium, we constructed a reporter vector expressing red fluorescent protein (RFP) optimized for expression in *Enterobacteriaceae*. We designed and synthesised an antisense PNA sequence (anti-*rfp* PNA) targeted at mRNA of the Red Fluorescence Protein (RFP). To evaluate the potential of antisense PNA to inhibit the production of RFP, we grew bacteria in the presence of anti-*rfp* PNA covalently linked to five different vitamin B_{12} derivatives. As a control we used PNA conjugated to the most widely used cell-penetrating peptide $(KFF)_3K$. We examined different types and lengths of the spacer between vitamin B_{12} and PNA, including a cleavable disulfide bond. We found that vitamin B_{12} transports antisense PNA to Gram – negative cells more efficiently than the $(KFF)_3K$ peptide. We also found that the structure of the linker impacts the antisense effect.

Conclusions

Our study provides the foundation for developing vitamin B_{12} as a carrier for PNA oligonucleotides to bacterial cells for any desired applications.

DEVELOPMENT OF A MALDI IMAGING MASS SPECTROMETRY APPROACH TO BACTERIAL PROTEOMICS: FIRST APPLICATION TO LISTERIA MONOCYTOGENES BIOFILMS EXPOSED TO DESICCATION

T. Santos[1], D. Centeno[2], C. Chambon[2], D. Viala[2], M. Hébraud[1,2]
[1]INRA, Université Clermont Auvergne- INRA- UMR MEDiS, Saint-Genès-Champanelle, France
[2]INRA, Plateforme d'Exploration du Métabolisme PFEM, Saint-Genès-Champanelle, France

Backgrounds

Human listeriosis cases are due to the ingestion of contaminated foods with *Listeria monocytogenes* and most cases are connected with food contamination in industries. The control of *L. monocytogenes* is difficult to achieve in processing environments due to its survival capabilities. Water availability has particular biological importance and bacteria are submitted to variations in air relative humidity (RH) in food processing plants. This bacterium is also able to grow as a biofilm but the underline features as how biofilms adapt to desiccation are not well-known. Matrix-assisted laser desorption/ionization time-of-flight imaging mass spectrometry (MALDI-TOF IMS) is a surface-sampling technology that can determine spatial information and relative abundance of analytes directly from biological samples. Spectra are collected and each peak intensity in the spectra is used to generate an ion intensity map.

Objectives

This study aims to develop an IMS approach to explore the protein expression and *in situ* distribution of proteins within *L. monocytogenes* biofilms exposed to desiccation.

Methods

L. monocytogenes biofilms were grown in MCDB medium during 48h before being exposed to a moderate desiccation environment (24h at 10ºC/ 75% RH), mimicking the food workshop conditions. After matrix spraying, mass spectra were acquired on a MALDI-TOF/TOF MS and processed through SCiLS software.

Conclusions

Data analyses allowed to distinguish protein localization patterns between the two conditions and chose target mass peaks for further analysis. These data demonstrate how imaging can be used to dissect the spatial proteome of an intact bacterial biofilm giving a new insight into protein regulation relating to biofilm adaptation.

New Methods and Techniques

DEVELOPMENT OF A STRAIN-SPECIFIC REAL-TIME PCR ASSAY FOR ENUMERATION OF A PROBIOTIC LACTOBACILLUS REUTERI IN CHICKEN FEED AND INTESTINE

V.A. Sattler[1], *M. Mohnl*[1], *V. Klose*[1]
[1]*BIOMIN Research Center, TFZ, Tulln, Austria*

Backgrounds

Strain-specific identification of probiotics is essential for accurate quantification and monitoring of the bacteria in animal feeding studies.

Objectives

Objective was to develop a strain-specific real-time PCR assay for quantification of a probiotic *Lactobacillus reuteri* (DSM 16350) in poultry feed and intestine.

Methods

Strain-specific primers pwere designed from *L. reuteri* DSM 16350 genomic sequences derived after suppression subtractive hybridization with the type strain *L. reuteri* DSM 20016. Specificity was tested using a set of non-target strains. Applicability of the real-time PCR assay was evaluated in a controlled broiler feeding trial. The probiotic *L. reuteri* was quantified in feed from three feeding phases and in intestinal samples of the jejunum, ileum, and caecum of three, 14, and 39 day old birds. In all probiotic supplemented feed *L. reuteri* was enumerated close to the inclusion rate of 7.0 x 10^3 cfu/g, and was not detected in control feed. In three day old birds *L. reuteri* DSM 16350 was only detected in intestinal samples from probiotic fed animals ranging from 8.2 ± 7.8 x 10^5 cfu/g in the jejunum, 1.0 ± 1.1 x 10^7 cfu/g in the ileum, and 2.5 ± 5.7 x 10^5 cfu/g in the caecum. Similar results were obtained for intestinal samples of older birds. With increasing age of birds the amount of *L. reuteri* signals in the control animals also increased.

Conclusions

This strain-specific real-time PCR assay could be used to assure accurate inclusion of the probiotic to the feed and to monitor it’s uptake into the GIT of young chicken.

FEMS7-2006
New Methods and Techniques

EXPLORING NOVEL ANTIMICROBIAL AGENTS FROM GUT METAGENOME

V. Sharma[1], A. Sharma[1], S. Kumar[1], S. Gupta[1]
[1]Indian Institute of Science Education and Research Bhopal, Biological Sciences, Bhopal, India

Backgrounds

The efficacy of antibiotics against bacterial infections is decreasing, thus there is a need to search for potential alternatives to antibiotics.

Objectives

Two novel antibacterial agents, enzymes and peptides, appear promising for treating bacterial infections. Among these, Peptidoglycan hydrolases can be used as alternate antibacterial agents due to their unique property of cleaving peptidoglycan cell wall present in both gram-positive and gram-negative bacteria. Small peptides can be used as anti-microbial agents due to their potential as inhibitors of biofilm.

Methods

Based on the site of action of peptidoglycan hydrolases, a Random Forest-based computational tool 'HyPe' (http://metagenomics.iiserb.ac.in/hype/) is developed for identification and classification of novel peptidoglycan hydrolases from genomic and metagenomic data. It displayed 71.12%-100% sensitivity, 99.98% specificity, 99.55% accuracy and 0.80-0.94 MCC values, and thus can be used to predict novel antibacterial agents. Similarly, to predict the anti-microbial nature of small peptides on biofilms, we have developed a unique computational method ‘BioFin’ (http://metagenomics.iiserb.ac.in/biofin/) based on Support Vector Machine-based prediction models and additionally by including sequence motifs information. It displayed the > 97% accuracy and > 0.84 Matthews Correlation Coefficient (MCC) values and thus, can be used to predict antimicrobial peptides.

Conclusions

HyPe can be used for the identification and classification of novel antibacterial peptidoglycan hydrolases and BioFin can be used as a tool for the prediction of antibacterial peptides from complete genomic/metagenomic ORFs. The results and highlights of these two novel antibacterial agent prediction tools will be presented.

APPLICATION OF FUNGAL LACCASES FOR OXIDATION OF HYALURONIC ACID

D. Smirnou[1], M. Hermannová[2], L. Franke[1], J. Jílková[1], S. Pepeliaev[1], V. Velebný[3]
[1]Contirpo a.s., R&D, Dolni Dobrouc, Czech Republic
[2]Contipro.a.s., R&D, Dolni Dobrouc, Czech Republic
[3]Contirpo a.s., CEO, Dolni Dobrouc, Czech Republic

Backgrounds

Hyaluronan (HA) is a high-molecular glycosaminoglycan, which fulfils important functions in human organism. Due to unique properties and biocompatibility, HA is abundantly used in medicine and cosmetics. Extra functionality is added to HA by means of modification of its chemical structure. Introduction of aldehyde groups in HA molecule is one of the most required modifications. Our study shows that this reaction can be performed by applying fungal enzymes laccases.

Objectives

To develop a laccase-mediated process of primary hydroxyl on *N*-acetyl-D-glucose amine oxidation to aldehyde.

Methods

HA oxidation with enzyme-mediator system, composed of laccase from fungi *Trametes versicolor*, *Pleurotus ostreatus* or *Agaricus bisporus*, and mediators TEMPO, 4-amino-TEMPO or 4-acetamido-TEMPO was studied. For the best enzyme-mediator system reaction parameters were optimized. Chemical structure of oxidized HA was characterized using NMR and LC-MS.

Conclusions

“Green” technology for HA oxidation using enzyme-mediator system was elaborated. The reaction was conducted in mild conditions without application of highly corrosive reagents. Primary hydroxyl on C6 of *N*-acetyl-D-glucose amine in HA molecule was oxidized highly specifically. For oxidized HA with degree of substitution to aldehyde 7 – 12 %, over-oxidation to carboxyl was as high as 2.8% only. HA oxidation applying fungal enzymes laccases is an advantageous technology over the conventionally used TEMPO/NaOCl technique.

FEMS7-2001

CELLS-PMAQPCR ASSAY FOR DIRECT AND RAPID QUANTIFICATION OF SACCHAROMYCES CEREVISIAE VIABLE CELLS IN WINE

V. Soares-Santos[1], *P. Borredat*[1], *I. Pardo*[1], *S. Ferrer*[1]
[1]*ERIBiotecMed, ENOLAB, Valencia- Burjassot, Spain*

Backgrounds

Saccharomyces cerevisiae is the main species involved in alcoholic fermentation. Despite its main role in winemaking, *S. cerevisiae* is able to spoil sweet wines, causing refermentations. Molecular methods, as quantitative PCR (qPCR), have been developed for rapid detection and enumeration of yeasts. Recently, some dyes as propidium monoazide (PMA), have been used in conjunction with qPCR to selectively detect live cells. Nonetheless, this methodology requires a previous DNA extraction step that greatly increases the overall assay time and cost.

Objectives

To develop a fast and reliable qPCR method in conjunction with PMA, and without DNA extraction steps (Cells-PMAqPCR). To apply the developed methodology to detect and quantify viable cells of *S. cerevisiae* in white and red wines.

Methods

Optimization of cells suspensions treatment by different amounts of PMA (0, 5, 10, 25, 50, 100, 200 µM). Construction of standard curves in culture medium, white and red wines matrices. Comparison of the Cells-PMAqPCR assay with plate count values.

Conclusions

The developed method allows differentiating between live and dead cells of *S. cerevisiae* both in white and red wines, avoiding DNA extraction and overcoming the presence of inhibitors like polyphenols and ethanol. Cells quantification was linear over five orders of magnitude and detected as few as one viable cell per reaction in all the matrices. The Cells-PMAqCells provides a useful tool for the specific, fast and reliable quantification of viable cells, enabling winemakers to take quick decisions controlling the viability of the starters, the fermentation process, and the risk of refermentation.

FEMS7-2015

LAMP ASSAY FOR DIRECT AND RAPID DETECTION OF OENOCOCCUS OENI CELLS IN WINE

V. Soares-Santos[1], *I. Pardo*[2], *S. Ferrer*[2]
[1]*Universitat de Valencia, Departamento de Microbiologia y Ecologia, Valencia- Burjassot, Spain*
[2]*ERIBiotecMed, ENOLAB, BURJASSOT, Spain*

Backgrounds

Oenococcus oeni is the most common species of lactic acid bacteria associated with the malolactic fermentation (MLF) in wine. Fast enumeration of *O. oeni* is necessary to determine whether MLF is likely to be performed or not, and to decide if the use of a commercial starter is needed. Traditional methods for enumerating microorganisms involve time-consuming plating and microscopic observation techniques, which means delays in taking wine-processing decisions. Recently, a novel molecular method termed loop-mediated isothermal amplification (LAMP) allows fast amplification of DNA with high specificity, sensitivity under isothermal amplification condition.

Objectives

To design new primers and adapt the LAMP methodology to detect *O. oeni* directly in white and red grape musts and wines.

Methods

New *O. oeni* LAMP specific primers have been designed, and their specificity has been evaluated. LAMP reactions have been performed in culture media, and white and red grape musts and wines.

Conclusions

A designed primer set allowed the specific detection of *O. oeni* by LAMP in the culture medium, and in white and red grape must and wine matrices, overcoming the presence of inhibitors as ethanol and polyphenols. The detection limit was 12 and 120 cells per reaction in white and red wines, respectively. The LAMP assay for the identification of *O. oeni* is advantageous in terms of speed (<40 min), specificity and ease of operation compared with traditional methods. Only a thermostatic isothermal bath or block is required for a visual detection of microorganisms, and can be easily adapted for a specific quantification.

SWINE UROTHELIUM CELL CULTURE – A NEW MODEL FOR ASSESSING UROPATHOGENIC POTENTIAL OF HUMAN UPEC STRAINS

L. Predojević[1], D. Žgur-Bertok[1], D. Keše[2], M. Erdani Kreft[3], M. Starčič Erjavec[1]
[1]University of Ljubljana - Biotechnical Faculty, Department of Biology, Ljubljana, Slovenia
[2]University of Ljubljana- Faculty of Medicine, Institute of Microbiology and Immunology, Ljubljana, Slovenia
[3]University of Ljubljana- Faculty of Medicine, Institute of Cell Biology, Ljubljana, Slovenia

Backgrounds

Escherichia coli (*E. coli*) is a member of the gut microbiota however, *E. coli* strains capable of causing intra and extraintestinal infections do exist. A prominent group of pathogenic *E. coli* strains are uropathogenic *E. coli* strains (UPEC).

Objectives

The main aim of this study was to set up a model for evaluation of the uropathogenic potential of *E. coli* strains based on normal urothelial cell cultures derived from swine bladders.

Methods

The following *E. coli* strains were used: UPEC strains (J96 and 536), two laboratory strains (MG1655 and DH5α) and a commensal strain (BJ16) isolated from the feces of a healthy human. The following methods were used: cultivation of cell cultures in wells on plastic plates, preparation of bacterial suspensions, pathogenicity assays with determination of cell viability using the trypan blue staining method. On the basis of viability (percent of live cell culture cells) the pathogenic potential of tested *E. coli* strains was determined.

Conclusions

Viability of urothelium cells after 1h exposure to *E. coli* strains J96, 536, MG1655, DH5α and BJ16 was 85%, 94%, 83%, 88%, and 92%, respectively. The viability of urothelium cells after a 3h exposure to the employed *E. coli* strains was 53%, 73%, 91%, 95% and 89% (in the same order as above). The obtained results clearly demonstrate that the swine urothelium cell culture can be used as a model for human UPEC.

MYCROBIOTA: A USER-FRIENDLY GALAXY APPLICATION FOR MICROBIOTA DETERMINATION AND DYNAMIC REPORTING FROM 16S RRNA GENE SEQUENCES

A. Stubbs[1], S. Boers[2], S. Hiltemann[1], B. Kriesels[1], P. van der Spek[1], R. Jansen[3], J. Hays[2]
[1]Erasmus MC, Bioinformatics, Rottedam, The Netherlands
[2]Erasmus MC, MMIZ, Rottedam, The Netherlands
[3]Streeklab, Molecular biology, Haarlem, The Netherlands

Backgrounds

Many researchers have embraced 16S rRNA gene profiling techniques that has led to a wealth of publications and documented differences in the composition of microbial communities. The resultant microbiota profiles are generated using bioinformatics approaches for which sophisticated software, such as mothur and QIIME, are freely available. Unfortunately however, the use of these bioinformatics tools remains complex for the non-bioinformatics scientist.

Objectives

Development of MYcrobiota – a standardized analytical workflow to determine bacterial taxa from 16s rRNA gene sequences using the functionality enabled within Galaxy.

Methods

Galaxy is a user-friendly web tool, which provides access to complex bioinformatics tools and workflows via a simple graphical user interface (GUI). We have implement mothur as a set of ~100 Galaxy tools to deliver 16S rRNA gene analysis. These tools have been combined as an “end to end” analysis service (MYcrobiota) for one or multiple samples with user defined reporting based on our iReport functionality [Hilteman et al 2015]. The associated iReport includes a dynamic visualization of bacterial taxonomies – from phylum to genus level detected per sample and a means to summarize the whole experiment using the dynamic Phinch metagenomics viewer integrated into Galaxy. We demonstrate the functionality of MYcrobiota using a published 16S rRNA gene dataset from Boers, Hays and Jansen (2015).

Conclusions

The mothur Galaxy tool set are available for download from the Galaxy toolshed (https://toolshed.g2.bx.psu.edu/) and for use with MYcrobiota at https://bioinf-ttt.erasmusmc.nl/MMIZgalaxy. The utility of our mothur Galaxy toolset is demonstrated with our online tutorial (https://github.com/shiltemann/training-material/blob/add-metagenomics-module/Metagenomics/tutorials/MOTHUR-MiSeq-SOP.md) based on the mothur MiSeq SOP.

OBTENTION OF MINIMUM INHIBITORY CONCENTRATION (MIC) PREDICTION EQUATIONS FOR ANTIBACTERIAL QUINOLONES VERSUS PROTEUS MIRABILLIS AND MORAXELLA CATARRHALIS

B. Suay[1], J.I. Bueso-Bordils[1], M.T. Perez-Gracia[1], G. Anton-Fos[1], L. Lahuerta-Zamora[1], R. Martin-Algarra[1], P. Aleman-Lopez[1]
[1]University CEU Cardenal-Herrera, Pharmacy, Valencia, Spain

Backgrounds

The search of new molecules with therapeutic activity is a laborious process with an elevated economic cost. Quantitative relationships between chemical structure and activity have meant an important saving of money and time. Among the different methods used, molecular topology has showed to be a useful tool to find new drugs.

Objectives

In this work, a multilinear regression analysis was carried out in order to look for functions capable of accurately predicting biological properties of a group of quinolones.

Methods

The functions were developed with data regarding quinolone activity due to their fast evolution and pharmacological properties. The species targeted in this study were *Proteus mirabillis* and *Moraxella catarrhalis* because these Gram-negative bacteria are very common human pathogens. The studied properties were minimum inhibitory concentration 90 (MIC_{90}) versus these two microorganisms. Structural description was achieved through topological indices. Randomization and cross-validation by using leave-one-out test were also performed in order to assess the stability and the prediction ability of the functions selected.

Conclusions

The following prediction equations were obtained with good statistical data:

$$MIC_{90}Pm = -2.58 - 84.04^{6}\chi ch - 8.11^{3}\kappa + 36.93 IShannon$$

(n=14; SEE=1,487; SEE(cv)=1.866; r^2=0.92; r^2(cv)= 0.858)

$$MIC_{90}Mc = -2.83 - 0.103^{6}\chi_p + 0.987 NI_2 + 1.6 J_4$$

(n=13; SEE=0.018; SEE(cv)=0.033; r^2=0.884; r^2(cv)=0.637)

The obtained results demonstrate that molecular topology is a very useful tool in the prediction of microbiological properties.

BACTERIAL CELL MEMBRANE BARCODING, A SERS MAPPING METHODOLOGY FOR IDENTIFICATION AND DETECTION OF POTENTIAL PATHOGENIC BACTERIA

T. Szoke-Nagy[1,2], N.E. Dina[1], A. Colniță[1], I.B. Cozar[1]
[1]National Institute for Research and Development of Isotopic and Molecular Technologies, Department of Molecular and Biomolecular Physics, Cluj-Napoca, Romania
[2]Babes-Bolyai University - Faculty of Biology and Geology, Department of Molecular Biology and Biotechnology, Cluj-Napoca, Romania

Backgrounds

To develop a new technique for rapidly identification and detection of potential pathogenic microorganisms, using an ultrasensitive method based on Surface-enhanced Raman spectroscopy (SERS), as alternative to conventional culture-based and nucleic acid-based methods.

Objectives

Determination of SERS marker bands for identification of potential pathogenic microorganisms, isolated from the environment.
Preliminary tests for identification of bacteria from liquid media that mimic the complex biological sample.

Methods

Bacterial strains were isolated from environmental samples and were identified based on 16S rRNA molecular markers, using 27FB-1492R primer pair.
The SERS spectra was recorded with a confocal Renishaw inVia Reflex Raman Spectrometer using either the 532nm (Cobolt, Diode Pumped Solid State – DPSS – 200 mW) or 633 nm (He-Ne laser – 17 mW) excitation line, by using the 100× objective (Leica, NA 0.9, WD 3.4 mm). The SERS-active silver clusters were generated by using the *in situ* synthesis, in the presence of the bacterial biomass. The SERS fingerprinting is based on enhanced Raman signal arising from the “hot-spots” generated in the close proximity of the bacterial cell wall.
The bovine serum was used as complex biological media; prior to use, bovine sera was centrifuged using Vivaspin® 15R Centrifugal Concentrator in order to remove the serum proteins.

Conclusions

Specific SERS marker bands were identified for both Gram-positive and Gram-negative strains, specific for bacterial cell membrane components. By using robust chemometric data analysis tools, the discrimination at strain level of bacteria was assessed; even predicting their virulence or resistance to drug treatment is possible.

THE MULTI LOCUS SEQUENCE TYPING (MLST) OF PASTEURELLA MULTOCIDA, A TECHNICAL APPROACH

K. Tadayon[1], R. Ghgaderi[1], A.R. Jabbari[1], M. Sekhavati[1], A. sanchooli[1], A. arab[1], R. Banihashemi[1]
[1]Razi Vaccine & Serum Research Institute- Agricultural Research- Education and Ex, Aerobic Bacterial Vaccine, Karaj, Iran

Backgrounds

Currently, there are two *Pasteurella multocida* MLST schemes including the British Multiple host MLST that holds isolates from variety of animal hosts, including cattle, sheep, pigs and birds. This database is more concentrated on evolutionary relationships between the isolates. The second database is Australian and was developed by the Rural Industries Research and Development Corporation so-called RIRDC MLST with an initial focus on avian isolates and epidemiological theme.Both systems assay polymorphism in limited stretches of 7 housekeeping genes among which four are shared by both.

Objectives

The fact that there is no previous MLST experience on *Pasteurella multocida* in Iran, a principle scope of the present work was establishment of the technique.

Methods

Using the Primer 3 program, seven new primer pairs recommended by RIRDC MLST were designed against the genome of P. multocida P70 reference strain. This was performed in a way that 7 PCR products matching with the corresponding target sections of the of adk, est, gdh, mdh, pgi, pmi and zwf genes were all within the range of 500-700 bp.

Conclusions

Amplification protocols were optimized and set as a single identical protocol could be used for all the 7 loci. Feasibility of these modifications was successfully tested against a single field isolate and two vaccinal strains of *Pasteurella multocida.*Our observations proved suitability of the employed modifications that can be easily used in any MLST work on *Pasteurella multocida*

NOVEL DERIVATIVE OF ARYLIDENIMINO-1,3-PYRIMIDINES (MET-253) AS POTENTIAL DRUG CANDIDATES FOR THE TREATMENT OF PNEUMOCYSTIS PNEUMONIA

V. Tetz[1], *T. George*[2]
[1]*TGV-inhalonix- LLC, Microbiology, New York, USA*
[2]*TGV-inhalonix- Inc, Microbiology, New York, USA*

Backgrounds

Pneumocystis pneumonia is a life-threatening lung disease caused by fungus *Pneumocystis* spp. PCP is still a frequent and severe opportunistic infections in immunocompromised patients. Treatment of PCP remains a challenge due to high mutation rates of *Pneumocystis* spp. to standard compounds and treatment-associated toxicity. The goal was to examine in vitro MICs and LD50 of the novel antifungal "Met-253", against *P.carnii* and *P.murina*

Objectives

Both pentamidine and Met-253 (first-in-class antifungal, derivative of arylidenimino-1,3-pyrimidines (C12H8Cl2N3NaO3) were found to display antimicrobial activity anti-Pneumocystis activity (Tables 1 and 2).

Table 1. Average Met-253 IC50 Determinations

Fungi	24h (mcg/ml)	48h	72h
P.carnii	3.90+/-2.0	2.56+/-0.57	1.61+/-1.72
P.murina	3.30+/-0.19	1.50+/-0.13	0.165+/-0.06

Table 2. Percent reduction in ATP/media control

Fungi	Drug (mcg/ml)	24h	48h	72h
P.carnii	Pentamidine 1	81.14	86.55	87.57
	Met-253 10	68.2	90.27	95.58
	Met-253 1	10.2	12.78	26.78
P.murina	Pentamidine 1	92.07	97.7	98.12
	Met-253 10	76.56	98.51	97.92
	Met-253 1	10.82	42.11	94.42

Met-253 demonstrated moderate activity against *P.carnii* and marked activity in *P.murina*. Reduction in ATP occurred in a time and dose-dependent manner over the 72-h testing period LD50 values of Met-253 in mice were 7980±750mg/kg (p.o.) and 13880±920mg/kg (p.o.) in rats.

Methods

P.carnii and *P.murina*, were distributed into 48-well-plates with final concentration of 7.5log10nuclei/ml Pc anf 6.5log10nuclei/ml Pm. Control and compound dilutions were added and

incubated at 36^{O}C, 5%CO2. At 24-48-72h 10% of the well volume was removed and the ATP content was measured using luciferin-luciferase assay. IC50 was calculated using INSTAT linear regression program. Triplicate IC50 determinations were averaged. Oral LD50 of Met-253 in was determined. Experiments were executed in accordance with the Guide for the Care and Use of Laboratory. LD_{50} was calculated according to the method described by Litchfield and Wilcoxon.

Conclusions

Our study (some data were generated by NIH/NIAID) demonstrated that novel antifungal Met-253 possesses high anti-Pneumocystis activity and low toxicity.

UV AND MASS SPECTROMETRY IMAGING METABOLOMICS FOR THE DECONVOLUTION OF MICROBIAL INTERACTIONS.

V. Gonzalez-Menendez[1], R. Serrano[1], F. Muñoz[2], J. Martin[2], G. Martinez[1], O. Genilloud[1], J.R. Tormo[2]
[1]Fundacion MEDINA, Microbiology, Granada, Spain
[2]Fundacion MEDINA, Chemistry, Granada, Spain

Backgrounds

Co-culturing has proved to be an effective tool to simulate the physiological conditions that occur during microbial interaction in their natural environment and may have an enormous potential for the discovery of new molecules with therapeutic applications. Recent detection techniques that evaluate natural products by Image Mass Spectrometry (IMS) have been shown to be extremely suitable for analyzing microbial interactions and detecting in situ activation of cryptic pathways.

Objectives

Develop a methodology to visually map the secondary metabolites produced by microorganisms and identify those induced by the interactive co-cultivation.

Methods

In order to provide a spatial dimension to the microbial interaction, samples were analyzed by uHPLC-UV and by low resolution mass spectrometry (LR-MS) in the range of positive m/z for each extract. Mass spectra were collected from 150 m/z to 1500 m/z in positive mode. Compound management and automated micro-extraction methodologies were combined with in house HPLC Studio 2.0 and MASS Studio 1.0 software developments to generate ultraviolet and mass spectrometry images of interacting co-cultured endophytes.

Conclusions

After a screening of interesting co-cultures this technology was applied on two clear antagonic strains in order to set up this characterization methodology and their metabolomics interactions. Data analyses highlighted patterns of localized induction of secondary metabolites, otherwise not produced when strains were cultured axenically, and proved that this technology can speed up the discovery of induced natural products from on microbial interactions.

BACTERIOPHAGE AS EFFECTIVE DECOLONIZING AGENT FOR STAPHYLOCOCCUS AUREUS CARRIERS

A. Ulu Kilic[1], A. Gundogdu[2], H. Kilic[3], B. Aslan[4], E. Alp[1]
[1]Erciyes University, Infectious Diseases and Clinical Microbiology, Kayseri, Turkey
[2]Erciyes University- Faculty of Medicine-, Microbiology and Clinical Microbiology, Kayseri, Turkey
[3]Erciyes University Medical Faculty, Microbiology and Clinical Microbiology, Kayseri, Turkey
[4]Erciyes University, Microbiology, Kayseri, Turkey

Backgrounds

Staphylococcus aureus (SA) is a common cause of hospital- and community-acquired infections. Asymptomatic colonization with SA in the nares may precede infection. There is great interest in preventing the transmission of SA and decolonizing persons who harbor these bacteria.

Objectives

We aimed to investigate invitro activity of multiple lytic phage cocktails as decolonising agent.

Methods

This study included *SA* strains isolated from nasal swabs of hospitalized patients and blood culture of bacteremic patients. Identification of strains was performed using conventional microbiological methods. The in vitro susceptibilities of SA isolates obtained from colonized and bacteremic adult patients examined by using six different commercial phage preparations. These were Pyo-bacteriophage (Pyo), Intesti-bacteriophage (intesti), Enko-phage (Enko), SES-bacteriophage (Ses), Fersisi-bacteriophage and Staphylococcal bacteriophage (Sb). Susceptibility of isolates was determined by observing confluent, semi-confluent, opaque lysis or individual plaques. The absence of any lysis has been reported as resistance.

Conclusions

Forty two MRSA strains isolated from blood culture of bacteremic patients were included to the study. Of them 5 (12%) found resistant to phage cocktails for Pyo, 9 (21%) for SES, 10 (23.8%) for Fersisi, 3 (7%) for İntesti, 10 (24%) for Enko, 6 (14.2%) for Sb. Only one of these strains was resistant to all six phage cocktails.Twenty eight isolates obtained from nasal swabs of patients routinely screened for colonization by *SA* were included to the study. Of all, among methicilin sensitive isolates only one (1/25, 4%) was resistant to all six phage cocktails. Of all 3 MRSA strains one was resistant to all phage cocktails. Bacteriophages may be considered as effective decolonizing agent for SA nasal carriers. For this approach to be successful in clinical settings, need to study a cocktail of phages covering a larger spectrum of strains is required.

AN INTEGRATIVE PROTEOGENOMICS STRATEGY TO IDENTIFY THE ENTIRE PROTEIN CODING POTENTIAL OF PROKARYOTIC GENOMES

A. Varadarajan[1,2], U. Omasits[1], S. Goetze[2], M. Robinson[3], B. Wollsceid[2], C. Ahrens[1]
[1]Agroscope & SIB Swiss Institute of Bioinformatics,
Research Group Molecular Diagnostics- Genomics and Bioinformatics, Wadenswil, Switzerland
[2]ETH Zurich,
Department of Health Sciences and Technology & Institute of Molecular Systems Biology & BioMedical Proteomics Platform BMPP, Zurich, Switzerland
[3]University of Zurich, Institute for Molecular Life Sciences & SIB Swiss Institute of Bioinformatics, Zurich, Switzerland

Backgrounds

Accurate genome annotation is relevant at all levels, from small, focused experiments to large functional screens, systems biology studies, upto prediction of gene regulatory, interaction and metabolic networks. Yet, the over-prediction of random ORFs and underrepresentation of true, functional sORFs (short ORFs) represent a major limitation.

Objectives

We present a proteogenomics strategy that integrates protein-coding genes from major reference genome annotation resources, gene prediction algorithms and *in silico* ORFs. Using this approach, we create minimally redundant integrated proteogenomics databases (iPtgxDBs) that cover the entire protein-coding potential of prokaryotic genomes.

Methods

Data from a complete expressed proteome searched against the iPtgxDB helped to uncover novel ORFs, start sites and incorrectly predicted pseudogenes including cases uniquely predicted by each resource. We show that the E-value distributions of PSMs for novel hits and target proteins is similar, and confirm expression of novel ORFs and expressed pseudogenes by parallel reaction monitoring (PRM).

Conclusions

Our approach is generic (it worked for genomes with widely varying GC content), and flexible: iPtgxDBs can be created for key model organisms (e.g. E.coli BW25113, parental strain of the Keio-knockout collection) up to newly sequenced genomes. We illustrate this with expression evidence for ORFs in unique genome regions of a lab strain compared to its NCBI reference genome, down to even single amino acid variations, which will have implications in clinical proteomics and beyond. We will release iPtgxDBs for several organisms to enable a large number of research groups to apply proteogenomics in the initial genome annotation step.

DETECTION AND QUANTIFICATION OF ML01, A GENETICALLY MODIFIED SACCHAROMYCES CEREVISIAE WINE STRAIN, USING EVENT-SPECIFIC METHOD BASED ON QUANTITATIVE PCR

E. Vaudano[1], *A. Costantini*[1], *E. Garcia-Moruno*[1]
[1]*CREA-Consiglio per la Ricerca in Agricoltura e l'Analisi dell'Economia Agraria -, microbiology, Asti, Italy*

Backgrounds

Despite the availability of transgenic wine yeast for several years, their use is only authorized in a few countries and limited to two strains: ML01, able to convert malic acid into lactic acid during alcoholic fermentation, and ECMo01 suitable for reducing the risk of carbamate production. In the remaining countries which produce wine, to date, their use has not been allowed.

Objectives

In this work we propose an event-specific qPCR technique based on the use of specific primers and probes for the detection and quantification of a transgene event in GM ML01 *Saccharomyces cerevisiae* in relation to the *S. cerevisiae* taxon-specific target *MRP2*. The applicability of the technique has been tested for determination of the GM ML01 strain in active dry yeast preparation.

Methods

The method consists in efficient extraction of DNA and qPCR (quantitative PCR) analysis based on event-specific assay targeting *MLC* (malolactic cassette), and a taxon-specific *S. cerevisiae* assay detecting the *MRP2* gene.

Conclusions

The ADY DNA extraction methodology has been shown to provide good purity DNA suitable for subsequent qPCR. The *MLC* and *MRP2* qPCR assays showed characteristics of specificity, dynamic range, limit of quantification (LOQ) limit of detection (LOD), precision and trueness, which were fully compliant with international reference guidelines. The method has been shown to reliably detect 0.005% (mass/mass) of GM ML01 *S. cerevisiae* in commercial preparations of ADY.

EVALUATING OGATAEA POLYMORPHA MALTASE SUBSTRATE SPECIFICITY VIA CLASSICAL ACTIVITY-BASED ASSAYS AND A NOVEL DSF METHOD

K. Viigand[1], *K. Ernits*[1], *K. Põšnograjeva*[1], *T. Visnapuu*[1], *T. Alamäe*[1]
[1]*University of Tartu, Genetics, Tartu, Estonia*

Backgrounds

Maltases (EC 3.2.1.20) and isomaltases (EC 3.2.1.10) are α-glucosidases releasing glucose from a set of α-glucosidic substrates and belong to family 13 of glycoside hydrolases (GH13) according to CAZy classification. These enzymes are hypothesized to have evolved from an ancestral promiscuous α-glucosidase ancMALS through gene duplications and mutations as described in Voordeckers *et al*. (2012). *S. cerevisiae* maltases use maltose-like sugars whereas isomaltases use isomaltose-like ones. Resurrected ancMALS used both. We are studying methylotrophic yeast *Ogataea (Hansenula) polymorpha* which has diverged early from the yeast main line of evolution and is considered a "phylogenetically old" yeast. MAL1 has extended substrate specificity and its properties are highly similar to those of hypothetical ancMALS.

Objectives

To introduce the methods for evaluation of substrate specificity of α-glucosidases using MAL1 of *O. polymorpha* and a variety of α-glucosidic sugars.

Methods

Two activity-based methods (including a microplate assay) using monitoring of glucose release from various α-glucosidic substrates by the wild-type MAL1 and a differential scanning fluorimetry (DSF) of a catalytically inactive mutant of MAL1 in the presence and absence of α-glucosidic substrates are characterized.

Conclusions

A high-throughput DSF method allows to predict substrate selection pattern of the MAL1. The DSF results were in good accordance with substrate specificity data obtained from the activity-based assay. A cost-efficient microplate-based activity assay was successfully employed.

Acknowledgements: This work was financed by ERC grant GLTMR1050P (PUT1050).

ALIVE OR DEAD - LIMITS OF ENUMERATION

L. Vondrakova[1], J. Pazlarova[1], K. Demnerova[1]
[1]University of Chemistry and Technology Prague, Department of Biochemistry and Microbiology, Prague 6, Czech Republic

Backgrounds

Molecular-genetic methods based on nucleic acid detection are indisputably very reliable and fast tools used to identify various pathogens that pose a threat to public health. However, main disadvantage of these methods is the inability to distinguish signals originating from different sources (live, dead and compromised cells or free DNA) which is significant limitation especially when used for quantification of live infective agents.

Objectives

The aim of this study was to perform comprehensive research and comparison of methods applicable when precise quantification of pathogens is desirable. Since the definition of “dead cell” in microbiology is rather delicate, several techniques based on different approach were included.

Methods

Taking into account the most common criteria of cell viability determination, the multiplex qPCR in combination with various sample pre-treatment approaches was introduced. Two DNA-intercalating dyes - ethidium monoazide and propidium monoazide (membrane integrity), flotation (cell buoyant density), and flow cytometry (metabolic activity) were examined. In addition, one of the most important variable of cell life - its death, was included in the study. Since the mechanism of cell destruction can strongly influence the effectivity and result interpretation of abovementioned sample pre-treatments, several different strategies of cell inactivation were applied (UV, peracetic acid, hydrogen peroxide, cold plasma, autoclaving etc.).

Conclusions

Reliable method for identification and quantification of three most abundant thermotolerant campylobacters in the form of multiplex qPCR was designed. Impact of various sample pre-treatment approaches and possible errors in order to distinguish the origin of detected DNA was evaluated.

A PROBE-FREE AND SENSITIVE DETECTION METHOD FOR HUMAN DIARRHEA-CAUSING PATHOGENS USING QUADRIPLEX RT-PCR COMBINED HIGH RESOLUTION MELTING ANALYSIS

H. Wang[1], Q. Mo[1], Z. Yang[1], Q. Wang[1], C. Tu[1], J. Lin[1]
[1]Zhuhai International Travel Healthcare Center, State Key Laboratory of Diarrhea Disease Detection, Zhuhai, China

Backgrounds

Diarrhea is one of the most common public health issues worldwide. Rapid and sensitive diagnostic methods are urgently needed to help physicians make faster and better treatment decisions for those patients who suffered from diarrhea.

Objectives

To establish a probe-free quadriplex RT-PCR combined high resolution melting analysis (HRMA) assay for the rapid and sensitive detection of four major diarrhea-causing pathogens, including rotaviruses, astroviruses, noroviruses and sapoviruses.

Methods

Specific primers and amplification parameters of the probe-free quadriplex RT-PCR as well as the range and ramp of melting temperature in the HRMA were optimized to establish the assay. Specificity and sensitivity of the assay were analyzed and compared with conventional RT-PCR. Clinical stool samples were used to evaluate the efficacy of the new assay.

Conclusions

After several rounds of optimization, the quadriplex RT-PCR combined HRMA assay was established successfully with high specificity. Sensitivity analysis indicated that the lower limit of detection were 10^0, 10^2, 10^0 and 10^3 copies/reaction for rotaviruses, astroviruses, noroviruses and sapoviruses, respectively, which were 1000-fold, 10-fold, 1000-fold and 10-fold more sensitive than conventional RT-PCR. Clinical evaluation showed that the assay was 100% concordant to conventional RT-PCR, indicating the high reliability of the new assay.To the best of our knowledge, this is the first quadriplex RT-PCR combined HRMA assay established for the detection of four major diarrhea-causing viruses. The assay would provide a valuable platform for the probe-free, rapid and sensitive diagnosis of these pathogens.

HIGH-CONTENT SCREENING OF MORPHOLOGICAL CHANGES IN RESPONSE TO ANTIBIOTIC TREATMENT

T. Zahir[1], R. Camacho[2], J. Hofkens[2], J. Vermant[3], M. Fauvart[1], J. Michiels[1]
[1]KU Leuven, Bioscience Engineering, Leuven, Belgium
[2]KU Leuven, Molecular Imaging and Photonics, Leuven, Belgium
[3]ETH Zurich, Materials, Zurich, Switzerland

Backgrounds

High-content screening is a powerful and emerging method in molecular biology. Automated microscopy, sophisticated image analysis algorithms and genome-scale knock-out/knock-down libraries are increasingly being used for functional genetics, genetic profiling and for building genetic networks.

Objectives

Genome-wide screening of mutant phenotypes upon antibiotic treatment is the aim of many studies. One particularly daunting challenge in this regard is the high-throughput observation of morphological changes in individual bacteria over time. Here, we use automated microscopy for time-resolved measurement of responses to antibiotics at the single-cell level.

Methods

We have developed a high-content screening method using automated phase-contrast microscopy and image analysis for the purpose of high-throughput morphology-based studies in bacteria. As a case study, we measured dynamic responses (morphological changes and killing kinetics) of mutants in all non-essential genes of *Escherichia coli* after treatment with β-lactam antibiotics – cefsulodin, cephalexin and mecillinam.

Conclusions

The screen resulted in a comprehensive image dataset characterizing all mutants' response to inhibition of different penicillin-binding proteins. Using image-based cell counts, we identified mutants with altered killing kinetics. Mutants that showed atypical cell morphologies were identified by implementing machine learning algorithms. These results not only reveal genetic determinants of bacterial drug tolerance and susceptibility but also indicate roles of in cell envelope biogenesis. The high-content screening method will enable the study of dynamic phenotypes, hitherto restricted to low-throughput analysis techniques, on an unprecedented scale, promising new and important insights into mechanisms of antibiotic activity and gene function.

SPECTRA PATTERN MATCHING WITH IN SILICO HYPOTHESIS VALIDATION FOR BACTERIAL TYPING

Y. Zhu[1]
[1]*Ecole Polytechnique Federale de Lausanne, Institut of chemical sciences and engineering, Sion- Valais, Switzerland*

Backgrounds

Rapid and reliable microbial identification is crucial for effective antibiotics therapy and reduction of public health cost. Matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS) profiling of bacteria has been exploited for quick bacterial identification since 1990s, based on spectra pattern matching between sample spectra and a bank of standard bacterial spectra (*i.e.* a database). The algorithm used for pattern matching and the database are important for the success of this MS-based identification.

Objectives

We aim to develop an effective algorithm for mass spectra pattern matching that can be used for bacterial typing.

Methods

A four-step approach is included in the new algorithm: *1)* a raw sample mass spectrum is pre-processed to generate a peak-list with mass-to-charge ratio, normalized intensity, and full width at half maximum; *2)* three similarity scoring methods, *i.e.* relative Euclidean distance, relative Euclidean distance weighted by peak intensity, and Cosine correlation, are applied to calculate the similarity score between the sample spectrum and each reference spectrum in a database based on peak-lists; *3) in silico* random spectra model is used for calculation of false discovery rate ; and *4) in silico* similar spectra model is adopted for calculation of P-value (the ratio of similar spectra with similarity scores against the combined spectrum lower than the similarity score between the combined spectrum and the matched reference spectrum).

Conclusions

A new algorithm was developed for MALDI-MS based bacterial typing. According, a web-based application at http://bacteriams.fudan.edu.cn/ is built and is open freely to public usage.

ELECTROPORATION-MEDIATED INACTIVATION OF C. LUSITANIAE CELLS AND PSEUDOHYPHAE

A. Zinkeviciene[1], E. Lastauskiene[2], V. Novickij[3], A. Grainys[3], I. Girkontaite[1], A. Paskevicius[4], J. Svediene[4], S. Markovskaja[5], J. Novickij[3]
[1]State Research Institute Centre for Innovative Medicine, Immunology, Vilnius, Lithuania
[2]Vilnius University, Microbiology and Biotechnology, Vilnius, Lithuania
[3]Vilnius Gediminas Technical University, Institute of High Magnetic Fields, Vilnius, Lithuania
[4]Nature Research Centre, Laboratory of Biodeterioration Research, Vilnius, Lithuania
[5]Nature Research Centre, Laboratory of Mycology, Vilnius, Lithuania

Backgrounds

Antifungal resistance is a growing concern worldwide and research for the alternative methods for the biocontrol of *Candida* yeasts is systematically performed. *Candida lusitaniae* is unique among *Candida* species due to its quick development of resistance to amphotericin B and antifungal resistance-associated phenotypic switching, which allows rapid adaptation to changing environment. As a result alternative non-chemical methods for biocontrol of Candida-associated surface infections are of particular interest, one of which could be electroporation. Electroporation utilizes high pulsed electric fields for induction of cell membrane permeability changes and thus increasing molecular transport. It is safe for use on human and already covers a wide range of applications in biotechnology, food processing and biomedicine.

Objectives

Investigate the feasibility of electroporation for inactivation *C. lusitaniae* cellular and pseudohyphae phenotypes and determine the threshold electric field for high permeabilization of yeast.

Methods

Electroporation protocol – square wave pulse 100 µs x 8, 2.5–25 kV/cm. Permeabilization was evaluated using propidium iodide assay (50 µM) by flow cytometry using Amnis FlowSight system at 550 nm wavelength. Cell viability assay was performed by plating cells after electroporation on the YPD medium and counting CFU. Amphotericin B susceptibility assay was performed by microdilution and agar diffusion methods.

Conclusions

We showed that 2.5 – 25 kV/cm electric field pulses of a fixed duration (100 µs x 8) induce a dose dependent permeabilization of yeast. Pseudohyphae morphology yeasts with the 25 times increased resistance to amphotericin B can be effectively inactivated after applying pulsed electric field higher than 15 kV/cm.

DNA STRUCTURAL ALIGNMENT ALGORITHM CAN PREDICT PLASMID MOBILITY AND HOST RANGE BY LOCATING DNA SUBSTRATES FOR PLASMID TRANSFER

J. Zrimec[1], *A. Lapanje*[2]
[1]*Faculty of Health Sciences, Computational biology and bioinformatics, Izola, Slovenia*
[2]*Institute Jozef Stefan, Department for Environmental Sciences, Ljubljana, Slovenia*

Backgrounds

Due to the increasing problem of antimicrobial resistance, modelling and analysis of horizontal gene transfer processes is an essential research area. We focus on the most widespread and harmful of these processes, conjugation, where transfer of plasmids between different microbial hosts allows the storage and transfer of resistance genes.

Objectives

I will present a new approach to analysis of plasmids based on interpreting the origin-of-transfer, a merely 200 bp long non-coding plasmid DNA region that is the enzymatic substrate for the relaxase. Using a statistical approach we have only recently verified that these enzymatic DNA substrates contain conserved structural properties in relation to groups of conserved relaxases, and that computational DNA structure prediction much more accurately distinguishes substrate properties than analysis of nucleotide sequences.

Methods

Using a newly developed structural representation of DNA and bioinformatic algorithms, we developed a procedure to determine the mobility of plasmids, which can predict even the range of potential plasmid hosts. The procedure is based on structural alignment algorithms that proved effective in uncovering new DNA substrates. Based on an initial set of 64 experimentally determined transfer substrates we have identified hundreds of new ones.

Conclusions

The tools for prediction of DNA structural properties and for determining the mobility and host range of plasmids were implemented as web tools on the server http://dnatools.eu. The algorithm for structural alignment of DNA enables characterisation of a number of new DNA substrates and regulatory regions that until now could not be detected using existing methods.

A SIMPLE AND CONVENIENT METHOD TO ASSESS THE DIVERSITY OF METAGENOMIC SAMPLES BASED ON PCR AMPLIFICATION OF 16S RRNA

J. Zrimec[1], *T. Rijavec*[2], *A. Lapanje*[2]
[1]*Faculty of Health Sciences, Computational biology and bioinformatics, Izola, Slovenia*
[2]*Institute Jozef Stefan, Department of Environmental Sciences, Ljubljana, Slovenia*

Backgrounds

Metagenomic analyses are crucial to study the diversity, activity and dynamics of uncultivable microbes. An integral part in the analyses is the polymerase chain reaction (PCR), which can present a bottleneck due to PCR errors, such as when amplifying parts of 16S rRNA genes.

Objectives

Often in agarose electrophoresis gels we see smeared DNA bands of wrong size, which are considered to be non-specific PCR errors and are eliminated. However, if these amplicons are not errors, then a part of the sample's true diversity is lost. Therefore, we explore if band smearing after PCR is in fact caused by imperfectly paired strands of the amplified DNA.

Methods

We used synthetic oligonucleotides to mimic 16S rRNA variable regions in PCR and analyse how smear in agarose gels and 16S rRNA sequence heterogeneity are related. DNA structures from separate band and smear gel fractions were extracted using a new electroelution procedure, sequenced, and analysed with bioinformatic tools to show correctly and imperfectly paired DNA strands.

Conclusions

When amplifying highly heterogeneous target DNA, such as 16S rRNA, imperfect pairing of the amplified DNA can lead to band smearing in agarose gels, which is not an indicator of low specificity of the PCR, but in fact, of sample diversity. Since the smear in agarose gels is only a structural part of the correctly amplified DNA, it carries important information about the richness and diversity of the analysed microbial communities. Quantifying the amount of smear can be a useful method to assess the diversity of metagenomic samples.

SILVER NANOPARTICLES SYNTHESIS FROM DRACOCEPHALUM MOLDAVICA AS NEW CANDIDATE FOR ANTIBACTERIAL ACTIVITY

H. Abbaspour[1], Z. Haghighi Pak[1], N. Karim[2], A. Fattahi[3]
[1]Islamic Azad University, Biology, Damghan, Iran
[2]Razi University, Biology, Kermanshah, Iran
[3]kermanshah University, Pharmaceutics, kermanshah, Iran

Backgrounds

Nowadays, scientists are going to after finding a way to control and prevent many diseases by new biomaterial with the lowest side effects. From scientific point of view, silver nanoparticle extracted from plants such as *Dracocephalum moldavica* is the matter of importantce. Since this nanoparticle have many advantages such as cost effective, ability to adaptation to environment, antibacterial and antifungal effects, it can be used as a good candidate for medical care.

Objectives

In this study extraction of silver nanoparticle from *D. moldavica* and its antibacterial effects were investigated.

Methods

Dracocephalum moldavica seeds were purchased from Pakan Bazr Isfehan. Green synthesis method was done to synthesise of nano-silver from mentioned plant.To confirm this synthesis, some analysis such as EDX,TFIR,XRD and TEM were done. Antibacterial effects of silver nanoparticle on *Staphylococcus aureus*, *Staphylococcus epidermidis, Esherichia coli and pseudomonas aeruginosa* were investigated by well diffusion method and minimal inhibitory concentration were determined too.

Conclusions

The results showed that silver nanoparticle extracted from *D.moldavica* had antimicrobial effect. The zone of Inhibition growth of *Staphylococcus aureus*, *Staphylococcus epidermidis ,Esherichia coli and pseudomonas aeruginosa* in the present of nano-silver were obtained,8/5mm,11mm,17/5mm and 13 mm, respectively. The best minimal inhibitory concentration was gained 11µg ml^{-1} for *E.coli*.

Knowledge-wise *D.moldavica* is one of the beneficial plants and this study showed that nano-silver extracted from this plant had antibacterial effect, so this plant's extraction can be a proper candidate tool to treat and control disease in near future.

THE SERINOPROTEASE PIC FROM ESCHERICHIA COLI INDUCES AN INTENSE INFLAMMATORY RESPONSE BY M1 MACROPHAGES IMMUNOMODULATION

Y.A. Lima[1], I.L. Dutra[2], J.R. Nascimento[2], A.A.M. Vale[2], E.M. Sousa[3], R.M. Silva[4], W.P. Elias[5], F.R.F. Nascimento[2], A.G. Abreu[2,3]
[1]Federal University of Maranhão, Laboratory of Immunophysiology, São Luís, Brazil
[2]Federal University of Maranhão, Programa de Pós-Graduação em Ciências da Saúde, SÃO LUIS, Brazil
[3]CEUMA University, Programa de Pós-Graduação em Biologia Parasitária, São Luís, Brazil
[4]Federal University of São Paulo, Departament of Microbiology- Immunology and Parasitology, São Paulo, Brazil
[5]Instituto Butantan, Laboratory of Bacteriology, São Paulo, Brazil

Backgrounds

Some *Escherichia coli* strains are important pathogens responsible for a variety disease, and albeit using distinct mechanisms of pathogenesis, have in common the production of Pic. We have recently shown that Pic mediates immune evasion by the direct cleavage of complement molecules, significantly reducing complement activation by all three pathways.

Objectives

The aim of this study was to investigate the action of Pic on macrophages immunomodulation.

Methods

The ability of bacteria to induce macrophage polarization to M1 or M2 (pro-inflammatory and anti-inflammatory profile, respectively), as well as the cytokines and nitric oxide (NO) production were evaluated after infection of RAW264.7 macrophages. Macrophages were incubated with Pic-producing *E. coli* (F5), F5Δ*pic* mutant or purified Pic for 6, 12 and 24 h. Immunophenotyping was performed using specific antibodies and analyzed by flow cytometry. **Results:** Six hours after infection, an increase in NO production was observed in all groups infected with bacteria, being statistically significant in the cells infected with *E. coli* F5. Interestingly, purified Pic induced an intense NO production, as well as the cytokines IL-6, MCP-1 and TNF-α. On the other hand, there was no statistically significant IL-10 production among groups. In addition, the immunophenotyping also showed a high expression of pro-inflammatory markers (IaIe and LyC6) on the cells infected by Pic or Pic-producing bacteria.

Conclusions

Pic has a high potential to induce M1 macrophage polarization with intense inflammatory response. Evaluation of this mechanism in animal model is underway to better understand the role of Pic in the context of sepsis.

A SNAPSHOT OF THE MULTIDRUG-RESISTANT MYCOBACTERIUM TUBERCULOSIS STRAINS IN LIMA, PERU, AS A FIRST STEP TO TAILOR MOLECULAR TOOLS TO FAST TRACK HIGH-RISK CIRCULANT STRAINS

F. Acosta[1,2], J. Agapito[3], M. Herranz[1], F. Barletta[3], E. Abascal[1], L. Otero[3], G. Romero[3], C. Sola[4], E. Bouza[1], E. Gotuzzo[3], D. Garcia de Viedma[1]

[4]Institute for Integrative Biology of the Cell I2BC-, CEA- CNRS- Univ. Paris-Sud- Université Paris-Saclay, F-91405 Orsay-Cedex, France

Backgrounds

Multidrug-resistant tuberculosis (MDR-TB) has become a major health problem. According to the WHO-TB report, cure rates for MDR-TB are lower (50%-70%). The high rates of MDR-TB in Peru, demands the implementation of more effective epidemiology strategies. Among them, to tailor strain-specific PCRs targeting high-risk strains could mean a new strategy in controlling MDR-TB.

Objectives

To describe the transmission clusters of MDR-TB in Lima, looking for hot-spot transmission areas where specific MDR strains are more actively spread.

Methods

We genotyped by MIRU-VNTR (24-loci) all the consecutive MDR-TB cases in 2014-15 from the 32 health centers of San Juan de Lurigancho district (North-Lima). MIRU-VNTR patterns were analyzed using MIRU-VNTRplus to assign lineages and BioNumerics to identify transmission clusters.
Among 59 MDR-MTB isolates (around 20% of the total MDR cases), the most prevalent sublineages were LAM (L4.3; 62.7%) and Haarlem (L4.1.2; 22.0%). The Beijing lineage (L2) was identified in 6.7% of the isolates. 34 isolates (57.6 %) were included in 9 transmission clusters (2-9 isolates). Five of these clusters, including one involving a Beijing strain, corresponded to strains that had already been identified in a previous study of 51 MDR strains isolated in the same district in 2011.

Conclusions

Genotyping of MDR-TB allowed us to identify high-risk strains actively transmitted in localized settings in Lima. These data allow to activate the design of tailored strain-specific PCRs to fast track their detection and optimize the control of their transmission.

CLONAL OUTBREAKS OF [PASTEURELLA] PNEUMOTROPICA BIOVAR HEYL IN TWO MICE COLONIES

S. Adhikary[1], H. Christensen[1], M. Bisgaard[2], F. Dagnæs-Hansen[3]
[1]University of Copenhagen, Department of Veterinary Disease Biology, Frederiksberg C, Denmark
[2]University of Copenhagen, Emeritus, Sjælland, Denmark
[3]Aarhus University, Department of Biomedicine, Aarhus, Denmark

Backgrounds

[*Pasteurella*] *pneumotropica* is generally considered as an opportunistic pathogen in rodents. The bracket indicates that the bacterium is not a true member of the family *Pasteurellaceae*. It is classified as two biovars, Jawetz and Heyl. In [*P.*] *pneumotropica* infections, clinical diseases have mainly been associated with the respiratory tract of rodents. Furthermore, mastitis, orbital, urogenital and subcutaneous infections have also been reported. However, these reports have not referred the specific biovar of [*P.*] *pneumotropica.* This study investigated the association of biovar Heyl with the outbreak strains that are related to mastitis, orbital, cutaneous and vaginal abscesses.

Objectives

To document that [*P.*] *pneumotropica* biovar Heyl is pathogenic and can cause clonal outbreaks in mice.

Methods

Fifty three isolates from two mice colonies were studied. Primary identification was done by colony morphology and 'classical' biochemical test. To investigate clonal relationship, Pulsed-field gel electrophoresis (PFGE) was performed and assessed by cluster analysis. Five strains were selected for partial sequencing of the *rpoB* gene to represent the clusters. For comparison with outbreak strains, the epidemiologically unrelated six strains were also included.

Conclusions

The isolates were identified as [*P.*] *pneumotropica* biovar Heyl based on phenotype and genotype. PFGE analysis resulted in five related profiles that differed in one to four fragments, considered as the same outbreak clone according to 'Tenover criteria'. The outbreak strains were diverged from the epidemiologically unrelated strains. Therefore, this natural outbreak of different clinical conditions caused by the same clone provides evidence of the pathogenicity of [*P.*] *pneumotropica* biovar Heyl.

ANTIMICROBIAL ACTIVITY AGAINST MYCOBACTERIUM TUBERCULOSIS UNDER IN VITRO DORMANCY CONDITIONS

D.A. Aguilar Ayala[1,2], S. Rivera Gutiérrez[1], J.F. Cerna Cortés[1], J.C. Palomino[2], P. Vandamme[2], J.A. González y Merchand[1], A. Martin[3]
[1]ENCB - IPN, Microbiología, Ciudad de México, Mexico
[2]Ghent University, Biochemistry and Microbiology, Gent, Belgium
[3]Institute of Experimental and Clinical Research, Université Catholique de Louvain, Brussels, Belgium

Backgrounds

Although tuberculosis (TB) treatment is dependent on the implementation of drug susceptibility testing (DST) of *Mycobacterium tuberculosis* (*Mtb*) clinical isolates, and molecular detection of gene mutations associated with drug resistance, treatment failure remains a challenge for better controlling TB. Some studies have suggested that treatment failure is probably due to the survival of dormant mycobacteria. Additionally, host lipids have shown an important role during the dormant stage as well as during resuscitation of *Mtb*.

Objectives

The objective of this study was to evaluate in a lipid-rich dormancy model, the susceptibility of *Mtb* to two known anti-TB drug combinations: rifampicin, moxifloxacin, amikacin and metronidazole (R-MX-A-MZ), and R-MX-A plus pretomanid (PA).

Methods

Mtb H37Rv was cultured in the presence of a mixture of cholesterol and fatty acids, until reaching exponential and stationary phases of growth as well as NRP1 and NRP2 hypoxic stages of dormancy. Once the mycobacteria reached each experimental phase, the mixture of antibiotics, R-MX-A-MZ or R-MX-A-PA, was added. The antibiotic activity was evaluated at 7, 14 and 21 days by estimating mycobacterial survival in solid and liquid media.

Conclusions

Our results show for the first time that the presence of lipids as carbon source may confer *Mtb* some tolerance against the mixture of antibiotics tested, and this tolerance could be even higher during dormant stages. Since current DST are based on aerobic cultures with dextrose as carbon source, implementation of a DST in clinical strains that includes lipids as carbon source could potentially lead to a better treatment strategy.

BACTERIOCINS AGAINST MYCOBACTERIA: THE CASE OF CIRCULAR PEPTIDE AS-48

C. AGUILAR[1,2,3], B. GRACIA[1,2,3], A. VITORIA[1,2,3], A. LUCIA[1,2,3], R. CEBRIAN[4], M. MAQUEDA[4], J. AINSA[2,3,5]
[1]UNIVERSIDAD DE ZARAGOZA, DEPARTAMENTO DE MICROBIOLOGÍA, ZARAGOZA, Spain
[2]INSTITUTO DE INVESTIGACION SANITARIA ARAGON, IIS-ARAGON, ZARAGOZA, Spain
[3]Instituto de Salud Carlos III, CIBER de Enfermedades Respiratorias CIBERES-, MADRID, Spain
[4]UNIVERSIDAD DE GRANADA, DEPARTAMENTO DE MICROBIOLOGÍA, GRANADA, Spain
[5]UNIVERSIDAD DE ZARAGOZA, DEPARTAMENTO DE MICROBIOLOGÍA- AND BIFI, ZARAGOZA, Spain

Backgrounds

Mycobacteria are highly resistant to antimicrobials, thus leaving very few drugs available for treatment of tuberculosis. Since the incidence of multi-drug resistant strains of *Mycobacterium tuberculosis* is increasing worldwide this is promoting the development of new therapeutic approaches.

Objectives

We have investigated the antimycobacterial activity of peptide AS-48, produced by *E. faecalis*, which is targeting the bacterial membrane, and it is active against several other Gram-positive bacteria.

Methods

Susceptibility was tested by resazurin microtiter assay, using the checkerboard test for determining synergy. Cytotoxicity against cell lines was tested by the MTT and neutral red assays. Changes in membrane functions were tested by DiOC2(3) and ethidium bromide accumulation.

Conclusions

Bacteriocin AS-48 is active against *M. tuberculosis* clinical and reference strains, and against non-tuberculous clinical isolates of other mycobacterial species. The combination of AS-48 with either lysozyme or first line drugs (commonly used in the treatment of tuberculosis) increases bactericidal action of AS-48, showing a synergic interaction. At concentrations close to the MIC of AS-48, we could not detect any cytotoxic effect against THP-1 and MHS macrophage cell lines. In summary, we consider that bacteriocin AS-48 has an interesting potential in the treatment of infectious diseases, including tuberculosis therapy because of its antimicrobial activity and its low cytotoxicity against cell lines.

[8]Georgetown Public Hospital Corporation, Microbiology Laboratory, Georgetown, Guyana
[9]King Edward VII Memorial Hospital, Department of Pharmacy, Hamilton, Bermuda

Backgrounds

Global emergence of vancomycin-resistant *Enterococcus faecium* (VRE) has been attributed to the clonal spread of clonal complex 17 (CC17). The CC17 is characterized by resistance to quinolones and ampicillin and presence of enterococci surface protein (*esp*) in majority of isolates.

.

Objectives

This multinational study was undertaken to investigate the antimicrobial resistance patterns, clonal relationships, virulent factors (*esp* and *hyl* genes) and population genetics of VRE isolates recovered from twelve hospitals in eight Caribbean nations

Methods

Seventy VRE isolates recovered from clinical specimens of patients admitted in 12 hospitals in eight Caribbean nations were characterized by pulsed-field gel electrophoresis (PFGE) and multilocus sequence typing (MLST). Genes encoding antibiotic resistance and putative virulence traits were investigated by PCR. Antimicrobial susceptibility testing (AST) was conventionally performed and interpreted according to Clinical and Laboratory Standard Institute (CLSI) guidelines. Patient clinical records were analyzed during the isolates collection.

Conclusions

None of VRE isolates from the Caribbean countries is multi-drug resistant and vancomycin resistant is mediated mainly by *van*A gene. Infections associated with VRE isolates in the region were all hospital related. Although all VRE isolates mainly harbored the *esp* gene which is known to be involved in outbreaks, yet there has never been any report of outbreaks of VRE infections in the region. None of the VRE isolates carry *hyl* gene. Predominant sequence types (ST) in the region include ST 412, 750, 203, 736 and 18. All these STs are from the CC17 ancestor, that is similar to clonal complex also circulating in North and South American countries.

MICROBIAL COMPOSITION OF PERIIMPLANTITIS ASSOCIATED ORAL BIOFILM AS REVEALED BY CULTURE INDEPENDENT CLONING TECHNIQUE

A. Al-Ahmad[1], F. Muzafferiy[1], A. Anderson[1], J.P. Woelber[1], P. Ratka-Krüger[1], T. Fretwurst[2], K. Nelson[2], E. Hellwig[1]
[1]Albert-Ludwigs-University Freiburg, Operative Dentistry and Periodontology, Freiburg, Germany
[2]Albert-Ludwigs-University Freiburg, Oral- and Craniomaxillofacial Surgery, Freiburg, Germany

Backgrounds

Persistent subgingival oral biofilm associated with oral implants can lead to periimplantitis and subsequently to loss of oral implants. Up to now, it is not clear which pathogens are associated with periimplantitis.

Objectives

In the present clinical study, the microbial composition of the subgingival oral biofilm from oral implants with periimplantitis has been studied in comparison to healthy implants.

Methods

Oral biofilm samples were taken from ten periimplantitis patients who also had at least one healthy oral implant. The biofilm samples of the healthy oral implant sites served as control. After DNA extraction, the 16S rDNA of bacteria and 18S rDNA of fungi were amplified and the PCR products were used to construct clone libraries. The DNA of selected representative clones was sequenced and microbial species were identified by comparing the sequences with public databases (http://blast.ncbi.nlm.nih.gov/Blast.cgi). The study was approved by the ethics committee of the University of Freiburg.

Conclusions

The results showed an association of the specific periodontal pathogens *Porphyromonas gingivalis, Tannerella forsythia* und *Treponema denticola* with periimplantitis. The proportion of the aforementioned pathogens in the periimplantitis samples was significantly higher than in the subgingival biofilm samples gained from the healthy implants. Furthermore, other microorganisms such as *Peptostreptococcus micra* and *Candida* spp. which are not specific for periodontitis were detected in the biofilm samples from the periimplantitis sites.
Typical periodontal oral pathogens should be considered as associated factors for periimplantitis. The composition of periimplantitis associated biofilm should be considered if antibiotic therapy has to be applied.

INCREASED SUSCEPTIBILITY OF AGED C57BL/6 MICE TO LISTERIA MONOCYTOGENES (LM): UPREGULATED CD39/CD73 EXPRESSION IN TREG CELLS AND IMBALANCE OF TH1/TH2 RESPONSES

M.S. Alam[1], C. Cavanaugh[1], K. Williams[1]
[1]US Food and Drug Administration, Center for Food Safety and Applied Nutrition, Laurel, USA

Backgrounds

The case-fatality rate of invasive *Listeria monocytogenes* (*Lm*) infection is >19%. The number of listeriosis cases for elderly is >50%. Aging affects host susceptibility due to an imbalance of protective immunity and T-cell–mediated suppression.

Objectives

We developed a geriatric murine model for listeriosis and investigated *Lm* dose-response and *Lm* susceptibility in the elderly by examining the regulatory role of Th cells.

Methods

Young-adults, middle-aged, and aged C57BL/6 mice were gavaged with incremental doses of *Lm*. Post-infection tissues were examined for bacterial burden and immune response. Splenocytes were analyzed for intracellular Th1/Th2 cytokines (IL-10, IFN-γ), distribution of Treg ($CD4^{+}CD25^{h}$) and Th17 cells before/after infection. The expression of, adenosine (Ado) producing enzymes, CD39 (nucleoside triphosphate dephosphorylase) and CD73 (ecto-5'-nucleotidase) were also analyzed by FACS or qRT-PCR.

Conclusions

Geriatric *Lm*-infected mice lost body-weight dose-dependently, had higher *Lm* colonization and succumbed to infection faster than young-adult infected mice. Uninfected, aged-mice showed a higher baseline pro-inflammatory (IFN-γ) response than young-adult mice. After infection, IFN-γ level was significantly lower in aged-mice as compared to young-adult mice. Increased numbers of Th-17 cells were observed in the aged mice before and after infection. Increased levels of IL-10 and Treg cells were observed in infected aged-mice. Age-dependent upregulated expression of CD39/CD73 was observed in purified Treg cells, suggesting increased Ado (an immune-suppressive-mediator) production. Increased *Lm* susceptibility in aged-mice may be associated with imbalanced anti-inflammatory responses, upregulated expression of CD39/CD73 in Treg-cells and reduced IFN-γ response. Increased *Lm* tissue load in aged-mice seemed unaffected by accumulation of pro-inflammatory splenic Th17 cells.

Pathogens / Pathogenicity

THE IMPAIRED QUORUM SENSING RESPONSE OBSERVED IN ANTIBIOTIC RESISTANT PSEUDOMONAS AERUGINOSA MEXR* MUTANTS IS NOT CAUSED BY THE EXTRUSION OF 3-OXO-C12-HSL THROUGH MEXAB-OPRM EFFLUX SYSTEM

M. Alcalde-Rico[1], *J. Olivares*[2], *J.L. Martínez*[1]
[1]*National Center for Biotechnology- CSIC, Microbial Biotechnology, Madrid, Spain*
[2]*Pontificia Universidad Católica de Chile, Institute of Biology, Valparaiso, Chile*

Backgrounds

Pseudomonas aeruginosa is one important opportunistic pathogen causing many different nosocomial infections difficult to treat due to its low susceptibility to antibiotics. Among the elements involved in resistance, the RND efflux system MexAB-OprM is implied in both intrinsic and acquired resistance. Its overexpression also leads to a lower production of quorum sensing regulated virulence factors, being the extrusion of 3-oxo-C_{12}-HSL by this efflux system the cause proposed for this impaired virulence.

Objectives

Determine the accumulation level of the quorum sensing signal molecules (QSSMs) 3-oxo-C_{12}-HSL, C_4-HSL and PQS/HHQ in both supernatants and cellular extracts from a MexAB-OprM overproducer strain in order to clarify the relevance of each QSSMs in the low QS response observed in *mexR** mutants.

Methods

We analysed in early-stationary phase by real time RT-PCR the expression level of the genes belonging to the Las, Rhl and Pqs regulons controlled by 3-oxo-C_{12}-HSL, C_4-HSL and PQS/HHQ respectively. Different techniques based on biosensor strains to determine the QS signals accumulation were used: i) Thin Layer Chromatography; ii) combined automated luminometer-spectrophotomer assays; iii) chromosomal insertion of *luxCDABE*-based reporter constructions.

Conclusions

The impaired QS response associated to MexAB-OprM overproduction in a *mexR** mutant of *P. aeruginosa* is consequence of the strong defect in C_4-HSL and PQS/HHQ accumulation and not by the slightly affected 3-oxo-C_{12}-HSL production. This issue is opposite to previous claims proposing that which the low virulence phenotype observed in MexAB-OprM overproducer strains would be mainly caused by the extrusion of 3-oxo-C_{12}-HSL through this efflux system.

DISSEMINATION OF MULTIDRUG-RESISTANT ACINETOBACTER BAUMANNII CLONES AMONG MEXICAN HOSPITALS

M.D. Alcántar-Curiel[1], M.D. Jarillo-Quijada[1], C. Gayosso-Vázquez[1], J.L. Fernández-Vázquez[1], R. Morfín-Otero[2], E. Rodríguez-Noriega[2], J.E. Toledano-Tableros[3], S. Giono-Cerezo[3], M.D.R. López[4], C. Espinosa-Sotero[5], M.A. Morales-Gil[5], J.I. Santos-Preciado[1]
[1]Facultad de Medicina- Universidad Nacional Autónoma de México, Unidad de Investigación en Medicina Experimental, Ciudad de México, Mexico
[2]Hospital Civil de Guadalajara, Enfermedades Infecciosas, Guadalajara- Jalisco, Mexico
[3]Escuela Nacional de Ciencias Biológicas. Instituto Politécnico Nacional, Microbiología, Ciudad de México, Mexico
[4]Hospital Regional "General Ignacio Zaragoza" ISSSTE, Microbiología, Ciudad de México, Mexico
[5]Hospital General de México Dr. Eduardo Liceaga, Pediatría, Ciudad de México, Mexico

Backgrounds

Multi-drug-resistant *A. baumannii* have emerged as a major cause of nosocomial infections in Mexico often serving as reservoirs of resistant determinants. Carbapenem-resistance has been continuously reported among isolates, causing major therapeutic challenges, similarly to what has been described worldwide.

Objectives

The aim of this study was to investigate the hospital dissemination of antimicrobial-resistant *A. baumannii* clones in three Mexican hospitals.

Methods

Two hundred fifty one *A. baumannii* isolates were obtained from three tertiary referral hospitals in two different regions of Mexico: Hospital Civil de Guadalajara, in western Mexico, and Hospital Regional "General Ignacio Zaragoza" ISSSTE and Hospital General de Mexico, in central Mexico from January 2015 to December 2016. Antimicrobial susceptibility was determined by different automatic testing systems. Metallo-beta-lactamases (MBLs) phenotype was confirmed by modified Hodge test and screened for OXA and MBL-encoding genes by PCR. We genotyped and compared the similarities of isolates using *ApaI* digestion and Pulsed Field Gel Electrophoresis (PFGE). Analysis of the PFGE patterns was performed visually to classify the isolates into clones according to the Tenover criteria. Cluster analysis was performed by the unweighted pair group method with mathematical averaging, and DNA relatedness was calculated by using the Dice coefficient.

Conclusions

This study identifies the widespread carbapenem-resistant *A. baumannii* clones involved in nosocomial infections and the inter hospital transmission mainly of one clone in three tertiary referral hospitals from two different geographical regions of Mexico. It also underscores the importance of molecular epidemiology of antimicrobial resistance as an integral part of hospital surveillance.

LONGITUDINAL SAMPLING OF ELDERLY ASYMPTOMATIC BACTERURIA PATIENTS HIGHLIGHTS ANTIMICROBIAL RESISTANCE PROPAGATION AND COLONISATION

P. Aldridge[1], L. Drage[1], R. Pickard[2], C. Harding[3], J. Hall[4]
[1]Newcastle University, Centre for Bacterial Cell Biology, Newcastle upon Tyne, United Kingdom
[2]Newcastle University, Institute for Cellular Medicine, Newcastle upon Tyne, United Kingdom
[3]Freeman Hospital, Urology, Newcastle upon Tyne, United Kingdom
[4]Newcastle University, Institute for Cell and Molecular Biosciences, Newcastle upon Tyne, United Kingdom

Backgrounds

Urinary tract infections (UTIs) are the second most common cause of infection worldwide, making them a huge economic burden. People can carry diagnostic loads of bacteria within the bladder without experiencing any symptoms, this is asymptomatic bacteriuria (ABU). ABU can reactivate sporadically, causing symptomatic episodes, known as recurrence. Current treatment is with antibiotics, either short-courses or prophylaxis. Guidelines state to only treat symptomatic episodes. However, UTI symptoms are often diffuse and unclear, especially in older people. Thus, ABU is inappropriately treated in up to 52% of cases, encouraging antibiotic resistance.

Objectives

Better ways of discriminating between symptomatic and asymptomatic cases are needed. Our objective was to analyse potential changes in the host response and the colonising bacteria around ABU to symptomatic transitions, allowing for analysis into potential predictive biomarkers for symptoms.

Methods

We designed a clinical study where 30 patients over 65 years of age with recurrent UTI were recruited for 6 months. Every 2 weeks a urine sample and symptom questionnaire was collected. Urine was analysed for cytokine content and the viable microflora.

Conclusions

Despite varying levels of immune activation, a range of bacterial uropathogenic species were able to evade host-defences and thrive in the bladder long-term. Our study has provided an insight into the long-term colonisation of the ageing bladder and the impact treatment can have on reaching a stabilised microflora. Our study suggests that what the health care system observes and what patients perceive are not necessarily consistent. We argue greater emphasis on medical education could significantly improve patient well-being.

PREVALENCE AND MOLECULAR CHARACTERIZATION OF MULTI-DRUG RESISTANT EXTENDED-SPECTRUM BETA-LACTAMASE (ESBL)-PRODUCING ESCHERICHIA COLI ISOLATED FROM BOVINE MASTITIS

T. Ali[1], S. ur Rahman[2], H. Dandan[1], Z. Limei[1], M. Shahid[1], D. Youtian[1], G. JIan[1], H. Bo[1]
[1]China Agricultural University,
Department of Clinical Veterianry Medicine- College of Veterinary Medicine, Beijing, China
[2]Abdul Wali Khan University, College of Veterinary Sciences and Animal Husbandry, Mardan, Pakistan

Backgrounds

Antimicrobial resistance in bacteria is becoming a serious threat to animals as well as to human health worldwide. Particularly, extended-spectrum beta-lactamase (ESBL)-producing *Escherichia coli,* is a major challenge to the modern era.

Objectives

Therefore, this study was conducted to investigate the prevalence of ESBL-producing *E. coli* isolated from bovine mastitis and to characterise these isolates. A total of 1340 mastitic milk samples were collected from different dairy herds located in sixteen provinces of China.

Methods

Screening of ESBL-producing *E. coli* and antibiotic susceptibility was performed according to CLSI guidelines. ESBL encoding genes, multi-locus sequence typing and plasmid typing was performed by PCR and sequence analysis. Among 173 isolated *E. coli*, 49 ESBL-producing *E. coli* were identified, with CXT-M (87.76%; CTX-M-15) being the most prevalent genotype followed by TEM (51.03%) and SHV (13.56%). Two ESBL-positive isolates (CTX-M-15) from bulk milk samples were also identified. All the ESBL-producing isolates were multi-drug resistant, showing high resistance (100% to 55%) to common antibiotics such as beta-lactams, aminoglycoside, tetracycline and fluoroquinolones. Majority of isolates belong to the commensal phylogenetic group A (69.39%), followed by D (20.41%). MLST data showed high molecular diversity among the ESBL-producers. Importantly, majority of ESBL-producing *E. coli* harboured IncF (IncFIA, IncFIB, IncFIC and IncFIIs) plasmids. Furthermore, conjugation experiments exhibited the successful transfer of resistance phenotypes in the transconjugates.

Conclusions

This study concludes on high occurrence of ESBL-producing *E. coli* isolated from dairy cows, which is worrisome for the dairy industry and for the public health as ESBL-genes could rapidly spread via horizontal gene transfer.

VIRUS- AND ANTIBIOTIC- RESISTANCE PHENOTYPES OF NATURAL AND CLINICAL E. COLI

R. Allen[1], K. Pfrunder-Cardozo[1], D. Meinel[2], A. Egli[2], A. Hall[1]
[1]ETH Zürich, Environmental Systems Science, Zürich, Switzerland
[2]University of Basel, Biomedicine, Basel, Switzerland

Backgrounds

Associations among different resistance phenotypes are important for understanding bacterial evolution and designing rational therapies. However we lack a quantitative understanding of how resistance against different stressors and types of stressors are associated in natural and clinical populations.

Objectives

To test this, we measured the resistance phenotypes of 94 isolates of *Escherichia coli* against a wide range of antibiotics and bacteriophages. We then tested for associations among different resistance phenotypes and the predictive power of information such as phylogenetic relatedness and plasmid content.

Methods

We found correlations between some resistance phenotypes across isolates, and this was more common for pairs of stressors of the same type (antibiotic-antibiotic or phage-phage) than different types (antibiotic-phage). Both phage- and antibiotic- resistance were predicted by core genome phylogeny, but only antibiotic resistance was predicted by plasmid content. We then used the correlations among resistance phenotypes to identify genes involved in an uncharacterized phage-resistance mechanism, which we verified using single-gene knockouts and experimental evolution.

Conclusions

This suggests associations among resistance phenotypes offer predictive power over the genetic basis of resistance to uncharacterized or novel antimicrobials. That resistance to antibiotics and phages appears to be evolving independently is encouraging in the context of phage therapy.

THE MAPK HOG1 PROMOTES RECOVERY FROM CELL CYCLE ARREST INDUCED BY OXIDATIVE STRESS IN THE PATHOGENIC FUNGUS CANDIDA ALBICANS

R. Alonso-Monge[1], *I. Correia*[2], *E. Román*[1], *D. Prieto*[1], *J. Pla*[1]
[1]*Universidad Complutense de Madrid, Microbiología II, Madrid, Spain*
[2]*IBMC- Instituto para a Investigação e Inovação em Saúde, Instituto de Biologia Molecular e Celular, Porto, Portugal*

Backgrounds

Eukaryotic cell cycle needs to be tightly regulated in order to ensure cell survival. Cell cycle progression depends on environmental conditions while signal transduction pathways play a crucial role in sensing surrounding stresses. In *Saccharomyces cerevisiae* the MAPK (Mitogen Activated Protein Kinase) Hog1 has been implicated in cell cycle arrest induced by osmotic shock. In the opportunistic pathogen *Candida albicans* the HOG pathway has been involved in response to osmotic and oxidative stress. However, there is a lack of knowledge on how cell cycle is regulated in response to stress.

Objectives

1.Analyse the effect of oxidative stress induced by hydrogen peroxide in cell cycle progression in *C.albicans.*
2.Analyse the role of the MAPK Hog1 in cell cycle progression under oxidative stress

Methods

The *C. albicans* wild type strain was tagged with GFP in order to distinguish it from the *hog1* mutant strain. Then, mixed cultures (wild type-GFP /*hog1* mutant strains) were elutriated and G1 phase cells were released in the presence (or not) of hydrogen peroxide. Cell cycle progression was followed in time by Flow Cytometry and cyclins expression was quantified by RT-PCR-Q

Conclusions

1.Hydrogen peroxide induced a transient arrest at G1 phase in *C.albicans* cell cycle.
2.The *hog1* mutant required longer time to resume growth after arrest induced by oxidative challenge
3.The *hog1* mutant progresses faster through the cell cycle under standard growth conditions
3.Expression of certain cyclins (Cln3, Pcl2 and Hgc1) was altered in the *hog1* mutant compare to the wild type strain

VIBRIO VULNIFICUS RTXA13 TRIGGERS A CYTOKINE STORM IN MICE

C. Murciano[1], A. Fernández-Bravo[2], C.T. Lee[3], C. Amaro[1]
[1]ERI BioTecMed, Microbiology and Ecology, Burjassot, Spain
[2]ERI BioTecMed, Microbiología y Ecología, Valencia 46100, Spain
[3]College of Medicine- National Cheng-Kung University, Department of Microbiology & Immunology, Tainan, Taiwan R.O.C.

Backgrounds

Vibrio vulnificus biotype 2-serovar E causes death by sepsis in humans/fish. It produces a modular-toxin ($RtxA1_3$) that contains a putative actin-cross-linking domain (ACD). *rtxA1₃* is duplicated in plasmid and chromosome-I. Our hypothesis is that $RtxA1_3$ induces a cytokine-storm at short term that can cause death by sepsis.

Objectives

i) To get single/multiple mutants deficient in ACD/$RtxA1_3$/VvhA (another important cytolysin) and determine its role in cell-death and mouse-virulence. ii) To relate the toxin with cytokine-storm at short term in infected mice. iii) To follow bacterial growth and *rtxA1₃* expression in human blood with and without iron.

Methods

Bacterial mutants: allelic interchange. **Cytotoxicity**: LDH release /flow-cytometry. **Actin-cross-linking activity**: western-blotting. **Virulence**: Lethal-dose-50% after intraperitoneal infection of mice. **Murine immune-response**: by quantifying the transcription of 84 immune-related genes in blood from infected mice by qRT-PCR. **Bacterial invasion in mouse**: Bacterial growth in murine internal organs plus *rtxA1₃*-expression by qRT-PCR**. Bacterial invasion in humans and role of iron**: Bacterial growth in human blood (with or without iron) plus *rtxA1₃* expression by qRT-PCR

Conclusions

i) $RtxA1_3$ causes death by necrosis/apoptosis in human endotheliocytes/monocytes; ii) ACD has actin-cross-linking activity; iii) Biotype 2-serovar E is only successful in invasion in iron-overloaded humans; iv) $RtxA1_3$ induces the up-regulation of 47 murine genes at 4h post-infection: some involved in immune-response against intracellular-pathogens (interferon-related, *Tlr9* and *Nod2*…) and pyroptosis (*Pycard*, *Casp1* and *Nlrc4*). The crucial role of $RtxA1_3$ in inducing a cytokine-storm is ground-breaking, as it is the first description of a bacterial toxin, apart from superantigens, involved in this life-threatening immune-response.

[4]Fasa University of Medical Sciences- Fasa- Iran, Deptment of Microbiology, Fasa, Iran
[5]Isfahan University of Medical Sciences- Isfahan- IR Iran,
Department of Medical Parasitology and Mycology, Isfahan, Iran

Backgrounds

Candida glabrata is a pathogenic yeast with several unique biological features and associated with an increased incidence

rate of candidiasis. It exhibits a great degree of variation in its pathogenicity and antifungal susceptibility.

Objectives

The aim of the present study was to evaluate the in vitro antifungal susceptibilities of the following six antifungal drugs

against clinical *C. glabrata* strains: amphotericin B (AmB), ketoconazole (KTZ), fluconazole (FCZ), itraconazole (ITZ), voriconazole

(VCZ), and caspofungin (CASP).**Methods**

Forty clinical *C. glabrata* strains were identifed using DNA sequencing. The in vitro antifungal susceptibility

was determined as described in clinical laboratory standard institute (CLSI) documents (M27-A3 and M27-S4).**Conclusions**

These findings confirm that CASP, compared to the other antifungals, is the potent agent for treating candidiasis

caused by *C. glabrata*. However, the clinical efficacy of these novel antifungals yet to be determined.

SEROPREVALENCE OF TOXOPLASMA GONDII IN THE IRANIAN GENERAL POPULATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Ahmad Daryani[1], M. Mehdi Sharif[1], S. Shahabeddin Sarvi[1], A. Azadeh Mizani[1], A. Afsaneh Amouei[1]
[1]Toxoplasmosis Research Center- Mazandaran University of Medical Sciences- Sari- Mazandaran-4847191971- Iran, Parasitology and Mycology, Sari, Iran

Backgrounds

Toxoplasma gondii is one of the most common protozoan parasites with widespread distribution globally. While *T. gondii* infection in healthy people is usually asymptomatic, it can lead to serious pathological effects in congenital cases and immunodeficient patients.

Objectives

We sought to identify the seroprevalence rate of *Toxoplasma* infection in the Iranian general population to develop a comprehensive description of the disease condition in Iran for future use.

Methods

8 Electronic databases and Persian language databases were searched. Furthermore, graduate student dissertations and proceedings of national parasitology congresses were searched manually.

Conclusions

Our search resulted in a total of 35 reports published from 1978 to 2012.These include 52,294 individuals and 23,385 IgG seropositive cases. The random errors method was used for this meta-analysis. The result shows that the overall seroprevalence rate of toxoplasmosis among the general population in Iran was 39.3% (95% CI = 33.0%–45.7%). There was no significant difference in the seroprevalence rate between male and female patients. In addition, the data indicates that there are high seroprevalence in groups who have direct contact with cats, consume uncooked meat and raw fruits or vegetables, in farmers and Housewife, individuals who have a low level of education, and live in rural areas. To the best of our knowledge, this is the first systematic review of *T. gondii* infection seroprevalence in Iran, which shows a high prevalence of *Toxoplasma* infection (more than one third). We highly recommend further study for the purposes of aiding patient management and developing more efficient diagnostic tests and effective prevention approaches.

[3]Departamento de Bioquímica y Biología Molecular y Celular- Universidad de Zaragoza, Departamento de Bioquímica y Biología Molecular y Celular- Universidad de Zaragoza, Zaragoza, Spain

Backgrounds

The prokaryotic FAD synthetases (FADS) are bifunctional enzymes that catalyze the biosynthesis of the essential cofactors flavin mononucleotide (FMN) and flavin adenine dinucleotide (FAD). FADS are key proteins in flavin and flavoproteome homeostasis, since the alteration of their enzymatic activities leads into a FMN and FAD deficiency, and consequently into the accumulation of the apo forms of numerous flavoproteins, which are unable to carry out their expected functions in the cellular metabolism and other essential processes.

Objectives

This crucial role in cellular metabolism, together with the significant differences with their eukaryotic counterparts, converts the FADS in an attractive potential drug target for the development of inhibitors endowed with antimicrobial activity.

Methods

Through the high-throughput screening based on the inhibition of CaFADS and SpnFADS (FADS from *Corynebacterium ammoniagenes* and *Streptococcus pneumoniae,* representative members of the prokaryotic FADS), we have identified 40 potential inhibitors. These compounds have been thoroughly characterized by the determination of their antimicrobial spectrum and their cytotoxic effect on eukaryotic cells.

Conclusions

Only 5 compounds show antimicrobial activity against Gram-positives, and one of them against Gram-negative microorganisms as well. Nevertheless, their therapeutic application could be limited due to their cytotoxicity on eukaryotic cells at the concentrations required for the antimicrobial activity. Both antibacterial and cytotoxic effects may be associated with the unspecific alteration of other essential flavoproteins and flavoenzymes.

In a further step, the molecular information of the antimicrobial mechanism will be used for the optimization of these compounds in order to generate second-generation antimicrobials with higher efficacy and less toxicity.

IMPAIRED ANTI-FIBROTIC EFFECT OF BONE MARROW-DERIVED MESENCHYMAL STEM CELL IN A MOUSE MODEL OF PULMONARY PARACOCCIDIOIDOMYCOSIS

J. Arango[1,2], J.D. Puerta-Arias[2], P.A. Pino-Tamayo[3], L.M. Salazar-Peláez[4], A. González[1,5]
[1]Universidad de Antioquia, Escuela de Microbiolgía, Medellín, Colombia
[2]Universidad de Antioquia, Medical and Experimental Mycology Group- CIB, Medellín, Colombia
[3]Weill Cornell Medical College, Department of Microbiology and Immunology, New York, USA
[4]Universidad CES, Basic Sciences Group, Medellín, Colombia
[5]Universidad de Antioquia, Basic and Applied Microbiology Research Group MICROBRA, Medellín, Colombia

Backgrounds

Paracoccidioides spp is the causal agent of paracoccidioidomycosis (PCM), an endemic and systemic mycosis widely distributed in Latin America; this disease is characterized by a chronic granulomatous inflammatory response with development of pulmonary fibrosis (PF), even after antifungal treatment. Recently, it has been demonstrated that bone marrow-derived mesenchymal stem cells (BM-MSCs) therapy could be used as an alternative to treat chemical-induced PF.

Objectives

To evaluate the anti-fibrotic therapeutic potential effect of BM-MSCs in a mouse model of pulmonary PCM.

Methods

BM-MSCs were isolated and purified from BALB/c mice using standardized methods. BALB/c male mice were inoculated i.n. with $1.5x10^6$ *P. brasiliensis* yeasts. An additional group of mice was treated with itraconazole (ITC) at the 6^{th} week p.i.; $1x10^6$ BM-MSCs were administered i.v. at eight weeks p.i. to all groups of mice in a single dose; animals were sacrificed on the 12th week p.i. in order to evaluate: fibrocytes counts, soluble collagen, pro-fibrotic genes expression and histopathological aspects.

Conclusions

BM-MSCs-treated mice showed a significant increase of fibrocytes, soluble collagen and collagen-3a1 expression in comparison with infected untreated-mice. Lung histopathological analysis showed an increased of granulomas and collagen deposition in those BM-MSCs treated-mice. Interestingly, the combined therapy BM-MSCs/ITC induced a reduction of TIMP-1 gene expression in comparison with the respective control groups. This is the first study to evaluate the effect of BM-MSCs therapy in PCM; however, these results indicate that the immunoregulatory function of BMSCs, maybe triggered by the interaction with *P. brasiliensis*, exacerbates the pulmonary fibrosis response.Supported: Colciencias (project_358-2011)

Pathogens / Pathogenicity

ROLE OF C. DIFFICILE C-DI-GMP REGULATED PROTEINS IN BIOFILM FORMATION AND ADHESION TO HUMAN CELLS

V. Arato[1], *R. Leuzzi*[1]
[1]*GSK Vaccines, AIMB, Siena, Italy*

Backgrounds

C. difficile (*CD*) is a Gram-positive and anaerobic bacterium which causes several gut diseases. Like other bacteria, *CD* modulates the transition from a motile to a sessile lifestyle through a mechanism of riboswitch regulated by the second messenger cyclic diguanosine monophosphate (c-di-GMP).

High levels of c-di-GMP are involved in the regulation of *CD* colonization processes by modulating the expression of an extracellular protease and surface proteins. The zinc metalloprotease CD2830 has been shown to cleave the putative adhesin CD2831 likely preventing its contribution to adhesion to the host. Importantly, both genes are located downstream of a c-di-GMP riboswitch and intracellular c-di-GMP concentrations modulate adhesive phenotypes by alternatively expressing CD2831 or CD2830.

Objectives

Our studies aim to understand the role of c-di-GMP signaling in the lifecycle of *CD* and its effect on the above-mentioned proteins CD2830 and CD2831.

Methods

To determine the role of c-di-GMP in *CD*, we constitutively expressed the *dccA* gene encoding adiguanylate cyclase enzyme, which synthesizes c-di-GMP. This, together with knocking-out CD2830 and CD2831 genes will contribute to understand the role of the two proteins in biofilm formation *in vitro*. Moreover, in order to study the binding of *CD* to human cells we implemented a 3D co-culture of fibroblasts, enterocytes and mucus-secreting cells representing the human intestinal epithelium.

Conclusions

Preliminary results show that high levels of c-di-GMP promote the down-regulation of CD2830 and therefore the expression of CD2831 on the cell wall. This condition shows to facilitate biofilm formation *in vitro*.

MANIPULATION OF THE NADH/NAD+ RATIO TO DISCLOSE THE MECHANISMS UNDERLYING BACTERICIDAL ACTIVITY OF ANTIBIOTICS IN PSEUDOMONAS AERUGINOSA

A. Arce-Rodriguez[1], *S. Häußler*[1]
[1]*Helmholtz Centre for Infection Research, Molecular Bacteriology, Braunschweig, Germany*

Backgrounds

The metabolic plasticity encoded in the genome of *Pseudomonas aeruginosa*, endow this pathogen with the genetic arsenal required to surpass antimicrobial treatments. However, the mode of killing of antimicrobials and the mechanisms underlying its resistance in this bacterium are not fully understood. Recent theories suggest a common mechanism of antimicrobial killing by alterations in the metabolism, inducing the hyperoxidation of NADH in the respiratory chain and thus leading to the formation of reactive oxygen species.

Objectives

In this work we seek to manipulate the intracellular concentrations of NADH/NAD^+ to study this effect in the context of antibiotic killing and antibiotic resistance in *P. aeruginosa*.

Methods

The coding sequence of the NADH oxidase from *Streptococcus pneumoniae* (Nox^{Sp}) and the NADH-producing formate dehydrogenase from *Candida boidinii* ($FDH1^{Cb}$) were overexpressed into *P. aeruginosa* PA14. Both enzymes were shown to be fully functional, decreasing (Nox^{Sp}) or increasing ($FDH1^{Cb}$) the intracellular NADH/NAD^+ ratios.

Conclusions

Transcriptional profile by RNA-Seq of both overexpressing strains showed pleiotropic effects. The oxidation of NADH by Nox^{Sp} induced the overexpression of general stress factors (mainly related to energy unbalance due to the waste of NADH), chemotaxis and virulence (*las*AB, *rhl*, *rpo*S, alkaline proteases and phenazines). Moreover, ribosomal proteins, tRNA metabolism, transporters and the H^+-transporting ATPase were downregulated. The induction of $FDH1^{Cb}$ caused opposite effects, down-regulating genes related to chemotaxis and virulence, and up-regulating ribosomal proteins, tRNA metabolism and genes involved in antibiotic resistance like multidrug-efflux pumps and β-lactamases. Interestingly, $FDH1^{Cb}$-overexpressing cells resisted higher concentrations of ciprofloxacin when compared to empty plasmid-bearing cells.

OXIDATIVE STRESS IS AN IMPORTANT COMPONENT IN THE FUNGICIDAL ACTION EXERTED BY POLYENES AND ECHINOCANDINS AGAINST CANDIDA ALBICANS

J.P. Guirao-Abad[1], R. Sánchez-Fresneda[1], B. Alburquerque[1], E.I. Agüera[1], J.C. Argüelles[1]
[1]Universidad de Murcia, Genética y Microbiología, MURCIA, Spain

Backgrounds

Our knowledge on the action mechanisms of the main types of antifungals used in medical practice is still incomplete. A convenient strategy to prevent the appearance of resistance would involve the elucidation of whole sets of fungicidal activities, which, for some established compounds, is currently far from being reached

Objectives

To elucidate the role played by the intracellular formation of reactive oxygen species (ROS) in the fungicidal action carried out by Amphotericin B (AmB) and Micafungin (MF) against Candida albicans

Methods

Clinical MICs were determined using the CLSI protocol and cell survival by viable counting. The oxidative burst was assessed by flow cytometry (dihydrofluorescein diacetate) and the antioxidant enzymatic activities (Catalase, Superoxide dismutase and Glutathione reductase) by spectrophotometric quantification. Intracellular trehalose was measured with purified trehalase following the glucose-oxidase method. Any damage to cell integrity and the structural alterations caused by both antifungals were recorded by optical and electronic microscopy.

Conclusions

The clinical MICs for MF and AmB were 0.016 and 0.012 mg/L, respectively. AmB (0.5-1.0 x MIC) induced a high degree of cell killing accompanied by significant ROS production in exponential Candida albicans SC5314 cell, while the fungicidal effect of MF led to a low level of intracellular ROS formation. Preincubation with thiourea suppressed ROS generation with a concomitant increase in cell viability, regardless of the antifungal applied. The simultaneous measurement of several antioxidant enzymes revealed strong AmB-induced activation of enzymatic activities, whereas MF had only a weak stimulating effect. Likewise, AmB but not MF promoted a conspicuous endogenous synthesis of trehalose, which is a specific protector against oxidative stress in C. albicans.
Our results allow to conclude that the induction of internal oxidative stress in C. albicans through the accumulation of ROS is an important component of the antifungal action of polyenes (AmB) but not of echinocandins (MF).

SENSITIVITY OF CANDIDA ALBICANS TREHALOSE-DEFICIENT MUTANTS TO AMPHOTERICIN B AND MICAFUNGIN

R. Sánchez-Fresneda[1], J.P. Guirao-Abad[1], V. Pujante[1], B. Alburquerque[1], J.C. Arguelles[1]
[1]Universidad de Murcia, Genética y Microbiología, MURCIA, Spain

Backgrounds

Trehalose has been proposed as a potential target for new antifungals.

Objectives

The putative role of trehalose as cell protector against antifungal exposure with AmB and MF has been investigated in the null mutants *tps1/tps1* and *tps2/tps2*, which are deficient in trehalose synthase and trehalose phosphatase activity, respectively in *Candida albicans*.

Methods

Cultures were grown in YPD until exponential phase and then treated with both antifungal at 37ºC for 1 h. Viability was determined in samples diluted with sterile water by plating in triplicate on solid YPD after incubation for 2 days at 37ºC. The antioxidant enzymatic activities (Catalase, Superoxide dismutase and Glutathione reductase) by spectrophotometric quantification. Intracellular trehalose was measured with purified trehalase following the glucose-oxidase method.

Conclusions

The two homozygous mutants (*tps1Δ* and *tps2Δ*) showed different cell sensitivity upon exposure with the antifungals AmB (0.25 µg/ml) and MF (0.05 µg/ml). Whereas *tps1Δ* cells were very susceptible to AmB, they showed high resistance to MF. Conversely, *tps2Δ* displayed an opposite degree of sensitivity. Catalase activity was inhibited by both antifungals in the two mutants. Surprisingly, however, MF induced a conspicuous SOD activation only in *tps1Δ*. The opposite pattern in SOD activity was recorded upon AmB exposure. As regards trehalose synthesis, only AmB triggered a marked accumulation of the disaccharide, while MF had a negligible effect.

Collectively, our results suggest that the enzymes involved in trehalose biosynthesis display a different pattern of sensitivity to AmB and MF.

GENOME SEQUENCING OF TREPONEMA PALLIDUM REVEALS A PANDEMIC CLUSTER AND PROVIDES INSIGHTS INTO ITS ORIGINS

N. Arora[1]
[1]*University of Zurich, IEU/IRM, Zurich, Switzerland*

Backgrounds

Syphilis, a multi-stage infection caused by the spiral shaped bacterium *Treponema pallidum pallidum (TPA)*, has been re-emerging globally in recent decades despite the availability of effective treatment with antibiotics. Little is known about the genetic patterns of current infections or the evolutionary origins of the disease due to the challenges in obtaining DNA from clinical samples. Moreover, TPA is non-cultivable and displays limited genetic diversity. While resistance to penicillin has not been identified, there has been an increase in the number of strains that do not respond to treatment with the second line antibiotic azithromycin.

Objectives

Our aims are to examine the patterns of genetic diversity and differentiation, especially focusing on samples from contemporary infections, and to gain insights into the history of TPA.

Methods

We used DNA capture and whole genome sequencing to obtain genome-wide data from syphilis patient specimens, combining it with laboratory samples of TPA and two other subspecies (*T. pallidum* subsp. *pertenue*, TPE, and *T. pallidum* subsp. *endemicum*, TEN).

Conclusions

Our phylogenetic analyses using genome-wide sequences point to a common ancestor for all TPA strains in the 18th century. Our analyses also show that most strains from contemporary infections have the mutation associated with azithromycin resistance. Furthermore, most of the clinical strains form part of a globally dominant cluster, named SS14-Ω, which diversified after the discovery of antibiotics in the mid-20th century. The recent phylogenetic expansion of this cluster and its wide geographical distribution are indicative of the emergence and expansion of a pandemic strain.

TN1721, A VECTOR OF CHOICE FOR ANTIBIOTIC RESISTANCE IN AEROMONAS SALMONICIDA?

S.A. Attere[1,2,3], *A.T. Vincent*[1,2,3], *M. Paccaud*[1,2,3], *S.J. Charette*[1,2,3]
[1]*Université Laval, Microbiology, Quebec, Canada*
[2]*Université Laval, Institut de biologie intégrative et des systèmes, Quebec, Canada*
[3]*Université Laval, Institut Universitaire de cardiologie et de pneumologie de Québec, Quebec, Canada*

Backgrounds

Antibiotic resistance is a major worldwide problem for fish farming since many waterborne pathogenic bacteria harbor a large panel of drug resistance. Resistance genes can be often acquired through mobile genetic elements such as non-composite transposons. This is the case for *Aeromonas salmonicida* subsp. *salmonicida,* a bacterium causing furunculosis and having a large repertoire of antibiotic resistance genes introduced by mobile elements. Tn*1721*, a non-composite transposon discovered in this microorganism, is known to be a vector for the dissemination of the tetracycline resistance.

Objectives

This study investigates how the spread of Tn*1721* took place in *Aeromonas salmonicida* subsp. *salmonicida*, in correlation with the plasmidome.

Methods

Plasmid profiling was performed by PCR genotyping and also by plasmid extraction, followed by an enzymatic digestion and a migration on an electrophoresis gel. Plasmidic DNA of interest was then sequenced using Illumina technology. Finally, a bioinformatic characterization of the new plasmids was performed to determine their features, including antibiotic resistance genes and transposons.

Conclusions

Tn*1721* was found in two new plasmids of *A. salmonicida* subsp. *salmonicida*. In the large plasmid pAsa8 (110,6 kb), it is fully present but interrupted by two other mobile genetic elements. However, in the small plasmid pAsa10 (10 kb), only the part providing the tetracycline resistance is present. Also, the insertion of the transposon probably occurred through a different mechanism in the case of pAsa10 according to the orientation of the inverted repeats. This study sheds light on an unsuspected importance and diversity of the Tn*1721* in *A. salmonicida* subsp. *salmonicida*.

DUAL REPRESSION OF A BACTERIAL PROMOTER BY THE HISTONE-LIKE NUCLEOID STRUCTURING PROTEIN (H-NS) AND THE LYSR-TYPE TRANSCRIPTION FACTOR LEUO

J. Ayala Figueredo[1], *J. Benitez*[1], *A. Silva*[1]
[1]*Morehouse School Of Medicine, Biochemistry Microbiology And Immunology, Atlanta, Usa*

Backgrounds

The *vieSAB* operon encodes a three-component system that regulates virulence gene expression in *V. cholerae* O1, the causative agent of cholera. Transcription of *vieSAB* is silenced by the nucleoid-associated protein H-NS.

Objectives

The objective of this study was to identify antagonists of H-NS repression.

Methods

An assay for proteins that can bind to the *vieSAB* promoter identified the stationary phase regulator LeuO. H-NS and LeuO interacted with overlapping sequences at the *vieSAB* promoter with Kd values of 44.1 and 31.2 nM, respectively. Furthermore, LeuO displaced pre-bound H-NS from the promoter. However, ectopic expression of LeuO from the *araBAD* promoter indicated that LeuO functions as a transcriptional repressor at this locus. To examine the cooperation between H-NS and LeuO in the silencing of *vieSAB* expression, we conducted *in vitro* transcription at two concentrations of RNA polymerase holoenzyme (Es^{70}) (25 and 50 nM). LeuO inhibited *vieSAB* transcription with similar IC_{50} at both Es^{70} concentrations. In contrast, H-NS inhibited *vieSAB* transcription with IC_{50} values of 3.65 and 0.83 nM at low and high Es^{70} concentration, respectively.

Conclusions

We propose a model in which H-NS silences *vieSAB* transcription during exponential growth when the concentration of Es^{70} is highest. In the stationary phase, the concentration of Es^{70} decreases due to sigma factor competition and H-NS exerts weaker repression. At this stage, LeuO is expressed to assist in the silencing of *vieSAB* transcription. This is a rare example in which two repressors target similar recognition sequences at a promoter to effectively silence gene expression at different physiological stages.

GENETIC CHARACTERIZATION OF THE VIRULENCE PROPERTIES AND PATHOGENICITY OF BORDETELLA BRONCHISEPTICA STRAIN HT200 ISOLATED FROM A THERMAL SPRING

J. Badhai[1], S.K. Das[1]
[1]Institute of Life Sciences, Division of Gene Function and Regulation, Bhubaneswar, India

Backgrounds

The classical *Bordetella* species *B. pertussis*, *B. parapertussis,* and *B. bronchiseptica*, are obligate parasites of mammalian hosts including humans which exclusively infect the respiratory epithelium causing a range of severe, often fatal, respiratory diseases. Although *B. bronchiseptica* has been found to survive in natural environments such as lake water, so far there is no report on any environmental isolate. Strains of these classical species are very closely related at the genetic level and divide into complexes I-IV, yet are distinct pathogens in terms of virulence, disease severity, persistence, and host specificity. Phylogenetic analysis based on 16S rRNA gene revealed the strain HT200, isolated from warm spring water with temperature 40 °C, belonged to the classical Bordetellae.

Objectives

To characterize the virulence and pathogenicity of *Bordetella bronchiseptica* strain HT200 isolated from warm spring water.

Methods

Methods used includes PCR based genotyping, serum agglutination and immunoblotting assays for detection of virulence factors, mice trachea and lungs colonization, and antibiotic susceptibility test.

Conclusions

Sequence analysis of genes encoding various housekeeping functions, the common *Bordetella* virulence factors including adhesins, autotransporters, and the virulence regulatory system suggests strain HT200 to have evolved divergently from a distinct lineage of *Bordetella bronchiseptica*-like ancestor. It does not produce some of the major virulence factors including pertussis toxin, adenylate cyclase toxin and dermonecrotic toxin produced by clinical isolates of the classical species. However, it colonizes the trachea and lungs in mice. It is resistant to multiple antibiotics. Genotypic and functional divergence compared to the host-restricted pathogenic classical Bordetellae indicates its niche adaptions.

IDENTIFICATION OF THE SIDEROPHORE PISCIBACTIN AS A RELEVANT VIRULENCE FACTOR FOR VIBRIO ANGUILLARUM SEROTYPE O2

M. Balado Dacosta[1], J.C. Fuentes-Monteverde[2], J.M. Cabaleiro[1], J. Rodríguez[2], C. Jiménez[2], M.L. Lemos[1]
[1]Institute of Aquaculture, Department of Microbiology and Parasitology, Santiago de Compostela, Spain
[2]Facultad de Ciencias, Departamento de Química Fundamental, A Coruña, Spain

Backgrounds

Vibrio anguillarum causes vibriosis, an haemorrhagic septicaemia that affects many cultured marine fish species worldwide. Siderophores are key virulence factors since they participate in iron uptake from host sources during bacterial infections. In *V. anguillarum* two catechol siderophores, vanchrobactin and anguibactin, were previously identified. While vanchrobactin is a chromosomally encoded system widespread in all pathogenic and environmental strains, anguibactin is a plasmid encoded system restricted to serotype O1 pathogenic strains. An analysis of the genome sequence of strain RV22 (serotype O2) shows that it contains a gene cluster that could encode a siderophore related to piscibactin, the siderophore of *Photobacterium damselae* subsp *piscicida*.

Objectives

The main goal of the present work was to identify this third siderophore in *V. anguillarum,* analyze its role in the cell fitness and determine its contribution to virulence.

Methods

In silico analysis allowed the identification of a genomic island that encodes the piscibactin-like siderophore and the prediction of its chemical structure. The characterization of the siderophore by LC-HRMS confirmed that its stucture corresponded to piscibactin.

Conclusions

The construction of single and double biosynthesis mutants for vanchrobactin and/or piscibactin allowed us to study its contribution to iron uptake and its role in virulence. The results showed that *V. anguillarum* serotype O2-O10 isolates harbour a genomic island that codes enzymes for synthesis of piscibactin. Interestingly, vanchrobactin and piscibactin are simultaneously produced, but piscibactin contribute more than vanchrobactin to virulence for turbot. It is noteworthy that the genomic island encoding piscibactin is widespread in many other *Vibrio* species.

UNCOVERING THE ROLE OF ETHYLENE PRODUCED BY PENICILLIUM DIGITATUM IN THE PATHOGENICITY TOWARDS CITRUS FRUIT

A.R. Ballester[1], *L. González-Candelas*[1]
[1]*Instituto de Agroquímica y Tecnología de Alimentos IATA-CSIC, Food Biotechnology, Paterna, Spain*

Backgrounds

Infection of citrus fruit by *Penicillium digitatum* is accompanied by a large increase in ethylene production. Classical studies have shown that this phytohormone is produced both by the fruit and the pathogen. There are three known routes for ethylene production. In plants, ethylene is produced in a two-step reaction from methionine via S-adenosyl-methionine (SAM), which is converted into aminocyclopropane-1-carbxoxylate (ACC) by AAC synthase. Then, ACC oxidase converts ACC into ethylene and cyanide. Many microorganisms also produce ethylene, but using two different pathways. In one of them, methionine is also the precursor compound, but in this pathway it is transaminated into 2-keto-4-methylthiobutyric acid (KMBA), which is spontaneously oxidized to produce ethylene. The last known pathway for ethylene production utilizes α-ketoglutarate (AKG), which derives from glutamic acid, and arginine as substrates in a reaction catalyzed by an ethylene-forming enzyme (EFE), an enzyme that requires ferrous iron and oxygen, yielding ethylene, carbon dioxide, succinate, 1-pyrroline-5-carboxylic acid and guanidine. These last two pathways have been shown to be present in *P. digitatum*. Under *in vitro* growth conditions, the KMBA pathway is the predominant in shake cultures grown in liquid medium, whereas the AKG pathway is predominant in static cultures.

Objectives

To elucidate the contribution of EFE to ethylene production during infection of citrus fruit by *P. digitatum*.

Methods

We have obtained a *P. digitatum* Δ*efeA* knockout mutant using *Agrobacterium*-mediated transformation.

Conclusions

We will present the characterization of this mutant as a valuable tool to understand the role of ethylene in the virulence of *P. digitatum*.

EPIDEMIOLOGY OF MULTI-RESISTANT BACTERIA IN THE HOSPITAL ENVIRONMENT OF HIGH-RISK INFECTIOUS UNITS, IBN TOFAIL HOSPITAL- UNIVERSTARY HOSPITALCENTER OF MARRAKECH

A. El Mekes[1, 2], *K. Zahlane*[1], *L. Ait Said*[1], *A. Tadlaoui Ouafi*[3], *M. Barakate*[1]
[1]*Laboratoire des analyses médicales, Hôpital Ibn Tofail, CHU Marrakech*
[2]*Laboratoire de Biologie et Biotechnologie des Microorganismes, Faculté des Sciences Semlalia, Université Cadi Ayyad-Marrakech*
[3]*Laboratoire de Biotechnologie et Bio-ingenierie moléculaire, Faculté des sciences et techniques, Université Cadi Ayyad-Marrakech*

Abstract:

The objective of this study is to analyze the qualitative and quantitative microbial composition of the environment of high risk infectious units at the Ibn Tofail hospital, CHU Mohammed VI, Marrakech.

Material and Methods: This is a prospective study carried out at four units (two operating units, two adult intensive care units Intensive Cure Unit (ICU) of CHU Mohammed VI Marrakech during a period of four months. The samples concerned inanimate surfaces and the hands of different staff. The level of antibiotic resistance was studied by the diffusion method agar medium. The choice of antibiotics and the criteria for interpretation of the antibiogram were made according to the standards of the European Committee on Antibiograms (EUCAST).

Results: 95 bacterial strains were isolated from the 125 samples. The antibiotic resistance profile showed that 46% were multidrug resistant strain, 19% of them were *acinetobacter baumannii* resistant to imipenem (ABRI), 17 % of the *enterobacteriacae* producing extended spectrum of beta-lactamase (ESBLE), and 8 % were methicillin-resistant *Stapylococcus aureus* (MRSA). The lowest rate (4%) was obtained for *Pseudomonas aeruginosa* resistant to carbapenem (PARC). The ABRI was mainly found in the inanimate surfaces of ICU, the EBLSE were predominant in the surfaces of the operating units. However, the MRSA was isolated mostly from the staff handprints and the surfaces of the four studied units.

Conclusion: The alarming presence of MDR bacteria in the hospital environment urges the hospital actors (biologists, hygienists, clinicians, nursing staff) to double their efforts to control these bacteria.

NOVEL ANTIINFLAMMATORY, ANTIMICROBIAL AND ANTIBIOFILM PEPTIDE

S. Bárcena-Varela[1], G. Martínez de Tejada[1], L. Heinbockel[2], K. Brandenburg[2]
[1]Universidad de Navarra, Department of Microbiology, Pamplona, Spain
[2]Research Center Borstel, Clinical & Experimental Pathology, Borstel, Germany

Backgrounds

Antimicrobial peptides (AMPs) produced by the innate immune system are promising agents for antibiotic development because these molecules bind to essential and highly conserved structural targets on the bacterial surface. Our group developed a new class of AMPs and demonstrated that the leading candidate, Aspidasept® I (Pep19-2.5), protects mice and rabbits against sepsis caused by an otherwise lethal bacterial infection. However, due to its modest antibacterial activity Aspidasept® I has to be co-administered with antibiotics to be effective. Now, we have synthesized another peptide, Pep19-4LF Aspidasept® II (Pep19-4LF), displaying a much better profile of antimicrobial activity.

Objectives

I, to characterize the antimicrobial, antiinflammatory and antibiotic-enhancing activity of Pep19-4LF. II, to evaluate its capacity to prevent the formation and/or to eliminate bacterial biofilms.

Methods

Antimicrobial activity and antibiotic-enhancing activity was measured using conventional MIC/MBC testing and growth kinetics in the Bioscreen system, respectively. A mouse model of endotoxemia was used to characterize the peptide's ability to neutralize sepsis. The anti-biofilm activity was measured on *P. aeruginosa* biofilms grown in the CDC Biofilm Reactor or using peptide immobilized on the surface of silicone.

Conclusions

Pep19-4LF exhibited a broad spectrum of antimicrobial activity against Gram-positive and Gram-negative strains with MICs as low as 2 µg/mL and acted in synergy with several classes of antibiotics against multi-resistant Gram-negative pathogens.. The anti-biofilm activity of the peptide was comparable to that of levofloxacin. When immobilized, Pep19-4LF prevented the formation of *P. aeruginosa* biofilm and killed preformed biofilm of that organism as efficiently as a colistin coating.

FIRST REPORT OF MASS MORTALITIES IN NATURAL POPULATION OF PINNA NOBILIS. A MICROBIAL PERSPECTIVE

S. Rodríguez[1], S. Balboa[1], G. Olveira[1], J. Montes[2], D. Moreno[3], A. Barrajón[3], J.L. Barja Pérez[1]
[1]CIBUS- Facultad de Biología. Universidade de Santiago de Compostela, Departamento de Microbiología y Parasitología, Santiago de Compostela, Spain
[2]Centro de Investigaciones Marinas, Departamento de Patología, Vilagarcia de Arousa, Spain
[3]Agencia de Medio Ambiente y Agua, Medio Ambiente, Sevilla, Spain

Backgrounds

Large bivalves as *Pinna nobilis* are of remarkable importance in seagrasses fields (mainly *Posidonia oceanica*) along the Mediterranean Sea. Wild populations of this threatened species, considered as "vulnerable" by the spanish law, have been greatly reduced due to abusive fishing and alteration of their habitat. Lately, populations of *Pinna* from Almeria (south-east Spain), are being affected by high mortalities up to 90%, with still unknown origin.

Objectives

To determine the possible cause of the mortalities by means of a multidisciplinary approach including complete microbiota analysis seeking for viral, bacterial and parasitic bivalve pathogens, as well as phytotoxins.

Methods

Adult specimens were aseptically biopsied and samples of mantle, gills, gonad and hepatopancreas were taken. Pieces were fixed for histopathologic analysis. Virus detection was done by PCR and culture methods. For bacterial identification, tissues were spread in TCBS and MA, and representative colonies were isolated. Phenotypic profiles and sequencing of the 16S rRNA gene from a number of isolates were done.

Conclusions

- No parasites of bivalves, as *Perkinsus*, *Marteilia* and *Bonamia* were found.
- Ostreid herpesvirus (OsHV-1), was not detected by PCR, however, IPNV-like was isolated by cell culture, although it is unlikely to be the causative agent of the mortality, since that virus seems not replicates in mollusc tissues.
- Surprisingly, the mollusc pathogen *Vibrio tapetis* was isolated within the high diversity of vibrios characterized.
- However the pathogen that caused the *Pinna nobilis* mortality should be very specific because it does not affect, apparently, to *Pinna rudis* sharing the same niche.

DOES ORAL SEX CAUSE FEMALE INFERTILITY?

P. Bavoil[1], P. Marques[1], R. Brotman[2], J. Ravel[3]
[1]University of Maryland - Baltimore, Department of Microbial Pathogenesis, Baltimore, USA
[2]Institute for Genome Sciences, Department of Epidemiology and Public Health, Baltimore, USA
[3]Institute for Genome Sciences, Department of Microbiology and Immunology, Baltimore, USA

Backgrounds

The origin of persistent/resurgent chlamydial infection post-antibiotic treatment is unexplained.

Objectives

To address this question(s), we hypothesize that:

1. The *Chlamydiaceae* have evolved as commensals of the gastrointestinal (GI) tract with fecal-oral transmission (FOT) as the principal route of dissemination to new hosts. Where FOT is reduced (e.g., via sanitation), the occurrence of chlamydiae in the GI tract is reduced.

2. *Chlamydia trachomatis* is a commensal microorganism of the human GI tract, and an opportunistic pathogen in the conjunctiva, genital and respiratory tracts. Where FOT is reduced, direct contact is the primary mode of transmission.

3. *C. trachomatis* is efficiently transmitted to the GI tract of new hosts via oral sex. The practice of oral sex has 'reintroduced' *C. trachomatis* to the human GI tract in communities where FOT was previously reduced.**Methods**

Circumstantial, historical and recent evidence that support the hypothesis is reviewed. Imaging of mCherry-expressing *Chlamydia muridarum* in the murine GI tract was obtained.

Conclusions

Tenets 1 & 2 imply a revision of the status of *C. trachomatis* from principal pathogen to commensal organism that may cause opportunistic infection at non-GI mucosal epithelia. Observed on/off expression of polymorphic membrane proteins, unique properties of peptidoglycan and lipo-oligosaccharide, and extruded inclusions may facilitate chlamydial survival and colonization of the GI tract.

Tenet 3 suggests that orally inoculated chlamydiae may colonize the GI tract, reach the rectum and chronically/episodically, infect the female genital tract causing/contributing to tubal pathology and infertility. The global hypothesis therefore raises the provocative question: does oral sex cause or contribute to female infertility?

CLONAL POPULATION STRUCTURE OF MYCOPLASMA HOMINIS TUNISIAN ISOLATES ASSOCIATED WITH GENITAL MANIFESTATIONS

B. Ben Abdelmoumen Mardassi[1]
[1]*Institut Pasteur de Tunis, Mycoplasmas, Belvedere Tunis, Tunisia*

Backgrounds

Mycoplasma hominis is a bacterium that is capable of invasive diseases such as genital infections, adverse pregnancy outcomes and infertility. Little is known on the genetic diversity and pathogenicity of *M. hominis* isolated in Tunisia.

Objectives

The aim of this study was to develop a combined Multi-Locus and Multi- Virulence-Locus Sequence Typing (MLST and MVLST, respectively) scheme for the characterization of *M. hominis* Tunisian isolates.

Methods

The combined MLST-MVLST assay that we developed is based on five housekeeping genes and five virulence genes. These loci were sequenced, aligned, and sequence types (STs) were deduced. This approach was applied to *M. hominis* PG21 reference strain and 55 clinical isolates recovered from the genital tract of Tunisian patients with genital infections and infertility disorders. START2 software was used to determine the Standardized Index of Association (I_A^S). The phylogenetic analysis were inferred using MEGA v6 and SplitsTree v4.0 softwares.

Conclusions

The MLST-MVLST analysis of 55 isolates of *M. hominis* identified 29 STs, with a $I_A^S$of 0,3289 ($p<0,001$), indicating a strong clonal population structure. Phylogenetic analyses further identified two major lineages: Lineage A (17 STs) and Lineage B (12 STs). Interestingly, we noticed that STs from Lineage A were associated with infertility while STs from lineage B were linked to genital infections.

This study uncovered a clonal population structure of *Mycoplasma hominis* Tunisian isolates with a clear distinction between clinical strains causing genital infections and those associated with infertility. ure. Phylogenetic analyses further identified two major lineages: Lineage A (17 STs) and Lineage B (12 STs). Interestingly, we noticed that STs from Lineage A were associated with infertility while STs from lineage B were linked to genital infections.

BIOFILM FORMATION POTENTIAL AND TOXIN GENES CONTENT IN STAPHYLOCOCCUS AUREUS STRAINS ISOLATED FROM AN ALGERIAN HOSPITAL'S ENVIRONMENT

F. Bendali[1]
[1]*Bejaia University, Microbiology, Bejaia, Algeria*

Backgrounds

Staphylococcus (*S.*) *aureus* is a major cause of infections associated with medical devices (urinary catheters, orthopedic implants…). Its pathogenicity is related to an exhaustive arsenal of virulence factors and toxins. Biofilm formation is one of the major pathogenic factors which facilitates adherence to medical devices and depends on different types of adhesins especially the polysaccharide intercellular adhesin (PIA) coded within the *icaADBC* operon.

Objectives

In this study, twenty two (22) *S. aureus* isolates from hospital environment were analyzed to investigate the presence or absence of the *icaA, icaD* genes and their biofilm formation potential.

Methods

Biofilm potential of the strains was investigated by Tissue Culture Plate (TCP) and Congo Red Agar (CRA) methods. The toxinic genes content was determined by multiplex-PCR using specific primers.

Conclusions

All the strains were demonstrated strong biofilm producers in Trypticase Soy Broth (TSB; $0.270 \leq A_{630nm} \leq 0.656$) and only three of them were moderate in Brain Heart Infusion Broth (BHI; $0.170 \leq A_{630nm} \leq 0.237$). Among them, 18 strains were *slime* producers. Their biofilm formation potential was independent of the presence of *icaAD* genes. Investigation of their toxin genes content and antibiotic resistance revealed that almost all the strains harbored at least one of the toxin genes investigated with a high level of resistance to multitude antibiotics. Furthermore, 54 % of the strains were identified as methicillin- resistant *S. aureus* (MRSA). This study showed the high virulence degrees of the *S. aureus* strains which colonize different inert surfaces, susceptible to be present in a health care unit, and could be transferred to hospitalized patients.

COMPARISON OF TWO AUTOMATIC PATHOGEN DNA ISOLATION METHODS

K. Benulič[1], T. Cerar Kisek[1], M. Kodre[1], V. Cvitkovic Spik[1], E. Ruzic-Sabljic[1]
[1]Institute of Microbiology and Immunology- Faculty of Medicine- University of Ljubljana, Laboratory for Molecular Bacteriology and Micology, Ljubljana, Slovenia

Backgrounds

Broad-range 16S rRNA PCR/sequencing is a widely used molecular diagnostic method for detecting bacterial pathogens in clinical samples. Clinical samples usually contain smaller amounts of bacterial DNA compared to human DNA, which can also have an inhibitory effect. While commercially available SelectNA plus® (Molzym, Bremen, Germany) facilitates isolation of microbial DNA by degradation of human DNA, MagNA Pure Compact Nucleic Acid Isolation Kit® (Roche, Germany), routinely used in our laboratory, isolates the total DNA present in a specimen.

Objectives

The aim of the study was to evaluate and compare SelectNA plus® and MagNA Pure Compact® nucleic acid isolation methods.

Methods

Nucleic acid was extracted from 85 clinical specimens (19 synovial fluid, 23 pleural effusion, 13 cerebrospinal fluid, 10 abscess content, 6 drainage content, 8 tissue samples, 2 whole blood, 1 pericardial fluid, 2 peritoneal fluid, 1 haematoma) using SelectNA plus® and MagNA Pure Compact® nucleic acid isolation kits. The success of isolation by the two kits was evaluated by performing an in-house 16S rRNA/sequencing method.

Conclusions

Broad-range PCR resulted in 55/85 (64.7%) negative samples with both DNA isolation methods. Both DNA isolation methods yielded positive results in 16/85 (18.8%) samples, in 11/16 samples the identification of the pathogen was identical. The results were concordant in 66 (77.6%) samples. Regarding the number of detected and identified bacteria in our samples, the Magna Pure Compact® method for DNA isolation was better. A considerable advantage of Magna Pure Compact® system is also its convenience and shorter hands-on time.

PHENOTYPIC HETEROGENEITY INSIDE THE LEAF: PSEUDOMONAS SYRINGAE WITHIN ITS HOST

N. López-Pagán[1], J.S. Rufián[1], D. López-Márquez[1], J. Ruiz-Albert[1], C.R. Beuzón[1]
[1]Instituto de Hortofruticultura Subtropical y Mediterránea La Mayora IHSM-UMA-CS, Plant Protection, Málaga, Spain

Backgrounds

Advances in genomics and single-cell analysis have demonstrated the extraordinary complexity that microbial populations reach within their hosts. Communities range from complex multispecies groups, to homogeneous populations differentiating through genetic or non-genetic mechanisms. Diversity within populations is recognised as a key driver of evolution in animal pathogens. However, much less is known in plants pathogens about how populations differentiate, the extend of these processes, or how interactions between pathogenic and non-pathogenic variants impacts defence responses or the fate of each variant.

Objectives

To investigate how the model plant pathogen *Pseudomonas syringae* differentiates into subpopulations through non-genetic means, the extent of these processes, or how variation impacts on bacterial adaptation to the plant apoplast, are some of the aims of our work.

Methods

Confocal and time-lapse fluorescent microscopy and flow cytometry have been applied to the analysis of *P. syringae pv. phaseolicola* strains carrying chromosome-located transcriptional fusions to fluorescent reporter genes to genes important for bacterial adaptation to the plant host, as well as to that of bacterial derivatives carrying mutations and/or plasmids affecting regulatory genes.

Conclusions

Non-pathogenic variants of *P. syringae* can proliferate and even spread when in close proximity to pathogenic bacteria. High bacterial concentrations can be reached at natural entry points and promote such interactions during the infection process. But we also found diversity affecting virulence traits originating through non-genetic mechanisms within clonal populations. Our results illustrate the dynamics and complexity of the interactions found within *P. syringa*e infections, and their potential impact on bacterial adaptation

A GENOME-WIDE EPIDEMIOLOGICAL STUDY OF PSEUDOMONAS AERUGINOSA IN NORTHEAST ITALY

I. Bianconi[1], *O. Jousson*[1]
[1]*University of Trento, Centre for Integrative Biology CIBIO, Trento, Italy*

Backgrounds

Pseudomonas aeruginosa is a ubiquitous bacterium which can be found in soil and aquatic environments and is able to colonize plants, animals and humans. *It* has a characteristic non-clonal population structure consisting of a limited number of widespread major clones that are highly versatile in their habitat and of minor clones with preference for a peculiar niche. While patient-to-patient transmission is well documented, the role of the environment as a reservoir of initial infectious clones is still unclear and may lead to inadequate preventive measures. Moreover, a better understanding of *P. aeruginosa* transmissibility between different environments and the human host is important to develop more targeted therapies against the pathogen.

Objectives

To date, no systematic epidemiological studies of *P. aeruginosa* have been conducted in Italy. We are therefore performing a cross-sectional genomic epidemiological study to provide an overview of *P. aeruginosa* population structure in Northeast Italy and to investigate the circulation of strains between human and animal hosts and the environment.

Methods

*S*trains have been collected from water, soil, animal and human hosts and their genome will be sequenced and analysed.

Conclusions

Whole genome sequencing and population studies will allow (i) to elucidate the source of new strains causing infections in humans; (ii) to determine if major clones are present within the population and to analyse their distribution among the different hosts and environments; (iii) to verify the presence in Northeast Italy of putative epidemic lineages and track their mode of transmission.

PREDICTING ANTIBIOTIC RESISTANCE BY EXPERIMENTAL EVOLUTION IN STENOTROPHOMONAS MALTOPHILIA

P. Blanco Torres[1], *J.L. Martínez Menéndez*[1]
[1]*Centro Nacional de Biotecnología- CSIC, Microbial Biotechnology, Madrid, Spain*

Backgrounds

Stenotrophomonas maltophilia is an opportunistic pathogen with increasing prevalence characterized by a reduced susceptibility to currently used antibiotics. Such resistance is mainly due to the presence of antibiotic-inactivating enzymes and several multidrug efflux pump (MDR) systems encoded in its genome. However, less is known about the mutations involved in the acquisition of resistance of this bacterium that are selected in the presence of antibiotics.

Objectives

The aim of our study was to predict the emergence of resistance in *S. maltophilia* during 28 days of experimental evolution in the presence of tigecycline or ceftazidime and to determine the mutations involved. The order of appearance of each of the mutations is of relevance for predicting the contribution of each independent mutation to antibiotic resistance.

Methods

A stepwise experiment was performed in the presence of increasing inhibitory concentrations of each antibiotic, starting at minimum inhibitory concentration (MIC) and stopping at 32MIC. Evolution was also performed at subinhibitory concentrations, using 1/10 and 1/50 MIC continuously. Controls without any compound were also grown in parallel. At the end of the experimental evolution, four independent populations of each treatment were taken for whole-genome sequencing (WGS). At several time points, samples were taken to establish the order of appearance of each mutation by PCR amplification and Sanger sequencing.

Conclusions

High levels of resistance have been obtained in all cases at inhibitory concentrations of both antibiotics; however, at subinhibitory concentrations no changes in the MICs were recorded. Different mutations that will be discussed in the presentation, account for the observed phenotype.

THE ANTIFUNGAL PHENOTYPE OF MYELOID CELLS DIFFERENTIATED FROM HEMATOPOIETIC PROGENITORS WITH M-CSF, BUT NOT WITH GM-CSF, IS ENHANCED BY CANDIDA ALBICANS IN A TLR2-DEPENDENT MANNER

C. Bono[1], A. Martínez[1], J. Megías[2], D. Gozalbo[1], M.L. Gil[1]
[1]Universitat de Valencia,
Microbiología y Ecología and Estructura de Recerca Interdisciplinar en Biotecnologia i Biomedicina E RI BIOTECMED, Valencia- Burjassot, Spain
[2]Universitat de Valencia, Patología, Valencia, Spain

Backgrounds

In vitro recognition of *C. albicans* by hematopoietic stem and progenitor mouse cells (purified as lineage negative or Lin^- cells) promotes differentiation toward macrophages. Additionally, the antifungal phenotype of macrophages obtained in the presence of M-CSF is enhanced by *C. albicans* [1].

Objectives

Our objectives were to determine the involvement of TLR2 in this phenotype and to elucidate whether fungal recognition also modulates the antifungal properties of GM-CSF-differentiated myeloid cells.

Methods

GM-CSF-differentiated mature myeloid cells obtained from Lin^- cells showed an increased ability to kill *C. albicans*, as compared with cells differentiated with M-CSF. Co-incubation of Lin^- cells with GM-CSF and *C. albicans* yeasts did not modify: (i) the ability of the differentiated cells to kill yeasts and (ii) the cytokine production (TNF-alpha and IL-6) in response to pure TLR ligands. Interestingly, myeloid cells obtained from Lin^- progenitors of TLR2 KO mice, showed identical killing ability regardless the presence or absence of *C. albicans* during their differentiation with M-CSF.

Conclusions

Recognition of *C. albicans* by Lin^- cells affects differentially the antifungal phenotype of derived mature myeloid cells in a cytokine-dependent manner. Fungal killing of M-CSF-differentiated cells is enhanced by *C. albicans* in a TLR2-dependent manner, whereas this effect is not observed when Lin^- cells are differentiated with GM-CSF.

MYCOPLASMA BOVIS ISMBOV1 AND ITS DERIVATIVES ARE CONSERVED GENETIC ELEMENTS OF RNA POLYMERASE ALTERNATIVE SIGMA FACTOR GENOMIC LOCUS

I. Lysnyansky[1], *I. Borovok*[2]
[1]*Kimron Veterinary Institute, Avian and Aquatic Diseases, Beit Dagan, Israel*
[2]*Tel Aviv University, Molecular Microbiology and Biotechnology, Tel Aviv, Israel*

Backgrounds

Analysis of *Mycoplasma bovis* genomic data determined genes encoding two RNA polymerase sigma factors. One is a putative primary RpoD-like subunit, and another one resembles alternative sigma factors of the ECF (Extracytoplasmic Function) family.

Objectives

Revealing genomic organization of the gene cluster encoding alternative sigma factor.

Methods

Standard bioinformatics tools including blast algorithms, sequence alignments, and phylogeny were used to mine and analyze available *M. bovis* genomes.

Conclusions

While the *rpoD* locus has the same organization in analyzed *M. bovis* genomes, an alternative sigma factor operon reveals the differences of its regulatory region. One or two copies of IS*Mbov1* are located immediately upstream of the *cysS-spoU-sigECF-rpmG-secE-nusG* operon. When two IS*Mbov1* copies coexist, they may perform different arrangements (e.g. two copies have the same or an opposite orientation). *M. bovis* strains of different geographic origins have always one defective IS*Mbov1* upstream of *cysS*. Internal deletions within an IS*Mbov1* transposase gene suggest that this IS element is dysfunctional. The reference *M. bovis* strain PG45 has two IS*Mbov1* copies located upstream of *cysS* - a distal (relatively to *cysS*) copy carries a transposase pseudogene, while a proximal IS copy encodes an intact transposase. Genomes of several Chinese *M. bovis* isolates have only a defective copy of IS*Mbov1* upstream of *cysS*. Comparative analysis of geographically distinct strains revealed that a defective IS*Mbov1* copy upstream of *cysS* shares a high DNA sequence conservation (an average identity >95%) suggesting a putative role of this IS*Mbov1* remnant in regulation of the downstream located operon encoding an alternative sigma factor.

[6]CNRS-UPS UMR5100, CBI-LMGM Molecular genetic and microbiology laboratory, Toulouse, France

Backgrounds

N-acetylglucosamine (GlcNAc) is an amino sugar important for a broad range of organisms ranging from bacteria to plants and animals. Because GlcNAc is only present in trace amounts in plants, it has not previously been considered as a possible substrate exploited by phytopathogenic bacteria during infection. *Xanthomonas campestris* pv. *campestris* (*Xcc*), the causal agent of black rot, infects a wide range of Brassicaceae crop plants and expresses a carbohydrate utilization system devoted to GlcNAc exploitation to be characterized.

Objectives

Characterize organization, regulation and roles of the *Xcc* GlcNAc system.

Methods

We used a combination of methods including molecular genetics, pathoassays, mass spectrometry, and biochemistry to decrypt this GlcNAc utilization pathway.

Conclusions

In addition to genes involved in GlcNAc catabolism, this system codes for four TonB-dependent outer membrane transporters (TBDT), nine glycoside hydrolases (GH) and two transcriptional repressors. Expression of all these genes is induced in presence of GlcNAc. This regulon confer to *Xcc* the ability to exploit chitooligosaccharides that could originate from fungi or insects, to recycle *Xcc*-derived peptidoglycan/muropeptides and to metabolize plant GlcNAc-containing molecules during infection. *In vitro* analyses also demonstrate that five of the nine GHs are involved in the sequential degradation of a plant *N*-glycopeptide. Altogether these results extend the range of sources of GlcNAc metabolized by *Xcc* during its life cycle. This is the first evidence of GlcNAc consumption and *N*-glycan degradation during infection by a phytopathogenic bacterium, a feature shared with human pathogenic bacteria.

[4]University of Surrey, Department of Pathology and Infectious Diseases, Guilford- Surrey, United Kingdom
[5]Universidad de Extremadura, Departamento de Bioquímica y Biología Molecular y Genética, Cáceres, Spain

Backgrounds

Recently, there has been evidence showing that coinfections with porcine circovirus type 2 (PCV2) may favour higher prevalences and the development of more severe tuberculosis pattern in wild boar populations. Therefore, measures focused on controlling PCV2 could be useful for reducing the impact of tuberculosis in this species.

Objectives

The objective of this study is to evaluate the effect of PCV2 vaccines on the prevalence and lesional severity of tuberculosis in wild boar populations.

Methods

The study was developed in a fenced estate in which two groups of wild boars were generated: a group of animals that were captured, identified by transponder and vaccinated against PCV2 (n = 36); and a control group (n = 48), that was not vaccinated. The animals of both groups lived in the same habitat until a percentage of them were captured in hunting events celebrated in December of 2013, 2014 and 2015. Clinical and microbiological diagnoses was performed to determine which of these animals suffered from tuberculosis and, if appropriate, their lesional pattern (localized or generalized). These parameters were compared between the two groups using statistical tests.

Conclusions

Our preliminary results suggest that vaccination against PCV2 may be a valuable measure to reduce the severity of tuberculosis lesions in wild boar, since a lower percentage of animals with generalized lesions was found among the vaccinated group.

This vaccination did not significantly reduce the percentage of infected animals. Potentially longer period of time would be necessary to observe any effect on the prevalence of tuberculosis.

ATTENUATED MYCOBACTERIUM TUBERCULOSIS VACCINE SECRETING DTP ANTIGENS: BASIS FOR A MULTIVALENT PROTECTION

E. Broset[1], A.I. Kanno[2], L.C.C. Leite[2], C. Martin[1], J. Gonzalo-Asensio[1]
[1]Universidad de Zaragoza, Microbiología- Medicina Preventiva- y Salud Pública, Zaragoza, Spain
[2]Instituto Butantan, Centro de Biotecnologia, São Paulo, Brazil

Backgrounds

BCG is al live attenuated vaccine effective in reducing severe forms of tuberculosis (TB) in children but confers variable protection against pulmonary TB in adults. To overcome this handicap, we have developed the live vaccine MTBVAC currently in phase Ib clinical trials in South Africa (NTC02729571).MTBVAC is based on the attenuation of *Mycobacterium tuberculosis* by inactivation of the *phoP* and *fadD26* virulence genes.

Objectives

Because its adjuvant capacity, BCG has been traditionally proposed as vector to deliver several antigens. In this context, we propose the study of MTBVAC as a multivalent recombinant vaccine against different infectious diseases including diphtheria, tetanus and whooping cough, which actually forming DTP vaccine.

Methods

In order to construct a multivalent MTBVAC, genetically inactivated and codon optimized genes for diphtheria (CRM197), pertussis toxoids (S1), or Fragment C of tetanus toxin (FC) were synthesized. Each gene was cloned under the control of a new mycobacteriophage L5 derived promoter. To lead the secretion of these antigens, the signal sequence of Ag85A (a known mycobacterial secreted protein) was placed in frame before each antigen. Protein expression and secretion of CRM197, S1 and FC was confirmed by Western blot and mass spectrometry.

Conclusions

Preliminary experiments in mice showed that vaccination with rMTBVAC expressing S1 toxoid protects against *Bordetella pertussis* colonization. On-going experiments aimed to detect anti-DTP antibodies in mice vaccinated with these rMTBVAC. Taking together, these results provide *proof-of concept* that MTBVAC is an efficient vector to deliver heterologous antigens and put forward rMTBVAC to protect against different infectious diseases.

THE HUMAN URINARY MICROBIOME IN BLADDER CANCER

V. Bučević Popović[1], *M. Šitum*[2], *V. Punda Polić*[3], *J. Terzić*[4]
[1]*Faculty of Science- University of Split, Department of Chemistry, Split, Croatia*
[2]*Clinical Hospital Split, Department of Urology, Split, Croatia*
[3]*School of Medicine- University of Split, Department of Microbiology, Split, Croatia*
[4]*School of Medicine- University of Split, Department of Immunology, Split, Croatia*

Backgrounds

Although traditionally considered sterile, recent studies have shown that bladder, similar to other body sites, harbours a diverse microbial population which could be a contributing factor to urinary bladder pathogenesis. Most of the studies published so far were analysing females, proposing an association of female urinary microbiota with disorders such as urgency urinary incontinence and urinary tract infection. Knowledge of male urinary microbiota is very limited, and the link between urinary microbiota and bladder cancer, known to be three times more common in men then in women, has not been explored yet.

Objectives

The main goal of our study was to examine male urinary microbiome in bladder cancer patients and compare it with urinary microbiome of healthy controls.

Methods

Urine samples were obtained from male bladder cancer patients and healthy controls. DNA was isolated from urines and enriched for bacterial 16S V4 rDNA region by PCR amplification. The amplicons were sequenced on Illumina MiSeq platform and data analysis was performed in collaboration with Second Genome's Microbial Profiling Service.

Conclusions

The urine microbiome from bladder cancer patients and healthy controls did not exhibit significant alternations at a microbial community level. Operational taxonomic units that differed significantly between the two groups included the genera *Kocuria*, *Actinobaculum*, *Fusobacterium*, *Micrococcus*, *Pyramidobacter* and *Corynebacterium* which were more abundant in bladder cancer, and the genera *Streptococcus* and *Veillonella*, enriched in healthy samples. Further studies with larger cohort are needed to establish the role of urinary microbiota in bladder cancer development and treatment response.

CROSS-STRESS BEHAVIOR OF GENERAL PORINS IN YERSINIA PSEUDOTUBERCULOSIS UNDER PROLONGED ANTIBIOTIC EXPOSURE

E. Bystritskaya[1,2], *A. Stenkova*[1,2], *A. Rakin*[3], *M. Isaeva*[1,2]
[1]*G.B. Elyakov Pacific Institute of Bioorganic Chemistry, Laboratory of Marine Biochemistry, Vladivostok, Russia*
[2]*Far Eastern Federal University, Biomedical School, Vladivostok, Russia*
[3]*Max von Pettenkofer Institute for Hygiene and Clinical Microbiology, Yersinia Phylogenomics Laboratory, Munich, Germany*

Backgrounds

One of survival strategy for bacteria confronted with unfavorable conditions such as antibiotics is altering membrane permeability via expression of general porins. During prolonged exposure to antibiotics, the bacteria encounter many other stresses caused by stationary phase (starvation, pH change, high metabolite concentration). These factors can provide cross-protection against antibiotic stress. Little is known about how reciprocally regulated porins affect the adaptive response of *Y. pseudotuberculosis* to antibiotics under multiple stresses.

Objectives

Our aim was to determine if general porins are essential for adaptive behavior of *Y. pseudotuberculosis* to a wide spectrum of stress conditions.

Methods

We investigated porin gene expression in *Y. pseudotuberculosis* 488 exposed to sublethal concentrations of different classes of antibiotics using real-time RT-PCR and GFP-based flow cytometry analyses.

Conclusions

We found no significant changes in *ompC* and *ompF* transcription, indicating that the stationary-phase stress strongly regulated the porin expression balance and protected from sublethal antibiotic treatment. Results with GFP-reporter strains were more complex. *ompF* was predominant in all investigated unfavorable conditions, probably playing more important role in protective bacterial strategy. This gene was strongly downregulated under 37°C, however remaining at higher level compared to *ompC*. Tetracycline and nalidixic acid slightly decreased expression of *ompC*. Carbenicillin treatment led to the appearance of heterogeneously fluorescent bacterial subpopulations. We believe that the survival of *Y. pseudotuberculosis* under prolonged antibiotic exposure is not due to porin deficiency, but is associated with other resistance mechanisms provided by environmental cross-stresses.

[5]Smurfit Institute of Genetics- Trinity College Dublin, Department of Genetics, Dublin, Ireland
[6]University of Liverpool, Institute of Infection & Global Health, Liverpool, United Kingdom

Backgrounds

Salmonella Typhimurium infects a wide range of animal hosts, and generally causes a self-limiting gastroenteritis in humans. New variants of this serovar, sequence-type ST313, are associated with an emerging invasive nontyphoidal *Salmonella* (iNTS) disease in sub-Saharan Africa that targets immunocompromised HIV^+ or malarial individuals. We studied an ST313 isolate, D23580, and the well-characterized isolate 4/74 (sequence-type ST19) that causes gastroenteritis across the globe. A genomic comparison showed that the two strains share 96% of coding genes, and genetic differences included 1000 SNPs, two D23580-specific prophages, a different plasmid repertoire, and the presence of pseudogenes.

Objectives

We hypothesized that the two strains had different pathogenic mechanisms, and searched for altered gene expression patterns and gene fitness in infection-relevant environmental conditions.

Methods

RNA-seq-based transcriptomic data were obtained for strains 4/74 and D23580, grown under sixteen infection-relevant *in vitro* conditions and during infection of murine macrophages. Key transcriptomic data were validated with a proteomic approach. In addition, transposon insertion sequencing was used to identify genes in the D23580 strain required for growth in infection-relevant conditions, and intracellular survival in macrophages.

Conclusions

Differences observed in gene expression of virulence-associated genes under specific environmental conditions reflect the distinct pathogenic mechanisms of these two *S*. Typhimurium strains. We will present our latest results involving the analyses of transcriptomic, proteomic and transposon insertion sequencing data.

UNCOMMON VIRULENCE POTENTIAL IN ST-14 KPC-3 KLEBSIELLA PNEUMONIAE: A HIGH RISK CLONE IN PORTUGAL

C. Caneiras[1], L. Lito[2], J. Melo-Cristino[2,3], A. Duarte[1]
[1]Research Institute for Medicines iMed.ULisboa - Faculty of Pharmacy - University of Lisbon, Department of Microbiology and Immunology, Lisboa, Portugal
[2]Centro Hospitalar Lisboa Norte, Laboratory of Microbiology, Lisboa, Portugal
[3]Institute of Molecular Medicine - Faculty of Medicine - University of Lisbon, Institute of Microbiology, Lisboa, Portugal

Backgrounds

The emergence of KPC-type carbapenemases in *Klebsiella pneumoniae* poses a serious threat to public health worldwide and have recently undergone a relevant increasing prevalence in Portugal. Studies regarding the *K. pneumoniae* identification of virulence markers and high-risk clones are critical for the development of novel diagnostic methods and new therapeutic strategies.

Objectives

The aim of this study was the identification of virulence markers and characterization of the clonal relationship among multidrug resistant *Klebsiella pneumoniae* isolates producing KPC-3 carbapenemases since 2009, in Portugal.

Methods

This study included 27 representative clinical isolates of *K.pneumoniae* KPC-3 producers collected in a tertiary hospital centre in Lisboa, Portugal, between 2009 and 2013. Antimicrobial susceptibility testing was performed by disk diffusion and the results were interpreted according to CLSI and EUCAST guidelines. Genes encoding other β-lactamases including OXA, NDM, CTX-M, TEM, SHV, DHA, FOX, and CMY were screened by PCR and confirmed by sequencing. The isolates were also screened for gene markers of virulence factors: *K2A, fimH, mrkD$_{V1}$, mrkD$_{V2-4}$, khe, rmpA, magA,* and *iucC* by PCR amplification.The clonal relationship was evaluated by M13 fingerprinting and multilocus sequence typing (MLST).

Conclusions

We firstly report an uncommon and concerning overlapping of multidrug-resistance and accumulation of virulence genes in the prevalent (>80%) ST-14 clone identified. The combination of the KPC-3 gene with virulence genes as K2 capsular serotype, fimbrial adhesins, haemolysin, and aerobactin - a bacterial iron chelating agent, can constitute a serious threat, especially for vulnerable populations and may further exacerbate infections caused by this pathogen.

POLYAMINE MOLECULES TARGETING EPIGENETIC EFFECTORS IN THE EXPRESSION PROFILES OF NONRIBOSOMAL PEPTIDE SYNTHETASES GENE FAMILY IN THE PHYTOPATHOGEN FUNGUS BOTRYTIS CINEREA

F.M. Ana[1], G.R. Victoria E.[1], G. Carlos[1], C. Maria[1], B. Alejandro[1], J.M. Cantoral Fernandez[1]
[1]Universidad De Cadiz, Biomedicina- Biotecnologia Y Salud Publica. Lab. Microbiologia, Puerto Real, Spain

Backgrounds

Botrytis cinerea is a phytopathogen fungus that shows an interesting secondary metabolism. It involves the biosynthesis of a broad range of cell wall--degrading enzymes, toxins, polyketides and fatty acid-derived compounds, terpenes and nonribosomal peptides and amino acid-derived compounds.

Nonribosomal peptide synthetases (NRPS) are a group of enzymes that play important roles in fungal metabolisms. They are related with siderophores biosynthesis and obtaining ion metal from the environment. Genome of *B. cinerea* contains nine NRPS encoding genes but the role of them is unknown to this day.

Polyamines are a family of chemical compounds in relation, between other, with the biosynthesis of siderophores in microorganisms. Several studies have proved the importance of polyamines in the host-pathogen interaction during the development of disease causing by *B. cinerea*.

Objectives

This work shows how the presence of polyamines affects to the expression profiles of NRPS gene family in *B. cinerea*.

Methods

Culture mediums are supplemented with no-lethal concentration of four polyamines: 1,3-diaminopropane, spermidine, spermine and suberoylanilide-hydroxamic acid. *B. cinerea* B05.10 grows during 22 days with six sample-times. After, expression profiles are studied by RT-qPCR.

Conclusions

Expression of these genes is clearly modified in the presence of polyamines. Depending of their chemical structure, genes are upregulated or downregulated in comparison with control condition. This study provides interesting data about how this chemical compound can produce the expression of gene that were silenced in normal growth of *B. cinerea*, opening a door to future metabolomic studies in the secondary metabolisms of this important fungus.

CHARACTERIZATION OF THE RHIZOFERRIN BIOSYNTHETIC GENE IN THE FUNGAL PATHOGEN, RHIZOPUS DELEMAR

C. Carroll[1], C. Grieve[1], I. Murugathasan[1], C. Czekster[2], H. Lui[2], J. Naismith[2], M. Moore[1]
[1]Simon Fraser University, Biological Sciences, Burnaby, Canada
[2]University of St. Andrews, Biomedical Sciences Research Complex, St. Andrews, United Kingdom

Backgrounds

Iron is essential for growth and in low iron environments, some microbes secrete ferric iron (Fe^{3+})-chelating molecules called siderophores. All fungi produce hydroxamate siderophores with the exception of Mucorales fungi; these secrete the polycarboxylate siderophore, rhizoferrin. At present, the importance of rhizoferrin biosynthesis to Mucorales pathogenesis is unknown.

Objectives

To identify and characterize the enzyme responsible for biosynthesis of rhizoferrin by the pathogenic fungus, *Rhizopus delemar*.

Methods

A putative rhizoferrin synthetase (*rfs*) gene belonging to the NRPS-independent siderophore (NIS) family was identified in the genome of *R. delemar* 99-880. qPCR confirmed that expression of the putative *rfs* gene was repressed by iron. *rfs* was cloned and expressed in *E. coli* and the Rfs protein was purified using affinity chromatography. Siderophore biosynthesis by recombinant Rfs from citrate and diaminobutane, the two building blocks of rhizoferrin, was confirmed using high resolution LC-MS/MS. Rfs also used the substrate derivatives ornithine, oxaloacetic acid, hydroxylamine, diaminopentane and diaminopropane, and produced mono-citryl intermediates for all derivatives except tricarballylic acid. Di-citryl compounds were detected with all derivatives except oxaloacetic acid. Site-directed mutagenesis studies showed that histidine 444 is required for Rfs activity, while leucine 544 may play a role in governing amino-substrate specificity.

Conclusions

Rfs catalyzes rhizoferrin biosynthesis in a two-step manner; first, activating citrate through adenylation and second, condensing the citryl intermediate with a nucleophile. We propose that Rfs is a new fungal member of the superfamily of adenylating enzymes. Studies are underway to assess the effect of *rfs* in virulence of Mucorales fungi.

EFFECT OF VACCINATION AGAINST ORAL HPV INFECTION IN WOMEN IN HIGH SCHOOLS FROM CALI, COLOMBIA

A. Castillo[1], A. Arbelaez[2], J.C. Osorio[2], L.E. Bravo[3]
[1]Universidad del Valle, Department of Biology- Faculty of Exact and Natural Sciences, Cali, Colombia
[2]Universidad del Valle, School of Biomedical Sciences, Cali, Colombia
[3]Universidad del Valle, Cali Cancer Registry- Department of Pathology, Cali, Colombia

Backgrounds

Human papillomavirus (HPV) is responsible for an increasing proportion of oropharyngeal squamous cell cancers. However, it is not clear whether the vaccine for HPV, to prevent cervical cancer, could provide protection against oral HPV infections.

Objectives

A risk/prevalence study that examines the relationship between HPV vaccination and HPV oral detection in 300 women vaccinated for HPV.

Methods

Oral cell samples were collected in 300 women aged between 14 and 17 years old who had been vaccinated for HPV, and in 76 women who had not been vaccinated. The procedure to obtain the samples consisted in 15-second rinse and 15-second gargle with 15 ml mouthwash. DNA extraction was made using DNeasy Blood & Tissue Kit (QIAGEN) and the HPV DNA detection by GP5+/GP6+ primers set-mediated PCR. Statistics produced include the mid-p exact tests, and risk/prevalence ratio (relative risk) that were performed using the OpenEpi statistics program (http://www.openepi.com/TwobyTwo/TwobyTwo.htm).

Conclusions

HPV detection in women vaccinated was 2 out 300 (0.7%), and in women without a vaccine was 5 out 76 (6.6%). The mid-P exact results were less than 0.01, which suggest that there is an association. The Risk Ratio (RR) was 0.1013, a modest effect indeed (5.9% decrease in risk), with 95% confidence limits barely excluding 0 or 1.
The study shows a modest association between vaccination for HPV and a decreasing of HPV oral infection. Our results suggest the need to develop community-level strategies of information and education to encourage HPV vaccination in girls in Cali, Colombia

ISOLATION AND CHARACTERISATION OF SHIGA TOXIN-PRODUCING ESCHERICHIA COLI FROM NORWEGIAN BLUE MUSSELS (MYTILUS EDULIS)

C. Cedillo Martin[1], C.S. Svanevik[2], G. Johannessen[3], C. Sekse[4], B.T. Lunestad[2]
[1]University of Bergen, Department of Biology, Bergen, Norway
[2]National Institute of Nutrition and Seafood Research, Seafood safety and health, Bergen, Norway
[3]Norwegian Veterinary Institute, Bacteriology - Food and GMO, Oslo, Norway
[4]Norwegian Veterinary Institute, Bacteriology - Aquatic and Terrestrial Animals, Oslo, Norway

Backgrounds

There have been no outbreaks by Shiga toxin-producing *E.coli* from blue mussels, and only few studies concerning STEC detection in coastal environments and bivalves have been reported.

Objectives

To improve our understanding of STEC, presence of STEC was investigated in 270 blue mussels collected from harvesting areas along the Norwegian coast in 2016.

Methods

Microbial enrichment of the blue mussel samples followed by DNA extraction for screening of STEC-associated genes was performed as described in ISO/TS -13136. Real-time PCR assays were conducted for genes encoding Shiga toxin (*stx*), intimin (*eae*) and the five major European serogroups (O157, O26, O111, O145 and O103). Isolation of STEC was attempted from samples with positive PCR result for *stx* and *eae* by plating the enriched samples and picking of 50 colonies. Colonies were screened for presence of *stx* and positive isolates were further characterized to determine their serotype and virulence profile. For two samples immunomagnetic separation (IMS) was performed to facilitate isolation of STEC. Up to 30 colonies per serogroup were selected for identification and the isolates were further characterised.

Conclusions

The screening results revealed the presence of the virulence genes (*eae* and *stx*) in the 19 blue mussel samples. *stx* positive isolates were isolated from four of these samples as described above. Presumptive colonies from different serogroups were identified from the IMS and confirmed by real-time PCR for each serogroup. This preliminary data indicates a low prevalence and therefore low risk of human infection by STEC if bivalves from these harvesting areas were to be consumed.

NEW SEQUENCE TYPES OF N. GONORRHOEAE IN KENYA REVEAL HIGH PREVALENCE OF MOBILE GENETIC ELEMENTS

A. Cehovin[1], O. Harrison[2], S. Lewis[1], P. Ward[1], S. Lea[1], E. Sanders[3], M. Maiden[2], C. Tang[1]
[1]University of Oxford, Sir William Dunn School of Pathology, Oxford, United Kingdom
[2]University of Oxford, Department of Zoology, Oxford, United Kingdom
[3]Kemri-Wellcome Trust Research Program, Kemri, Kilifi, Kenya

Backgrounds

The sexually transmitted infection gonorrhoea caused by *Neisseria gonorrhoeae* is a major public health concern, associated with significant morbidity worldwide. In Africa, the incidence rates are the highest in the world but little is known about the strains causing gonococcal disease in adults.

Objectives

Characterisation of a collection of gonococcal strains from high-risk individuals in Kenya by:

- determining their multi-locus sequence types (MLSTs) and antimicrobial resistance (AMR) profiles,

- studying genealogical associations between MLST and conjugative plasmid types,

- determining whether repeat infections are due to relapse or re-infection with a different strain.

Methods

The gonococcal strains were sequenced and annotated in PubMLST.org/Neisseria, which annotates defined loci. To determine MLSTs and AMR profiles, we defined the core genome and AMR loci of strains, respectively. We then used gene-by-gene comparison to resolve population relationships and elucidate the sites of genetic variation.

Conclusions

Gonococcal strains in coastal Kenya belong to new MLSTs that are distinct from those found in other parts of the world. Compared to strains circulating in the UK and US, this gonococcal population harbours high prevalence of conjugative plasmids conferring tetracycline resistance. Genealogical plasmid associations indicate that each lineage is associated with a distinct plasmid backbone. In particular, genetic variation between lineages occur in *tetM* and a toxin-antitoxin system. In addition, our gene-by-gene comparison reveals that repeat gonococcal infections are due to re-infections with different strains. This analysis provides insights into the gonococcal population in Kenya and plasmid evolution among gonococcal strains.

COMPARATIVE GENOMICS OF CLINICAL AND ENVIRONMENTAL SAMPLES OF CAMPYLOBACTER JEJUNI

D. Cejkova[1], M. Medvecky[1], Z. Sekelova[1], O. Polansky[1], T. Kubasova[1], K. Simunovic[2], S. Smolte Mozina[2], I. Rychlik[1]
[1]Veterinary Research Institute, Department of Immunology, Brno, Czech Republic
[2]Biotechnical Faculty- University of Ljubljana, Department of Food Science and Technology, Ljubljana, Slovenia

Backgrounds

Campylobacteriosis is major bacterial food-borne disease in industrialized countries in recent years with a large economic burden. The major causative agent of human campylobacteriosis is *Campylobacter jejuni* which accounts for 90% of human cases. *C. jejuni* is considered as a member of commensal microbiota in birds, thus the raw or undercooked poultry products are the major sources of human cases. However, *C. jejuni* strains can also survive in water and waterborne outbreaks of campylobacteriosis are also widely and frequently reported.

Objectives

In order to identify genotypes associated with clinical and environmental sources, we determined and compared the complete genome sequences of 15 *C. jejuni* isolates originating from water sources (5 isolates) and human beings (10 isolates).

Methods

Extracted DNA from each isolate was subjected to DNA sequencing on the Illumina MiSeq and NextSeq platforms, followed by *de novo* read assembly via IDBA-UD software and *ab initio* gene prediction using the Prokka pipeline.

Conclusions

The total pan-genome of sequenced isolates comprises 2345 proteins, whereas core-genome consists of 1371 proteins. Comparing genomes of human and water isolates, thirty-six proteins were only associated with human isolates. These human-associated proteins were mainly involved in sugar, amino and fatty acid metabolism, transport, iron uptake and cell wall biosynthesis. On contrary, water-associated proteins included eight hypothetical proteins. In addition, human isolates showed intra-strain variation in homopolymeric tract length in genes coding for flagellar and other motility proteins. These data indicate that human isolates of *C. jejuni* are more virulent and showed increased adaptation to a novel host.

METHYLENE BLUE AS AN EFFECTIVE PHOTOACTIVE DYE IN ERADICATION OF RESISTANT BIOFILMS FORMED BY PATHOGENIC YEASTS OF CANDIDA PARAPSILOSIS AND CANDIDA ALBICANS

L. Černáková[1], S. Dižová[1], H. Bujdáková[1]
[1]Comenius University in Bratislava- Faculty of Natural Sciences,
Department of Microbiology and Virology, Bratislava, Slovak Republic

Backgrounds

Treatment of biofilm formed by *Candida* species on medical devices is limited. Therefore, current research is searching for new options, like photodynamic inactivation (PDI). PDI works through activation of photoactive dye (methylene blue – MB) with the light of appropriate wavelength resulting in reactive oxygen species production.

Objectives

This study was focused on effectiveness of PDI compared to caspofungin (CAS) on biofilms formed by *C. parapsilosis* and *C. albicans.*

Methods

Two light sources were used for irradiation: red LED light (1.67 mW/cm^2) or laser (190 mW/cm^2). Inhibition of sessile biofilm cells was considered to be effective when reduction was minimally 50% ($SMIC_{50}$) compared to the control sample without MB. Two sets of experiments were performed when MB was added to the adherence phase or to the pre-formed 24-h biofilm. Experiments were evaluated after 48 and 72 h, respectively.

Conclusions

Results proved that application of CAS to the adherence phase can prevent biofilm development ($SMIC_{50}$ was 1 µg/ml for *C. parapsilosis* and 0.13 µg/ml for *C. albicans*), while an addition of this compound (16 µg/ml) to the 24-h biofilm was not efficient. Determination of colony forming units and XTT reduction assay confirmed efficacy of MB (1 mmol/l) used in PDI on different biofilm stages. Moreover, microscopy of biofilms formed on mouse tongues sections (*ex vivo* model, 72 h) explicitly confirmed previous observations. Both light sources were effective, but laser enabled a decreasing period of irradiation while maintaining the high effectiveness of PDI. MB used for PDI can combat fully developed resistant biofilms.

HOW PROTEASES PRODUCED BY ENTEROCOCCUS FAECALIS PROTECT IT AGAINST THE SHORT A-HELICAL ANTIMICROBIAL PEPTIDES

V. Čeřovský[1], O. Nešuta[1], M. Buděšínský[2], R. Hadravová[3], R. Hexnerová[4]
[1]Institute of Organic Chemistry and Biochemistry - Academy of Sciences of the Czech Republic, Antimicrobial Peptides, Prague 6, Czech Republic
[2]Institute of Organic Chemistry and Biochemistry - Academy of Sciences of the Czech Republic, NMR and Molecular Spectroscopy, Prague 6, Czech Republic
[3]Institute of Organic Chemistry and Biochemistry- Academy of Sciences of the Czech Republic, Biochemistry and Molecular Biology, Prague 6, Czech Republic
[4]Institute of Organic Chemistry and Biochemistry - Academy of Sciences of the Czech Republic, Structural Biology, Prague 6, Czech Republic

Backgrounds

Enterococcus faecalis is a common Gram-positive bacterium colonizing the gastrointestinal tract and oral cavity of animals and humans. As an opportunistic pathogen, it causes life-threatening nosocomial infections because of its frequent multidrug resistance. Its resistance to antimicrobial peptides (AMPs) resides in the secretion of two proteases - gelatinase (GelE) and serine protease (SprE) able to degrade them.

Objectives

We have focused on understanding the role of these two proteases in the degradation of short α-helical AMPs called HYL-20 (GILSSLWKKLKKIIAK-NH_2) and 14-NH_2 (KRLFKELKFSLRKY-NH_2).

Methods

Cleavage sites in HYL-20 and 14-NH_2 after the incubation with *E. faecalis* were identified using RP-HPLC fractionation and MS analysis of fragments. We used 1,10-phenanthroline, a specific GelE inhibitor, to determine contribution of both proteases to the degradation. In addition, an analogous peptide with D-Lys at its C-terminus (HYL-20*k*) was used as a substrate to study a role of C-terminal de-amidation step in the process. We also studied the effect of secondary structure of HYL-20 and HYL-20*k* determined by NMR spectroscopy on their antimicrobial activity.

Conclusions

The C-terminal deamidation of HYL-20 is the first step of peptide degradation by *E. faecalis* making the peptide susceptible to consecutive cleavage by GelE at internal peptide bonds, which finally results in deterioration of its antimicrobial activity. This is attributed to an unexpected and not yet unidentified protease which also cleaves internal peptide bonds of AMPs at hydrophobic residues. In the contrast to published data participation of SprE in the protective mechanism of *E. faecalis* against AMPs was not proved.

STUDY OF BARTONELLA PREVALENCE AMONG WILD AND DOMESTIC ANIMALS IN GEORGIA

N. Chakvetadze[1], N. Abazashvili[1], B. Ying[2], L. Malania[1], M. Kosoy[2]
[1]National Center for Disease Control and Public Health, Science, Tbilisi, Georgia
[2]Centers for Disease Control and Prevention, Division of Vector-Borne Diseases, Fort Collins, USA

Backgrounds

Bartonella species are intracellular bacteria of erythrocytes and endothelial cells. The bacteria in the genus *Bartonella* are zoonotic pathogens of wild and domestic animals.

Objectives

Our objective was to detect the presence of *Bartonella* species in animals in Georgia.

Methods

During 2015-2016 had been collected 382 animal samples, among which 151 were rodents, 81-cattle, 116 - dogs, 34 - sheep, captured from 7 districts of Georgia. Bacteriological investigation of all samples had been conducted as well as molecular typing of isolated cultures.

We identified 29 rodent-associated *Bartonella* species (*B. elizabethae, B. tribocorum, B. grahamii*) by culturing from rodent samples – 19.20%; from cattle samples had been isolated 23 B. bovis and 3 B. schonbuchensis (32%), 5 isolates of *Bartonella vinsonii* subsp. *berkhoffii* had been isolated from dog samples (4.3%) and no bacterial growth was detected among sheep. *Bartonella* isolates were confirmed by polymerase chain reaction (PCR) as well as cultures were further genetically characterized by sequence analysis of five chromosomal regions 16S rRNA, gltA, ftsZ, rpoB, and the intergenic spacer region (ITS).

Conclusions

On the basis of these data, we propose that findings in Georgia only indicating the highest diversity of *Bartonella* spp. These results have important public health implications, because identified *Bartonella* species have been reported as pathogenic bacteria for human.

These data will allow us to build a comprehensive picture of the risks associated with exposure to *Bartonella* species.

We are grateful to the International Science and Technology Center for the financial support.

NATURALLY OCCURRING INLB VARIANTS WITH A DIFFERENT POTENTIAL TO CAUSE PERINATAL LISTERIOSIS IN MICE.

Y. Chalenko[1], S. Ermolaeva[2], K. Sobyanin[3]
[1], Moscow, Russia
[2]Center, Gamalei Center of Microbiology and Epidemiology, Moscow, Russia
[3]Gamalei center of Microbiology and Epidemiology, laboratory of ecology pathogens, Moscow, Russia

Backgrounds

The Gram-positive bacterium Listeria monocytogenes causes listeriosis, a severe disease with multiple manifestations including stillbirths and meningitis of newborns. The invasion factor of the internalin family InlB I involved in crossing the maternal-fetal barrier (Disson et al., 2008). Previously, we described several InlB variants that differed in the ability to support intragastric infection in mice Sobyanin et al., 2017).

Objectives

To compare effects of InlB variants on perinatal infection in mice.

Methods

The InlB variants differing in 10 amino acid substitutions were expressed under the same promoter in the *L. monocytogenes* strain EGDeΔinlB. Work with animals was performed with approval of local bioethical committee. Mice were intragastrically infected on the 14th day of pregnancy, euthanized 1 and 3 dpi, bacterial loads were determined by plating.

Conclusions

One of two InlB variants provided infection of both placentas and fetuses while another did not. Bacteria were revealed in placentas 24 and 72 hpi. Infection was unequal for different fetuses in the same animal. Obtained results suggested that some InlB variants might promote perinatal infection in mice.

IMMUNOGENICITY PROFILING OF PROTEINS FROM CAPSULAR GROUP B NEISSERIA MENINGITIDIS

C.M. Chang[1], A. Awanye[1], L. Marsay[2], C. Dold[2], C. Rollier[2], A. Pollard[2], J. Derrick[1]
[1]Faculty of Biology- Medicine and Health, Division of Infection- Immunity and Respiratory Medicine, Manchester, United Kingdom
[2]Oxford Vaccine Group, Department of Paediatric, Oxford, United Kingdom

Backgrounds

Outer membrane vesicle (OMV) based vaccines have been used to provide strain-specific protection to serogroup B *Neisseria meningitidis* infection. The identification of immunogenic outer membrane proteins (OMPs) may help to develop a vaccine with broader strain coverage.

Objectives

A meningococcal OMPs microarray panel was manufactured and used to determine the highly immunogenic antigens. Differences in IgG responses in human and mouse were compared.

Methods

Ninety-three OMPs were selected based on a proteomic study of OMVs. OMPs were individually expressed, purified, and refolded before printed on the slides. IgG responses were determined using antisera from vaccinated mice, or adults who had received an OMV vaccine in a Phase I Clinical Trial (PMCID: PMC4535279). For human antisera, IgG binding was quantified at pre-immunization, and two post-immunization stages. Highly immunogenic antigens in mouse and human were determined based on the magnitude and significance of responses between pre- and post-immunizations.

Conclusions

All antigens with the highest responses to human IgG were integral OMPs (iOMPs) but, in mice, the proportion of iOMPs and soluble proteins was more evenly distributed. The repertoire of highly responding antigens in human and mouse was similar, but not identical. The dominance of responses to iOMPs in humans emphasizes the importance of these antigens in the immunoresponse to OMV vaccination. This result raises the importance of maintaining protein conformational integrity, particularly for integral membrane proteins. Additionally, our work shows that protein antigen microarray panels can be a valuable asset to study responses to vaccines which contain complex mixtures of antigens, such as OMVs.

COMPARISON OF O-POLYSACCHARIDE AND HEMOLYSIN CO-REGULATED PROTEIN AS TARGET ANTIGENS FOR SERODIAGNOSIS OF MELIOIDOSIS

N. Chantratita[1]
[1]*Faculty of Tropical Medicine - Mahidol University, Microbiology and Immunology, Bangkok, Thailand*

Backgrounds

Melioidosis is a severe disease caused by *Burkholderia pseudomallei*. Clinical manifestations are diverse and acute infections require immediate treatment with effective antibiotics. While culture is the current diagnostic standard, it is time-consuming. A lack of good serodiagnostic tools can impede diagnosis and disease surveillance. Recent studies have suggested that O-polysaccharide (OPS) and hemolysin co-regulated protein 1 (Hcp1) are promising target antigens for serodiagnosis of melioidosis.

Objectives

We evaluated rapid ELISAs using crude antigens, purified OPS and Hcp1 to measure antibody levels in three sets of sera: (i) 419 serum samples from melioidosis patients, Thai and U.S. healthy donors, (ii) 120 serum samples from patients with other bacterial infections, and (iii) 423 serum samples from 200 melioidosis patients obtained upon admission and at 12 and 52 weeks post-recovery.

Methods

We observed significantly higher antibody levels using the crude antigen prepared from wild type *B. pseudomallei* compared to that of an OPS-mutant. The areas-under-receiver-operator-characteristics (AUROCCs) for diagnosis were compared for individual Hcp1-ELISA or OPS-ELISA or combined Hcp1/OPS-ELISA. For Thai donors, AUROCCs were highest and comparable between the Hcp1-ELISA and the combined Hcp1/OPS-ELISA (0.95 versus 0.94). For U.S. donors, the AUROCC was highest for the combined Hcp1/OPS-ELISA (0.96). Significantly higher seropositivity was observed in diabetic patients compared to those without diabetes for both the Hcp1-ELISA (87.3% versus 69.7%) and OPS-ELISA (88.1% versus 60.6%). Although antibody levels for Hcp1 were highest upon admission, the titers declined by week 52 post-recovery.

Conclusions

Hcp1 represents a promising target antigen for the development of POC tests for acute melioidosis.

SURVIVAL AND BIOFILM FORMATION OF ACINETOBACTER PITTII UNDER UNFAVORABLE CONDITIONS RESEMBLING HOSPITAL SETTINGS

I. Chapartegui Gonzalez[1], *M. Lazaro Diez*[1], *Z. Bravo Del Hoyo*[1], *J. Ramos Vivas*[1]
[1]*IDIVAL, Microbiology, Santander, Spain*

Backgrounds

The importance of the gram-negative rod *Acinetobacter* as the cause of nosocomial infections has increased during the last years. *A. pittii* is an opportunistic pathogen frequently isolated from *Acinetobacter* infections. It was recognized that at least some *A. baumannii* strains are able to survive for long periods under dry conditions, increasing its probability of causing infections in the hospital settings. However, the survival of *A. pittii* on inanimate surfaces under unfavorable environmental conditions is unknown.

Objectives

The aim of the present work was to study both the survival capacity and the biofilm formation ability of six *Acinetobacter pittii* clinical isolates under desiccation conditions, on surfaces typical of those found in the hospital environment (plastic, glass and lab coat) up to 6 weeks.

Methods

For this work we selected 6 *Acinetobacter pittii* clinical isolates. Viable counts present on inert surfaces under unfavorable conditions were determined up to 43 days, by colony counting. Also, cell viability was determined with a Live/Dead staining and CLS Microscopy. Biofilm formation ability along time was assessed in 24-well plates by crystal violet staining.

Conclusions

Survival and biofilm formation capacities of *A. pittii* were strain-dependent.
In all isolates a significant decline of culturable count took place after desiccation, although for some strains, a viable cell subpopulation is maintained beyond 6 weeks. No significant differences between surfaces were observed. Live/Dead staining corroborated these results. Importantly, our results showed an overall tendency to increase the biofilm formation over time, suggesting that unfavorable environmental conditions may trigger virulent phenotypes.

IDENTIFICATION OF A COMMON TRANSCRIPTION FACTOR REGULATING VIRULENCE AND ANTIBIOTIC RESISTANCE: A KEY STRATEGY TO EVADE MDR AND UPEC PATHOGENESIS

A.K. Chaurasia[1], N. Batool[1], R. Subramaniyam[1], K.K. Kim[1]
[1]School of Medicine- Sungkyunkwan University, Department of Molecular Cell Biology, Suwon, Republic of Korea

Backgrounds

Rapid emergence of multiple drugs resistant (MDR) pathogenic bacteria through clonal selection is one the major setback of indiscriminate uses of antibiotics. Recent reports on resistance against last-resort antibiotics, colistin in uropathogenic *Escherichia coli* (*UPEC*), raised an urgent need to devise a novel strategy to inhibit virulence and drug resistance.

Objectives

Since the establishment of successful infection is a favorable tilt of offense/defense of host and pathogen towards pathogen. Therefore, supporting the host innate immune response by targeting conceptual virulence and antibiotics responsive transcription factor (VarTF) of pathogens may prove as a cornerstone strategy to evade MDR and pathogenesis of *UPEC*.

Methods

By employing multinomics approach, we identified a hypothetical transcription factor *c0879* (*varTF*) and its downstream regulatory network, derepressed during infection. The expression of VarTF is controlled by non-canonical G-quadruplex structure in its divergent promoter (P_{c0879}) which was experimentally verified G4 specific signature peak and melting temperature. The deletion mutant of *varTF* does not show any physiological disadvantage in rich media while the overexpression of VarTF showed antibiotic susceptibility and extremely reduced invasion/survival potential in macrophage compared to wild type. RNA sequencing data showed VarTF regulates a cascade of virulence and antibiotics resistance genes involved in hemolysin activity, cell-division proteins and nuclear occlusion factor, hydroperoxidase I, iron II uptake and gtutaredoxin etc. Moreover, VarTF acts as a repressor for ArcA, SlyA and Fur transcriptional regulators responsible for micro-aerobic environment adaptation, bacterial survival in macrophage and ferric uptake repressor, respectively.

Conclusions

The repression of hydroperoxidase I and consequent accumulation of hydrogen peroxide; and excessive uptake of iron II are expected to favor Fenton reaction to produced highly reactive oxygen and nitrogen species, subjecting *UPEC* cells susceptible to both host innate immune system and chloramphenicol including other antibiotics.

DELETION OF SDHA INFLUENCES TYPE THREE SECRETION SYSTEM OF ESCHERICHIA COLI O157:H7

W.C. Cheng[1], H.Y. Tasi[1], C.S. Chen[2], J.W. Chen[3], S.T. Hu[1], W.J. Syu[1]
[1]National Yang-Ming University, Microbiology and Immunology, taipei, Taiwan R.O.C.
[2]National Cheng Kung University, Biochemical and Molecular Biology, Tainan, Taiwan R.O.C.
[3]National Cheng Kung University, Microbiology and Immunology, Tainan, Taiwan R.O.C.

Backgrounds

Enterohaemorhagic *Eschericia coli* (EHEC), one virotype of the pathogenic *E. coli,* causes hemorrhagic colitis and sometimes renders hemolytic uremic syndrome. EHEC can inject effector proteins into host cells via type-3 secretion system (T3SS) and consequently induce pathological alterations on the infected host cells. Metabolic gene *sdhA* that codes for succinate dehydrogenase subunit A has been shown to affect the EHEC virulence in the *Caenorhabditis elegans* model. SdhA is one of the enzymes in TCA cycle and catalyzes the reaction of succinate into fumarate.

Objectives

We aimed at knowing the possible effect of *sdhA* on the expression and secretion of T3S proteins.

Methods

To study the influence of *sdhA* on T3S, we cultured an EHEC wild-type strain (EDL933) and its *sdhA*-deleted mutant in M9 aerobically, with the presence of 5% CO_2, or anaerobically without O_2 and then separated the culture into supernatant and bacterial pellet. Representative T3S proteins in these two fractions were detected by Western blotting, and, subsequently, the differences between the *sdhA* knockout and the parental strain were compared. Besides the *sdhA*-deleted strain, we also examined these proteins expressed and secreted from mutants with other genes disrupted in the TCA cycle.

Conclusions

We observed that deletion of *sdhA* enhanced T3S proteins secretion and expression aerobically while this deletion induced selective T3S proteins secreted anaerobically. The phenomena were also seen with other TCA gene-disrupted mutants, but not with all.

REACTIVE OXYGEN SPECIES DRIVE THE EVOLUTION OF PRO-BIOFILM VARIANTS IN PATHOGENS BY MODULATING CYCLIC-DI-GMP LEVELS

S.L. Chua[1], *L. Yang*[2]
[1]*Nanyang Technological University, Lee Kong Chian School of Medicine, Singapore, Singapore*
[2]*Nanyang Technological University, SCELSE, Singapore, Singapore*

Backgrounds

The host immune system offers a hostile environment with antimicrobials and reactive oxygen species (ROS) that are detrimental to bacterial pathogens, forcing them to evolve for survival. For instance, *Pseudomonas aeruginosa* can survive and form host-adapted variants in cystic fibrosis lungs, despite the presence of host immune system and antibiotics treatment. While the evolution of bacteria to antibiotics was well-studied, the contribution of oxidative stress by immune system to pathogen evolution remains elusive.

Objectives

[1] Study the evolution of pathogens to resistance of oxidative stress and identify the mutations important in the resistance of oxidative stress by DNA sequencing

[2] Elucidate the mutations-associated mechanisms, leading to the resistance of oxidative stress

[3] Study the relevance of evolved variants in macrophage infection

Methods

Using an experimental evolution strategy, we show that exposure of *P. aeruginosa* to sub-lethal hydrogen peroxide (H2O2) levels over 120 generations led to the emergence of pro-biofilm rough small colony variants (RSCVs), which could be abrogated by L-glutathione antioxidant. Comparative genomic analysis of the RSCVs revealed that mutations in the *wspF* gene, which encodes for a repressor of WspR diguanylate cyclase (DGC), were responsible for increased intracellular cyclic-di-GMP content and production of Psl exopolysaccharide. Psl provides the first line of defence against ROS and macrophages, ensuring the survival fitness of RSCVs over wild-type *P. aeruginosa*.

Conclusions

Our study demonstrated that ROS is an essential driving force for the selection of pro-biofilm forming pathogenic variants. Understanding the fundamental mechanism of these genotypic and phenotypic adaptations will improve treatment strategies for combating chronic infections.

HARNESSING THE INNATE IMMUNITY IN THE TREATMENT OF STAPHYLOCOCCUS EPIDERMIDIS BIOFILM FORMATION

P.Y. Chung[1], R. Khanum[2], B.Y. Chin[3]
[1]International Medical University, Department of Pathology- School of Medicine, Kuala Lumpur, Malaysia
[2]International Medical University, School of Postgraduate Studies, Kuala Lumpur, Malaysia
[3]International Medical University, School of Health Sciences, Kuala Lumpur, Malaysia

Backgrounds

The alarming rate of bacterial resistance to antibiotics is one of the major challenges to global public health, as antibiotics resistance has been found in all classes of antibiotics used in clinical practice. Of particular concern are the opportunistic and multidrug-resistant pathogens known as ESKAPE (*Enterococcus faecium*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Acinetobacter baumannii, Pseudomonas aeruginosa* and *Enterobacter* species) that commonly cause nosocomial infections in indwelling medical devices, wound sites and bacteremia. A major virulence factor in these ESKAPE pathogens is biofilm formation, whereby the cells attach irreversibly on various biotic and abiotic surfaces, in an encased hydrated matrix of exopolymeric substances. In addition to the ESKAPE pathogens, multidrug-resistant and biofilm-forming *Staphylococcus epidermidis* has emerged in the recent years as one of the most important global nosocomial and opportunistic pathogen. Thus, it is of paramount importance that more effective treatments for biofilm-associated infections are discovered. One of the strategies to prevent and eradicate biofilm formation which has shown potential is the activation of antimicrobial peptide (AMP), which is an important component of the innate immune system of the host.

Objectives

To determine the activities of lactoferrin, an endogenous AMP with broad antimicrobial spectrum, against reference multidrug-resistant and biofilm-forming *S. epidermidis*

Methods

The biomass of the biofilm and metabolic activity of planktonic and biofilm cells of *S. epidermidis* upon exposure to lactoferrin were determined using standard microtiter plate assays.

Conclusions

Lactoferrin has been shown to eradicate biofilms of *S. epidermidis*, while the metabolism of the bacteria in the biofilms was reduced.

Pathogens / Pathogenicity

CANDIDA ALBICANS VS. CANDIDA DUBLINIENSIS: THE COMPARISON OF ADHERENCE PROPERTIES AND BIOFILM DEVELOPMENT IN VITRO, IN VIVO, AND EX VIVO

J. Chupáčová[1], *H. Bujdáková*[1]
[1]*Comenius University in Bratislava- Faculty of Natural Sciences,*
Department of Microbiology and Virology, Bratislava, Slovak Republic

Backgrounds

Candida albicans and *Candida dubliniensis* are closely related organisms in respect to morphology and phylogeny, but with different virulence and pathogenicity.

Objectives

This research compared adhesion properties and biofilm development of *C. albicans* and *C. dubliniensis*, and studied role of biofilm-associated genes (*ALS1*, *ALS9*) in these processes. For this study, *in vitro*, *ex vivo* (mouse tongues), and *in vivo* (*Galleria mellonella* host model) experiments were performed.

Methods

The kinetic of adhesion was studied by metabolic activity (XTT reduction assay) of cells adhered to surface of microtiter plate in selected time points (0, 30, 60, 90, 120 min). Metabolic activities of the matured 48-h biofilms were determined as well. In *ex vivo* experiments, cryo-cuts from mouse tongues were evaluated after PAS staining. *In vivo* model *G.mellonella* was selected for comparison of pathogenicity of biofilms formed by both *Candida* species. Additionally, the RT-PCR was performed in order to determine regulation of the *ALS1*and *ALS9* genes in adhesion and matured biofilm.

Conclusions

Results revealed that in spite of strong ability of *C. dubliniensis* to adhere during adhesion phase (XTT assay), the matured biofilm was thinner, with decreased penetration to the tissue, and composed mainly of the yeast cells (light microscopy and Confocal Laser Scanning Microscopy). Survival of larvae was higher (up to 30%) when they were infected with *C. dubliniensis* compared to the *C. albicans* infection. The *ALS1* and *ALS9* genes seem to be regulated during biofilm development.

Despite of higher fitness of *C. albicans*, *C. dubliniensis* confirmed enough “power” in biofilm development in all models.

EVALUATION OF UTP-GLUCOSE-1-PHOSPHATE URIDYLYLTRANSFERASE (UDPG:PP) AS A POTENTIAL NOVEL DRUG TARGET IN STREPTOCOCCUS PNEUMONIAE

F. Cools[1], B. Vanhoutte[1], E. Torfs[1], M. Bidart de Macedo[1], L. Bonofilgio[2], D. Cappoen[1], M. Mollerach[2], P. Cos[1]
[1]University of Antwerp, Laboratory of Microbiology- Parasitology and Hygiene LMPH, Antwerp, Belgium
[2]Universidad de Buenos Aires- Facultad de Farmacia y Bioquímica- CONICET, Microbiología, Buenos Aires, Argentina

Backgrounds

The most important virulence factor of the human pathogen *Streptococcus pneumoniae* is its polysaccharide capsule, which prevents opsonization by complement factors, adhesion and macrophage phagocytosis. Uridine diphosphate glucose (UDP-Glc) is a key component in the biosynthetic pathway of capsular polysaccharides and is also present in other bacteria where it plays a role in lipopolysaccharide and capsule production. It is formed out of glucose 1-phosphate (Glc-1P) by the enzyme UTP-glucose-1-phosphate uridylyltransferase (UDPG:PP), which is encoded by the *galU* gene. UDPG:PP is widely distributed amongst animals, plants and other microorganisms, but eukaryotic UDPG:PPs are evolutionary unrelated to their prokaryotic counterparts. Therefore, it is postulated that UDPG:PP might be a valuable novel target in fighting bacterial diseases.

Objectives

To assess the potential value of UDPG:PP in antimicrobial therapy, several *in vitro* characteristics and the *in vivo* infectivity of different pneumococcal *galU* knockout strains were compared with those of their non-mutated parent strains.

Methods

In vitro data on biofilm formation, antimicrobial susceptibility and co-cultures with macrophages and epithelial cells were generated using standard methods. Transmission electron microscopy was used to visualize the capsule and *in vivo* infectivity was determined using a *Galleria mellonella* model.

Conclusions

Although there is no definitive correlation found for all strains and their knockouts, our results suggest that *galU* mutations influence *in vitro* biofilm formation. Furthermore, results of cellular co-cultures combined with the primary results of infectivity imply UDPG:PP might indeed be a potential new target.

MODELLING PATHOGEN INTERACTIONS WITHIN THE BOVINE RESPIRATORY TRACT USING A THREE-DIMENSIONAL DIFFERENTIATED AIRWAY EPITHELIAL CELL MODEL

D. Cozens[1], E. Sutherland[1], G. Taylor[2], C. Berry[3], R. Davies[1]
[1]University of Glasgow, Infection- Immunity and Inflammation, Glasgow, United Kingdom
[2]Pirbright Institute, Virology, Pirbright, United Kingdom
[3]University of Glasgow, Institute of Molecular Cell and Systems Biology, Glasgow, United Kingdom

Backgrounds

Bovine respiratory disease (BRD) complex is a multifactorial infection of cattle that is responsible for substantial economic losses to the livestock industries. Various viral and bacterial agents are associated with BRD although *Mannheimia haemolytica* is one of the major bacterial pathogens involved. The complex interactions involving bacteria, viruses and the host are poorly understood; this is partly due to the lack of physiologically-relevant and reproducible *in vitro* models and the reliance on experiments involving cattle.

Objectives

The aim of the present study was to optimize a three-dimensional differentiated airway epithelial cell (AEC) model of the bovine respiratory tract for studying host-pathogen interactions involved in BRD.

Methods

Primary bovine bronchial epithelial cells, isolated from fresh abattoir material, were cultivated at an air-liquid interface to stimulate differentiation into typical airway epithelial cells. Differentiation was compared under different growth conditions and at different time points. The AEC model was subsequently used to compare infection by different strains of *M. haemolytica* isolated from diseased and healthy cattle.

Conclusions

The AEC model displayed tight junction formation and mucocilary activity, hallmarks of the respiratory tract epithelium. Optimum growth conditions and time-points were determined for infection studies. Strains of *M. haemolytica* isolated from diseased cattle successfully colonised the epithelial layer and caused significant tissue damage by 48 h; conversely, commensal strains isolated from healthy animals were incapable of colonisation. Thus, the AEC model represents a very useful tool for studying the interactions of *M. haemolytica* with the bovine respiratory tract and will have wider applications.

PHENOTYPIC AND GENOTYPIC CHARACTERIZATION OF MULTIDRUG RESISTANT ACINETOBACTER BAUMANNII FROM NEONATAL FEEDING TUBES IN NEONATAL INTENSIVE CARE UNITS

K. Dahmani[1], M. Saad[1], P. Ogrodzki[1], T. Osaili[2], J. Winter[1], S. Forsythe.[1]
[1]Nottingham Trent University, School of Science and Technology, Nottingham, United Kingdom
[2]Jordan University of Science and Technology, Nutrition and Food Technologyhool, Irbid, Jordan

Backgrounds

Acinetobacter baumannii is one of the most opportunistic pathogens responsible for serious infections in intensive care units (ICUs).

Objectives

The aim of this study was to profile a diverse clinical collection of *A. baumannii* by applying a range of phenotyping and genotyping methods to determine the potential infection risk to neonates.

Methods

Forty-three clinical strains had been isolated from neonatal feeding tubes from two neonatal ICUs. They were genotyped using pulsed-field gel electrophoresis using *ApaI* and *AscI* restriction enzymes. The isolates were identified by sequence analysis of the *rpoB* allele (350 bp). Representative strains were subjected to MLST analysis. Isolates were examined for potential, virulence factors, antibiotic resistance, biofilm production, human serum resistance, acid resistance and ability to attach to and invade Caco-2 cells.

All strains were identified as *A. baumannii* and clustered into five pulsotypes. MLST analysis revealed 2 different STs (ST193 and ST113). The majority of strains were resistant to all β-lactam antibiotics tested, but susceptible to ciprofloxacin. blaOXA-51 and blaOXA-64 genes were present in all of the isolates whereas blaOXA-23 was only found in strains belonging to ST113. The majority of the strains showed the ability to form significant biofilms, tolerance of acidic condition and resistance to human serum. All strains testes attached strongly to intestinal cells (Caco-2), except for an ST193 strain which showed low attachment.

Conclusions

The *A. baumannii* strains revealed remarkable virulence factors. These features could allow them to survive in the host and persist in hospitals where neonates are at high risk.

LOSS OF THE FUR REGULATOR RESULTS IN DISTINCT PHENOTYPES FOR SALMONELLA ENTERICA SEROVARS TYPHIMURIUM AND TYPHI

J.M. Leclerc[1], C.M. Dozois[2], F. Daigle[1]
[1]Université de Montréal, Microbiology, Montreal, Canada
[2]Institut Armand-Frappier.INRS, Microbiology, Laval, Canada

Backgrounds

Salmonella enterica serovars Typhimurium and Typhi are two closely related bacteria that cause different types of infection in humans. The global regulator Fur, involved in iron homeostasis, stress response and virulence, is present and conserved in both serovars.

Objectives

To investigated the role of Fur in *S.* Typhimurium and *S.* Typhi during growth, motility, infection of macrophages and to determine the total amount of siderophores produced.

Methods

Growth curves of the *fur* mutants under iron-rich and iron-limiting conditions revealed that only the *S.* Typhi *fur* mutant was defective. Also, formation of filamentous cells was only observed in this mutant. Fur was required for optimal swimming motility in both serovars, but motility was more markedly reduced for the *S.* Typhi *fur* mutant. Fur was also important for *S*. Typhi during interaction with human cultured macrophages. The *fur* mutant showed severe defects in uptake and survival within these cells. By contrast, loss of Fur had no effect on *S*. Typhimurium infection of macrophages. Finally, *S*. Typhi produced more siderophores than *S*. Typhimurium when grown to stationary phase in iron-free medium and both serovars produced more enterobactin than salmochelins.

Conclusions

These results demonstrate that Fur differentially affects the physiology and the virulence phenotypes of the two serovars and is more critical for *S*. Typhi growth, morphology, motility and interaction with host cells than for *S*. Typhimurium.

Pathogens / Pathogenicity

THE GUT PATHOBIONT HELICOBACTER HEPATICUS PRODUCES A LARGE POLYSACCHARIDE INDUCING A MSK/CREB-DEPENDENT ANTI-INFLAMMATORY GENE SIGNATURE IN MACROPHAGES

C. Danne[1]
[1]*Kennedy Institute, NDORMS, Oxford, United Kingdom*

Backgrounds

Shaped by co-evolution, host-microbiota mutualism depends on intricate molecular interactions. However, the identities of symbiotic molecules promoting tolerance, and the immune mechanisms that discriminate between the microbiota and infection-causing pathogens remain elusive. Especially as persistent colonizers can sometimes behave as pathobionts.

H. hepaticus is a common member of the mouse gut microbiota, but it induces colitis when the IL-10 signaling is blocked. The model of IBD using *H. hepaticus* and an anti-IL10R antibody shares many cardinal features of human IBD. IL10-producing Treg cells induced by *H. hepaticus* were shown to prevent inflammation in this model. However, little is known about *H. hepaticus* interactions with the innate immune compartment.

Objectives

We then investigated wether *H. hepaticus* could promote intestinal homeostasis.

Methods

We observed that *H. hepaticus* colonization induces IL-10 production in gut-resident macrophages and bone-marrow derived macrophages (BMDMs). Interestingly, we identified a large soluble polysaccharide produced by *H. hepaticus* that induces IL-10 *in vitro* and *in vivo*, along with a low pro-inflammatory response. We then showed that *H. hepaticus* polysaccharide signals through TLR2/MyD88. A microarray analysis revealed the specific anti-inflammatory/repair gene signature induced by *H. hepaticus* polysaccharide in BMDMs. By contrast, the canonical TLR2/1 ligand Pam3CSK4 induces a strong pro-inflammatory/activation response. The immunomodulatory properties of *H. hepaticus* polysaccharide are dependent on MSK1/2 and the transcription factor CREB, with a low induction of NF-kB.

Conclusions

A better understanding of the molecular crosstalk between cells and microbes is of major importance to decipher mutualism, with the ultimate goal to propose new preventive and therapeutic strategies.

A SMALL MOLECULE CANDIDATE FOR ANTIBIOTIC CO-THERAPY IN THE FIGHT AGAINST BACTERIAL PERSISTENCE

V. Defraine[1], V. Liebens[1], R. Corbau[2], A. Marchand[2], P. Chaltin[2,3], F. Van Bambeke[4], A. Anantharajah[4], M. Fauvart[1,5], M. Jan[1]
[1]KU Leuven, Centre for Microbial and Plant Genetics, Leuven, Belgium
[2]KU Leuven, Centre for Drug Design and Discovery, Heverlee, Belgium
[3]CISTIM, Leuven vzw, Leuven, Belgium
[4]Université Catholique de Louvain,
Pharmacologie cellulaire et moléculaire- Louvain Drug research Institute, Brussels, Belgium
[5]imec, Department of Life Science Technologies, Leuven, Belgium

Backgrounds

Bacterial infections pose a major public health threat and are predicted to cause 10 million deaths annually by 2050. This is mainly driven by rapidly increasing multidrug resistance and the presence of antibiotic-tolerant persister cells that greatly impede disease treatment.

Objectives

In the search for novel antibacterial strategies we discovered a novel small molecule that significantly decreases the surviving fraction of *Pseudomonas aeruginosa* in combination with ofloxacin. A multi-pronged approach was used to further characterize SPI009 and gain more insight into the mode of action.

Methods

Extensive antibacterial assays, using both SPI009 alone and in combination with either β-lactam, aminoglycoside, polymyxin or fluoroquinolone antibiotics successfully eradicated cultures of different Gram-negative and Gram-positive bacteria, including the ESKAPE pathogens and several (multidrug resistant) clinical isolates of *P. aeruginosa.* Testing of SPI009 in different model systems revealed potent biofilm inhibition and eradication while combination treatment with ciprofloxacin resulted in the efficient eradication of an intracellular *P. aeruginosa* infection in human monocytes. Different approaches were used to study the mode of action of SPI009, including macromolecular synthesis assays, membrane permeability studies and comparative genomic analysis of mutants with differing susceptibility. All pointed towards extensive membrane damaging activity of SPI009, leading to either direct cell death or facilitation of antibiotic-induced cell death.

Conclusions

Crucially, due to the observed broad-spectrum effect, antibiotic-independent activity and possibility to tackle persister cells, SPI009 provides a promising starting point for the development of novel co-therapies in the fight against multidrug-resistant and persistent infections.

BURKHOLDERIA BACTERIA AS A SOURCE OF NOVEL ANTIMICROBIALS

E. Depoorter[1], E. De Canck[1], T. Coenye[2], P. Vandamme[1]
[1]Ghent University, Department of Biochemistry and Microbiology, Gent, Belgium
[2]Ghent University, Department of Pharmaceutical Analysis, Gent, Belgium

Backgrounds

Because of the urgent need for new antibiotics and the low efficiency of high-throughput screens, it is time to reconsider drug discovery from natural sources. *Burkholderia* bacteria have large genomes with extensive potential for secondary metabolism and they are well-known for their metabolic diversity and biocontrol properties. The recent discovery that strains of *B. ambifaria*, *B. gladioli* and *B. vietnamiensis* produce antibiotics with activity against multidrug resistant pathogens, suggests they are potentially interesting novel sources of antimicrobial metabolites.

Objectives

A set of 300 *Burkholderia* strains was selected from our in-house strain collection and screened for antimicrobial activity.

Methods

An agar overlay assay was used to screen for activity against *Staphylococcus aureus*, *Acinetobacter baumannii* and *Candida albicans.* A selection of strains showing antimicrobial activity in this first screen was subjected to a more in-depth analysis to determine the spectrum of activity against Gram-positive, Gram-negative and fungal pathogens. An additional panel of 40 recent clinical isolates of *Enterobacteriaceae* and *Pseudomonas aeruginosa* was used to further explore the spectrum of activity against Gram-negative pathogens.

Conclusions

In the first screen for antimicrobial activity, 39% of the strains showed activity against one or more pathogens. Nineteen of these strains had activity against the Gram-negative pathogen *A. baumannii* and 28 strains were selected for the second screen. The large majority (n = 25) of these 28 strains had broad activity against Gram-positive pathogens and half of the strains showed activity against multiple drug-resistant Gram-negative pathogens, including *A. baumannii, Klebsiella pneumoniae, Enterobacter* spp. and *Escherichia coli*.

[3]Uppsala University, Department of Cell and Molecular Biology, Uppsala, Sweden

Backgrounds

VirF is an AraC-like regulator controlling virulence gene expression in *Shigella* spp., one of the main cause of bacillary dysentery in humans. VirF protein has been identified in different forms, but only the longer one, $VirF_{30}$, has been considered as an active form.

Objectives

This work investigates the function of $VirF_{21}$, a shorter form of the VirF regulator, its translation and its impact on *Shigella* virulence.

Methods

Site specific mutagenesis was performed to show the independent translation of VirF forms. Transcriptional *lacZ*-fusions and qRT-PCR were used to assess VirF forms functions. DNAseI footprinting was performed to map $VirF_{21}$ binding site on *virF* promoter. Transcriptional *lacZ*-fusions and Primer Extension were used to identify a new *virF* gene internal promoter. *In vivo* and *in vitro* translation as well as Toeprint Assays were performed to show that the newly identified *virF* leaderless mRNA is $VirF_{21}$ translational competent.

Conclusions

Here we show that in *Shigella*, the VirF protein is present in two different forms, independently translated. $VirF_{30}$ is responsible for activation of the virulence system, whereas $VirF_{21}$ negatively autoregulates *virF* expression itself. In addition we provide evidence supporting that $VirF_{30}$ and $VirF_{21}$ are translated by a single full length mRNA. $VirF_{21}$ can be also translated exclusively by a leaderless mRNA form, transcribed from a newly identified gene internal promoter. These new insights into the fine-tuned regulation of *Shigella* virulence open unexpected possibilities in the study of *Shigella* virulence and host cell invasion mechanisms.

FUNCTIONAL ANALYSIS OF A TRIMERIC AUTOTRANSPORTER ADHESIN DETECTED IN AN AVIAN PATHOGENIC ESCHERICHIA COLI STRAIN

T. Rojas[1], L. da Silva[1], J. de Paiva[1], R. Maluta[1], J. Leite[1], R. Conceição[1], G. Nakazato[2], W. Dias da Silveira[1]
[1]University of Campinas, Genetics- Evolution and Bioagents, Campinas, Brazil
[2]Center of Biological Sciences- State University of Londrina, Department of Microbiology, Londrina, Brazil

Backgrounds

Autotransporters (AT) are proteins with the ability to pass through the outer membrane of Gram-negative bacteria via the type V pathway. Trimeric autotransporter adhesins (TAAs) are a subcategory of AT that form stable trimers on bacterial outer membranes. Using *in silico* analysis, we detected a 5253-bp region encoding a putative TAA in an Avian Pathogenic *Escherichia coli* (APEC) strain. This putative TAA is 80.6% similar to the UpaG TAA.

Objectives

We aimed to perform functional analysis of this protein in APEC strain SEPT362.

Methods

A comparative study with a wild type strain and null TAA mutant demonstrated that there was no statistical difference between both isolates regarding motility, biofilm production, lethality to day-old chicks, invasion to CEC32 and HEp-2 cells, survival in HD11 cells, and adhesion to Chicken Embryo Fibroblast (CEF) cells with mannose analogue. On the other hand, the null mutant presented a decreased ability to be internalized into HeLa cells ($p < 0.01$) and to adhere to CEF cells without a mannose analogue ($p < 0.01$). An enrichment analysis of the transcriptome of the wild type and the mutant indicated a downregulation of the regulator *mod*E. This regulator represses the molybdenum ABC transport system. The upregulation of this ABC transport system seems to have modified the expression of anaerobic metabolic pathways and some virulence factors, such as type 1 fimbria and flagella.

Conclusions

These results indicate that this TAA is associated with increased fitness to colonize anaerobic environments and decreased adherence mediated via type-1 fimbria.

[3]São Paulo State University UNESP- Institute of Science and Technology, Restorative Dentistry, São Jose dos Campos, Brazil

Backgrounds

Taking into consideration the resistance of microorganisms to antibiotics, it becomes of great interest to analyze alternative antimicrobial agents, such as plant extracts.

Objectives

Evaluating *in vitro* antimicrobial activity of *Hamamelis virginiana* extract in contact with *Candida albicans* (CA), *Staphylococcus aureus* (SA), *Enterococcus faecalis* (EF) or *Streptococcus mutans* (SM) biofilms, during 5 min and 24 h.

Methods

The concentrations of 50, 100 and 200 mg/mL (n=10) were analyzed in both exposure times on each microbial 48 h-mature biofilm (n=10) in 96-wells microplates. Saline was used as control. After treatment, biofilm cells were scraped off and plated. After incubation (37°C/48 h), colony forming units per milliliter (CFU/mL) values were analyzed (ANOVA and Tukey test, 5%). There was a significant reduction of biofilms in comparison to the control group ($p<0.05$), in both exposure times. For EF, all the concentrations of extract showed CFU/mL reduction greater than 55% in the period of 5 min and greater than 90% in the period of 24 h. For SA, reduction was greater than 60% in 5 min and, in the period of 24 h, it was 97.97%. For SM, there was a reduction greater than 80% in 5 min and, in the period of 24 h, it was 92%. For CA, the extract promoted reduction of 80.90% in 5 min and, in 24 h, it promoted a reduction greater than 90%.

Conclusions

Hamamelis virginiana extract showed expressive antimicrobial action in contact with *S. mutans, S. aureus, E. faecalis* and *C. albicans* biofilms during 5 min and 24 h.

ANTIMICROBIAL EFFECTS OF PFAFFIA PANICULATA AND JUGLANS REGIA EXTRACTS AGAINST CANDIDA ALBICANS, STREPTOCOCCUS MUTANS AND PSEUDOMONAS AERUGINOSA

L.D. OLIVEIRA[1], L.P. RAMOS[1], C.A. PEREIRA[1], J.R. OLIVEIRA[1], F.E. OLIVEIRA[1], G. BACK BRITO[1], C.A.T. CARVALHO[2]
[1]São Paulo State University UNESP- Institute of Science and Technology, Biosciences and Oral Diagnosis, São Jose dos Campos, Brazil
[2]São Paulo State University UNESP- Institute of Science and Technology, Restorative Dentistry, São Jose dos Campos, Brazil

Backgrounds

Popular use of plant extracts demonstrates antimicrobial activity, however, it is necessary scientific studies that prove this action aiming correct therapeutic indication.

Objectives

This study aimed to investigate the antimicrobial effects of *Pfaffia paniculata* and *Juglans regia* extracts on *Candida albicans* (CA), *Streptococcus mutans* (SM) and *Pseudomonas aeruginosa* (PA) planktonic cultures and biofilms.

Methods

ATCC strains of *C. albicans, S. mutans* and *P. aeruginosa* were used. Minimum Inhibitory Concentration (MIC) and Minimum Microbicidal Concentration (CMM) of extracts were determined by microdilution broth method. Mature biofilms with 48 h in 96-well plates were treated for 5 min with 200, 100 and 50 mg/mL of each extract and measured by violet crystal and MTT tests. Results were analyzed by ANOVA and Tukey test, 5%. Biomass of CA, SM and PA reduced, respectively, 45.6, 14.7 and 23.5% in contact with *P. paniculata* at 200 mg/mL. When in contact with *J. regia*, at 200 mg/mL, CA, SM and PA biomass reduced 31.0, 14.7 and 23.5%, respectively. MTT assay indicated reductions of 77.4% for CA, 20.3% for SM and 78.6% for PA with the use of *P. paniculata* extract and with *J. regia*, reductions were 61.0% for CA, 13.6% for SM and 26.8% for PA.

Conclusions

P. paniculata e *J. regia* extracts showed microbicidal activity against *C. albicans, S. mutans* and *P. aeruginosa* planktonic forms and biofilms.

DRUG RESISTANT AND HOSPITAL SOURCES OF ASPERGILLUS CAUSING HOSPITAL ACQUIRED INFECTIONS

K. Diba[1], P. Badiee[2], A. Namaki[3]
[1]Urmia University of Medical Sciences, Medical Mycology, Urmia, Iran
[2]Shiraz University of Medical Sciences, Prof. Alborazi Microbiology Research Center, Shiraz, Iran
[3]Arefian General Hospital, Gynecology, Urmia, Iran

Backgrounds

In spite of a low percent (1%) of fungal hospital acquired infections, *Aspergillus* species are the main agents of fulminate fungal infections. Invasive aspergillosis has a mortality rate of 90%, among the *Aspergillus* infections.

Objectives

Regarding high frequently of *Aspergillus* spp. isolated from clinical and environmental sites in the nephrology ward, we tried to determine the azole resistance and perform a molecular epidemiologic study finding accurate and exact environmental sources for aspergillus infections and colonization in the large, general hospitals.

Methods

Our subjects included clinical specimens of case with HAI which collected during 48 month from October 2012 to September 2016 at the UMSU educational hospitals, Urmia, Iran. Also, environmental specimens including sterile swabs from surfaces of floor, walls, Curtains, beds, trolleys, air condition and cooling systems, medical devices were obtained as well as some samples from finger touches of the cast and visitors. The MICs for the azole family (fluconazole and ketoconazole) were described as the lowest concentration of the drug that could reduce 50% of fungal growth. The molecular method RAPD-PCR using six random Aspergillus primers was performed to study the hospital sources of the isolated Aspergillus.

Conclusions

Conclusions: The results of experimental studies on the specimens showed 93(47%) positive for a fungal or bacterial infections from the above case, 54(58%) had a fungal infection. Among the isolated *Aspergillus*, *A. flavus* (47%), *A. fumigatus* (29.4%) and *A.niger* (23.6%) were the most frequent. Using RAPD-PCR, two clinical-environmental sets including *A. niger* (sinus mass -floor) and *A. flavus* (BAL-air conditioner) were matched. All Aspergillus commonly clinical and environmental isolates were susceptible in MIC test. As expected, all three of the isolates obtained from one patient showed identical patterns (RAPD combined type A/D-12). However, the same pattern was found in two environmental isolates obtained from the wards.

[9]Memorial Sloan Kettering Cancer Center, Computational Biology, New York, USA

Backgrounds

Multidrug-resistant Enterobacteriaceae (MRE), including *Escherichia coli* and *Klebsiella pneumoniae*, are a major health problem to hospitalized patients. Infections with MRE frequently begin with the pathogen colonizing the intestine but, in normal conditions, the invader encounters a suppressive intestinal microbiota that resists colonization. Antibiotic treatments often disrupt the microbiota and accidentally open the way to MRE colonization. Despite its clinical relevance many human protective bacterial species and how they suppress MRE colonization remain unknown.

Objectives

The objective of our study is identifying commensal microbiota species and clinical variables that influence resistance to colonization by MRE.

Methods

We collected 817 fecal samples from 140 patients with acute leukemia, sampled weekly during hospitalization, over a period of eighteen months. Fecal samples were grown in selective media to determine MRE intestinal levels. We obtained the microbiota composition of each fecal sample by high-throughput sequencing of the 16s rRNA gene. The previously utilized Lotka-Volterra mathematical model (Buffie et al., Nature, 2015), was extended to identify both commensal bacteria and clinical variables that impact MRE intestinal colonization.

Conclusions

We determined that the type of antibiotic treatment received was among the strongest clinical variables influencing MRE intestinal levels. Interestingly, samples obtained during the transplant period show significantly lower MRE levels compared to those obtained during the chemotherapy. The Lotka-Volterra model identified four bacterial operational taxonomic units (OTUs) belonging to the genera *Lactobacillus*, *Bacteroides* and *Streptococcus* as those associated with decrease in MRE intestinal levels. These findings may lead to new probiotic therapies against MRE infection.

VIRULENCE GENES, O-SEROGROUPS AND F18 VARIANTS OF PATHOGENIC ESCHERICHIA COLI FROM DIARRHEIC PIGLETS IN KOREA

K.H. Do[1], J.W. Byun[2], W.K. Lee[1]
[1]Chungbuk National University College of Veterinary Medicine, Veterinary Bacteriology, Cheongju, Republic of Korea
[2]Animal and Plant Quarantine Agency, Department of Animal and Plant health research, Gimcheon, Republic of Korea

Backgrounds

Escherichia (*E*.) *coli* have been divided into several pathotypes according to their combinations of virulence factors. Among them, Enterotoxigenic *E. coli* (ETEC) and shiga toxin-producing *E. coli* (STEC) produce fimbriae and toxins, and cause diarrhea and edema disease in pigs. Three F18 antigenic variants (F18ab, F18ac and F18new) are frequently associated with ETEC or STEC.

Objectives

We examined prevalence of the O-serogroups and virulence genes among *E. coli* strains and investigated the frequency of antigenic variants in F18 positive ETEC and STEC isolated from diarrheic piglets in Korea.

Methods

Between 2007 and 2016, a total of 862 *E. coli* isolated from diarrheic piglets were serogrouped and tested for the fimbrial adhesin and toxin genes. The genes for the toxins and adhesins were amplified by PCR. Among them, 260 F18 positive isolates were differentiated F18 antigenic variants using real-time PCR technique.

Conclusions

In this study, the predominant serogroup was O139, and the most frequently detected adhesin was F18. Among 323 F18-encoding isolates, 111 (ETEC/STEC) and 90 (STEC) isolates were positive for Stx2e gene. We tested 260 F18-encoding isolates to discriminate F18 subtypes, and F18ac (145 isolates) was the most predominant F18 subtype. There were 58 (ETEC/STEC) and 8 (STEC) isolates which are positive for Stx2e gene. These indicate that there is high risk for edema disease to diarrheic piglets in Korea. This results provide not only epidemiological data regarding the prevalence of serogroups and virulence factors but could also be used to design control measures for colibacillosis in Korean piggeries.

COMPARATIVE ANALYSIS OF ESCHERICHIA COLI ISOLATES FROM BOVINE ORIGIN: IS THERE A SPECIFIC MASTITIS PATHOTYPE?

A. Leimbach[1], A. Poehlein[2], R. Daniel[2], U. Dobrindt[1]
[1]University of Münster, Institute of Hygiene, Münster, Germany
[2]University of Göttingen, Göttingen Genomics Laboratory, Göttingen, Germany

Backgrounds

Escherichia coli is a major pathogen of acute bovine mastitis. Pathogenic *E. coli* are traditionally classified into different pathotypes based on specific virulence factor sets and characteristic disease pathology. Although a mammary pathogenic *E. coli* pathotype has been proposed, no common virulence factors could be determined despite extensive research efforts.

Objectives

Environmental factors as well as the bovine innate immune response have been implicated as the sole parameters influencing mastitis outcome. Nevertheless, many studies tried to detect specific virulence factors subsets in *E. coli* mastitis isolates, with no success. Thus, we followed a whole genome and phenotypic approach to identify putative virulence traits by comparing bovine mastitis and commensal *E. coli* isolates.

Methods

A comparative genomics approach was used to characterize the gene content and phenotype of the strains in relation to phylogeny and pathogenicity.

Conclusions

Mastitis-associated *E.coli* (MAEC) and commensal strains could not be unambiguously discriminated by their phylogenetic background and the presence of virulence-associated genes. Nevertheless, a certain correlation between MAEC and phylogroup A and commensal isolates and phylogroup B1 has been observed. Gene content is significantly affected by phylogenetic background. MAEC mirror the phylogenetic and genotypic diversity of isolates from the gastrointestinal tract. There is no evidence for a mammary gland-specific pathotype. Putative virulence factors should rather be considered fitness factors for gastrointestinal colonization. MAEC are facultative pathogens that are recruited from the normal intestinal microbiota.

COMPARTIVE GENOME-WIDE TRANSCRIPTIONAL ANALYSIS OF TWO CANDIDA ALBICANS MUTANTS AFFECTED IN N-GLYCOSYLATION

A. Dominguez[1], *C. Cívicos*[1], *M.C. López*[1]
[1]*Universidad de Salamanca, Microbiology and Geneticas, Salamanca, Spain*

Backgrounds

Candida albicans is one of the most important opportunistic human pathogens, causing life-threatening infections in immunocompromised individuals. Protein glycosylation is important for folding, regulated secretion, localization and function of proteins. Defects in protein glycosylation cause surface alterations of cell wall, the first point of contact to host cell, therefore affecting pathogenicity attributes like adhesion and morphological plasticity that allow *Candida* to adapt to different ecological niches of the host. We constructed two *C. albicans* mutants, *mnn1Δ/Δ* and *mnn9 Δ/Δ*, which are defective in a α-1,3 and α-1,6 mannosyltransferases, respectively. We analyzed their expression profiles generated under different growth conditions with the aim of knowing the cell responses to glycosylation defects

Objectives

In order to investigate the importance of N-glycan modifications of proteins in morphogenetic and pathogenic processes in *C. albicans*, we have performed global expression analysis of mutants *mnn9Δ/Δ* and *mnn1Δ/Δ* affected in the N-glycosylation pathway in the Golgi Complex

Methods

C. albicans mutants have been constructed using the “Ura-blaster” method. Transcriptional profiling was carried out using cDNA microarrays purchased from Eurogentec (Seraing, Belgium). The data analysed included 4 replicates.

Conclusions

The *mnn9Δ/Δ* transcriptional profiles are consistent with their phenotypic characteristics, such as cell aggregation and inability to form true hyphae. Regarding these phenotypes, we did not detect any difference between *mnn1Δ/Δ* and the parental strain, the transcriptome of this mutant being in accordance with these results. Here we present other transcriptional features regarding to alterations in signalling pathways in response to glycosylation defects

INACTIVATION OF THE PST TRANSPORTER DEREGULATES THE C-DI-GMP PATHWAY AND DECREASES EXPRESSION OF TYPE 1 FIMBRIAE BY UROPATHOGENIC ESCHERICHIA COLI STRAIN CFT073

S. CRÉPIN[1], G. PORCHERON[1], S. HOULE[1], J. HAREL[2], C. MARTIN[3], C.M. DOZOIS[1]
[1]INRS-Institut Armand-Frappier, INRS-Institut Armand-Frappier, Laval- Quebec, Canada
[2]Université de Montréal, CRIPA and Faculté de médecine vétérinaire, Saint-Hyacinthe- Québec, Canada
[3]Institut National de la Recherche Agronomique, Laboratoire de Microbiologie, Saint-Genès-Champanelle, France

Backgrounds

The *pst* system encodes the phosphate transporter (Pst). Inactivation of Pst constitutively activates the two-component regulator PhoBR and has been shown to attenuate virulence of a variety of bacterial pathogens. In uropathogenic *Escherichia coli* strain CFT073, attenuation by inactivation of *pst* is predominantly attributed to the decreased expression of type 1 fimbriae.

Objectives

To elucidate mechanisms connecting the Pst system and decreased expression of type 1 fimbriae.

Methods

A transposon library in the *pst* mutant was generated and clones were tested for a regain in type 1 fimbriae production. The diguanylate cyclase encoded by *yaiC* (*adrA*) was identified to link the Pst system and type 1 fimbrial expression. In the *pst* mutant, *yaiC* was induced and shown to contribute to decreased expression of type 1 fimbriae by predominantly altering expression of the FimBE-like recombinases IpuA and IpbA, affecting at the same time, orientation of the the *fim* invertible promoter. In the *pst* mutant, inactivation of *yaiC* restored *fim*-mediated adhesion to epithelial cells and colonization of mouse bladders and kidneys. Expression of *yaiC* required PhoB, and transcription of *yaiC* was linked to the PhoB-dependent *phoA-psiF* operon. As YaiC is involved in c-di-GMP biosynthesis, an increased accumulation of c-di-GMP was observed in the *pst* mutant.

Conclusions

Overall, results suggest that one mechanism by which inactivation of the Pst system reduces expression of type 1 fimbriae is through PhoBR-mediated activation of *yaiC*, which in turn increases accumulation of c-di-GMP, represses the *fim* operon and consequently, attenuates virulence in the mouse urinary tract infection model.

DEVELOPMENT OF POLYMER-IMPREGNATED SILICONE URINARY CATHETERS RESISTANT TO PROTEUS MIRABILIS SURFACE ADHESION AND SWARMING MOTILITY

J.F. Dubern[1], A.L. Hook[2], A. Carabelli[2], J. Luckett[1], C.Y. Chang[3], P.E. Magennis[2], M.R. Alexander[2], P. Williams[1]
[1]Centre for Biomolecular Sciences, School of Life Sciences, Nottingham, United Kingdom
[2]Laboratory of Biophysics and Surface Analysis, School of Pharmacy, Nottingham, United Kingdom
[3]School of Life Sciences, Heriot-Watt University, Edinburgh, United Kingdom

Backgrounds

Proteus mirabilis is an opportunistic pathogen that causes complicated urinary tract infections (UTIs). *P. mirabilis* cells utilize the swarming behaviour to rapidly migrate across catheters and ascent the urinary tract. *P. mirabilis* employs a wide variety of virulence factors during the initial colonisation. One major virulence factor is urease, an enzyme that hydrolyses urea to free ammonia resulting in subsequent precipitation of calcium and magnesium phosphate. The alkaline condition leads to the formation of kidney stones and the crystalline biofilms that encrust the catheter tubing.

Objectives

Through structure-activity analysis, we investigate the ability of homopolymers to inhibit surface attachment and motility of *P. mirabilis* and other pathogens in order to identify pan inhibitory materials.

Methods

Several anti-attachment materials formed from acrylates with hydrocarbon pendant groups have been developed.Their ability to resist attachment of fluorescently labelled *P. mirabilis* to urinary catheters and to prevent cell migration was investigated. In addition, *P. mirabilis* swarming behaviour was examined using Differential Interference Contrast microscopy (DIC) and scanning electron microscopy.

Conclusions

In this study a new monomer combination formed from acrylates with hydrocarbon pendant groups is presented that is able to resist both the adhesion and swarming of *P. mirabilis.* The new coating is non-toxic and prevents attachment of other pathogens including *Pseudomonas aeruginosa*, *Staphylococcus aureus* and uropathogenic *Escherichia coli.* In addition, the microscopic examination of *P. mirabilis* swarming behaviour suggests its ability to sense and respond to surfaces of different chemical composition *via* an unknown molecular mechanism.

SUPPRESSIVE SOILS AGAINST GAEUMANNONYCES GRAMINIS OF SOILS UNDER MONOCULTURE MANAGEMENT IS REGULATED BY RHIZOSPHERE MICROORGANISMS

P. Duran[1], *M.D.L.L. Mora*[1]
[1]*Universidad de La Frontera, Scientific and Technologic Bioresorce Nucleus, Temuco, Chile*

Backgrounds

Wheat production around the world is severely compromised by the occurrence of “take-all” disease, which is caused by the soil-borne pathogen *Gaeumannomyces graminis* var tritici (Ggt). In this context, suppressive soils are those environments where plants comparatively suffer less soil-borne pathogen diseases than expected owing to the activities of native soil microorganisms.

Objectives

this study aimed to screen the occurrence of Ggt-suppressive soils from southern Chile and we compared the structure of the communities in suppressive and conductive soil

Methods

Two preliminary screenings for soils inhibition of Ggt growth *in vitro* allowed the identification of nine putative suppressive soils, and 7 of them were confirmed to be Ggt-suppressive in plant assays under greenhouse conditions. Supressiveness was lost upon sterilization of the soils, and recovered by adding 1% of non sterilized soil. The structure of the community was studied in both suppressive and conducive soils

Conclusions

Soil suppression was associated to the soil microbiota. Remarkably, bacteria community composition was similar in suppressive soils when compared with that in positive disease conducive control soil. Accordingly, suppressive soils constitute an important resource for the development of environmentally friendly and efficient biotechnological applications for the control of soil-borne diseases.

ST131 ESCHERICHIA COLI AND ITS H30 AND H30-RX SUBCLONES IN TURKEY

D. Er[1], D. Dundar[2], H. Uzuner[1]
[1]Kocaeli University- Institute of Health Sciences, Medical Microbiology, Kocaeli, Turkey
[2]Kocaeli University- Faculty of Medicine, Medical Microbiology, Kocaeli, Turkey

Backgrounds

ST131 *Escherichia coli* (*E. coli*) is one of the leading causative agent of urinary tract infections worldwide with mutidrug-resistance. The *fimH* alleles H30 and H30-Rx are associated with infections of ST131 *E. coli*.

Objectives

The ST131 *E. coli* has been identified in only few studies from our region and the prevalence of subgroups are not well known. The aim of this study is to assess *E. coli* ST131 and its subclones H30 and H30-Rx in uropathogenic *E. coli* isolates.

Methods

A total of 250 uropathogenic *E. coli* isolates were included in this study. Clinical features including age, sex, complication (complicated-uncomplicated), syndrome (cystitis-pyelonephritis), origin (community acquired-healthcare associated) were obtained. Phylogenetic determination was identified with multiplex PCR reaction. O25b, O16 and SNP PCRs were applied for isolates which belong to B2 phylogroup for ST131 determination. Antimicrobial resistance was determined by disk diffusion test for 16 antimicrobial agents. Also, ST131-positive isolates were investigated for H30, H30-Rx subclones and 8 adhesin virulence genes including *fimH*, *iha*, *papAH*, *sfa/focDE*, *afa/draBC*, *focG*, *gafD* and *bmaE*.

Conclusions

There is not enough information about the frequency of ST131 *E. coli* and its H30, H30-Rx subclones in Turkey. In this study, prevalence of ST131 isolates for this collection was 15,6%. ST131 isolates usually carry *fimH*, *iha* and afa/*draBC* genes; also ESBL and MDR positive. Investigation of the relationships between adhesin virulence profiles, clonal groups and host factors will provide the understanding of the pathogenesis. The determination of these relations may result in alternative treatment approaches geared towards virulence properties.

BIOFILM FORMATION AND VIRULENCE GENES AMONG MULTIDRUG RESISTANT A.BAUMANNII STRAINS ISOLATED FROM INTENSIVE CARE UNITS

Ö. Altınok Özgün[1], B. Boral[2], M.A. Ergin[3], Ö. Köseoglu Eser[4]
[1]İstanbul Aydın Unversity, Department of Medical Microbiology, İstanbul, Turkey
[2]Çukurova University, Department of Medical Microbiology, Adana, Turkey
[3]Hacettepe University, School of Health Services- Medical Laboratory Programme, Ankara, Turkey
[4]Hacettepe University, Department of Medical Microbiology, Ankara, Turkey

Backgrounds: Multidrug resistant Acinetobacter baumannii isolates lead to epidemics and loss of patients in the hospital setting.
Objectives: The aim of this study was to determine the relationship between the existence of biofilm and virulence genes among 156 invasive MDR A.baumannii isolates.
Methods: Isolates with known antibiotic susceptibility and PFGE patterns from ten ICUs of medical centers in five different geographical region of Turkey were included in the study. Quantitative microplate biofilm method was used to detect biofilm production. Formation of biofilm was interpreted as weak, moderate and strong. The presence of virulence genes bap, csgA, csuE, fimH, ompA and blaper-1 was investigated by PCR. A.baumannii ATCC 19606 was used as positive control.
Conclusions: Among all isolates, 60.25% (94/156) showed biofilm formation ability. Of the ninety four isolates, 17 were weakly, 33 were moderately and 44 were strongly positive. The mean biofilm biomass formation capacity of the negative/positive controls and isolates obtained during the test procedures was 2.2371±0.0033. Biofilm producing isolates were most frequently in pulsotype II 19.14%(18/94) and pulsotype IX 17.02%(16/94) and 26.59%(25/94) of the biofilm producer isolates were from a single center in PFGE profile. The frequency of genes bap, csgA, csuE, fimH, ompA and blaper-1 among the isolated strains (n:156) were 44.23%, 70.51%, 32.05%, 7.05%, 21.79% and 3.2%, respectively. This study shows that there is a strong relationship between the resistance and biofilm formation in invasive A.baumannii isolates and the patients with MDR invasive A.baumannii isolates should be evaluated in conjunction with the virulence factors and clonal spread.

[5]Instituto de Salud Carlos III. Centro Nacional de Microbiolgía, Laboratorio de referencia e investigación en enfermedades bacterianas prevenibles por vacunas, Madrid, Spain

Backgrounds

Many surface proteins show allelic variants with different number of repeats which affects to their function and immunogenicity.

Objectives

- To analyze the outer protein DiiA (Dimorphic invasion-involved protein A) encoded by the *sp1992* locus of *Streptococcus pneumoniae* TIGR4: specificity, epidemiology, role in pathogenesis and biological function.

- To study the contribution of different regions of protein DiiA to vaccine efficacy in terms of immunological response and level of protection.

Methods

DiiA architecture was determined using bioinformatic algorithms. The occurrence of *diiA* alleles was screened in clinical isolates by PCR. Isogenic mutants were constructed to study the relevance of DiiA sections in murine models. DiiA binding to human molecules was determined by surface plasmon resonance. Immunization assays were carried out in murine models using different purified DiiA variants. Immunoglobulin production was quantified by ELISA. Protection against pneumococcal sepsis and carriage challenges was quantified in mice through survival rate and bacterial load.

Conclusions

DiiA has a classical adhesin topology. This protein is involved in processes of colonization, pneumonia and sepsis, probably through the interaction to lactoferrin and collagen. DiiA is a promising vaccine candidate against *Streptococcus pneumoniae*.

MULTIDRUG RESISTANT TUBERCULOSIS IN ETHIOPIAN SETTINGS AND ITS ASSOCIATION WITH PREVIOUS HISTORY OF ANTI-TUBERCULOSIS TREATMENT: A SYSTEMATIC REVIEW AND META-ANALYSIS

S. Eshetie[1], M. Gizachew[1], M. Dagnew[1], H. Woldie[2], B. Tessema[1], F. Moges[1]
[1]University of Gondar-College of Medicine and Health Sciences, Medical Microbiology, Gondar, Ethiopia
[2]University of Gondar-College of Medicine and Health Sciences, Department of Nutrition, Gondar, Ethiopia

Backgrounds

Multi-drug resistant *tuberculosis* (MDR-TB) is remains a major public health concern in Ethiopia. Little is known about the burden of disease at national level.

Objectives

This meta-analysis is aimed, firstly, to determine the pooled prevalence of MDR-TB among newly diagnosed and previously treated TB cases, secondly, to measure the association between MDR-TB with the history of previous anti-TB drugs treatment.

Methods

PubMed, Embase and Google Scholar databases were consulted. Studies that reported prevalence of MDR-TB among new and previously treated TB patients were selected. Forest plots of all prevalence estimates were performed and summary estimates were also calculated using random effects models. Associations between previous TB treatment and MDR-TB infection were examined through subgroup analyses stratified by new and previously treated patients.

We identified 16 suitable studies and found an overall prevalence of MDR-TB among newly diagnosed and previously treated TB patients, 1.7% (95% CI 1.2% - 2.3%) and 14.1% (95% CI 10.9% - 17.2%), respectively. The observed difference was statistically significant (P<0.01). For the past 10 years (2006 to 2014) the overall MDR-TB prevalence showed a stable time trend. There was an odds ratio of 8.1 (95% CI 7.5 – 8.7) for previously treated TB patients to develop a MDR-TB infection compared to newly diagnosed cases.

Conclusions

The burden of MDR-TB remains high, especially in previously treated TB cases. Previous TB treatment was the most powerful predictor for MDR-MTB infection. Therefore, strict compliance with anti-TB regimens and improving case detection rate are the necessary steps to tackle the problem in Ethiopia.

PSEUDOMONAS AERUGINOSA CLINICAL ISOLATES: A RIBOSOMAL MUTATION CAUSES HIGH AMINOGLYCOSIDE RESISTANCE

R. Espinosa Portero[1], D. Matzov[2], A. Jiménez-Fernández[1], E. Zimmerman[2], A. Bashan[2], A. Yonath[2], H.K. Johansen[1], S. Molin[1]
[1]Technical University of Denmark, Biosustain, Lyngby, Denmark
[2]The Weizmann Institute of Science, Department of Structural Biology, Rehovot, Israel

Backgrounds

Pseudomonas aeruginosa is an opportunistic pathogen that causes chronic lung infections in Cystic Fibrosis (CF) patients. Clinical strains have been isolated over the years from sputum samples for genome sequencing. Bacterial ribosomes are formed by a small (30S) and a large subunit (50S). A mutation in the gene coding for 50S ribosomal protein L6 (*rplF*) has been recently described in two in *P. aeruginosa* clinical isolates from CF patients. These two mutants with a deletion in *rplF* gene have increased aminoglycoside resistance (to both gentamicin and tobramycin). Ribosomal proteins have a structural role in the organization of bacterial ribosomes, and protein L6 is located in the surface of the 50S subunit. Aminoglycosides have been described to interact with both subunits from ribosomes for translation inhibition

Objectives

To test whether gentamicin is able to bind to ribosomes with mutated L6 protein, and if this represents a growth advantage for these mutants. To determine what is causing the increase in aminoglycoside resistance. To determine translational fidelity

Methods

- Real-time PCR to assess the expression of ribosomal proteins
- Proteomic analysis to assess ribosomal protein abundance and screen effects on the mutation in the whole proteome
- *In vitro* translation to assess the role of gentamicin binding
- Ribosome quantification
- Fidelity assays

Conclusions

Final conclusions cannot be drawn currently, as this research is still going. Preliminary results suggest that ribosomal protein expression and abundance is not affected by *rplF* mutations. Results also show that gentamicin does not contribute to increased growth rate of *rplF* mutants.

SUPERFICIAL MYCOSIS IN CHILDREN FROM PUEBLA MEXICO

A.P. Espinosa Texis[1], *E.M. Vidal López*[2], *D. Castillo Hernández*[3]
[1]*Benemerita universidad Autonoma de Puebla, ICUAP, Puebla, Mexico*
[2]*Universidad de Sonora, Departamento de Ciencias Quimico Biologicas, Sonora, Mexico*
[3]*Centro de Investigaciones en Biotecnología Aplicada IPN, Microbiología, Tlaxcala, Mexico*

Backgrounds

Within the superficial mycoses that occur in humans, ringworm and white piedra have been described in the infantile stage, the first being the most frequent. The white piedra is associated with diseases that cause immunosuppression as HIV/AIDS among others.

Objectives

The objective was determine the presence of cases clinical of ringworm and white piedra in children of the city of Puebla.

Methods

We´re taken 50 Hair samples in children with clinical lesions compatible with tinea capitis or white piedra. Five were positive to tinea capitis and two was positive for white piedra. The mycological diagnosis was performed by microscopic examination of hair and cultivation of the etiologic agent in agar glucose Sabouraud with and without antibiotics, incubating at 28° C for 15 days. The identification was carried out considering the morphology macroscopic and microscopic of the fungus.

The observation microscopic of the hair to them cases of ringworm showed arthoconidia type endothrix and ectothrix, for the cases of white piedra is observed *structures type ectothrix with filaments and arthoconidia rectangular, ovoid willing in groups.* The culture allowed isolate *Microsporum canis, Trichophyton rubrum*.and *Trichosporon.* Treatment included benzoate benzyl, oral itraconazole and ketoconazole topical.**Conclusions**

The Mycosis surface more frequent in children was the ringworm capitis, followed of the white piedra. Of the antifungal agents used the ketoconazole presented the best results.

ADHESION OF PATHOGEN BACTERIA TO POLYSTYRENE, SKIN AND GUT MUCUS OF GILTHEAD SEABREAM (SPARUS AURATA), INFECTIOUS CAPACITY ON SAF-1 CELL LINE AND RESISTANCE TO ANTIBIOTICS

D. Ceballos-Francisco[1], B.H. Said[2], G. Francisco[1], C. Alberto[1], M.A. Esteban[1]
[1]University of Murcia, Cell Biology & Histology, Murcia, Spain
[2]University of Gabès, LaLaboratory of Microbiology, Gabès, Tunisia

Backgrounds

Giving increasing worldwide demand of seafood, there is an escalating need for research to identify solutions to fish health problems without any offensive uses of antibiotics.

Objectives

The capacity of ten pathogenic bacteria isolated from fish and marine environment, to adhere to polystyrene, skin mucus and gut mucus of gilthead seabream (*Sparus aurata*) was investigated. The pathogenicity of these strains was tested *in vitro* on gilthead seabream fibroblast cell line SAF-1. Additionally, the sensitivity of the isolates was tested for thirteen antibiotics having different mode of action.

Methods

Vibrio harveyi H28 (HQ449775) and *Halomonas venusta* (HQ727663) displayed a strong adhesion to polystyrene surface. *Dietzia maris* (HQ425656) has showed a strong adhesion to skin mucus substratum. Around 40% of isolates were moderately adherents. Interestingly, for gut mucus, there were no strongly adherents bacteria. For infectivity test, *D. maris* (HQ425656), *V. harveyi* H28 (HQ449775) and *Aeromonas bivalvium* (DQ504430) decreased the SAF-1 cells viability to 89% after only 3 hours of exposure. All isolates presented resistance to sulfonamide and 60% were resistant to both sulfonamide and penicillin G.

Conclusions

Present findings could be relevant in fish aquaculture and underscore the importance of the linkage between adhesion capacity, *in vitro* infectivity, and antibiotic susceptibility of pathogen bacteria to avoid fish diseases that causes serious economic lost in aquaculture.

IDENTIFICATION OF BACTERIAL STRAINS FROM GUT MICROBIOTA ASSOCIATES WITH DIARRHEOGENIC E. COLI INFECTION

F. Mauricio[1], I. Mariana[1], G. Pablo[1], R.M. Ramon[2], V. Roberto[3]
[1]Centro de Estudios Moleculares,
Departamento de Pediatría- Hospital Luis Calvo Mackenna- Universidad de Chile, Santiago, Chile
[2]IMEDEA, Departament de Ecologia i Recursos Marins, Illes Balears, Spain
[3]ICBM, Facultad de Medicina- Universidad de Chile, Santiago, Chile

Backgrounds

Diarrheagenic *Escherichia coli* (DEC) strains remain a major cause of diarrhea in children under 5 years of age. DEC pathogenesis depends on the interaction of the pathogen with environmental factors such as the intestinal microbiota. Several studies have shown changes in the composition of the microbiota in diarrheal infections and that strains of the intestinal microbiota may participate in the pathogenic process of DEC strains. However, there is no much information of specific microbiota strains that might be involved in DEC infection.

Objectives

To identify cultivable strains of intestinal microbiota associated with DEC infections in children under 5 years of age

Methods

120 stool samples from children between 1 and 5 years of age analyzed by FilmArray GI® test were grouped whether they were positive for one of the DEC pathotypes, an enteric virus or a bacterial pathogen other than DEC; stool samples negative for pathogens and stool samples from healthy children negative for pathogens were included. In all samples, 16S ribosomal gene was sequenced to identify operative transcriptional units (OTUs) associated with each ethiological group. These OTUs were compared to a database of cultivable bacterial species, to determine the major species of the microbiota associated with each group.

Conclusions

We found variations in the microbiota in the different groups analyzed. In DEC group, strains belonging to the phylum *Firmicutes*, *Preoteobacteria* and *Bacteroidetes* were identified, the latter two being predominant in relation to the rest of the groups. Strains of *Bacteroides*, *Parabacteroides*, *Ruminococcus* and *Veilonella* present in greater proportion in the DEC group.

SCREENING OF ANTAGONISTIC ACTIVITY OF LACTIC ACID BACTERIA LACTOBACILLUS SPP. AGAINST DRUG-RESISTANT STRAINS OF KLEBSIELLA SPP.

T. Fedorova[1], I.V. Rozhkova[2], E.Y. Agarkova[3], A.V. Begunova[4], K.A. Ryazantseva[3], A.G. Kruchinin[3]
[1]Federal State Institution "Federal Research Centre "Fundamentals of Biotechnology" of Russian Aca demy of Sciences, Bach Institute of biochemistry, Moscow, Russia
[2]Federal State Budgetary Scientific Institution "All-Russian Research Institute of Dairy Industry, Microbiology, Moscow, Russia
[3]Federal State Budgetary Scientific Institution "All-Russian Research Institute of Dairy Industry", Milk protein concentrates laboratory, Moscow, Russia
[4]Federal State Budgetary Scientific Institution "All-Russian Research Institute of Dairy Industry", Microbiology, Moscow, Russia

Backgrounds

A lot of *Lactobacillus* strains show antagonistic activity against the majority of pathogenic microorganisms including gram-negative bacteria which establish the probability of cross infective episode. *Klebsiella* spp. strains are the most dangerous among them. They often posses multiple antibiotic resistance and herewith resistance determinants circulate among different strains.

Objectives

The aim of the present study is screening of antagonistic activity of lactic acid bacteria strains collection against drug-resistance strains of *Klebsiella* spp. isolated as the source of hospital infection.

Methods

Lactobacillus spp. strains were identified by genetic-molecular method using the analysis of nucleotide sequence of 16S rRNA gene. The method of growing mixed populations in comparison with test strains growth in monoculture was used for determination of lactic acid bacteria antagonistic activity. Cultivation of strains was carried out on MRS medium, thermostating at 37C within 24-48 hrs.

Conclusions

The apparent antagonistic activity against hospital *Klebsiella* spp. strains of three lactic acid bacteria - *Lactobacillus rhamnosus*, *Lactobacillus reuteri* and *Lactobacillus acidophilus* - has been proved. Within the first day of joint cultivation with *L. acidophilus*, *L. rhamnosus* and *L. reuteri* inhibition of the studied *Klebsiella* spp. strains compounded 13-28%, 36% and 60%, respectively; within the second day – 57-91%, 76-83% and up to 72%, respectively. Thus the discovered lactic acid bacteria strains can be used for development of antibiotic preparations and medical foodstuffs and for maintenance of patients health staying in hospitals especially on the background of immunosuppressive and radiation therapy.

[7]Antiplague Research Institute, Laboratory of Microbiology of Yersinia pestis, Rostov-on-Don, Russia
[8]Saratov State Medical University named after V.I. Razumovsky, Department for Infectious Diseases, Saratov, Russia

Backgrounds

Y. pestis, a gram-negative bacterium causing plague, a deadly infectious disease. The outer membrane Pla protease is considered to be the virulence-associated multifunctional protein playing a critical role in pathogenesis of bubonic and pneumonic plague and providing detectable levels of the relevant antibodies (anti-Pla-Ab) in convalescent sera of human patients that survived plague infection.

Objectives

The goal of this study was to evaluate both human humoral and cellular immune responses to Pla antigen followed by mapping of linear immune-reactive epitope(s).

Methods

Sera from donors (n=34) with multiple immunizations with LPV, as well as from healthy non-immune controls (n=17), were analysed in ELISA for the presence of anti-Pla-Ab using highly purified recombinant Pla antigen. A lymphocyte proliferation assay and cytokine profile (IFN-gamma/TNF-alpha/IL-4/IL-10/IL-17A) in response to *in vitro* stimulation with recombinant Pla were also conducted. B-cell immune-reactive epitope mapping of the target antigen was performed in ELISA by using a library of 59 overlapping synthetic peptides (GenScript, USA).

Conclusions

We found that fifteen out of 34 (44.1%) sera samples from vaccinees and seventeen out 17 (100%) derived from naïve donors were positive for the presence of anti-Pla-Abs (titers ranged from 1:50-1:800) demonstrated the marked cross-reactivity of the Pla antigen. *In vitro*-proliferative response to Pla revealed a negligible production of IFN-gamma/TNF-alpha/IL-10. In vaccinees Pla reduced of IL-4 by 3.4-fold, but increased of IL-17A by 14.7-fold pointing to a possible Th17-polarisation of Pla-related immune response. Nine potential immune-reactive 15-mer peptides were identified by library screening.

Pathogens / Pathogenicity

DETECTION OF CHLAMYDIA TRACHOMATIS IN ABORTED CATTLE

V. Feodorova[1,2], *Y. Saltykov*[1,2], *T. Polyanina*[1], *S. Zaitsev*[1], *O. Ulianova*[1,3]
[1]*Saratov Scientific and Research Veterinary Institute- Federal Research Center for Virology and Micro biology- Branch in Saratov, Department for Zoo and Zooanthroponotic Bacterial Infections, Saratov, Russia*
[2]*Saratov State Agrarian University named after N.I. Vavilov,*
Department for Microbiology- Biotechnology and Chemistry, Saratov, Russia
[3]*Saratov State National University, Scientific Bacteriological Laboratory, Saratov, Russia*

Backgrounds

The obligatory intracellular bacterium *C. trachomatis* (CT) is primary known as the causative agent of Chlamydia genital infection in humans. However, some studies have reported that CT was proved to be detected in aborted livestock including cattle (Ozbek et al., 2008). Moreover, human biovars of CT is now considered as risk factors and severity of active trachoma associated with familial cattle ownership.

Objectives

The aim of this study was to determine whether CT could be detected in aborted cattle suspected in chlamydial infection.

Methods

Sera and blood from 21 aborted breeding cows were tested for either specific chlamydial antibody in ELISA or DNA in real-time PCR (InterLabService&Fractal-Bio, Russia) and microscopically. Additionally, each specimen was examined for the presence of CT-specific plasmid followed by PCR target sequencing, as well as PCR testing for *Campylobacter/Listeria/Salmonella/Brucella/Leptospira spp/Toxoplasma gondii/Yersinia pseudotuberculosis*.

Conclusions

We found specific chlamydial antibody in sera of 21/21 cows (100%). No specific DNAs of four the most common Chlamydia species, namely *Chlamydia psittaci/Chlamydia felis/Chlamydia abortus/Chlamydia caviae* were detected. However, detectable concentration of DNA for the presence of CT-specific plasmid target was easily revealed in 8/21 cows (38.1%) that was (8/8, 100%) confirmed by sequence. These PCR&sequencing results were strongly correlated with those obtained by both ELISA and microscopy. No DNA of other pathogens that in known as causative agent for common abortogenic infections were detected. We believe that *C. trachomatis* could play a certain role in zoonotic chlamydial infection as either a single pathogen or co-infection with other Chlamydia which is difficult to detect due to their low concentration in clinical specimens.

[5]Bioisi - Biosystems & Integrative Sciences Institute- Campo Grande, Faculdade de Ciências- Universidade de Lisboa, Lisboa, Portugal

Backgrounds

Xanthomonas arboricola pv. *juglandis* (*Xaj*) is a plant pathogen responsible for bacterial blight in walnut trees (*Juglans regia*), and also associated with brown apical necrosis and vertical oozing canker. Detection and identification of *Xaj* are still carried out mainly via culture-based methods, which lack the specificity and time-efficiency characteristic of DNA-based methods. Despite previous efforts, *Xaj*-specific DNA-based detection and identification assays are currently unavailable.

Objectives

This work focused on the development and validation of culture-independent methods for rapid and efficient detection and identification of *Xaj*. For this purpose, *Xaj*-specific DNA markers were selected and applied in PCR- and hybridization-based assays.

Methods

Nine *Xaj*-specific markers were selected using dedicated *in silico* approaches. The use of a high throughput dot blot platform allowed to validate the specificity of the markers, and also to determine strain-specific hybridization patterns. The application of the most promising markers in a multiplex PCR allowed to efficiently detect *Xaj* in naturally infected walnut leaves and fruit samples.

Conclusions

The selected markers were shown to be useful in both hybridization and PCR-based assays. While the obtained hybridization patterns allowed prompt identification of different *Xaj* clonal lineages, the multiplex PCR was validated as an effective culture-independent method for detection of *Xaj* in symptomatic walnut field samples. Ultimately**,** the proposed methods might be particularly useful for routine phytosanitary screenings, to disclose alternative host species and the pathogen lifecycle outside the plant hosts, and, attending to the strain-specific profile of the hybridization patterns, to assess *Xaj* diversity and epidemiology.

HOST-AEROMONAS INTERACTION: INFLAMMATORY RESPONSE IN THP-1

A. Fernández Bravo[1], *M.J. Figueras*[1]
[1]*Universitat Rovira i Virgili, Ciencias Médicas Básicas, Reus Tarragona, Spain*

Backgrounds

Case reports have identified *Aeromonas* as an emerging pathogen that cause a wide spectrum of diseases in humans, mainly gastroenteritis, septicemia and wound infections. In spite of the worldwide distribution of *Aeromonas*, its relevance to human health and the way in which the pathogen causes septicemia and death remains poorly understood, besides little is known about its interaction with the human immune system. Monocytes act as first defense against bacterial infections playing a critical role in recognizing and responding to these pathogens. However, so far the impact of *Aeromonas* on human monocytes has not been investigated.

Objectives

To investigate the effect of *Aeromonas* on human monocytes.

Methods

As a first step we have designed an *in vitro* model of infection using a cell line of human monocytes (THP-1) and representative strains of clinical and environmental *Aeromonas*. We tested different infectious doses and incubation times, including in all the experiments a well know *Vibrio vulnificus* strain (CECT 4999) as positive control.

Conclusions

Preliminary results demonstrated that *Aeromonas* showed a tendency to activate a strong immune response in monocytes, transcriptional analysis showed an upregulation in the expression of a variety of immune-related genes including those involved in pathogen recognition, cytokines, chemokines and apoptosis. The latter genes were clearly expressed as derived from the observed degree of cell damage and apoptosis. To determine more accurately these findings, we are studying more strains to clarify if there exists a distinct immune response in different *Aeromonas* species that could explain their differential prevalence in human infections.

NEW ANTI-BIOFILM PERSPECTIVES OF THE EUGENOL FOR BIOMEDICAL APPLICATIONS

M.C. Fernández Calderón[1,2], M.T. Blanco Roca[1,2], M.A. Galán Ladero[1], M.T. Blanco Blanco[1], A.C. Gómez García[1,2], C. Pérez Giraldo[1,2]
[1]Faculty of Medicine. University of Extremadura., Biomedical Sciences, Badajoz, Spain
[2]Biomedical Research Centre in Bioengineering Biomaterials and Nanomedicine Network, CIBER-BBN, Badajoz, Spain

Backgrounds

Biomaterials associated infections have a great impact in terms of morbidity, mortality and medical costs. *Staphylococcus epidermidis*, is the microorganism most frequently isolated in these infections, due to exhibits resistance growing in biofilm. Eugenol (E) is a phenolic derivative with analgesic and anti-inflammatory properties; also reduce pain in adjacent tissues. The associating with the mucolytic N-acetylcysteine (NAC) will be enables better therapeutic applications.

Objectives

Evaluate effectiveness of E + NAC for the control of biofilm-associated infections.

Methods

The minimum inhibitory concentration (MIC) of the E alone or in combination with NAC against two biofilm producing strains, *S. epidermidis* ATCC 35984 and ATCC 35983 was determined. The influence of subhinhibitory concentrations (sub-MIC) on the growth and biofilms formation was evaluated. The relationship between these two parameters by "slime index" (SI) was also calculated.

Results: The combination of both compounds did not modify the MIC for any of the strains (MIC = 2 mg / ml) compared to value of then alone. Biofilm production by the highly biofilm-producing strain, ATCC 35984, was increased in the presence of E, even though the growth remained the same or decreased. However, the association of E + NAC reduced the biofilm formation and the IS decreased up to 84.3% with respect to control.

Conclusions

The E + NAC association presented a high capacity to decrease the *S. epidermidis* biofilm formation, which makes them an anti-biofilm alternative for the biomaterials-associated infections control.

Pathogens / Pathogenicity

PRESENCE OF VIRULENCE FACTORS IN STRAINS OF CANDIDA KRUSEI COLLECTED FROM HEMOCULTURES. STUDY COMPARED TO CANDIDA ALBICANS.

M.A. Galán-Ladero[1], M.T. Blanco-Blanco[1], M.C. Fernández-Calderón[1,2], M.T. Blanco[1,2], C. Pérez-Giraldo[1,2], A.C. Gómez-García[1,2]
[1]University of Extremadura, Biomedical Sciences- Microbiology, Badajoz, Spain
[2]Biomedical Research Center, Bioengineering- Biomaterials and Nanomedicine, Badajoz, Spain

Backgrounds

Candida krusei cause candidemia although with low incidence.

Objectives

In this study we evaluated virulence factors as Cellular Surface Hydrophobicity (CSH), Polystyrene Adherence (PA), Biofilm Formation (BF) and Secreted aspartyl-proteases (Saps) in *C. krusei*, compared to *Candida albicans*

Methods

C. krusei (N=3) and *C. albicans (N=16)* collected from hemocultures during two years were used. Two *C. krusei* strains were isolated from oncohaematologic patients and one from a neutropenic neonate

Virulence factors: HSC was assessed by the MATH method (3). *PA* on microtiter-plates with PBS yeast suspension (1). *BF* on microtiter-plates with RPMI-1640 cultures (4). *Saps activity* on plates with YCB-BSA medium evaluated by Pz index (2).

CSH: All *C. krusei* were hydrophobic with 71.6±14.4% CSH vs 6.8±4% in *C. albicans*

PA: *C. krusei* and *C. albicans* were adherent, both with similar adherent layer (OD: 0.06-0.07)

BF: All *C. krusei* tested were non-biofilm producing, giving identical OD to PA, while *C. albicans* BF achieves a 10-fold OD (0.63± 0.24)

Saps: *C. krusei* strains do not have Saps activity, unlike high activity of *C. albicans*

Conclusions

Virulence factors constitute the mechanisms used to avoid host defences. *C. krusei* are adherent, related to hydrophobicity. The absence of other factors such as non-BF ability, nor protease activity, suggests low virulence levels. This is consistent with the presence of infections in immunocompromised patients

Acknowledgments Junta de Extremadura (GR15025) and FEDER funds

[2]Bionanoplus S. L., -, Noain- Navarra, Spain
[3]Montana State University, Center for Biofilm Engineering, Bozeman- Montana, USA

Backgrounds

Resistance to antibiotics poses a “major global threat” to public health according to the World Health Organization. The increasing emergence of bacterial clones insensitive to these drugs greatly limits the therapeutic options and highlights the urgent need to develop novel and effective treatments for infections caused by these microorganisms. We hypothesized that subinhibitory concentrations of a permeability-increasing antimicrobial peptide (AMP) could enhance the activity of efflux pump inhibitors (EPIs) and sensitize bacteria to antibiotics that are efflux substrates.

Objectives

Our objective was to measure the ability of a model AMP, polymyxin B nonapeptide (PMBN), to synergize with antibiotics such as aztreonam, ceftazidime, doxycycline, levofloxacin, piperacillin or azithromycin in the presence of EPIs (1-(1-naphthylmethyl)-piperazine (NMP) or Phenylalanine-Arginine β-Naphthylamide (PAβN)). Tests were performed using planktonic and biofilm-forming cells of MexAB-OprM overexpressing *Pseudomonas aeruginosa* strains.

Methods

To characterize the antimicrobial activity of the combinations, we used conventional MIC testing, checkerboard analysis, growth inhibition curves and anti-biofilm activity measured by viable counts on biofilms grown in a reactor operating in the turbulent flow regime.

Conclusions

We demonstrated for the first time that PMBN greatly enhanced EPIs activity against two different MexAB-OprM overproducing strains and sensitized them to all tested antibiotics. The selected triple combination (Azithromycin/PAβN/PMBN) caused a 10 million fold reduction in biofilm forming cells. This phenomenon can be exploited to sensitize efflux pump overexpressing strains of *P. aeruginosa* to antibiotic substrates of those mechanisms of resistance.

IDENTIFICATION OF GENOMIC ISLANDS IN CHILEAN PISCIRICKETTSIA SALMONIS STRAINS AND ANALYSIS OF GENE EXPRESSION INVOLVED IN VIRULENCE

J. Figueroa[1], *F. Lagos*[1], *C. Cartes*[1], *D. Haussmann*[1]
[1]*Instituto de Bioquímica & Microbiología., Biochemistry & Microbiology, Valdivia, Chile*

Backgrounds

Piscirickettsiosis is a septicemic disease that affects salmonids. *P. salmonis* is a non-encapsulated, Gram-negative immobile pleomorphic, but generally coccoid bacteria with a diameter between 0.2 and 1.5 microns and is a facultative bacteria.

Objectives

The aim of this study was to bioinformatically identify genomic islands in genomes from different chilean strains of *P. salmonis*, in order to later select probable genes involved in the infective process *in vitro*.

Methods

We identified, characterised and bioinformatically analysed genomic islands in field strains of *P. Salmonis*, using the bioinformatic software PIPS, that uses the characteristics of the islands of pathogenicity to identify them.

Conclusions

We analysed 9 partially sequenced genomes in different new field strains, and compared them with the LF-89 genome, selecting a genomic island present in all of them. We then evaluated the relative expression of three genes present in that island. From the obtained results, we conclude that the expression of the *tcf* gene is directly proportional to the cytopathogenicity *in vitro* of the bacteria; the product of the *dnsa* gene could contribute to its pathogenicity. The product of the gene *liso* is necessary for the virulence process and could have functions in early stages of infection. Regarding the strains, the IBM-040 strain showed a significant increase in the expression of all the genes in the study. Contrarily, LF-89 only presented a significant increase in expression of the gene *liso*, which correlates with the cytopathogenicity in vitro observed in the SHK-1 cells.

VIRULENCE-ASSOCIATED TRAITS OF ACHROMOBACTER SPECIES OF CF AND NON-CF ORIGIN

B. Filipić[1,2], M. Malešević[2], Z. Vasiljević[3], J. Lukić[2], K. Novović[2], M. Kojić[2], B. Jovčić[2,4]
[1]Faculty of Pharmacy- University of Belgrade, Department of Microbiology and Immunology, Belgrade, Serbia
[2]Institute of molecular genetics and genetic engineering- University of Belgrade, Laboratory for molecular microbiology, Belgrade, Serbia
[3]Mother and Child Health Care Institute of Serbia „Dr Vukan Cupic“, Laboratory for clinical microbiology, Belgrade, Serbia
[4]Faculty of Biology- University of Belgrade, Biochemistry and Molecular Biology, Belgrade, Serbia

Backgrounds

Achromobacter spp. are oportunistic pathogens that can lead to various infections in immunocompromised individuals as well as in cystic fibrosis (CF) patients. Beside the fact that incidence of achromobacterial disease continues to rise, little is known about virulence factors of this species. From 2012 to 2015, we collected 69 clinical isolates of *Achromobacter* spp. from patients with CF (CF isolates, n=32) and patients receiving care for other health conditions (non-CF isolates, n=37) in order to examine their virulence traits.

Objectives

The main goal of this study was to investigate virulence potential of both CF and non-CF *Achromobacter* spp. isolates through caracteristics such as ability of biofilm formation, motility and binding affinity to mucin, collagen and fibronectin.

Methods

Motility of isolates was examined on plates with low content of agar, while biofilm formation assay was performed in 96-well microtiter plates. Mucin, collagen and fibronectin binding abilities were also tested in microtiter plates with wells coated with a suitable substrate.

Conclusions

CF isolates from this study were less motile compared to non-CF isolates. Diminished motility among our CF isolates probably serves as an competitive advantage in establishing an infection in the airways. About one third of the isolates were classified as strong biofilm producers, and the proportion of CF and non-CF isolates with the ability to form biofilm was almost identical. At the other hand, CF group of isolates exhibited higher binding affinity to mucin, collagen and fibronectin, making CF isolates apparently more virulent compared to the non-CF group.

[4]State Research Center for Applied Microbiology & Biotechnology, Tularemia microbiology, Obolensk, Russia
[5]State Research Center for Applied Microbiology & Biotechnology, Particularly dangerous infections, Obolensk, Russia
[6]State Research Center for Applied Microbiology & Biotechnology, Tularemia infection, Obolensk, Russia
[7]State Research Center for Applied Microbiology & Biotechnology, Director, Obolensk, Russia

Backgrounds

Live tularemia vaccine requires further improvement in connection with instability and residual reactogenicity. *iglC* and *sodB* genes are encoded products which necessary for survival and multiplication of bacteria inside the phagocytes and inactivation of oxygen and nitrogen free radicals. Derivative strains of *F.tularensis* 15NIIEG with one copy of the *iglC* gene deletion, *recA* gene deletion (to reduce the amounts of recombination) and/or with a modified *sodB* gene were constructed.

Objectives

Comparison between mice groups immunized with various vaccine strain derivatives in the protection level against challenge with *F.tularensis* Schu and lymphocytes specific activation in response to restimulation with *F.tularensis* antigens.

Methods

BALb/c mice were immunized with vaccine strain or its derivatives and then on 28 day were challenged with *F.tularensis* Schu. Blood and spleens from five mice of each immunised group were obtained. Lymphocytes were incubated in the presence of *F. tularensis* antigens with subsequent cytometric and ELISA analysis of activation and co-stimulatory molecules and cytokine activities of cells.

Conclusions

Comparative studies showed that maximum protection against challenge with *F.tularensis* Schu was observed in mice previously immunized with *F.tularensis* 15/10Δ23sodBrecA. In this mice group was found the most significant IFN-γ secretion by T-helpers and B-lymphocytes in response to restimulation by antigens of *F. tularensis*. The level of lymphocyte proliferative activity and the number of antibodies to *F. tularensis* antigens in all animal groups were identical. These data confirm the importance of IFN-γ in protection against infection with *F.tularensis* Schu - highly virulent for humans and other mammals.

EFFECT OF PROLONGED ANTIBIOTIC USE ON THE ADULT GUT RESISTOME

E. Fletcher[1], L. Imamovic[1], M. Ellabaan[1], E. van der Helm[1], W. van Schaik[2], M. Sommer[1]
[1]Technical University of Denmark, Novo Nordisk Foundation Centre for Biosustainability, Lyngby, Denmark
[2]University Medical Center Utrecht, Department of Medical Microbiology, Utrecht, The Netherlands

Backgrounds

Antibiotics play a major role in treating minor infections and are also used to decontaminate the digestive tract of patients on admission at the hospital to prevent the risk of infection during surgery.

Objectives

Antibiotic use, however, has profound effects on the gut microflora resulting in the selection of bacteria that are resistant to the antibiotics administered. We, therefore, investigated changes in the resistome of adults given prolonged exposure to multiple antibiotics.

Methods

We used functional metagenomic selections on 14 antibiotics to identify known and novel antibiotic resistance genes that constitute the gut resistome of adults admitted at the Intensive Care Unit (ICU). Functional annotation of the patients' resistomes revealed the presence of 47, 89 and 99 unique gene types found in the CARD, ARDB and Resfams databases respectively. Beta-lactamases and aminoglycosides represented the most abundant resistance gene class. This can be linked to prolonged exposure of adult ICU patients to beta-lactam and cephalosporin drugs as well as selective digestive tract decontamination (SDD) treatment containing aminoglycosides. By comparing this resistome to an *in silico* analysis of two other human gut resistomes we confirmed that antibiotic use significantly reduced the genetic diversity of the resistome as specific resistance genes were selected by the antibiotics administered. By further exploring the resistome of the adult ICU patients, we also identified previously uncharacterized (novel) genes that conferred resistance to beta-lactams, aminoglycosides and fosfomycin.

Conclusions

Our study, therefore, presents a comprehensive description of the effect of prolonged antibiotic use on the adult gut resistome indicating that antibiotic use alters the diversity of the gut resistome.

VIBRIO HARVEYI: AN EMERGENT PATHOGEN IN MARINECULTURE

O. Tomás[1], A. Llorens[2], D. Liz[2], C. Amaro[2], B. Fouz[2]
[1]University of Valencia, Department of Microbiology and Ecology and ERI Biotecmed, Burjasot-Valencia-46100., Spain
[2]University of Valencia, Department of Microbiology and Ecology and ERI Biotecmed, Burjasot- Valencia- 46100., Spain

Backgrounds

In the last two years, *Vibrio* strains have been isolated from epizootics occurred in European sea bass (*Dicentrarchus labrax*) farms located on the Iberian Peninsula coast. Given that fish had been vaccinated against *V. anguillarum*, the emergence of another pathogenic vibrio was occurring. Within the *Vibrio* genus, *V. harveyi* is a recognized secondary pathogen of marine vertebrates and invertebrates, including important cultured species.

Objectives

i) To identify and characterize the fish pathogenic isolates; ii) To study their virulent potential both “in vitro” and ” in vivo” conditions.

Methods

We have identified the *Vibrio* isolates by using phenotypic and genotypic (including specific PCR protocols) tests and have characterized their production of exoenzymes involved in virulence. Moreover, we have assessed their ability to survive in fish and human plasma and their virulent potential for different hosts.

Conclusions

Fish pathogenic isolates, identified as *V. harveyi*, successfully multiplied in plasma of sea bass and were virulent for this species. Furthermore, all strains gave positive results for two fish virulence plasmid markers (*vep20* and *vep07* genes*)* well characterized in the close fish pathogen *V. vulnificus*. In contrast, all strains did not survive in human plasma and were not virulent for mouse. Therefore, *V. harveyi* could be considered an emergent primary pathogen for marine fish that would not represent a risk for Public Health. In order to minimize economic losses in Aquaculture industry, the development of novel specific vaccines would be convenient.

MOLECULAR EPIDEMIOLOGY OF EXTENDED-SPECTRUM B-LACTAMASE-PRODUCING ESCHERICHIA COLI CAUSING BACTERAEMIA IN SPAIN

S.C. Flament-Simon[1], R. Mamani[1], V. García Menéndez[1], C. López[1], M.P. Alonso García[2], J.E. Blanco Álvarez[1], J. Blanco Álvarez[1]
[1]Universidad de Santiago de Compostela, Microbioloxia e Parasitoloxia, Lugo, Spain
[2]Hospital Universitario Lucus Augusti, Microbiology, Lugo, Spain

Backgrounds

Pathogenic *E. coli* are the predominant cause of Gram-negative bloodstream infections and bacteraemia caused by extended-spectrum β-lactamase-producing *E. coli* (ESBLEC) is associated with adverse patient outcomes and increased costs.

Objectives

The objective of this study was to assess the prevalence and molecular epidemiology of ESBLEC causing bacteraemia in a Spanish Hospital over a 23-Year Period (1989 to 2011).

Methods

During 1989 to 2011, 3,260 bacteraemic *E. coli* isolates were studied and 96 (2.9%) ESBLEC were detected and characterized. ESBL enzymes, phylogenetic groups, clonotypes (CHs), sequence types (STs), serotypes and virulence genes were determined.

The most prevalent ESBLs were CTX-M-15 (41.7%), CTX-M-14 (37.5%) and CTX-M-1 (8.3%). Forty-four (45.8%) isolates belonged to phylogroup B2, 18.8% to group B1, 11.5% to group A, 11.5% to group E, 6.3% to group F, 5.2% to group C and 1.0% to group D. Thirty-six STs and 40 CHs were identified. However, 41 (42.7%) of the 96 ESBLEC isolates belonged to the clonal group ST131. The ST131 isolates exhibited a significantly higher virulence score compared with the non-ST131 isolates. All 41 ST131 isolates belonged to phylogroup B2 and 39 belonged to serotype O25b:H4. The other two ST131 isolates belonged to serotypes O16:H5 and ONT:H5. The *H*30Rx subclone accounted for most ST131 isolates (35 CTX-M-15 isolates). Three ST131 isolates belonged to subclone H22 and two isolates to subclone H41.

Conclusions

ST131 was the most antimicrobial-resistant sequence type and the *H*30Rx subclone was responsible for the significant increase of ESBLEC isolates since 2006.

GENOME SEQUENCE OF ST131 ESCHERICHIA COLI STRAIN ENCODING COLISTIN RESISTANCE DETERMINANT MCR-1 ISOLATED FROM PORK MEAT: COMPARISON WITH HUMAN CLINICAL ST131 ISOLATES

I. García Meniño[1], M. Sergeant[2], D. Díaz Jiménez[1], A. Herrera Estévez[1], S. Viso González[1], L. Costoya Seco[1], M. Blanco Álvarez[1], A. Mora Gutiérrez[1]
[1]Universidad de Santiago de Compostela, Microbioloxía e Parasitoloxía, Lugo, Spain
[2]University of Warwick- Warwick Medical School, Microbiology and Infection Unit, Coventry, United Kingdom

Backgrounds

Sequence type 131 (ST131) is one of the successfully spread *Escherichia coli* groups among extraintestinal pathogenic *E. coli* (ExPEC). The plasmid-mediated colistin resistance mechanism MCR-1 has been recently described in *E. coli* isolates. Presently, only four ST131 *E. coli* strains carrying *mcr-1* have been reported.

Objectives

The aim of this study was to analyze and compare a colistin-resistant *Escherichia coli* ST131 isolated in Spain in 2011 from pork meat with human clinical isolates.

Methods

By conventional molecular typing, the *mcr-1* carrying *E. coli* isolate LREC-109 was O25b:H4-B2-ST131/PST43, *fimH298 papGIII cdtB iutA iucD iroN kpsMII-K5 cvaC iss traT ibeA malX usp*.

LREC-109 and 11 highly similar ST131 isolates (PFGE similarity >84,6%) were whole genome sequenced. In the Minimum Spanning Tree of the core genome analysis based on the cgMLST scheme from Enterobase (https://enterobase.warwick.ac.uk/), 7 human clinical isolates included in the analysis showed 37-131 differences compared to LREC-109, and 124-160 SNPs in the core genomic regions present in 90% of the 12 compared genomes. PlasmidFinder and ResFinder tools (http://www.genomicepidemiology.org/) showed the presence in LREC-109 of IncHI2 (ST4) and IncF (F2:A-:B-) plasmids, as well as several resistance genes.

Interestingly, we have detected in Enterobase a human clinical ST131 genome from an *E. coli* isolated in UK in 2010, showing only 10 differences in the cgMLST comparison with LREC-109, and 51 SNPs.

Conclusions

We report the presence in Spain of a colistin-resistant ST131 strain from pork meat, carrier of a wide number of virulence genes, MDR, and sharing close relationship with human isolates.

Pathogens / Pathogenicity

ENTEROCOCCUS FAECIUM VESICULOGENESIS: IS A MECHANISM TO EXPORT PERIPLASMIC PROTEINS

M. Garcia Solache[1], *L.B. Rice*[1]
[1]*Rhode Island Hospital, Medicine, Providence, USA*

Backgrounds

Background: *Enterococcus faecium* is an important agent of nosocomial infections. Many clinical *E. faecium* strains are resistant to β–lactam antibiotics and vancomycin. Resistance to β–lactams is mainly attributed to Pbp5, a low-affinity Class B penicillin-binding protein, but other proteins, such as the recently identified P_5AP, also participate. Although the P_5AP sequence suggests a cytoplasmic location, we had localized it extracellularly associated with Pbp5. The presence of P_5AP in the extracellular milieu suggests a non-classical secretion mechanism.

Objectives

Objectives Identify the mechanism of P_5AP export.

Methods

Methods Membrane-derived vesicles (MV) were purified from E faecium strain C68. The protein content of MV was analysed with Mass Spectrometry. MV preparations underwent P_5AP and Pbp5 western blot. Fluorescently labelled P_5AP was also tracked *in vivo*.

Conclusions

Conclusions: We identified P_5AP as part of MV cargo along with Pbp5. Mass spectrometry indicated that P_5AP was one of the most abundant proteins in MV along with the penicillin binding proteins Pbp5, PonA, Pbp2B and the cell division protein FtsZ. The fluorescently labelled P_5AP localised mainly to the poles and septum. The identification of a novel mechanism for export of P_5AP and other proteins to the periplasmic space might suggest new targets for drug development to help curb antimicrobial resistance.

Pathogens / Pathogenicity

HIGHLY POTENT SYNERGISTIC COMPOSITION OF AN OIL AND HERBAL EXTRACT FOR THERAPEUTIC APPLICATIONS.

V. Gautam[1], *S. Kaur*[1], *L. Singhal*[2], *P. Ray*[1]
[1]*Post Graduate Institute of Medical Education & Research, Medical Microbiology, Chandigarh, India*
[2]*Government Medical College & Hospital, Mocrobiology, Chandigarh, India*

Backgrounds

The present invention discloses a synergistic composition of herbs based oil (Oil based on Herbs A, OHA) and Herb B (HB) whole plant extract with drastically enhanced efficacy as compared to the ingredients alone. In India, these oil & herb are used for non-healing wounds, burns, sinus, blisters, abscess, bite wounds etc. and also applied over infected skin diseases such as hand-foot-and-mouth disease, eczema, syphilis etc.

Objectives

In this study, we checked the anti-bacterial activity of both the herb and oil individually and in combination against four most common non-fermenters.

Methods

The *in vitro* anti-bacterial activity of methanolic extract of OHA and HB was checked against *Acinetobacter baumannii* (ATCC 19606), *Pseudomonas aeruginosa* (ATCC 27853), *Stenotrophomonas maltophilia* (ATCC 13637) and *Burkholderia cepacia* complex (ATCC 25609). Minimum inhibitory concentrations (MICs) & checkerboard assay of MHA and HB were determined using micro broth dilution method in ATCC as well as clinical strains of all the four non-fermenters.

Conclusions

MIC of OHA against the four non-fermenters was found to be 5,000 µg/ml while MIC of HB was 4,500 µg/ml – 9,000 µg/ml respectively in ATCC as well as clinical strains of all these four NFGNB. Surprisingly, no growth at all was observed in checkerboard with different concentrations combinations of MHA and HB. A highly potent antimicrobial effect was obtained after using combinations of MHA and HB resulted in reduction of MIC, approx. 250-500 fold for OHA (i.e. 4,500-9,000/17.5); and approx. 7 million fold for HB (i.e. 5,000/0.0007). It has been patented (Patent no. 201611030748, Intellectual property India).

CHARACTERISTICS OF POLISH PENICILLIN-RESISTANT CLINICAL ISOLATES OF ENTEROCOCCUS FAECALIS

I. Gawryszewska[1], D. Żabicka[2], K. Malinowska[2], W. Hryniewicz[2], E. Sadowy[1]
[1]National Medicines Institute, Department of Molecular Microbiology, Warsaw, Poland
[2]National Medicines Institute, Department of Epidemiology and Clinical Microbiology, Warsaw, Poland

Backgrounds

Enterococcus faecalis is natural part of human microflora but also a common cause of hospital infections. Nosocomial *E. faecalis* strains are predominantly grouped in high-risk enterococcal clonal complexes (HiRECCs). Penicillin-resistant isolates of *E. faecalis* remain rare, however the number of such isolates reported to the National Reference Centre for Susceptibility Testing recently increases.

Objectives

The objective was to perform analysis of Polish penicillin-resistant hospital isolates of *E. faecalis* to elucidate the path of emergence of this strains.

Methods

Antimicrobial susceptibility was evaluated by broth microdilution and Etest. The presence of pheromone-responsive plasmids was investigated by the clumping test, and PCR detection of plasmid-specific genes. Biofilm formation was determined as adherence to polystyrene plates. The relatedness among isolates and identification of clonal complexes was established by multilocus sequence typing (MLST) and eBURST analysis with the data from the MLST database. The β-lactamase production was examined by a cefinase test. The penicillin-binding protein *pbp5* gene was sequenced to search for putative mutation(s).

Conclusions

Polish penicillin-resistant clinical *E. faecalis* isolates were multidrug resistant. The majority of isolates formed biofilm, important for virulence and persistence in hospital environment. While the production of aggregation substance was observed for few isolates, genes of pheromone plasmids were commonly detected, indicating the potential of such strains to disseminate resistance determinants both associated with such plasmids and by mobilization of chromosomal genes. Penicillin resistance emerged in HiRECCs due to *pbp5* mutations. The acquisition of penicillin resistance by HiRECCs may be the next step in the evolution of *E. faecalis* as nosocomial pathogen.

ERWINIA AMYLOVORA: A GLOBAL PHAGE HOST RANGE STUDY USING STANDARDIZED QUANTITATIVE PCR

S. Gayder[1], A. Castle[2], A. Svircev[3]
[1]Brock University, Centre for Biotechnology, St. Catharines, Canada
[2]Brock University, Department of Biological Sciences, St. Catharines, Canada
[3]Agriculture and Agri-Food Canada, Science and Technology Branch, Vineland, Canada

Backgrounds

Erwinia amylovora is a pathogen of commercially grown pear and apple trees. Bacteriophages, isolated from orchard soils, were previously combined with the epiphyte *Pantoea agglomerans* to form an effective biological control agent.

Objectives

A standardized quantitative PCR (qPCR) host range protocol was developed to study the ability of 5 *Myoviridae* and 5 *Podoviridae* phages, isolated in Canada, to replicate in 99 *E. amylovora* and 30 *P. agglomerans* isolates from North America, Europe, Northern Africa, and New Zealand.

Methods

A standard plasmid, containing amplicons from the bacteriophages, was designed to relate the cycle threshold in qPCR to DNA copy number for rapid phage quantification. All bacterial isolates were inoculated with phage at a low multiplicity of infection and incubated for 8 h. This standardized qPCR was used to determine each host's ability to produce phage progeny.

Conclusions

The results showed that while all *E. amylovora* hosts could replicate phage to some extent, 10 isolates from the west coast of North America and one from Poland could only replicate one family of phage. The best hosts increased phage titre up to 7 log units, while these poor hosts increased the titre by less than one log. Additionally, only three *P. agglomerans* hosts could replicate phages from both families, with most isolates being infected only by *Myoviridae* phages. These results showing a broad host range of these 10 tested phages on the pathogen *E. amylovora* and narrow host range on *P. agglomerans* could be used to select the ideal components in the carrier-phage biological control agent.

ADHERENCE OF CANDIDA ALBICANS TO METHYL (POLYMETHYL METHACRYLATE) SURFACES WHEN SUBMITTED TO ATMOSPHERIC-PRESSURE COLD PLASMA

E. Stieven[1], C. Bosi[1], G.C. Lain[2], A. Conde[1], R. Elsemann[1], E. Elsemann[1], J.F. Cano[3], A. Gazzoni[1]
[1]Centro Universitário da Serra Gaúcha, School of Dentistry, Caxias do Sul, Brazil
[2]Plasmar Tecnologia, Departamento de Desenvolvimento, Caxias do Sul, Brazil
[3]Universitat Rovira i Virgili, Mycology Unit- Medical School and IISPV-, Reus, Spain

Backgrounds

Development of methods that modify the denture base surface properties to prevent the adherence of *C. albicans* be a significant advancement in the prevention of Candida-associated denture stomatitis.

Objectives

To investigated the effects of atmospheric pressure cold plasma treatment in early *C. albicans* adherence on heat-polymerized acrylic resin.

Methods

Thirty polymethyl methacrylate specimens were made from heat-polymerized acrylic resin base material. Specimens were prepared as square shaped with a width of 10 mm and 4 mm thickness. All pieces were polished in the upper portion, in low rotation with felt disc. For plasma application, Teflon tube with a mixture gas of argon (98%) and oxigen (2%) was used at a flow rate of 5L/min. Specimens were grouped as follows: fifteen specimens were non-treated (Group A), while the remaining especimens were treated with cold plasma for 120 seconds (Groups B). *C. albicans* (ATCC 90028) was used for fungal adherence studies. After the plasma treatment, specimens were inoculated with a suspension standardized to a concentration of $1x10^6$ CFU/mL. After 24 hours of incubation, the amount of the yeasts adhering to specimen surfaces was evaluated by CFU.

Conclusions

In Group A was observed mean of fungal adhesion equal to 4.84 (2.0-8.1 ± 1.81). In Group B, an average of adhered microorganisms was 0.28 (0.12-0.6 ± 0.10). When Group A was compared to Group B, there was a significant difference ($P < 0,0001$). Teh use of cold plasma seems to be a promising and convenient strategy to prevent the adhesion of *C. albicans* to acrylic resins.

IN VITRO STUDY ABOUT THE ADHERENCE OF CANDIDA ALBICANS TO THREE TYPES OF POLISHING ON COMPOSITE RESIN SURFACES

A. Mondadori Garcia[1], A. Conde[1], C. Boniatti Mussato[1], R. Elsemann[1], E. Elsemann[1], J.F. Cano[2], A. Gazzoni[1]
[1]Centro Universitário da Serra Gaúcha, School of Dentistry, Caxias do Sul, Brazil
[2]Mycology Unit, Medical School and IISPV, Reus, Spain

Backgrounds

Candida albicans is responsible of the exponential growth of *Streptococcus oralis* and *Actinomyces oris* in dental materials as well as of the development of dental caries.

Objectives

To demonstrate the adhesion potential of *C. albicans* on three types of polishing on photopolymerizable composite resin surfaces.

Methods

In light-curing composite resin (Z350XT, 3M®), rectangular-shape samples with dimensions of 10 mm x 5 mm x 30 mm were prepared. They were grouped according to the following criteria: Group A - Sof-Lex sandpaper discs (3M®), Group B - Sof-Lex sandpaper discs (3M®) plus Velvety disc Polifix (TDV®) plus Polishing paste Diamond Excel (FGM®) and Group C - finishing and polishing rubbers for composite resin Jiffy (ULTRADENT®). Specimens were inoculated with a standardized solution of 10^6 CFU/mL of *C. albicans* strain (ATCC 90028). After 24 hours of incubation, the CFU/mL were established for each group. Differences in adherence rates among the groups were compared using one-way ANOVA analysis.

Conclusions

Group A presented a mean of fungal adhesion of $0.03x10^{10}$ (0.013–0.096±0,24). In group B, the adherence was $0,012\ x10^{10}$ (0.008–0.80± 0.02). In group C, the mean of adhesion was $6.50\ x10^{10}$ (5.10–9.50±1.49). Significant difference was observed among groups B and C (P=0.0002). There was significant difference between groups A, B and C with a higher adhesion rates observed on group C (P<0.0001). Increase of surface roughness significantly increases the adhesion rates of *C. albicans* to the surfaces of composite resin, since this microorganism has influence on the exponential growth of *S. oralis- oris* in dental materials.

PHYLOGEOGRAPHY AND POPULATION STRUCTURE OF XANTHOMONAS FRAGARIAE TO IDENTIFY SOURCES AND PATHWAYS OF THIS BACTERIAL PHYTOPATHOGEN THROUGH PLANT MATERIAL TRADE

M. Gétaz[1], M. Krijger[2], J. van der Wolf[2], B. Duffy[1], J. Pothier[1]
[1]Zurich University of Applied Sciences ZHAW, Institute of Natural Resource Sciences, Wädenswil, Switzerland
[2]Wageningen UR, Biointeraction and Plant Health, Wageningen, The Netherlands

Backgrounds

Angular leaf spots are caused by *Xanthomonas fragariae* with particular severe effects under protected cultivation with high-density plots aided by high humidity and sprinkler irrigation systems. *X. fragariae* was first observed in the USA in 1960, in Europe in 1970 and then spread worldwide in strawberry growing regions, causing yield loss of harvested fruits.

Objectives

Due to its quick spread, thought to be due to importation of plant material through trade and more generally of human activities, there is a real need for reliable methods accurately discriminating between strains for crop surveillance, outbreak investigation and establishing disease control strategies.

Methods

As relatively low diversity was observed among 59 *X. fragariae* strains of various geographic and time origins, the discrimination power of several molecular markers was determined. Among these markers for source tracking purpose, variable number of tandem repeats (55 VNTRs) were used as an efficient genotyping method, where numbers of repeats acted as molecular clocks with sufficient resolution to discriminate strains. In addition, clustered regularly interspaced short palindromic repeats (2 CRISPRs) were useful markers, also used in epidemiology and host-bacteria surveys, bringing complementary information for genetic diversity characterization and direction of evolution.

Conclusions

This study highlighted the flux of evolution of *X. fragariae* strains and two main origins of evolution that could be responsible for the world-wide invasion of *X. fragariae*. An understanding on population structures of the quarantine pathogen *X. fragariae* and how the disease can emerge and spread over a given geographical region are trivial for bacterial monitoring.

ANALYSIS OF THE POTENTIAL INVOLVEMENT OF THE PIL FIMBRIAE IN THE ADHESION OF ENTEROPATHOGENIC ESCHERICHIA COLI (EPEC)

F.S. Castro[1], M.A.M. Vieira[1], B.G. Garcia[1], F.T. Romao[1], D. Yamamoto[1], T.A.T. Gomes[1]
[1]Federal University of Sao Paulo, Microbiology- Immunology and Parasitology, Sao Paulo, Brazil

Backgrounds

Enteropathogenic (EPEC) and enteroaggregative (EAEC) *Escherichia coli* are significant diarrheal agents, which produce localized adherence (LA) (mediated by the Bundle-forming Pilus) and aggregative adherence (AA) patterns on HeLa cells, respectively. We have previously identified EPEC strains producing LA and AA-like patterns concurrently (LA/AA-like+). Transfer of an 80-kb plasmid (pGM80), which bears the *pil* operon that encodes a variant-Pil fimbria from one LA/AA-like+ strain (EC404/03, serotype O119:H6) to a non-adherent *E. coli* (MA3456) yield AA-like+ transconjugants carrying pGM80. However, we have also observed that some LA positive (LA+) O119:H6 strains also carry *pil*.

Objectives

To analyze the involvement of Pil in O119:H6 EPEC adhesiveness.

Methods

Three LA+ strains were compared with EC404/03 (LA/AA-like+) concerning their ability to transfer *pil* by conjugation. Transconjugants were tested for HeLa cells adhesion, plasmid profiles and presence of all 14 *pil* genes. Additionally, expression of five essential Pil-assembly genes (*piLN, pilQ, pilR, pilS* and *pilU*) was compared by qRT-PCR between each LA+ strain and the LA/AA+ strain. All transconjugants were non-adherent and devoid of *pil*. Although the LA+ strains carried all 14 *pil* genes, variable expressions of the five *pil* genes tested were observed between each LA+ strain and the LA/AA+ strain, some of which were repressed while others were overexpressed.

Conclusions

A fine regulation of the *pil* genes is probably required for expression of functional Pil fimbriae. Undergoing molecular studies, and immunolabelling and competition assays with specific antisera will further help to elucidate the involvement of Pil in the EPEC AA-like pattern.

[9]National Reference Centre of Legionella, Hospices Civils de Lyon, Lyon, France
[10]University of Melbourne, Microbiology and Inmunology, Melbourne, Australia

Backgrounds

Legionellosis is a severe pneumonia caused by bacteria belonging to the genus *Legionella*. Currently there are 66 species/subspecies described within this genus but over 95% of Legionnaires' disease cases are caused by only two species: *L. pneumophila* and *L. longbeachae*.

Objectives

The purpose of this work was to carry out the largest genomic comparison done until now at the genus level between different *Legionella* species/strains to decipher the genomic components that are responsible of their different capacities for human infection.

Methods

With this aim we have analysed and compared 80 *Legionella* strains belonging to 58 *Legionella* species-subespecies. We have also developed bioinformatics approaches that allowed us to detect new eukaryotic motifs not described before and to predict new putative effectors in all studied species. Moreover we have validated for selected effectors that they are translocated via the Dot/Icm secretion system. Finally the potential virulence capacity of most of the strains has been explored using the human monocytic cell line THP-1

Conclusions

We found that species with higher clinical incidence also display enhanced infectivity *in-vitro*. Comparative genomics showed that presence of the Dot/Icm secretion system and of many eukaryotic like proteins are universal features of this genus. However, among the over 300 Dot/Icm effectors described for *L. pneumophila*, only 7 belong to the genus core genome. In addition our evolutionary analysis indicated that most of the predicted Dot/Icm effectors in the genus *Legionella* have been incorporated trough gene gain events and that loss events are less frequent.

IDENTIFICATION AND CHARACTERIZATION OF DOT/ICM SUBSTRATES WITH EUKARYOTIC CONSERVED DOMAINS IN THE FISH PATHOGEN PISCIRICKETTSIA SALMONIS

F. Gomez[1], O. Arredondo-Zelada[1], F.A. Hanriquez[1], P. Flores-Herrera[1], S.H. Marshall[1]
[1]Pontificia Universidad Católica de Valparaíso, Instituto de Biologia, Valparaiso, Chile

Backgrounds

Piscirickettsia salmonis is a gram-negative facultative intracellular bacterium, the etiological agent of Piscirickettsiosis, an infectious disease that affects the global salmon farming since the late 80's. The recent genome sequencing of different *P. salmonis* strains and natural isolates demonstrates that this agent contains a Dot/Icm Secretion System, homologue to those described for *Legionella pneumophila* and *Coxiella burnetii*. Based upon this information, we have demonstrated that *P.* destabilizes the actin cytoskeleton of the host and that is also able to inhibit the phagosome-lysosome fusion, putatively in a Dot/Icm dependent way.

Objectives

This work was focused in identifying and characterizing Dot/Icm substrates in *P. salmonis*, using *in silico* and subsequently molecular characterization of those putative virulent effectors.

Methods

The *in silico* identification was done using as reference Dot/Icm substrates described for *L. pneumophila* and *C. burnetii*, using as distinctive parameter the Dot/Icm secretion signal. Later, the identified ORFs in *P. salmonis* genome where analyzed in order to find conserved domains using the CDD search, SMART and Motif Search tools. Finally, the ORFs were cloned and expressed as recombinant proteins in order to determine their toxic effect over eukaryotic cells.

Conclusions

We have identified a number of Dot/Icm putative substrates in the *P. salmonis* genome. These proteins contains characteristic eukaryotic conserved domains: i) ankyrin repeats, ii) ADP-Ribosyl Transferase, iii) U-BOX, iv) PKc, v) ubiquitin ligase, vi) patatin, and vii) SEL-1. Expression of these proteins is in two different eukaryotic models: a fish macrophage cell line and in yeast, suggesting their putative role as virulence effectors.

RIBOSWITCH REGULATION OF METHIONINE METABOLISM AND VITAMIN B12 UPTAKE IN MYCOBACTERIA – A ROLE IN PATHOGENESIS?

T. Kipkorir[1], *G. Mashabela*[1], *V. Mizrahi*[1], *D.F. Warner*[1]
[1]*University of Cape Town, Pathology and Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa*

Backgrounds

Mycobacterium tuberculosis (MTB) is thought to recognize fluctuations in specific environmental stimuli within the host, and to respond with corresponding alterations to gene expression and metabolism. Accordingly, the MTB genome contains a large number of regulatory elements which could contribute to this capacity. These include two vitamin B_{12} (B_{12}) riboswitches that have been identified upstream of *metE* – encoding a B_{12}-independent methionine synthase, and *ppe2* – the first gene in a putative operon with the B_{12} biosynthetic genes, *cobQ1* and *cobU*. We showed previously that disruption of the alternative, B_{12}-dependent methionine synthase, MetH, rendered MTB sensitive to B_{12}, presumably via methionine auxotrophy owing to B_{12} riboswitch-dependent suppression of MetE levels.

Objectives

Unlike MTB, MSM is a constitutive B_{12} producer under standard conditions *in vitro*. Therefore, we hypothesized that MetH would be essential in MSM, and that deletion of *metH* would be possible only by *metE* riboswitch inactivation or in a B_{12} deficient background.

Methods

Targeted knock-out of *metH* proved facile in a MSM Δ*cobK* mutant in which *de novo* B_{12} biosynthesis is disrupted. Curiously, however, the double Δ*metH* Δ*cobK* deletion mutant was not sensitive to exogenous B_{12}. Comparative genomic analyses identified additional B_{12} riboswitches controlling two separate BtuFCD-type B_{12} transporters that are present in MSM but not MTB.

Conclusions

These findings suggest that B_{12}-dependent metabolism in MSM is regulated both at the level of cofactor transport and enzymatic function, thus identifying B_{12} uptake as one potential point of departure in the evolution of the pathogenic MTB from the most recent common mycobacterial ancestor.

CANDIDA ALBICANS IS ABLE TO ALTER ENTEROCYTE TIGHT JUNCTIONS THAT ENHANCES ITS TRANSLOCATION THROUGH THE GUT BARRIER

A. Loiselet[1,2], F. Bon[1], A. Ducreux[1], C. d'Enfert[3], B. Hube[4,5], F. Dalle[1,2]
[1]UMR A PAM Univ Bourgogne-Franche-Comte, UFR Sciences de Santé- Bât B3, Dijon, France
[2]Centre Hospitalier Universitaire, Service de Parasitologie Mycologie, Dijon, France
[3]Institut Pasteur- INRA, Unité Biologie et Pathogénicité Fongiques, Paris, France
[4]Leibniz Institute for Natural Product Research and Infection Biology—Hans Knoell Institute, Department of Microbial Pathogenicity Mechanisms, Jena, Germany
[5]University Hospital Jena, Center for Sepsis Control and Care, Jena, Germany

Backgrounds

C.albicans is commensal yeast of the mucosa in healthy humans that can be responsible for disseminated candidiasis, mainly originating from the gut. Deciphering the cellular and molecular mechanisms of the interaction of *C.albicans* with enterocytes is necessary to better understand the basis of commensalism and pathogenicity of the yeast and to improve the management of disseminated candidiasis. Different routes of tissue invasion by *C.albicans* are reported, partly due to differences in the structure of the epithelial layer. The intestinal epithelium consists in a monolayer of enterocytes where adjacent cells are jointed each other through cell junctions. Among those, tight junctions (TJ) ensure integrity and impermeability of the intestinal barrier, limiting invasion of the gut by *C.albicans.*

Objectives

The aim of our work is to investigate the impact of *C. albicans* interaction upon the integrity of the intestinal barrier.

Methods

Permeability of the intestinal barrier is investigated measuring the transepithelial electrical resistance of Caco-2 cell monolayers interacting with *C. albicans*. The organization of the TJ protein complex is studied by (i) monitoring their cellular localization using microscopy and (ii) their cellular distribution by using western blotting and Nano-HPLC. Molecules of the fungus responsible for these cellular alterations are currently under investigation.

Conclusions

Candida albicans is able to disorganize the TJ protein complex, altering the integrity of the intestinal barrier. As a consequence, *C. albicans* enhances its translocation through the gut barrier. Better understanding the first steps of *Candida* invasion will help to find target molecules to prevent its dissemination during severe candidiasis.

SCREENING DISRUPTORS OF THE TOXIN–ANTITOXIN COMPLEX IN STAPHYLOCOCCUS AUREUS

Y. Ota[1], T. Miyamoto[1], A. Yokota[2], S. Tsuneda[1], N. Noda[2]
[1]Waseda University, Department of life science and medical bioscience, Tokyo, Japan
[2]National Institute of Advanced Industrial Science and Technology, Biomedical research institute, Tsukuba, Japan

Backgrounds

Toxin–antitoxin (TA) modules, which are implicated in microbial cell growth and survival, are widespread in prokaryotic cells. These modules comprise toxins, which are harmful to the host cell and antitoxins, which commonly neutralize the cognate toxins by forming these TA complexes. Therefore, TA complexes are considered promising targets for the development of novel antimicrobial agents to combat the rapid spread of antibiotic resistance in major human pathogens such as *Staphylococcus aureus*.

Objectives

Herein, we aimed to identify new antimicrobial peptides directly targeting the MazEF module, a typical TA module, in *S. aureus* by using a high-throughput screening method combining the phage display technique, massively parallel sequencing, and a continuous fluorometric assay.

Methods

We enriched candidate peptides with a high affinity for the MazF toxin by using phage display technology involving repetitive biopanning. The peptide amino acid sequences were comprehensively determined using massively parallel sequencing. Thereafter, we utilized a continuous fluorometric assay to assess the ability of the peptides to liberate the MazF toxin in the presence of the MazE antitoxin.

Conclusions

Using biopanning followed by massively parallel sequencing, we identified several peptides that specifically bind to the MazF toxin, and subsequently, using a continuous fluorometric assay, we revealed that some peptides overcome the inhibitory effect of the MazE antitoxin on the MazF toxin *in vitro*. Our method can be readily applied in the discovery of disruptors of other TA systems using direct binding mechanisms.

COMPARATIVE GENOMICS OF THE WHOLE GENUS TENACIBACULUM REVEALS POTENTIAL NEW VIRULENCE FACTORS IN THE FISH PATHOGEN T. MARITIMUM

J.F. Bernardet[1], D. Pérez-Pascual[2], G. Michel[3], R. Larocque[3], E. Duchaud[1]
[1]Institut National de la Recherche Agronomique, Molecular Virology and Immunology, Jouy-en-Josas, France
[2]Institut Pasteur, Genetics of Biofilms, Paris, France
[3]Sorbonne Universités UMR 8227 CNRS-UPMC,
Integrative Biology of Marine Models- Station Biologique de Roscoff, Roscoff, France

Backgrounds

The genus *Tenacibaculum* currently encompasses 23 species with validly published names. While most *Tenacibaculum* species were isolated from marine animals, macro-algae, tidal flats and the open sea and likely play significant roles in organic matter recycling, a few other species are devastating marine fish pathogens. Among these, *T. maritimum* is a major concern to the marine fish farming industry worldwide.

Objectives

Despite the ecological and economic significance of *Tenacibaculum* species in marine environments, little is known about the molecular traits that define their contrasting lifestyles. Hence, this work aimed at identifying relevant features in relation to their ecological niches, including virulence determinants for the pathogenic species.

Methods

We carried out the complete genome sequencing of the type strains of all available *Tenacibaculum* species and performed extensive comparative genomic studies. These analyses revealed several potential virulence factors using *T. maritimum* as a reference species, among them a chondroitin AC lyase and a sphingomyelinase. The genes coding for these proteins were cloned in the pFO4 vector, and recombinant proteins were produced in soluble form in *Escherichia coli* BL21(DE3). The activity of the purified chondroitin AC lyase was assayed by measuring the increase in absorbance at 232 nm of the reaction products using chondroitin A and C sulfates as substrates. The specific enzymatic activity of the purified sphingomyelinase was evaluated using the fluorimetric Amplex Red Sphingomyelinase assay kit.

Conclusions

Our results yielded significant insights into the evolution of the genus *Tenacibaculum* and provided a unique opportunity to compare environmental and pathogenic species within the same genus. The genomic data encompassing the whole genus will serve as references to facilitate further studies, to devise new genotyping tools for epidemiological surveys, and to help identifying new enzymes potentially of interest, e.g. able to degrade the algal polysaccharides widely used in the food industry or involved in bacterial pathogenesis.

SALMONELLA TYPHIMURIUM REQUIRES SOPB AND SIFA TO SURVIVE INTRACELLULARLY IN A SCV-LIKE COMPARTMENT IN DICTYOSTELIUM DISCOIDEUM

C. Valenzuela[1], *A. Sabag*[1], *Í.M. Urrutia*[1], *M. Varas*[2], *C.A. Santiviago*[1]
[1]*Universidad de Chile, Facultad de Ciencias Químicas y Farmacéuticas, Santiago, Chile*
[2]*Universidad de Chile, Facultad de Ciencias, Santiago, Chile*

Backgrounds

Salmonella survival within eukaryotic cells is explained, in part, by its ability to establish an intracellular compartment known as the *Salmonella* containing vacuole (SCV). To this end, *Salmonella* exploits several effector proteins secreted by type-three secretion systems $T3SS_{SPI-1}$ and $T3SS_{SPI-2}$. We recently reported a role for effector proteins SopB and SifA in the survival of *Salmonella* Typhimurium in *Dictyostelium discoideum*, and the presence of wild-type bacteria in a vacuolar compartment within this amoeba.

Objectives

We evaluated whether the defect in intracellular survival of Δ*sopB* and Δ*sifA* mutants is explained by their inability to survive within SCV-like vacuoles.

Methods

We performed infections of *D. discoideum* expressing a VatM-GFP fusion using bacterial strains expressing the red fluorescent protein mCherry, and analyzed infected cells by confocal laser microscopy. VatM is a vacuolar ATPase used as marker of SCV membranes in other host cells.

Conclusions

According to our results, viable wild-type bacteria were detected laying within VatM-GFP positive vacuoles up to 6 h of infection. In the case of Δ*sopB* and Δ*sifA* mutants, only a few bacteria were detected within VatM-GFP positive vacuoles at 3 h of infection, and most *D. discoideum* cells contained remnants of killed bacteria. Altogether, our results suggest that *S.* Typhimurium resides in a SCV-like compartment in *D. discoideum* and requires effectors SopB and SifA to avoid degradation by this amoeba. We are currently characterizing the composition of the SCV-like compartment in *D. discoideum*.

Supported by FONDECYT grants 1140754 and 1171814, and CONICYT fellowships 21140615, 22140758 and 21150005.

Pathogens / Pathogenicity - Part II

IGG PROTEASES IN CANINE MYCOPLASMAS

D.R. Brown[1], *D.L. Michaels*[1]
[1]*University of Florida, Infectious Diseases and Pathology, Gainesville Florida, USA*

Backgrounds

Certain streptococci encode endoproteases that cleave IgG at a specific epitope between the hinge and CH2 glycosylation sites. The IgG consequently loses all lymphocyte FcγR-mediated effector function and cannot activate complement. Orthologs differ among streptococcal species in their narrow selectivity for IgG of the hosts to which the bacteria are normally restricted, a feature thought to reflect fine-tuned adaptation to host immune defenses.

Objectives

We sought to identify streptococcal IgG protease orthologs in the genomes of mycoplasmas.

Methods

Mycoplasma canis, *Mycoplasma cynos*, *Mycoplasma opalescens*, *Mycoplasma spumans* and *Ureaplasma canigenitalium*, all normally found in dogs, encode the core sequence of the enzyme (GenBank Protein Cluster PCLA_442768). Its genomic context differs among species and some have N- or C-terminal fusions with other mycoplasmal proteins, which suggests origins by horizontal transfer possibly from *Streptococcus canis*. We compared non-synonymous to synonymous amino acid substitutions within the core sequence in streptococci and mycoplasmas but found little evidence that site-specific diversifying selection drives adaptation to the IgGs of different hosts. A predicted mannose and glucosamine ligand-binding exosite, possibly responsible for inital interactions with substrate IgG, was conserved in *M. canis*, *M. opalescens* and *U. canigenitalium* but degenerate in *M. cynos* and *M. spumans*. The IgG in normal dog serum was degraded in the signature pattern of streptococcal IgG proteases when incubated with *M. canis* but not with *M. cynos*.

Conclusions

We conclude that the IgG protease in certain mycoplasmas is evolutionarily, structurally and functionally related to streptococcal orthologs and may confer previously unrecognized immunosuppressive effects during mycoplasmosis of dogs.

VIRULANCE AND RESISTANCE TRAITS IN BACTERIAL AND FUNGAL STRAINS ISOLATED FROM AIR IN THE HOSPITAL ENVIRONMENT

M.M. Mitache[1], C. Curutiu[2], A. Suwaraiy[2], M.C. Chifiriuc[2]
[1]Unviersity of Medicine Titu Maiorescu, preclinic, Bucharest, Romania
[2]University of Bucharest- Faculty of Biology, Microbiology, Bucharest, Romania

Backgrounds

Air microbiological analysis in the hospital environment allows to establish the risk of the air borne infections on one side, as well as the risk of wounds contamination and allergic processes induced by air microbes.

Objectives

The purpose of this study was to invetigate the virulence and resistance features in bacterial and fungal strains isolated from the hospital environment during the air microbiological control.

Methods

The study was carried in five general hospitals. The volumetric method using the MAS- 100 Eco equipment was used to harvest the desired air volume. The strains were isolated on Sabouraud + chloramphenichol and blood agar media, incubated at 37 Celsius degrees for 48 h. The isolated microorganisms have been identified using miniAPI galleries and investigated for antibiotic susceptibility profiles and for the production of cell-asociated (adherence to inert and cellular substratum, biofilm development) and soluble, enzymatic (hemolysins, lecithinase, lipase, caseinase, gelatinase, amylase, esculin hydrolysis) virulence factors, using phenotypic (disk diffusion method, selective media for enzymatic factors production) and PCR-based methods.

Conclusions

The isolated strains were identified as Staphylococcus xylosus, S. cohnii, S. xylosus, S. aureus, Enterococcus cloacae , Ent. aerogenes, Escherichia coli, Trichoderma viride, Penicillium sp., Altenaria sp., Fusarium roseum and Aspergillus niger.

DISULFIDE BOND FORMATION IN GASTRIC PATHOGEN HELICOBACTER PYLORI: AN ACHILLAES' HEEL FOR SECRETION OF PRO-INFLAMMATORY VIRULENCE PROTEINS

C. Creuzenet[1], J. Lester[1], S. Kichler[1], H. Atanassov[2], C. Bodet[2], B. Oickle[1], S. Fairweather[1], M. Perivier[2], A. Oberc[1], J. Chahal[1], D. Ratnayake[1], C. Burucoa[2]
[1]Western University, Microbiology and Immunology, LONDON, Canada
[2]University Hospital, LITEC, Poitiers, France

Backgrounds

H. pylori causes gastritis, gastric ulcers and cancers but the mechanisms of virulence are not fully understood. It produces secreted proteins which may play a role in eliciting gastric inflammation, including the Helicobacter cysteine rich protein HcpE (HP0235) whose biological function is unknown.

Objectives

To investigate if HcpE is secreted by *H. pylori* and is involved in host / pathogen interactions, and identify components essential for its production.

Methods

This work uses anti-HcpE ELISA and Western blots, knockout mutagenesis, phenotypic analyses and biochemical assays.

Conclusions

We demonstrate that HcpE is secreted by many strains as a soluble protein and in association with outer membrane vesicles. We show that infected patients produce anti-HcpE antibodies, indicating in situ HcpE production. We show that HcpE comprises many disulfide bonds and identify DsbK (HP0231) as a folding factor necessary for HcpE production, and show that recombinant DsbK can refold unprocessed, reduced HcpE *in vitro*. This highlights the first biologically relevant substrate for DsbK. Furthermore, we show that DsbK has DiSulfide Bond (Dsb) forming activity on reduced lysozyme and has DsbA-like activity upon expression in *E. coli*, despite its similarity with DsbG. Also, we show a role of DsbK in redox homeostasis in *H. pylori*. Finally we show an important role for DsbK and HcpE in host-pathogen interactions, including murine gastric colonization and pro-inflammatory cytokine production in human gastric explants and in murine splenocytes. Both proteins will be investigated as therapeutic targets to treat *H. pylori* infections and prevent gastric ulcers and cancers.

COMPARISON OF PHENOTYPIC TESTING AND COMPLETE GENOME SEQUENCE ANALYSIS FOR ANTIBIOTIC RESISTANCE GENES IN KLEBSIELLA PNEUMONIAE ISOLATES

N. García-González[1], L. Mejía-Castañeda[1,2], S. Sabater[3], B. Gomila[3], R. Moreno[4], F. González-Candelas[1,5]
[1]FISABIO-CSISP/Univ. Valencia, Joint Research Unit Infection and Public Health, Valencia, Spain
[2]Universidad San Francisco Quito, Dept. of Microbiology, Quito, Ecuador
[3]Hospital General Universitario de Castellón, Microbiology Service, Castellón, Spain
[4]Hospital General Universitario Castellón, Microbiology Service, Castellon, Spain
[5]CIBER in Epidemiology and Public Health, Genomics and Health, Valencia, Spain

Backgrounds

Antibiotic resistance is recognised as one of the major threats to public health and welfare. Increasing efforts are being invested to prevent and control the dissemination of antibiotic resistance mutations (AMRs) but rapid and accurate diagnosis are essential in this context. The advent of new high-throughput sequencing technologies opens new possibilities in this line, but their implementation at the clinical level needs a detailed evaluation in terms of sensitivity and precision but also in investments in time, training, and interpretation of the results.

Objectives

To compare the results of the usual phenotypic tests in a clinical microbiology laboratory with the detection of AMRs from the analysis of reads from complete genome sequences.

Methods

From a total of 1038 *K. pneumoniae* strains from 657 patients between March 2014 and February 2015, 111 showed ESBL resistance. Phenotypic tests were performed with ESBL+AmpCScreen Kit (ROSCO), KPC+MBL-confirmation kit (ROSCO) y PCR con Xpert Carba-R (Cepheid). Next generation sequencing was performed with Illumina NextSeq (2x150 paired-ends) using libraries prepared with Nextera. AMRs were identified in the sequencing reads using SRST2 with the ARG-annot (AntibioticResistance Gene-ANNOTation) database.

Conclusions

We obtained a high but not perfect match between phenotypically determined resistance and the inferred presence of AMR genes as inferred from the analysis of sequencing reads. Most strains (>90%) harbour at least two ESBL-producing genes, usually bla_{SHV} and $bla_{CTX\text{-}M}$. Phenotypic tests failed in detecting a $bla_{OXA\text{-}48}$ carrying strain. At present, WGS can complement but not completely replace phenotypic tests for AMR.

ROLE OF REDUCTIVE AND NON-REDUCTIVE IRON ASSIMILATION ON THE VIRULENCE OF PENICILLIUM DIGITATUM

L. González-Candelas[1], C. Selma[1], A.R. Ballester[1]
[1]Instituto de Agroquímica y Tecnología de Alimentos IATA-CSIC, Food Biotechnology, Paterna, Spain

Backgrounds

Penicillium digitatum is the major postharvest pathogen of citrus fruit. It is a necrotrophic fungus with a very narrow host range that penetrates the fruit through injuries inflicted during harvesting and handling. In the last years, there has been an increasing interest in trying to find out the mechanisms used by this ascomycete to be such a successful pathogen. We have previously identified a set of fungal genes induced during pathogenesis. Gene ontology analysis of differentially expressed genes pointed to metal ion homeostasis as an important factor during pathogenesis. Iron is the most abundant metallic ion in nature and plays fundamental roles in living organisms. In aerobic environments, iron is mostly present as insoluble salts of Fe^{3+}. Fungi rely on two mechanisms for iron acquisition: a reductive iron assimilation (RIA) and a siderophore mediated assimilation.

Objectives

We aim to understand the role of these two iron assimilation pathways on the virulence of *P. digitatum*.

Methods

We have used *Agrobacterium*-mediated transformation to obtain *P. digitatum* knockout mutants lacking either *sidA*, the first gene in the siderophore biosynthesis pathway, or/and *ftrA*, encoding the permease involved in the RIA pathway, as well as on *hapX*, the major transcription factor that regulates the expression of iron dependent genes under iron-limited conditions.

Conclusions

We will present the characterization of these mutants and discuss their role on the virulence of *P. digitatum.*

FUNCTIONAL SPECIALIZATION OF PECTOBACTERIA CELLS DURING COLONIZATION OF THE PLANT

V. Gorshkov[1,2], A. Daminova[1], R. Gubaev[1], O. Petrova[1], M. Ageeva[3], N. Gogoleva[1], E. Kovtunov[1], N. Tarasova[1], Y. Gogolev[1,2]
[1]Kazan Institute of Biochemistry and Biophysics - RAS, Molecular Biology, Kazan, Russia
[2]Kazan Federal University, Botany and Plant Physiology, Kazan, Russia
[3]Kazan Institute of Biochemistry and Biophysics - RAS, Microscopy, Kazan, Russia

Backgrounds

Although bacteria are unicellular organisms, the microbial population represents highly organized and developing structure with different morpho-physiological cell types being functional parts of this complex system. The research of the formation of differentiated microbial cells is in its infancy, especially taking into account integrated host/pathogen systems. Harmful phytopathogenic pectobacteria are considered to interact with plants by means of “brute force”. However, several prerequisites indicate that pectobacterias’ behavior *in planta* may be related to “stealth”.

Objectives

We tested if the colonization of the plant is coupled with dissociation of pectobacteria population and tried to obtain information on causes and consequences of the functional specialization of pectobacteria cells *in planta*.

Methods

We have “looked inside” infected plants using a variety of complementary methods, e.g. various types of microscopy and chromatography, gene cloning and their heterologous expression, mutagenesis, gene expression analyses (qPCR, RNA-Seq).

Conclusions

Our results show that different plant compartments form the specific signaling backgrounds that drive the behavior of microbes resulting in *in planta* dissociation of bacterial population. Herewith, various sub-populations display functional specialization (e.g. blocking the vessels, stress adaptation, tissue maceration, cell migration, etc). Novel biofilm-like structures – bacterial emboli were described and discussed to play significant roles in the formation of pathosystem. *In planta* dissociation of bacterial population is coupled with plant susceptible response that provides conditioning of the colonized compartment. Our observations are strengthened and deepened by the whole-transcriptome analysis of both plant and pathogen during their interactions. This study was supported by RSF (15-14-10022).

C26 - A NOVEL COMPOUND INHIBITING THE EXPRESSION OF TYPE III SECRETION SYSTEM 1 OF SALMONELLA TYPHIMURIUM

I. Grin[1], A. Naini[2], S. Westerhausen[1], M. Riess[1], M. Brönstrup[2], S. Wagner[1]
[1]Interfaculty Institute of Microbiology and Infection Medicine Tübingen,
Research Group Prof. Samuel Wagner, Tübingen, Germany
[2]HZI Braunschweig, AG Prof. Mark Brönstrup, Braunschweig, Germany

Backgrounds

Antibiotic resistance of bacteria is a serious emerging threat and hence the search for new antibiotics is of high priority. A novel class of antibacterial compounds that block infection instead of killing bacteria is thought to exhibit a lower potential for the development of resistance because of a reduced selection pressure compared to conventional antibiotics. These antiinfectives target virulence mechanisms of pathogenic bacteria such as adhesion determinants or toxin delivery systems.

Type III secretion systems (T3SS) of Gram-negative bacteria, often enteropathogens, enable the injection of bacterial effector proteins into eukaryotic target cells to promote infection and colonization. Type III secretion systems are not only excellent targets for antiinfectives because the virulence of many pathogens depends on these systems but also because they are highly conserved and hence a single drug has the potential to act against a broad spectrum of enteropathogens.

Using a luciferase-based assay, we screened multiple proprietary as well as commercially available compound libraries for small molecule inhibitors of T3SS in our *Salmonella* model system. In this screen we could identify C26 - a novel selective inhibitor of *Salmonella* T3SS.**Objectives**

We want to identify the molecular target of C26 and elucidate the mode of action of the compound against the T3SS

Methods

Luciferase-based screening of small molecule inhibitors; mRNA sequencing; cytotoxicity assay;

Conclusions

We have identified C26, a strong inhibitor of the *Salmonella* type III secretion system 1.

The molecular target and mode of action of C26 are currently under investigation.

ABSCISIC ACID EFFECT ON PECTOBACTERIUM ATROSEPTICUM VIRULENCE

R. Gubaev[1], V. Gorshkov[1,2], O. Petrova[1], O. Parfirova[2], S. Tatarkin[1], N. Gogoleva[1], Y. Gogolev[1,2]
[1]Kazan Institute of Biochemistry and Biophysics - RAS, Molecular Biology, Kazan, Russia
[2]Kazan Federal University, Botany and Plant Physiology, Kazan, Russia

Backgrounds

Mutual "eavesdropping" of partner's endogenous signals is a common phenomenon in plant-pathogen interactions. Virulence of *Pectobacterium atrosepticum* (*Pba*), causing plant soft rots, depends on water balance and ontogenetic processes of the host plants that are controlled by phytohormone abscisic acid (ABA). It is well-known that *Pba*-induced disease symptoms are not expressed under low humidity when the concentration of ABA is elevated in plants. However, still there is no information on ABA effect on pectobacteria physiology.

Objectives

The aim of the present study was to explore ABA effect on the *Pba* physiology, including the whole-transcriptome profile.

Methods

ABA effect on *Pba* was monitored by measuring bacterial growth, activity of the main virulence factors (extracellular pectate lyases), and by analyzing transcriptome profile by means of RNA-Seq. Additionally, ABA-signaling in plants was assessed in the course of *Pba*-caused infection.

Conclusions

ABA significantly reduced extracellular pectate lyase activity when added into bacterial cultures. This effect was not mediated by the influence on bacterial growth or post-transcriptional regulation of the enzymes. Gene expression analysis by means of qPCR and RNA-Seq revealed down-regulation of pectate lyase genes as well as some other virulence factors and regulatory proteins in the presence of ABA. This is in agreement with our data on repression of plant ABA-mediated system during acute infection and increased susceptibility of plants pretreated by inhibitor of ABA biosynthesis to *Pba*. Thus, through ABA content *Pba* is likely to “feel” the physiological status of the host and fine-tunes its virulence accordingly. This study was supported by RSF (15-14-10022).

PIECING TOGETHER YSCX FUNCTION: THE CRITICAL PROTEIN IN YERSINIA TYPE III SECRETION SYSTEM

J.M. Gurung[1], A.A.A. Amer[1], S. Chen[2], M.S. Francis[1]
[1]Umeå University, Department of Molecular Biology, Umeå, Sweden
[2]Chinese Academy of Sciences, Wuhan Institute of Virology, Wuhan, China

Backgrounds

Yersinia bacteria utilize a type III secretion system (T3SS) to target effector toxins into the host cells which promote mutualistic or pathogenic associations. T3SS's are comprised of ~25 structural proteins many of whose functions remain obscure. In *Yersinia*, YscX and YscY are two poorly characterised proteins. However, the absence of Ysc-Yop T3SS in *yscX* or *yscY* null mutant suggests that YscX and YscY are important Ysc-Yop T3SS constituents. This may arise from a need to form a binary interaction involving YscX-YscY or a ternary interaction with the inner membrane export component YscV.

Objectives

Study the contribution of YscX secretion towards T3S function.

Methods

To understand the role of YscX, we initially investigated the functional interchangeability between genetically conserved members of YscX-YscY protein families from diverse bacteria. Our study suggested that the function of YscX might be specific to *Yersinia* despite reciprocal binding to YscY and YscV family members. To further dissect the uniqueness of YscX function, we scrutinized the role of YscX N-terminus in secretion of itself and other T3S proteins. Site-directed mutagenesis and defined domain swapping revealed YscX N-terminus to be central for Ysc-Yop activity as it prevented YscF needle assembly and abolished T3SS activity. Critically, the inability of these YscX variants to impede T3SS was not due to the disruption of their secretion ability or destabilization of binary and ternary interactions.

Conclusions

Hence, the YscX N-terminus is dual functional; on the one hand it is a secretion recognition motif and on the other, a novel structural component necessary for the correct assembly of the Ysc-Yop T3SS.

Pathogens / Pathogenicity - Part II

VIRULENCE POTENTIAL OF SHIGA TOXIN-PRODUCING ESCHERICHIA COLI ISOLATED FROM THE ANIMAL RESERVOIR IN BRAZIL

B.E.C. Guth[1], C.F. Freire[1], C. Matheus-Guimaraes[1], E.M. Gonçalves[1], L.F. Dos Santos[1]
[1]Universidade Federal de São Paulo, Microbiology- Immunology- and Parasitology, São Paulo, Brazil

Backgrounds

Shiga toxin-producing *Escherichia coli* (STEC) are food-borne pathogens being ruminant animals their main natural reservoir. Several non-O157 STEC serotypes unable to cause attaching and effacing lesion (A/E) have been implicated as agents of serious human diseases.

Objectives

Evaluate the distribution of *stx* subtypes and accessory virulence genes in non-O157 STEC isolates devoid of A/E from the animal reservoir in order to identify their pathogenic potential.

Methods

Gene sequences related to Stx1 and Stx2 subtypes, autotransporter proteins (EspP, EspI, EpeA, Sab), adhesins (Saa), toxins (EhxA), iron-repressible protein (Irp2) and metalloprotease (StcE) were sought by PCR in 125 STEC strains isolated from sheep, goat, buffalo and cattle. The strain phylogroup was also determined.

Conclusions

STEC isolates most frequently harbor *stx*2 (52%) and *stx1stx2* (38%), being subtypes *stx1a* (57%), *stx1c* (47%), *stx2a* (67%), and *stx2d* (38%) those most frequently identified. Distribution of subtypes varied according to the reservoir**:** *stx1a* prevailed in cattle and buffalo isolates, *stx1c* predominate in sheep and goat, *stx2a* in cattle, and *stx2d* prevailed in goat and buffalo.The *saa*, *espP*, *ehxA*, *espI, epeA*, *sab*, *irp2* and *stcE* genes were identified in 89%, 58%, 55%, 43%, 30%, 13%, 11% and 9% of the STEC isolates, respectively, and differences were also observed depending on the reservoir. *espP* and *ehxA* molecular subtyping showed that variants C (90%) and A (100%) prevailed, respectively. B1 was the predominant phylogroup identified. Overall STEC isolates from cattle most frequently carry the *stx2* subtypes related to human infections, and harbor virulence factors at higher frequencies.

DEVELOPMENT OF CHITOSAN/HEPARIN NANOPARTICLES FOR TARGETED ANTIMALARIAL DRUG DELIVERY

L. Gutiérrez Chamorro[1], *E. Lantero*[2], *X. Fernández-Busquets*[3]
[1]*ISGlobal- Hospital Clinic de Barcelona- Universitat de Barcelona, Nanomalaria, Barcelona, Spain*
[2]*Institute for Bioengineering of Catalonia IBEC, Nanomalaria, Barcelona, Spain*
[3]*Institute for Bioengineering of Catalonia IBEC- ISGlobal- Universitat de Barcelona, Nanomalaria, Barcelona, Spain*

Backgrounds

Malaria, a life-threatening disease caused by parasites of the genus *Plasmodium*, is still the most prevalent parasitic disease in the world. Keeping in mind that an effective vaccine against malaria is still under development, chemotherapy is one of the most important strategies to reduce its associated morbidity and mortality. However, the emergence of drug-resistant malaria parasites, combined with the non-specific targeting of current chemotherapies to intracellular parasites, highlights the necessity of new therapeutic and drug delivery approaches, like novel antimalarial drugs and improved methods for their efficient administration. In this context, nanomedicine enables numerous potential opportunities for malaria treatment such as nanovector-based drug delivery strategies. Polysaccharides, in particular chitosan -a deacetylated chitin derivative-, have gained increasing attention because of their numerous advantages. In addition, data from single-molecule force spectroscopy and fluorescence microscopy have shown binding specificity of heparin to *Plasmodium*-infected red blood cells *vs*. non-parasitized erythrocytes.

Objectives

In this project, we aim to establish a method for the synthesis of antimalarial drug-loaded chitosan/heparin nanoparticles and evaluate their specific antimalarial activity.

Methods

For this purpose, nanoparticles are prepared by the ionic gelation method. In order to characterize them, we use transmission electron microscopy and dynamic light scattering. Finally, growth inhibition assays in *Plasmodium falciparum* cultures are performed in order to determine antimalarial activity and targeting of the nanoparticles to parasitized red blood cells.

Conclusions

In conclusion, we explore a new cost-efficient approach for the treatment of malaria based on a nanomedical strategy that could provide a targeted delivery contributing to reducing resistance evolution.

Pathogens / Pathogenicity - Part II

GALLERIA MELLONELLA AS IN VIVO MODEL FOR THE STUDY OF THE PATHOGENICITY OF ADHERENT INVASIVE ESCHERICHIA COLI (AIEC)

D. Gutiérrez[1], C. Castaneda-Alvarez[2], G. Vidal[2], E. Aballay[2], F. Del Canto[2], R. Vidal[1]
[1]Universidad de Chile, Department of Microbiology and Mycology, 8380453, Chile
[2]Universidad de Chile, Department of plant health, 8380453, Chile

Backgrounds

Adherent Invasive *Escherichia coli* (AIEC) are defined by the in vitro capacity of adhere and invade intestinal epithelial cells and also survive and replicate within macrophages. AIEC has been frequently isolated from patients with Crohn's disease, a chronic inflammatory bowel disease.

Animal models, mainly mice, represent an indispensable tool for understand the physiological and mechanistic human-microbial interaction. Other in vivo models such as *Dictyostelium discoideum*, *Caenorhabditis elegans*, *Drosophila melanogaster* and *Danio rerio* have been implemented. However, none of these organisms is possible to maintain at 37°C, temperature at which most bacterial pathogens express their virulence factors. *Galleria mellonella* (wax moth) is a simple invertebrate that recently has been used as a model for the study of human pathogens and the early results reported so far suggest a correlation with the pathogenicity displayed in murine models.

Objectives

To determine if *Galleria mellonella* larvae could be used as a model to study AIEC pathogenesis.

Methods

Larvae were injected with AIEC strains and non-pathogenic *E. coli* HB101 (10^3-10^7 UFC/10 µL). Survivors were everyday recorded for five days.

Conclusions

G. mellonella are susceptible to AIEC infection, and larval mortality is dose dependent (100% lethality with 10^6 CFU / larvae of AIEC 4C01, LD_{50} = 2.1 x 10^4). In contrast, the inoculum with non-pathogenic *E. coli* HB101 strain didn't cause death at a dose of 10^6 CFU / larvae (100% survival). This is the first report in which *G. mellonella* is proposed as an *in vivo* model for future AIEC infection studies.

IMPLICATION OF MOBILE GENETIC ELEMENTS IN THE VIRULENCE OF STAPHYLOCOCCUS AUREUS STRAINS FROM CYSTIC FIBROSIS PATIENTS

K. Guzman[1], M. Cervera-Alamar[1], M. Žiemytė[1], A. García-Ortega[2], M. Martí Jimenez[3], R.M. del Campo Moreno[4], A. Solé Jover[2], M.A. Tormo Mas[1]
[1]HOSPITAL LA FE, Several Infeccion Group, VALENCIA, Spain
[2]HOSPITAL LA FE, Adult Cystic Fibrosis Unit- Microbiology Service, VALENCIA, Spain
[3]Catholic University of Valencia, Experimental Sciences and Mathematics Department, Valencia, Spain
[4]University Hospital Ramón y Cajal- and Instituto Ramón y Cajal de Investigación Sanitaria, Biology and Evolution of Microorganisms Group- Microbiology Department, Madrid, Spain

Backgrounds

Staphylococcus aureus is one common pathogen that colonize the lung of cystic fibrosis (CF) patients. *S. aureus* versatility is due to its ability to persist and multiply in different environments and to produce a several virulence factors, most of which are encoded by mobile genetic elements (MGE).

Objectives

The aim of this work was to molecularly characterize a collection of 200 *S. aureus* isolates obtained from 118 CF-patients attended in a single Unit, in Valencia, Spain.

Methods

Antibiotic susceptibility was determined by disk diffusion test and presence of *mec*A gene was corroborated by PCR. Multi Locus Sequence Typing (MLST) and Pulsed-Field Gel Electrophoresis (PFGE) techniques were performed in all isolates, and presence of Mobile-Genetic-Elements (MGEs) was determined by integrase PCR, Southern Blot and Screening Lysates.

Conclusions

Methicillin-resistance was observed in 21.5% of the isolates. Elevated adherence capability was demonstrated in about 60% of them. High genetic diversity was found including 47 STs, some of them non-previously described. Transmission between patients was not detected. Curiously, some discrepancies between MLST and PFGE fingerprinting were observed, probably in relation with MGE variations. All isolates carried at least one phage, and 85.5% of them were able to lysate the bacterial cultures. SaPI integrases detected in 49.5% of isolates. Unexpectedly, 28% of SaPIs were induced by its own endogenous phages.

CF-*S. aureus* present high rate of MGE that might be involved in pathogenicity and virulence activation and spread. Some discrepancies between the MLST and PFGE techniques were detected suggesting ecological adaptation to adverse conditions.

Pathogens / Pathogenicity - Part II

GROEL-MEDIATED INDUCTION OF PTX3 IS UNDER THE CONTROL OF NF-KB AND MIRNA-9

Y. Lee[1], J. Jeon[1], H. Shin[2], U.H. Ha[1]
[1]Korea University, Biotechnology & Bioinformatics, Sejong, Republic of Korea
[2]Medytox, DS Part, Cheongju, Republic of Korea

Backgrounds

PTX3 has been recognized as an important soluble form of pattern recognition receptor, which plays a role in the clearance of microbial pathogens including *Pseudomonas aeruginosa*. Recently, we found that GroEL released from *P. aeruginosa* could act as a potent inducer for the expression of *PTX3*.

Objectives

The related mechanisms promoting the production of PTX3 remain unclear.

Methods

We measured mRNA and protein levels of PTX3 by applying real-time Q-PCR and ELISA. Signaling pathways were monitored by using knockout cell lines as well as transfection of dominant negative and miRNA mimics.

Conclusions

To verify the inducing effect of purified recombinant GroEL, we used Triton X-114, known as an effective reagent to remove lipopolysaccharide (LPS). Triton X-114 treatment thoroughly removed LPS, which could be contaminated during purification, and the resulting recombinant GroEL clearly induced the expression of *PTX3*. In addition, the induction was completely diminished by pretreatment of proteinase K, further supporting the action of recombinant protein-mediated induction. The induction of *PTX3* expression in response to GroEL was shown to be under the control of TLR4/NF-kB signaling pathways. In addition, GroEL treatment decreased the expression of miRNA-9, which targets *PTX3* transcripts, and the resulting miRNA-9 reduction was also under the control of TLR4. *P. aeruginosa*-derived GroEL is able to increase the production of PTX3 through the signaling pathways of TLR4-NF-kB and miRNA-9.

Pathogens / Pathogenicity - Part II

T3SS EFFECTOR EXOY REDUCES THE EXPRESSIONS OF INFLAMMATORY CYTOKINES THROUGH DELAYING THE ACTIVATION OF NF-KB

J. Jeon[1], Y. Kim[2], H. Shin[3], U.H. Ha[1]
[1]Korea University, Biotechnology & Bioinformatics, Sejong, Republic of Korea
[2]KRIBB, Cell Factory Research Center, Daejeon, Republic of Korea
[3]Medytox, DS Part, Cheongju, Republic of Korea

Backgrounds

Pseudomonas aeruginosa possesses diverse virulence factors that are essential in the pathogenesis of bacteria to modulate host immune responses. Among them, type III secreted effectors, which are directly translocated into the cytoplasm of infected host cells through Type III Secretion System, have obtained much attention for their effects on manipulation of host cell function and viability.

Objectives

Little is known about the impact of one of effectors, ExoY, on the regulation of inflammatory cytokine expressions.

Methods

We analyzed effects of translocated ExoY in the expressions of pro-inflammatory cytokines at the levels of mRNA and protein.

Conclusions

We explored the impact of ExoY on the expressions of inflammatory cytokines including IL-1a, IL-1b, IL-8 and TNF-a. The expressions were clearly enhanced in response to *exoY* deletion mutants whereas the expressions were reduced by *exoY*-complementation. Furthermore, transfection of *exoY* into host cells was sufficient to reduce the expression of IL-1b stimulated by the treatment of not only *exoY* deletion mutants but also phorbol 12-myristate 13-acetate (PMA), a well-known inducer of inflammatory cytokines. The resulting suppression was found to be mediated by delaying the activation of NF-kB pathway. This study demonstrates that ExoY derived from *P. aeruginosa* can initiate anti-inflammatory responses by reducing the expressions of inflammatory cytokines through delaying the activation of NF-kB pathways.

CITRUS TRISTEZA VIRUS CHANGES THE BIOCHEMICAL AND PHYSIOLOGICAL STATUS OF INFECTED MEXICAN LIME PLANTS

K. Hančević[1], B. Urlić[1], I. Pasković[2], T. Radić[1]
[1]Institute for Adriatic Crops and Karst Reclamation, Department of Plant Sciences, Split, Croatia
[2]Institute of Agriculture and Tourism, Department of Agriculture and Nutrition, Poreč, Croatia

Backgrounds

Reactions that occur when the plant is subjected to *Citrus tristeza virus* infection often results in triggering numerous defence mechanisms to fight the infection. The reactions vary regarding virus strain, host genotype, time exposure to the infection and environmental conditions. To date no study has examined the consequence of ten-years exposure to CTV infection on biochemical and physiological status of susceptible Mexican lime plants.

Objectives

To understand such kind of infection, changes in nutrient status, total proteins, enzyme activities involved in scavenging stressed conditions, photosynthetic and transpiration rates, membrane permeability and relative water content were analysed in lime plants inoculated with different CTV strains and healthy plants.

Methods

Enzymes and minerals were assayed following spectrophotometric methods. Net photosynthesis and stomatal conductance were measure by open gas exchange system (Li-COR 6400) and membrane permeability by electrical conductivity.

Conclusions

The activity of superoxide dismutase and polyphenol oxidase significantly decreased in the infected leaves, as well as membrane permeability. Macro- and micro-nutrient statuses were significantly changed: concentrations of leaf nitrogen, zinc, magnesium and iron were elevated but potassium concentration depressed in relation to non-infected control leaves. As shown in this study, clear physiological changes were found between infected and non-infected plants but none between the plants inoculated with different CTV strains. Data suggest that the most of the defence mechanism investigated here were supressed due to the continuous and long-term pressure of CTV biotic stress.

Pathogens / Pathogenicity - Part II

IN VITRO ANTIMICROBIAL ACTIVITY OF ESSENTIAL OIL OF PIMPINELLA ANISUM ON CORYNEBACTERIUM BOVIS AND LISTERIA MONOCYTOGENES

A. Hashempour[1], S. Seyed gholizade[1], E. Mir ahmadi[1], M.H. Ebrahimi jam[2], A. Khorsandian[1]
[1]Urmia Branch -Islamic Azad Univercity, microbiology, Urmia, Iran
[2]Razi institute, virology vaccine, karaj, Iran

Backgrounds

Plants have played a significant role in maintaining human health and improving the quality of human life for thousands of years and have served humans as well as valuable components of seasonings, beverages, cosmetics, dyes, and medicines.Aromatic plants and essential oils extracted from these plants are becoming more important due to their antimicrobial effects and the stimulating effect on animal digestive systems. Aromatic plants have been used traditionally in the therapy of some diseases for a long time in the world.

Objectives

Therefore, the present investigation was undertaken to evaluate antibacterial activity of *Pimpinella anisum* seeds against *Corynebacterium bovis* and *Listeria monocytogenes***.**

Methods

The antimicrobial activity of essential oil was determined by the disc diffusion method. Susceptibility tests were performed by the disc diffusion method of Bauer et al with Mueller Hinton agar (W.Lawrence Drew et al 1972). Zones of inhibition were measured after 24 hr and again after 48 hr of incubation at 35-40 ˚C. Studies were also carried out by incubating the plates at 35 - 40 ˚C (Sadeghi Zali M.H. et al 2011).

Conclusions

The antibacterial activity of *Pimpinella anisum* essential oils was assayed in vitro by agar disc diffusion method against *Corynebacterium bovis* and *Listeria monocytogenes*. Table 2 summarizes the microbial growth of essential oils of the *Pimpinella anisum*. The *Pimpinella anisum* essential oil showed maximum antibacterial activity against Gram-positive bacteria.

Pathogens / Pathogenicity - Part II

THE EFFECT OF IPN VIRUS IN THE PROGRESSION OF IMMUME SYSTEM OF SALMO SALAR

D. Haussmann[1,2,3], J. Blanco[1], F. Lagos[1,3], I. Adolfo[1], F. Jaime[1,3]
[1]Instituto de Bioquímica y Microbiología, Laboratorio de Biología Molecular de Peces, Valdivia, Chile
[2]Departamento de Ciencias Básicas- Facultad de Ciencias, Universidad Santo Tomas, Valdivia, Chile
[3]Centro FONDAP, Interdisciplinary Center for Aquaculture Research INCAR., Valdivia, Chile

Backgrounds

Backgrounds: The infectious pancreatic necrosis is a multi-systemic disease that affects salmonid species, causing millions of losses in the world aquaculture industry. It is caused by the virus IPN (IPNv) and is classified within the genus aquabirnavirus, consisting of a bi-segmented double-stranded RNA genome.

The disease together with the virus triggers the immune response, a complex defense mechanism that is divided into innate and adaptive immunity. In fish, innate immunity is the most important in defending against pathogens; immunity is modulated by molecules called cytokines, non-type cytokine proteins and membrane receptors.

Objectives

Objectives and Methods: The objective was to determine if IPNv modifies the expression of transcripts related to the immune system (CD8 + α, NCCRP-1, IL-1β, IL-12, TNF-α, IRF-1, IFNγ, IFNα, IFNβ and Mx).

Methods

Using propagation and viral titration techniques, kinetics of infection in primary culture of *Salmo salar* head kidney and qPCR.

Conclusions

Results and Conclusions: It was determined that, IPNv modifies the expression of the transcripts studied, increasing both the expression of IRF-1, IFNβ, CD8 + α, NCCRP-1, IL-1β, IL-12, and increasing gene expression in late times as Mx and IFNγ. It is observed that between 4 and 16 hours post-infection, the expression of most transcripts is low.

In conclusion, the virus IPNv, inhibits the expression of certain markers in early stages of infection, however, the virus manages to persist during the course of the infection.

This study is important because it will contribute to establish an early and effective diagnosis of the fish a viral infection.

FEMS7-2963
Pathogens / Pathogenicity - Part II

OPPORTUNISTIC INFECTIONS IN HIV-INFECTED PATIENTS: HAART ERA DID NOT LEAD TO A CHANGE IN THEIR SPECTRA IN PATIENTS EXAMINED POSTMORTEM

P. Heneberg[1], *M.K. Powell*[1]
[1]*Charles University, Third Faculty of Medicine, Prague, Czech Republic*

Backgrounds

AIDS-related mortality has changed dramatically with the onset of highly active antiretroviral therapy (HAART), which has even allowed compensated HIV-infected patients to withdraw from secondary therapy directed against opportunistic pathogens.

Objectives

We hypothesized that the pathogens frequency and spectrumchanges found in HIV-infected patients examined postmortem did not recapitulate the changes found previously in HIV-infected patients examined antemortemin both the pre- and post-HAART eras.

Methods

We performed autopsies on 124 HIV-infected patients who died from AIDS or other co-morbidities in the Czech Republic between 1985 and 2014. The pathological findings were retrieved from the full postmortem examinations and autopsy records.

Conclusions

We collected a total of 502 host-pathogen records covering 82 pathogen species, a spectrum that did not change according to patients' therapy or since the onset of the epidemics, which can probably be explained by the fact that even recently deceased patients were usually decompensated (in 95% of the cases, the last available CD4+ cell count was falling below 200 cells*µl-1) regardless of the treatment they received. The newly identified pathogen taxa in HIV-infected patients included *Acinetobacter calcoaceticus*, *Aerococcus viridans* and *Escherichia hermannii*.We observed a very limited overlap in both the spectra and frequencies of the pathogen species found postmortem in HIV-infected patients in Europe, the USA and Latin America. The shifts documented previously in compensated HIV-infected patients examined antemortem in the post-HAART era are not recapitulated in mostly decompensated HIV-infected patients examined postmortem.

ANTIBACTERIAL ACTIVITY OF THE PLANT-DERIVED ISOTHIOCYANATES IS CONNECTED WITH INDUCTION OF THE STRINGENT RESPONSE

A. Herman-Antosiewicz[1], *M. Maciąg-Dorszyńska*[2], *D. Nowicki*[2], *A. Szalewska-Pałasz*[2]
[1]*University of Gdansk, Medical Biology and Genetics, Gdańsk, Poland*
[2]*University of Gdansk, Bacterial Molecular Genetics, Gdańsk, Poland*

Backgrounds

Isothiocyanates (ITC) are hydrolysis products of glucosinolates, secondary metabolites abundant in Brassicaceae plants. They are known from their chemopreventive and anticancer potential which relies on modulation of activity of enzymes responsible for carcinogen activation and detoxification in healthy cells as well as on inhibition of cell cycle and induction of apoptosis in cancer cells. ITC possess anti-inflammatory, immunomodulatory and anti-oxidant properties, and showed cardioprotective and neuroprotective activities in animal models of stroke, ischemia/reperfusion, neurodegeneration and spinal cord injury. Moreover, it has been shown that ITC have antimicrobial activity; however, the underlying mechanisms are still underexplored. Recently, it has been reported that some ITC induce stringent response in enterohemorrhagic *Escherichia coli*.

Objectives

We evaluated whether the activity of aliphatic (SFN) and aromatic isthiocyanate (PEITC) toward different Gram (-) and Gram (+) bacteria correlates with the stringent response induction.

Methods

We studied the effect of SFN (1- isothiocyanato-4- (methylsulfinyl)-butane) and PEITC (phenethyl isothiocyanate) on growth of different bacteria species: model bacterium, *Escherichia coli*, and opportunistic human pathogens, *Pseudomonas aeruginosa, Klebsiella pneumoniae, Staphylococcus aureus, Staphylococcus epidermidis, Enterococcus faecalis* and their clinical isolates. The minimum inhibitory concentration as well as impact of ITC on RNA synthesis and ppGpp production were evaluated.

Conclusions

ITC were more potent toward Gram-positive than Gram-negative bacteria, however response of individual bacteria species varied. Moreover, sensitivity of bacteria to ITC was correlated with induction of the stringent response.

Pathogens / Pathogenicity - Part II

INVOLVEMENT OF RALFURANONES IN THE QUORUM SENSING SIGNALING PATHWAY AND VIRULENCE OF RALSTONIA SOLANACEARUM STRAIN OE1-1

Y. Hikichi[1], Y. Mori[1], K. Hayashi[1], A. Kiba[1], K. Ohnishi[2], K. Kai[3]
[1]Kochi University, Laboratory of Plant Pathology & Biotechnology, Nankoku, Japan
[2]Kochi University, Research Institute of Molecular Genetics, Nankoku, Japan
[3]Osaka Prefecture University, Graduate School of Life and Environmental Sciences, Sakai, Japan

Backgrounds

The soil-borne plant pathogenic *Ralstonia solanacearum* strain OE1-1 produces and secretes methyl 3-hydroxymyristate (3-OH MAME) as a quorum sensing (QS) signal, which contributes to its virulence. A global virulence regulator, PhcA, functioning through the QS system positively regulates the expression of *ralA*, which encodes furanone synthase, to produce aryl-furanone secondary metabolites, ralfuranones. Ralfuranones contribute to full virulence of vstrain OE1-1.

Objectives

We investigated the functions of ralfuranones on OE1-1 virulence.

Methods

We analysed *R. solanacearum* transcriptome data generated by RNA sequencing technology. A ralfuranone-deficient mutant (Δ*ralA*)expressed *phcB*, which is associated with 3-OH MAME production, and *phcA* at levels similar to those in strain OE1-1. Additionally, Δ*ralA* exhibited downregulated expression of more than 90% of the QS-positively regulated genes, and upregulated expression of more than 75% of the QS-negatively regulated genes. These results suggest that ralfuranones affect the QS feedback loop. Ralfuranone supplementation restored the ability of Δ*ralA* cells to aggregate. Additionally,ralfuranones A and B restored the swimming motility of Δ*ralA* to wild-type levels. However, the application of exogenous ralfuranones did not affect the production of the major exopolysaccharide, EPS I, in Δ*ralA.* Quantitative real-time PCR assays revealed that the deletion of *ralA* results in downregulated expression of *vsrAD* and *vsrBC*, which encode a sensor kinase and a response regulator, respectively, in the two-component regulatory systems that influence EPS I production. The application of ralfuranone B restored the expression of these two genes.

Conclusions

Overall, our findings indicate that integrated signalling *via* ralfuranones influences the QS and virulence of *R. solanacearum*.

Pathogens / Pathogenicity - Part II

HOW TOXIN-ANTITOXIN SYSTEMS CONFER VIRULENCE PLASMID STABILITY IN SHIGELLA SPP

G. McVicker[1], S. Hollingshead[2], C. Tang[2]
[1]Nottingham Trent University, College of Science and Technology- School of Science & Technology, Nottingham, United Kingdom
[2]University of Oxford, Sir William Dunn School of Pathology, Oxford, United Kingdom

Backgrounds

Pathogenic *Shigella spp*. are the leading cause of bacterial dysentery, with *Shigella flexneri* and *Shigella sonnei* accounting for around 90% of cases worldwide. *S. flexneri* predominantly causes disease in low-income countries, whilst *S. sonnei* prevails in wealthy countries. Both species contain a large virulence plasmid, pINV, which is essential for pathogenesis. *S. sonnei* pINV is less stable than *S. flexneri* pINV. Both plasmids contain a number of toxin–antitoxin systems, which are required for plasmid maintenance. Differences between the toxin-antitoxin systems harboured on the *S. sonnei* and *S. flexneri* virulence plasmids are responsible for their differential stability.

Objectives

Here, we report the isolation of a *S. sonnei* virulence plasmid with greatly increased stability at physiologically relevant temperatures. Our objective was to identify the genetic and biochemical basis for increased plasmid stability.

Methods

Close inspection of the toxin-antitoxin systems on pINV, revealed heightened plasmid stability is caused by a mutation affecting an antitoxin. We subsequently identified the biological function of this antitoxin mutation *in vitro*.

Conclusions

Using biochemical and structural analyses we determined the mechanism by which increased plasmid stability is conferred and thus how this strain has the potential for heightened pathogenesis and prolonged infection.

LOW-LEVEL ANTIMICROBIAL RESISTANCE OF CRONOBACTER SPP. STRAINS ISOLATED FROM CLINICAL AND ENVIRONMENTAL MATERIAL

O. Holý[1], M. Röderová[2], J. Petrželová[2], J. Vlčková[1]
[1]Faculty of Medicine and Dentistry- Palacký University Olomouc, Preventive Medicne, Olomouc, Czech Republic
[2]Faculty of Medicine and Dentistry- Palacký University Olomouc, Microbiology, Olomouc, Czech Republic

Backgrounds

Cronobacter spp. is Gram-negative, facultative-anaerobic, nonspore-forming, motile bacteria belonging to the family *Enterobacteriaceae*. Infants up to two month of age, premature with low birth weight or immunocompromised newborns are at the highest risk for infection. *Cronobacter* spp. has been also recognized as the causative agents of various infections in elderly adults suffering from serious underlying disease or malignancy.

Objectives

The aim of the study was to estabilish antibiotics susceptibility of *Cronobacter* spp. strains isolated from clinical as well as environmental material.

Methods

Altogether, seventy-four *Cronobacter* spp. strains were used in this study (fifty clinical and twenty-four environmental strains). The strains had been collected during a survey of *Cronobacter* carriage by patients from two hospitals, during a 6-years period from May 2007 to August 2013. All *Cronobacter* spp. strains were tested for susceptibility against 17 types of antibiotics. The susceptibility to antibiotics was assessed by a standard microdilution method according to the European Committee on Antimicrobial Susceptibility Testing criteria. ESBL genes (*bla*$_{TEM}$, *bla*$_{SHV}$ and *bla*$_{CTX-M}$) were tested by PCR method.

Conclusions

Susceptibility tests revealed that the isolates were susceptible to all antibiotics. No resistant strain was identified. Simultaneously, all strains were negative for *bla*$_{TEM}$, *bla*$_{SHV}$ and *bla*$_{CTX-M}$ genes beta-lactamases. So far, antibiotics resistance is not a serious threat among *Cronobacter* spp. strains. However, the extensive use of antimicrobials in agriculture and health-care facilities has led to the emergence of resistant bacterial strains. Antimicrobial resistances are a public health concern, because it may cause failure of conventional treatment, resulting in prolonged illness and a higher risk of mortality.

The study was supported by the "Research Support Foundation Vaduz - Comprehensive Study at the Issue of Oncological Diseases" and IGA_LF_UP_2016_022.

Pathogens / Pathogenicity - Part II

DETECTION AND CHARACTERIZATION OF ENTEROBACTERIA PRODUCING BETA-LACTAMASES FROM PATIENTS WITH LEUKAEMIA

O. Holý[1], M. Röderová[2], J. Vlčková[1], P. Jana[2], D. Horáková[1]
[1]Faculty of Medicine and Dentistry- Palacký University Olomouc, Preventive Medicne, Olomouc, Czech Republic
[2]Faculty of Medicine and Dentistry- Palacký University Olomouc, Microbiology, Olomouc, Czech Republic

Backgrounds

Acute leukaemia (AL) is a heterogeneous group of malignant diseases of haematopoiesis. AL is divided into: acute myeloid leukaemia (AML) and acute lymphoblastic leukaemia (ALL).

Objectives

The aim of this study was to carry out active surveillance of antibiotics resistance among enterobacteria isolated from patients with acute leukaemia.

Methods

101 clinical isolates were obtained from the 95 patients from September 2015 to August 2016. Out of these, 26 patients suffered from ALL and 69 patients from AML. Bacterial isolates were identified using MALDI-TOF MS. This method was also used for strains typing and dendrograms were created. The susceptibility to antibiotics was assessed by a standard microdilution method. All isolates were tested for beta-lactamase genes (*bla*$_{TEM}$, *bla*$_{SHV}$ and *bla*$_{CTX-M}$) by PCR method.

Conclusions

Overall, the most common material was throat swab (n=35), stool (n=29) and urine (n=18). Most often, *K. pneumoniae* was present (n=31) and *K. oxytoca* (n=10), followed by *E. coli* (n=22). High clonality among strains was observed. Genes encoding production of TEM, SHV and CTX-M types of beta-lactamases were detected in 40 (39.6%), 33 (32.7%) and 29 (28.7%) isolates respectively. Eleven strains of *K. pneumoniae* and 1 strain of *Enterobacter cloacae* harbored all three genes.

Due to high immunosuppression, the active surveillance is absolutely crucial, because of infectious complications and antibiotic resistance, which is serious and increasing problem, especially among *Enterobacteriaceae*.

The study was supported by the "Research Support Foundation Vaduz - Comprehensive Study at the Issue of Oncological Diseases"

HIGH SEROPREVALENCE OF TOXOPLASMA GONDII IN WILD RATS IN NORTH OF IRAN

S.A. Hosseini[1], A. Ahmad Daryani[2], A. Afsaneh Amouei[2], A. Azadeh Mizani[2], M. Mehdi Sharif[2]
[1]Student research Committee- Mazandaran University of Medical Sciences- Sari- Mazandaran- 48178 44718- Iran, Parasitology and Mycology, Sari, Iran
[2]Toxoplasmosis Research Center- Mazandaran University of Medical Sciences- Sari- Mazandaran- 4847191971- Iran, Parasitology and Mycology, Sari, Iran

Backgrounds

Toxoplasma gondii, an intracellular parasite, is one of the most common parasitic diseases of animals and man. Rats as herbivores are susceptible to *T*. *gondii* infection due to ingestion food or water contaminated with oocysts. The determination of the prevalence of *T*. *gondii* infection in rodents may be of epidemiological importance because rodents can serve as sources of tissue cysts for Felidae.

Objectives

The aim of the present investigation was to survey on seroprevalence of *T*. *gondii* in wild rats in Sari city, Mazandaran, north of Iran.

Methods

The seroprevalence of T. gondii determined among wild rats (R. rattus) in north of Iran from April to December 2014. Modified agglutination test (MAT) to detect serum antibodies against T. gondii was performed for 100 adult wild rats. The rats were classified according to sex and age and habit type. The results were analyzed by Chi-square analysis and Fisher's exact test.

Conclusions

Antibodies IgG anti- Toxoplasma gondii were detected in sera of 56 of 100 rats in titers of 1:40 in 2, 1:80 in 34, 1:160 in 14, 1:320 in 5 and 1:640 in 1 samples. Our findings confirms the high prevalence of toxoplasmosis in north of Iran. This study concluded that wild rats represent a significant and persistent wildlife intermediate host reservoir for T.gondii. Therefore, infected rats play an important role in the transmission of toxoplasmosis among animals and hence integrated strategies and measures should be taken to control toxoplasmosis in wild rats.

Pathogens / Pathogenicity - Part II

CANDIDA ALBICANS SFP1 IN THE REGULATION OF BIOFILM FORMATION AND DRUG RESISTANCE

C. Hsueh-Fen[1], *C.Y. Lan*[2]
[1]*National Tsing Hua University, Hsinchu, Taiwan R.O.C.*
[2]*National Tsing Hua University, Institute of Molecular and Cellular Biology, Hsinchu, Taiwan R.O.C.*

Backgrounds

Candida albicans is a major human fungal pathogen. One of the important features of *C*. *albicans* pathogenicity is its ability to form biofilm. The cell surface of *C. albicans* adhere to supporting materials is critical for biofilm formation and device-associated infections.

Objectives

In this study, we studied the role of the transcription factors Sfp1 in biofilm formation and resistance to caspofungin, an antifungal agent targeting to cell wall.

Methods

The *SFP1*-deletion and *SFP1*-reintegrated mutant strains were generated. We compared wild type and the mutants in their ability in biofilm formation using XTT reduction assay, scanning electron microscopy and confocal laser scanning microscopy. We also examined the effects of *SFP1* deletion on cell wall properties and composition. Finally, cell susceptibility to caspofungin was determined using MIC and spot assay.

Conclusions

The *SFP1*-deletion mutants increased not only cell adhesion, biofilm formation but also caspofungin resistance. Our results provide new insights into the role of *C*. *albicans* Sfp1.

FEMS7-0525
Pathogens / Pathogenicity - Part II

A FASYN CLUSTER OUTSIDE THE LEE ISLAND AFFECTS EHEC BACTERIAL TYPE-III SECRETION THOUGH MULTIPLE REGULATORY SWITCHES

Y.H. Huang[1], W.J. Syu[1], S.T. Hu[1], I.T. Ling[1], H.Y. Tsai[1]
[1]National Yang-Ming University, Microbiology and Inmmunology, Taipei, Taiwan R.O.C.

Backgrounds

Comparing the two genomes between enterohaemorrhagic *Escherichia coli* (EHEC) and K-12 strain, we have previously identified a unique gene cluster named "*fasyn*" in EHEC and experimentally demonstrated that mutants with *fasyn*-deleted affects the type-3 secretion of EHEC. This *fasyn* cluster contains genes numbered Z4863, Z4864, Z4865, and Z4866.

Objectives

This study is to deduce the function(s) of *fasyn* and explore additional changes when *fasyn* is deleted.

Methods

Western blotting was used to compare the amounts of proteins synthesized and secreted with different strains. Bacterial two-hybrid system was used to examine whether two gene products are associated each other. Quantitative RT-PCR was applied to detect whether gene activators were regulated when *fasyn* is deleted at the transcriptional level. Minimal inhibitory concentration was measured to see whether gene deletion makes mutant change its sensitivities to antibiotics.

Conclusions

There was no strong pair-wise interaction among the four gene products encoded by the *fasyn* cluster as revealed by the bacterial two-hybrid assay. EHEC seemed to be more sensitive to rifampicin when *fasyn* was deleted. Furthermore, by qPCR, it was found that a down regulation happened to *ler*, the LEE island global activator, and to a few gene activators outside the LEE island such as *lrp*, *leuO*, and *kdpE*. Complementation with one *fasyn* gene at a time apparently could not restore well the original phenotypes. Therefore, EHEC with *fasyn* deleted may affect multiple gene regulatory switches so that unbalanced signals disturb the authentic bacterial phenotypes.

Pathogens / Pathogenicity - Part II

SCREENING OF NOVEL BIOFILM- AND QUORUM SENSING-MODULATING COMPOUNDS

H.J. Hwang[1], *S.K. Kim*[1]
[1]*Pusan National University, Department of Pharmacy, Busan, Republic of Korea*

Backgrounds

Biofilms are bacterial group behaviors that provide cells with many biological advantages, such as high infectivity, antibiotic resistance, and strong survivability. Currently, most persistent bacterial infections are associated with antibiotic-resistant biofilms of pathogenic bacteria. Quorum sensing (QS) is a key regulation system that induces a large number of virulence genes. *Pseudomonas aeruginosa* is an opportunistic human pathogen whose biofilm formation and QS regulation cause great losses in many industrial facilities and serious infections in humans. Therefore, controls of the *P. aeruginosa* biofilm and QS response are a very important issue in medicine, public health, and industry.

Objectives

We synthesized and screened a series of novel compounds for anti-biofilm and anti-QS activities.

Methods

To screen the compounds, we used static biofilm assays and bioassays using several reporter strains. A *cdrA-lacZ* fusion reporter was used for the measurement of the intracellular c-di-GMP level, and *lasI-lacZ* and *PA1897-lacZ* fusions, for the measurement of the QS activity.

Conclusions

We found that several synthetic compounds such as MHY384, MHY1329, MHY1344, MHY1351, and MHY1354 had a significantly modulating activity on the biofilm formation and QS of *P. aeruginosa*.

Pathogens / Pathogenicity - Part II

S. AUREUS ADAPTATION DURING PNEUMONIA IN MURINE MODEL: MODULATION OF EXPRESSION OF A SELECTED SET OF GENES

R. Iantomasi[1], D. Seguin[1], N. Arnaud Barbe[1], V. Sanchez[1], C. Chabanel[1], C. Gregoire[1], B. Rokbi[1]
[1]Sanofi Pasteur, R&D, Marcy-l'Étoile, France

Backgrounds

Staphylococcus aureus is a gram-positive opportunistic bacteria considered as the major pathogen in community-acquired and nosocomial infections and it has the potential to cause a broad range of disease. The pronounced adaptability to diverse physiologic niches resides in the vast array of virulent factors coded by *S. aureus* which needs to be deeply investigated in order to prevent specific infections.

Objectives

In this study, we investigated the in vivo transcriptional adaptation of *S. aureus* during pneumonia infection.

Methods

Female BalbC mice were infected via intranasal route with *S. aureus* USA 300 strain in order to mimic pneumonia infection. At 5h and 24h post infection (p.i.) infected lungs were collected and processed for prokaryotic RNA extraction. Gene expression was assessed by Fluidigm dynamic array on the BioMark™ HD System allowing quantitative high-throughput real-time PCR analysis. A set of 56 genes covering the mechanisms of replication/adhesion, biofilm formation, iron uptake/transport and immune evasion/stress response were included, as well as regulators factors and housekeeping genes.

Conclusions

The ability of *S. aureus* to adapt to extreme changes, like *in vitro* vs *in vivo*, implies the finely regulation of genes expression. In pneumonia model we observed the up-regulation of genes involved in the adhesion mechanisms, in particularly the MSCRAMM family, and iron acquisition since early time point post infection. *hla*, an important *S. aureus* α-toxin was also found expressed up to 24h post infection. The design and the development of a prevention strategy as well as infection treatment, must take into account the bacterial “physiological” state during infection.

PRECISION MICROBIOTA RECONSTITUTION AFTER ANTIBIOTIC THERAPY CONFERS RESISTANCE AGAINST VANCOMYCIN-RESISTANT ENTEROCOCCUS

S. Isaac[1], A. Djucovik[1], L. Puchades-Carrasco[2], A. Flores-Duro[1], J. Pons[1], N. Jiménez[1], A. Pineda-Lucena[2,3], M. Garcia-Garcerà[4], C. Ubeda[1,5]
[1]Fundación para el Fomento de la Investigación Sanitaria y Biomédica FISABIO, Genomics and Health, Valencia, Spain
[2]Centro de Investigación Príncipe Felipe, Structural Biochemistry Laboratory, Valencia, Spain
[3]Hospital Universitario i Politécnico La Fe, Instituto de Investigación Sanitaria La Fe, Valencia, Spain
[4]Université de Lausanne, Département de microbiologie fondamentale, Lausanne, Switzerland
[5]Centers of Biomedical Research Network CIBER in Epidemiology and Public Health, CIBEResp, Madrid, Spain

Backgrounds

Commensal bacteria are able to inhibit intestinal colonization by opportunistic pathogens, such as vancomycin-resistant Enterococcus (VRE). Antibiotics alter the microbiota and promote gut colonization by VRE. However, the specific commensal bacteria that protect against VRE and the mechanisms of such protection have not been defined yet.

Objectives

Our objectives are to identify members of the intestinal microbiota that confer protection against VRE and the mechanisms of such protection.

Methods

We used a VRE infection mouse model and 16s rRNA high-throughput sequencing to identify commensal bacteria that are associated with resistance to VRE in mice. We isolated and administered these bacteria to vancomycin-treated mice to test their capability to restore colonization resistance.
We used metatranscriptomic and metabolomic approaches to identify in vivo functions expressed and metabolites produced by protective commensal bacteria that could be involved in protection against VRE intestinal colonization.

Conclusions

We demonstrated that the administration of 5 bacterial isolates to mice (*Alistipes, Barnesiella, Olsenella, Oscillibacter* and a bacterium from Ruminococcaceae family) restores protection to VRE in antibiotic-treated mice. The mechanism of such protection may involved nutritional competition for carbohydrates (i.e. mannose or cellobiose) since: (i) protective bacteria diminish the intestinal availability of carbohydrates in antibiotic-treated mice, (ii) expression of transporters for internalization of mannose/cellobiose increases in vancomycin-treated mice upon administration of the five protective strains, (iii) within carbohydrates transporters expressed by VRE in the murine gut, cellobiose and mannose transporters are among the most expressed, (iv) *in vitro* VRE grows efficiently using cellobiose or mannose as unique carbon sources.

Pathogens / Pathogenicity - Part II

MYCOPHAGOUS LIFESTYLE OF BACILLUS SPHAERICUS AGAINST THE PHYTOPATHOGENIC FUNGUS RHIZOCTONIA SOLANI

I. Jamil[1], *S. Bindschedler*[1], *P. Junier*[1]
[1]*University of Neuchâtel, Laboratory of Microbiology, Neuchâtel, Switzerland*

Backgrounds

Bacteria are well known for their diversified nutritional capabilities. Many of these either arise from, or give origin to, interactions with other organisms. In some conditions, the nutritional ability of the bacterium can favor positive or negative interactions with other organisms. Mycophagy represents a series of phenotypic behaviors allowing bacteria to obtain nutrients from living fungi with a negative impact on the fungal partner. Soil is the main hub of bacterial-fungal interactions. Among bacterial soil dwellers, Bacilli are considered to be important components of the soil microbial community. This group includes species widely used in bio fertilization and biocontrol.

Objectives

To investigate the interaction between *Bacillus sphaericus* and the phytopathogenic fungus *Rizoctonia solani* in order to understand an unexplored mycophagous lifestyle and its potential use in sustainable agriculture.

Methods

In order to understand the mechanisms underlying this mycophagous lifestyle, a confrontation assay was performed, where *Rhizoctonia solani* biomass and its exudates were the sole carbon source for the bacteria.

Conclusions

Bacillus sphaericus inhibited fungal growth and used fungal hyphae for their dispersal. Fungal tissues that were in direct contact with bacteria were adversely damaged and unable to re-grow. Microscopic observations revealed both the deformation and the disintegration of the fungal cell wall. Moreover, bacterial growth occurred at the expense of fungal mycelium but no growth was measured in fungal exudates confirming that living mycelium is required for bacterial growth. This yet unexplored mycophagous lifestyle of *Bacillus sphaericus* could be exploited for the control of phytopathogens in sustainable agriculture.

FEMS7-1933
Pathogens / Pathogenicity - Part II

IDENTIFICATION OF GENETIC PATHWAYS FOR FORMATION OF INTRACELLULAR PERSISTERS OF SALMONELLA TYPHIMURIUM

K. Lauridsen[1], L. Jelsbak[1]
[1]Roskilde University, Science- Systems and Models, Roskilde, Denmark

Backgrounds

It is well-known that during growth in laboratory media (*in vitro*) bacteria are able to form a sub-population of non-growing bacteria (so-called persister cells), which, due to their inactive nature, exhibit a transient tolerance to treatment with antibiotics. The molecular mechanisms of *in vitro* persister cell formation have been studied intensively over the last decade. In recent studies, the presence of intracellular persisters of *Salmonella Typhimurium* bacteria infecting cultured macrophages has been reported (Helaine and co-workers).

Objectives

The aim of this study was to identify the genetic determinants of *in vivo* persisters of *S. Typhimurium* and investigate whether the host environment affects the mechanisms/pathways by which persister cells are formed.

Methods

In the present project we have screened a transposon library for mutants with increased persistence following infection of cultured macrophages (*in vivo*) and compared these results with a similar screen for increased persistence in Laboratory Growth media (*in vitro*). We have isolated ten mutants from each screen and are now further characterizing these with respect to persistence and growth physiology. We will determine the genetic determinants by whole genome sequencing of isolated mutants.

Conclusions

Based on our preliminary investigations, the two types of persister mutants (*in vitro* versus *in vivo*) exhibit distinct characteristics. Upon the results of the genome sequencing, we will further investigate the molecular mechanisms of both types of persister mutants, and these data will also be presented at the conference.

THE B COMPONENT OF THE BACILLUS CEREUS HBL ENTEROTOXIN COMPLEX DETERMINES THE TOXIC ACTIVITY TOWARDS DIFFERENT TARGET CELLS

N. Jessberger[1], R. Dietrich[1], F. Tausch[1], A. Didier[1], E. Märtlbauer[1]
[1]Institute for Hygiene and Technology of Milk, Department of Veterinary Sciences, Oberschleissheim, Germany

Backgrounds

A major virulence factor for *Bacillus cereus* food poisoning is the three component enterotoxin haemolysin BL. It consists of the binding component B and the lytic components L2 and L1.

Objectives

Studying the mode of action of Hbl has been difficult, as natural culture supernatants additionally contain Nhe, the second three component enterotoxin.

Methods

In the present study, pore formation as well as cytotoxic and haemolytic activity of recombinant Hbl components was investigated.

Conclusions

rHbl was toxic to cell lines from different origin and tissue. All three components were necessary for cytotoxicity and pore formation. Excess of rHbl B enhanced, excess of rHbl L1 hindered velocity of pore formation. Pore formation was fastest at concentration ratios of L2:L1:B = 1:1:10 and 10:1:10, while a ration of L2:L1:B of 1:1:1 resulted in maximum toxic activity. Hbl activity was due to sequential binding of B – L1 – L2. Binding of Hbl B to the cell surface took 4-5 min, while apposition of L1 and L2 occurred immediately. Diluting the individual components, it became obvious that binding of the B component to the target cell surface is the crucial step for pore formation.

These data suggest that the mechanism of pore formation of Hbl differs from that of Nhe, although both enterotoxin complexes are sequentially highly related.

The IGF Project 18677 N of the FEI is supported via AiF within the programme for promoting the Industrial Collective Research (IGF) of the German Ministry of Economic Affairs and Energy (BMWi), based on a resolution of the German Parliament.

EFFECTS OF THE BILE SALT SODIUM GLYCOCHOLATE HYDRATE ON GLOBAL GENE AND PROTEIN EXPRESSION IN CLINICAL ENTEROTOXIGENIC ESCHERICHIA COLI (ETEC) ISOLATES

E. Joffré[1], M. Nicklasson[2], S. Alvarez-Carretero[1], X. Xiao[3], B. Zhu[3], Å. Sjöling[1]
[1]Karolinska Institutet, Microbiology- Tumor and Cell Biology MTC, Stockholm, Sweden
[2]University of Gothenburg, Institute of Biomedicine- Department of Microbiology and Immunology, Göteborg, Sweden
[3]Chinese Academy of Sciences- Beijing,
CAS Key Laboratory of Pathogenic Microbiology & Immunology- Institute of Microbiology, Beijing, China

Backgrounds

Enterotoxigenic E. coli (ETEC) is one of the most common bacterial causes of acute watery diarrhea in the developing world, both among children and adults. When ETEC enter into the host and pass through the intestinal tract, the bacteria encounter an array of host factors to avoid bacterial colonization and spreading. Bile is one of the host factors conferring protection against bacteria; however, certain concentration has been demonstrated to regulate virulence in several pathogens. Still little is known about how the gene expression of ETEC is modulated by bile.

Objectives

The goal of the present study was to further explore the contribution of bile, and in particular NaGCH, to global gene expression in ETEC strains expressing CS5 and CS6.

Methods

To address this, we used bile salts and an individual bile salts, sodium glycocholate hydrate (NaGCH) enriched media to grow two ETEC CS5+CS6 strains E1777 and E2265 and subsequently we performed a transcriptome and proteome analysis using RNA-seq and iTRAQ-coupled LC-MS/MS to measure the global gene expression, transcriptome and proteome variation in presence of bile and NaGCH.

Conclusions

The resulting gene expression profiles showed that virulence genes: CS5 operon (csfA, csfC and csfD), csvR and cexE, were strongly upregulated by both bile and NaGCH. Bile upregulated genes involved in fatty acid oxidation while NaGCH upregulated nitrogen metabolism, biofilm formation and chemotaxis genes. fliC gene involved in bacterial motility was downregulated by NaGCH. As was expected, the proteomic data confirmed the significant upregulation of CS5 and CexE. Our data demonstrate that bile and especially individual bile salts NaGCH upregulate the virulence in ETEC and but also modulate differentially ETEC gene expression of different pathways and additional factors that are directly or indirectly involved in ETEC pathogenesis.

Pathogens / Pathogenicity - Part II

ENDOCARDITIS DUE TO STREPTOCOCCUS SUIS IN FARMED MINKS IN ICELAND

G. Jonsdottir[1]
[1]*The Institute for Experimental Pathology- University of Iceland- Keldur, Bacteriology and Pathology, Reykjavík, Iceland*

Backgrounds

Streptococcus suis (S. suis) is an opportunistic bacterium usually associated with pigs. The bacterium is found in the tonsils of most pigs and capable of causing meningitis and septicemia. *S. suis* has also been isolated from other animals, such as minks, horses, dogs, cats, and birds. The bacterium can cause disease both in animals and humans.

Objectives

The aim of this study is to describe endocarditis in farmed minks mainly caused by *S. suis.*

Methods

In the years 2010 to 2015 the Institute of Experimental Pathology, Keldur received 31 minks from one farm for post mortem examination.The minks had all been fed offal from a pig slaughterhouse and the feed had probably not been adequately heat-treated. Autopsy revealed vegetative endocarditis and *S. suis* was isolated in the majority of cases. Both *S. suis* serotype I and II were isolated.

Conclusions

Our study showed that death in minks due to endocarditis was primarily due to *S. suis*, either serotype I or II. Most of the minks acquired the infected in July to September and were found dead without clinical signs being observed. It is important to treat offal with caution especially if it's going to be used as animal feed. *S. suis* is a zoonotic agent that can be a serious pathogen both in animals and humans

FEMS7-1439
Pathogens / Pathogenicity - Part II

CHEMICAL QUORUM QUENCHING ATTENUATES RALSTONIA SOLANACEARUM VIRULENCE ON PLANTS

K. Kai[1], A. Yoshihara[1], M. Shimatani[1], Y. Hikichi[2]
[1]Osaka Prefecture University, Graduate School of Life and Environmental Sciences, Osaka, Japan
[2]Kochi University, Department of Agriculture, Kochi, Japan

Backgrounds

Ralstonia solanacearum is a beta-Proteobacterium bacterium that causes “bacterial wilt” on a wide range of plant species. Quorum sensing (QS), a bacterial cell-cell communication mechanism, controls virulence determinants, such as the production of extracellular polysaccharide (EPS) and biofilm formation, in *R. solanacearum*. The bacterial strains employ methyl 3-hydroxymyristate or methyl 3-hydroxypalmitate as the QS signals, which are synthesized and sensed by *phc* QS system.

Objectives

Here we describe the design, synthesis, and biological evaluation of the inhibitors of *phc* QS.

Methods

Initial screening of a small set of QS signal analogs found that PQI-1 (*phc* quorum sensing inhibitor-1), inhibits biofilm formation by *R. solanacearum*. To improve its inhibitory activity, the derivatives of PQI-1 were synthesized. PQI-2−5 inhibited not only biofilm formation but also other QS-controlled traits. Those antagonists reduced wilting symptoms of the tomato plants infected with *R. solanacearum.*

Conclusions

Targeting *phc* QS has potential for the development of agrochemicals that protect crops from bacterial wilt disease.

FEMS7-2187
Pathogens / Pathogenicity - Part II

IDENTIFICATION, FUNCTIONAL CHARACTERIZATION AND REGULON PREDICTION OF A NOVEL TWO COMPONENT SYSTEM COMPRISING BAS0540-BAS0541 OF BACILLUS ANTHRACIS

D. Kandari[1], *M. Gopalani*[1], *R. Bhatnagar*[1]
[1]*Jawaharlal Nehru University, School of Biotechnology, New Delhi, India*

Backgrounds

Two component systems (TCSs) comprise of a membrane bound sensor Histidine Kinase (HK), and a cytosolic Response Regulator (RR). TCSs are complex molecular devices that help bacteria sense its environment and respond aptly. 41 TCSs are predicted in *Bacillus anthracis*, a potential bioterrorism agent, of which only four have been studied so far.

Objectives

Implication of TCSs in the maintenance of a specialized lifestyle pattern and pathogenesis of B. anthracis remains largely unmapped and needs comprehensive exploration. Our study characterizes a novel TCS of B. anthracis and elucidates its role in the physiology of the pathogen.

Methods

qRT-PCR, immunoblotting, autophosphorylation/phosphotransfer assays, EMSA, electroporation, confocal/DIC microscopy.

Conclusions

BAS0540-BAS0541 constitutes a classical TCS of *B. anthracis*. The RR and HK are encoded by BAS0540 and BAS0541, respectively. BAS0541 exhibited autophosphorylation and phosphotransfer to its cognate RR BAS0540. BAS0540 exhibited a constitutive expression throughout the growth of *B. anthracis*. The *in silico* predicted regulon of BAS0540 comprised of 23 genes with a diverse set of functions excluding any of the proven virulence factors. EMSA demonstrated the direct binding of BAS0540 to the upstream regions of functionally important putative regulon genes like *ftsA*. Phosphorylation by small molecule phosphodonors led to a striking enhancement in the DNA binding capability of BAS0540. Overexpression of BAS0540 in *B. anthracis* led to a prodigious increase in the cell length and a discernible decrease in the sporulation efficiency of the bacteria. Thus, BAS0540-BAS0541 forms a functional TCS of *B. anthracis* which is implicated in cell division and sporulation of the pathogen.

FEMS7-1125

ANTIMICROBIAL AND ANTIBIOFILM ACTIVITIES OF MODIFIED-ANTIMICROBIAL PEPTIDE AGAINST BURKHOLDERIA PSEUDOMALLEI

S. Kanthawong[1], S. Wongkaewkhiaw[2], J.G.M. Bolscher[3], K. Nazmi[3], S. Wongratanacheewin[2], C. Anutrakunchai[4], S. Taweechaisupapong[5]
[1]Biofilm Research Group and Faculty of Medicine/Khon Kaen University, Department of Microbiology, Khon Kaen, Thailand
[2]Melioidosis Research Center MRC- Faculty of Medicine/Khon Kaen University, Department of Microbiology, Khon Kaen, Thailand
[3]Academic Centre for Dentistry Amsterdam ACTA, Department of Oral Biochemistry, Amsterdam, The Netherlands
[4]Biofilm Research Group and Faculty of Medicine/Khon Kaen University, Department of Biochemistry, Khon Kaen, Thailand
[5]Biofilm Research Group- Faculty of Dentistry/Khon Kaen University, Department of Oral Diagnosis, Khon Kaen, Thailand

Backgrounds

Melioidosis is a severe disease caused by *Burkholderia pseudomallei*. The growing *B. pseudomallei* in biofilm has been reported to induce resistance to several conventional antibiotics, a phenomenon that may be related to relapse cases in melioidosis patients.

Objectives

The aim of this study was to compare the antibiofilm activity of human cathelicidin antimicrobial peptides (LL-37, LL-31) and theirs D-enantiomeric form (D-LL-37, D-LL-31) against 3 isolates of *B. pseudomallei* 1026b, H777 and biofilm mutant M10.

Methods

Antibiofilm assay revealed that, a truncated variant of LL-37 lacking the six C-terminus residues in D-enatiomeric form, D-LL-31 revealed a strongest killing activity against all isolates of *B. pseudomallei* in dose-dependent manner. Moreover, the IC_{50} values of D-LL-31 was further investigated compared with CAZ against biofilm form of those isolates. The results showed that IC_{50} values of D-LL-31 were ranging from 1.07-5.55 µM, while, IC_{50} values of CAZ was higher than D-LL-31 about 45, 60 and 240 folds against biofilm form *B. pseudomallei* M10, H777 and 1026b, respectively. In addition, D-LL-31 showed strongly effects on biofilm of all isolates tested in static condition. Moreover, D-LL-31 was applied to biofilm of *B. pseudomallei* under BioFlux flowthrough conditions and caused disruption of the biofilms.

Conclusions

These results indicate that D-LL-31 not only disrupted preformed-biofilm but also exhibited potent killing activity against *B. pseudomallei* in biofilm form. Thus D-LL-31 should be considered to develop as novel antibiofilm agent against *B. pseudomallei* which is finally benefited to melioidosis patients.

KINETIC AND THERMODYNAMIC STUDIES ON INTERACTIONS BETWEEN HUMAN PLASMINOGEN AND CANDIDA TROPICALIS CELL WALL-ASSOCIATED ENOLASE AND HYPHALLY REGULATED PROTEIN

J. Karkowska-Kuleta[1], D. Zajac[2], G. Bras[1], O. Bochenska[2], A. Kozik[2], M. Rapala-Kozik[1]
[1]Jagiellonian University - Faculty of Biochemistry- Biophysics and Biotechnology, Department of Comparative Biochemistry and Bioanalytics, Krakow, Poland
[2]Jagiellonian University - Faculty of Biochemistry- Biophysics and Biotechnology, Department of Analytical Biochemistry, Krakow, Poland

Backgrounds

Recruitment of human proteolytic enzymes at the cell surface of pathogenic microorganisms gives them an incredible opportunity to acquire additional hydrolytic activity. Hence, binding of human plasminogen (HPG) by the surface-exposed proteins might be an important mechanism increasing also the virulence of *Candida tropicalis*, now regarded as a third, or even second *Candida* spp. most commonly isolated from the bloodstream of immunocompromised individuals suffering from candidemia.

Objectives

The detailed characterization of interactions between HPG and *C. tropicalis* surface-exposed proteins.

Methods

To select fungal HGP-binding proteins, affinity chromatography was performed with the use of the mixture of *C. tropicalis* beta-1,6-glucanase-extractable cell wall proteins. Then, fungal enolase (Eno) and hyphally regulated protein (Hyr) were purified with the ion exchange chromatography. The kinetic and thermodynamic characterization of interactions between human plasminogen and each fungal protein was performed with the use of BIACORE 3000 system.

Conclusions

The dissociation constants determined for complexes of HPG and Hyr, a typical, highly glycosylated GPI-anchored hyphal cell wall protein, or Eno, a glycolytic enzyme that moonlight at the cell surface, were of a 10^{-7} M order, indicating rather a moderate binding affinity. Since surface-bound plasmin might greatly facilitate fungal invasion on human organism, the detailed characterization of interactions between this human protein and *C. tropicalis* surface-exposed proteins can significantly increase the understanding of the molecular bases of pathogenesis of infections caused by these fungi.

IMPORTANCE OF FUMARATE AND NITRATE REDUCTION REGULATORY PROTEIN FOR INTESTINAL PROLIFERATION OF VIBRIO VULNIFICUS IN INTESTINE

T. Kado[1], T. KASHIMOTO[1], K. Yamazaki[1], S. Ueno[1]
[1]Kitasato Univ. School of Veterinary Medicine, Veterinary Public Health, Towada, Japan

Backgrounds

The sepsis caused by *Vibrio vulnificus* is characterized by an average incubation period of 26 hours and a high mortality rate exceeding 50 %. The fast growth and dissemination of *V. vulnificus in vivo* lead to poor clinical outcomes in patients. Therefore, elucidation of the proliferation mechanisms of this organism *in vivo* may lead to development of an effective therapeutic strategy.

Objectives

In this study, we focused on the low oxygen concentration in the intestinal milieu because of its drastic difference from that in the air. Fumarate and nitrate reduction regulatory protein (FNR) has been known as the global transcriptional regulator for adaptation to anaerobic conditions in various bacteria.

Methods

We generated a strain of *V. vulnificus* in which the *fnr* gene was replaced with an erythromycin resistance gene (*fnr*::*erm* mutant). And the *fnr*::*erm* mutant was tested in a growth competition assay against WT *in vivo.*

Conclusions

The competitive index of *fnr*::*erm* mutant to WT in the intestinal loop and liver was 0.378±0.192 (Mean ± S.D) and 0.243±0.123 respectively. These data suggested that FNR is important for the proliferation of *V. vulnificus* in the intestine to achieve a critical mass to be able to invade systemic circulation.

STOCHASTIC EXPRESSION OF LACTATE DEHYDROGENASE CAUSES E. COLI PERSISTER FORMATION

Y. Kawai[1], *R. Isshiki*[1], *N. Yamamoto*[1], *S. Matsumoto*[2], *S. Tsuneda*[1]
[1]*Waseda University, Department of Life Science and Medical Bioscience, Tokyo, Japan*
[2]*Nagoya University, Medicine, Nagoya, Japan*

Backgrounds

Persisters are multidrug tolerant cells that present within antibiotic sensitive population. In contrast to antibiotic resistant bacteria, the tolerance arises from transient phenotypic variants rather than genetic mutations. Cells which express persister gene stochastically can switch to persister states. Although previous study identified many genes involved in persister formation, molecular mechanisms of bacterial persistence remain unclear because of their redundancy. In order to identify novel persister genes, we developed a marker for *E.coli* persisters and performed transcriptome analysis of isolated persisters.

Objectives

The objective is to reveal molecular mechanisms of persister formation via lactate dehydrogenase (*ldhA*) which was identified from our transcriptome data.

Methods

Transcriptome data suggested expression of anaerobic respiration genes. We screened overexpression and knockdown strains derived from *E.coli* MG1655. CRISPR interference was used for gene knockdown. To visualize *ldhA* expression, YFP was cloned into pSC101 vector that contained *ldhA* promoter. The YFP fluorescence of reporter strain was analyzed by microfluidic devise.

Conclusions

ldhA overexpression increased persister population by 1000 times, and knockdown decrease the population by 10 times. Stochastic expression of *ldhA* may influence bacterial metabolic activity because *ldhA* uses central metabolite pyruvate and NADH. Time-lapse microscopy images of *ldhA* reporter strain showed the most of cells did not express *ldhA*, but a small portion of cells (~1%) highly expressed *ldhA*. These cells stopped dividing and tolerated lethal concentration of ampicillin. Interestingly, although *ldhA* was expressed transiently, the cells showed dormant phenotype over 1 hour. These results suggest that stochastic expression of *ldhA* triggers persister formation.

Pathogens / Pathogenicity - Part II

XTT ASSAY FOR EVALUATING THE EFFECT OF BASSIATIN AS A NOVEL ANTISEPTIC AGENT ON HOSPITAL-ACQUIRED METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS (MRSA) AND STREPTOCOCCUS PNEUMONIAE

E. Ozgor[1], N. Keskin[1], I. Celebier[1], M. Ulusoy[1]
[1]Hacettepe University Faculty Of Science, Biology, Ankara, Turkey

Backgrounds

Methicillin-resistant Staphylococcus aureus (MRSA) and *Streptococcus pneumoniae* are responsible for several serious infections in humans. Resistance does make infections more difficult to treat with standard types of antibiotics and thus more dangerous. Bassiatin is a newly discovered depsipeptide which is produced by fungal species. Bassiatin was observed that it inhibits cell proliferation and cell cycle progression in some cancer cell lines. Besides these studies, there is no another research with bassiatin.

Objectives

Objective of this study is investigate the effects of bassiatin for microbial inhibition on clinical MRSA and *S.pneumoniae* isolates from private hospital in Turkey.

Methods

Bassiatin which is produced by *Beauveria bassiana* was purified. *B.bassiana* was grown in specific medium at pH 6.5 under 28°. The extract of the culture broth afforded 150 mg of residue under reduced pressure and it was further separated by HPLC to give bassiatin. The XTT colorimetric assay was used to determine the percentage of viable cells following each treatment. For bacterial culture preparation, 200 µl of overnight culture adjusted to 5×10^5 cells/ml was added to 96-well plate. Following 17 h treatment with different concentrations of bassiatin, 100 µl from each well was transferred to new plate and 25 µl XTT/Menadione was added on them. After an incubation period of 1h at 37°C, the absorbance at 490 nm was measured.

Conclusions

The antimicrobial activity of bassiatin was evaluated in accordance to a predefined threshold of a minimum of 50% reduction in the produced formazan with XTT colorimetry assay. Bassiatin was found to be effective on MRSA and *S.pneumoniae*. Furthermore, it was found that there is a correlation between the concentration of Bassiatin and inhibition of MRSA and *S.pneumoniae*. Consequently, this study is promising for further clinical studies and bassiatin may be used as a potential drug against MRSA and *S.pneumoniae* in future.

Pathogens / Pathogenicity - Part II

CYCLO-(L-PHE-L-PRO) INDUCES EXPRESSION OF HYDROPEROXIDASE BY REGULATION OF RPOS TO FACILITATE THE SURVIVIAL OF PATHOGENIC VIBRIO SPP UNDER OXIDATIVE STRESS

K.S. Kim[1]
[1]*Sogang University, Department of Life Science, Seoul, Republic of Korea*

Backgrounds

Vibrio vulnificus, an opportunistic human pathogen, produces cyclo (L-Phe-L-Pro) (cFP), which serves as a signal molecule controlling the ToxR-dependent expression of innate bacterial genes, and as a virulence factor eliciting pathogenic symptom on human cells by enhancing the intracellular reactive oxygen species level. We found that cFP facilitates the survival of *V. vulnificus* under the oxidative stress induced by H_2O_2.

Objectives

Molecular mechanisms underlying the cFP-mediated resistance against the oxidative stress induced by H_2O_2 were to be elucidated.

Methods

Employing transcriptomic analyses and also various molecular genetic tools, we studied regulatory components associated with cFP-mediated resistance against oxidative stress.

Conclusions

We found a novel cFP-LeuO-vHUαβ-RpoS pathway that is responsible for the induction of *katG* encoding hydroperoxidase I that detoxifies H_2O_2 to overcome the oxidative stress condition. This pathway is also up-regulates genes known to be members of the RpoS regulon, suggesting that cFP is a cue for a signal transduction pathway responsible for regulons of LeuO as well as RpoS.

Pathogens / Pathogenicity - Part II

GENETIC RELATIONSHIPS OF ERWINIA AMYLOVORA ISOLATES OCCURRED IN KOREA

S.H. Kim[1], B.Y. Kim[1], Y.H. Yun[1], J.Y. Kim[1], S.J. Lee[2], O.K. Jung[3]
[1]Dankook University, Microbiology Department, Cheonan, Republic of Korea
[2]Animal and Plant Quarantine Agency, Plant Pest Control Department, Gimcheon, Republic of Korea
[3]Cheonan-si Agricultural Technology Center, Fruit Tree Department, Cheonan, Republic of Korea

Backgrounds

Erwinia amylovora, a Gram-negative bacterium in the family enterobacteriaceae, causes fire blight disease in apples and pears. In 2015, fire blight disease occurred for the first time in pear and apple orchards in Korea.

Objectives

A total of 64 *Erwinia amylovora* isolates were obtained from 40 farms located in Anseong, Cheonan, and Jecheon regions and their genetic relationships were studied with foreign isolates to understand their potent origin.

Methods

All the Korean isolates analyzed showed identical nucleotide sequence in the 16S rRNA, *gyr*B (DNA gyrase subunit B), and *rpo*D (RNA polymerase sigma factor RpoD) genes. When the pattern of clustered regularly interspaced short palindromic repeats (CRISPR) which have three spacer regions in *E. amylovora* was compared between the Korean isolates and 122 isolates from 14 countries, all the Korean isolates were analyzed as the 2-22-38 genotype that includes four isolates from USA and Canada. When the nucleotide sequence of six loci in variable number of tandem repeats (VNTR) was analyzed, five genotypes were resolved in the 64 Korean *E. amylovora* isolates. Among the five genotypes, the genotype 1 was found in 73% of the isolates.

Conclusions

When VNTR analysis of the Korean isolates was extended with foreign *E. amylovora* isolates from 26 countries, Korean isolates of the genotype 2 agreed with one isolate from Canada which belongs to the CRISPR genotype 2-22-38, revealing that the results of VNTR analysis supports those of CRISPR analysis. Overall, Korean *E. amylovora* isolates are genetically close to North American *E. amylovora* isolates.

GROWTH PROPERTIES OF KOREAN ISOLATES OF FIRE BLIGHT PATHOGEN

S.H. Kim[1], B.Y. Kim[1], Y.H. Yun[1], O.K. Jung[2]
[1]Dankook University, Microbiology Department, Cheonan, Republic of Korea
[2]Cheonan-si Agricultural Technology Center, Pomology, Cheonan, Republic of Korea

Backgrounds

In 2015, fire blight disease occurred in pear and apple trees in Korea. From the investigation of the disease occurred farms in Anseong, Cheonan, and Jecheon regions, 64 *Erwinia amylovora* were obtained and they were divided into five genotypes by the analysis of the pattern of variable number of tandem repeats (VNTR).

Objectives

The present study was performed to investigate the growth properties of these five types of Korean *E. amylovora* isolates.

Methods

Five isolates which were randomly selected from each VNTR genotype were used for the investigation. Their ability of utilizing 20 different nutrient substrates were tested using an API kit. For the production of extracellular enzymes, they were grown on chromagenic media supplemented with high molecular substrates such as pectin, amylose, xylan, CM-cellulose, avicel, cellobiose, and skim milk. Sensitivity to antibiotics was assessed by the disc-diffusion assay.

Conclusions

They all could utilize only six substrates including D-glucose, D-mannitol, N-acetyl-glucosamine, malic acid, and potassium gluconate. They could not reduce NO3 but utilize L-tryptophan. There was no apparent difference among the five genotype isolates. They grew well at 25, 30, and 37 ℃. All the five *E. amylovora* isolates could not grown on chromogenic media supplemented with high molecular substrates, suggesting they have no ability of producing extracellular enzymes for these substrates. All the five types of *E. amylovora* isolates showed sensitivity to streptomycin and no difference was found in the degree of sensitivity to the antibiotics among them.

Pathogens / Pathogenicity - Part II

CHANGES IN MEMBRANE CHARACTERISTICS WITH INCREASE OF ORNITHINE LIPID MODIFY THE INFECTIVITY OF P. AERUGINOSA

S.K. Kim[1], X.H. Li[1], J.H. Lee[1]
[1]Pusan National University, Department Of Pharmacy, Busan, Republic Of Korea

Backgrounds

Ornithine lipids (OLs) are bacteria-specific lipids that are widely found in outer membrane of many Gram (-) bacteria, but not detected in Eukarya and Archaea. Some bacteria produce OL to change the membrane composition in certain unusual situations like phosphate-limiting condition. *Pseudomonas aeruginosa* has *olsBA* operon for the OL biosynthesis to meet the phosphate limitation.

Objectives

We addressed how the OL production and resulting change of the lipid composition modulate the virulence of *P. aeruginosa* during the infection to host cells.

Methods

We controlled the OL level by overexpressing *olsBA* and confirmed the elevated level of OL by TLC and HPLC analyses. When the virulence of *P. aeruginosa* was investigated using two host models, *Tenebrio molitor* (insect) and *Caenorhabditis elegans* (nematode), the increase of OLs alleviated the virulence of *P. aeruginosa.* The host response to OLs was monitored through the expressions of COX-2 and iNOS using Western blot and real-time PCR analyses.

Conclusions

The elevated level of OL in membrane of *P. aeruginosa* increased hydrophobicity and positive charge of cell surface, which resulted in significant change of susceptibility of *P. aeruginosa* cells to antibiotics and host immunity, such as antimicrobial peptides and macrophages. OLs reduced the production of inflammatory factors such as iNOS, COX-2, PGE_2, and nitric oxide in host cells. Also, OL can increase the resistance to antimicrobial peptides such as LL-37 and magainin. The increase of OL content in *P. aeruginosa* modifies virulence by changing the cell surface property.

Pathogens / Pathogenicity - Part II

INTERACTION BETWEEN THE TYPE III EFFECTOR VOPO AND GEF-H1 ACTIVATES THE RHOA-ROCK PATHWAY

H. Hiyoshi[1], S. Matsuda[2], K. Gotoh[3], T. Iida[2], T. Kodama[2]
[1]School of Medicine- University of California at Davis, Medical Microbiology and Immunology, Davis, USA
[2]RIMD - Osaka University, Bacterial Infections, Osaka-Suita, Japan
[3]Okayama University Graduate School of Medicine, Bacteriology, Okayama, Japan

Backgrounds

Vibrio parahaemolyticus is an important pathogen that causes food-borne gastroenteritis in humans. The type III secretion system encoded on chromosome 2 (T3SS2) plays a critical role in the enterotoxic activity of this bacterium. Previous studies have demonstrated that T3SS2 induces actin stress fibers in various epithelial cell lines during infection. This stress fiber formation is strongly related to pathogenicity, but the mechanisms that underlie T3SS2-dependent actin stress fiber formation and the main effector have not been elucidated.

Objectives

Objective of this study is the identification and the functional characterization of T3SS2 effector responsible for stress fiber formation.

Methods

V. parahaemolyticus strain RIMD2210633 (KP-positive, serotype O3:K6) was used as a parent strain. A four-primer polymerase chain reaction (PCR) technique was used to engineer an in-frame deletion mutation.

Conclusions

We identified VopO as a critical T3SS2 effector protein that activates the RhoA-ROCK pathway, which is essential pathway for the induction of the T3SS2-dependent stress fiber formation. We also determined that GEF-H1, a RhoA guanine nucleotide exchange factor (GEF), directly binds VopO and is necessary for T3SS2-dependent stress fiber formation. The GEF-H1-binding activity of VopO via an alpha helix region correlated well with its stress fiber-inducing capacity. Furthermore, we showed that VopO is involved in the T3SS2-dependent disruption of the epithelial barrier. Thus, VopO hijacks the RhoA-ROCK pathway in a different manner compared with previously reported bacterial toxins and effectors that modulate the Rho GTPase signaling pathway.

Pathogens / Pathogenicity - Part II

FARNESOL POTENTIATES TMPYP-MEDIATED PHOTODYNAMIC INACTIVATION OF STAPHYLOCOCCUS AUREUS

M. Kossakowska-Zwierucho[1], *J. Nakonieczna*[1]
[1]*Intercollegiate Faculty of Biotechnology- University of Gdansk and Medical University of Gdansk, Department of Biotechnology- Laboratory of Molecular Diagnostics, Gdansk, Poland*

Backgrounds

Photodynamic inactivation (PDI) utilizes light-activated photosensitizing compounds, which in the presence of oxygen trigger local generation of reactive oxygen species and lead to death of target cells. This method can be used to eradicate human pathogens independently on their antibiotic resistance pattern. However, in the case of *Staphylococcus aureus*, a strain-specific sensitivity to PDI is observed which hampers its practical application. To overcome this heterogeneity, PDI can be combined with adjuvants sensitizing bacteria to photoinactivation.

Objectives

To analyse a combined action of red light-activated cationic porphyrin TMPyP (5.10.15.20-tetrakis(1-methyl-4-pyridinio)porphyrin) and *trans-trans*-farnesol – a natural compound of plant origin. The research hypothesis is that farnesol acts as an adjuvant-like agent specifically sensitizing *S. aureus* to the action of light-activated TMPyP via yet unknown molecular mechanism.

Methods

To identify molecular elements triggered by synergistic action of red light-activated TMPyP and farnesol in *S. aureus,* the primary changes in gene expression are analyzed using Tn*917-lacZ* reporter system. This method is based on a random transposon mutagenesis in strain RN4220, coupled with insertion of promoterless β-galactosidase gene in order to identify up-regulated genes under sub-lethal PDI conditions.

Conclusions

Observed potentiation of PDI with farnesol appears as a novel strategy to combat multiresistant *S. aureus* infections. Obtained results constitute the first step in a characterization of the mechanism of PDI and farnesol combined antibacterial action.

PSEUDOMONAS AERUGINOSA PHOSPHOLIPASES AND LECTINS ARE POTENTIAL THERAPEUTIC TARGETS

F. Kovacic[1], F. Bleffert[1], T. Schwabroch[1], C.H. Strunk[1], M. Caliskan[1], J. Granzin[2], M. Siebers[3], P. Dörmann[3], L. Rahme[4], R. Batra-Safferling[2], K.E. Jaeger[1,5]
[1]Institute of Molecular Enzyme Technology- Heinrich-Heine-University Düsseldorf, Bacterial Enzymology, Jülich, Germany
[2]Institute of Complex Systems- Forschungszentrum Jülich GmbH, ICS-6: Structural Biochemistry, Jülich, Germany
[3]Institute of Molecular Biotechnology- Universität Bonn, IMBIO, Bonn, Germany
[4]Harvard Medical School, Department of Microbiology and Immunology, Boston, USA
[5]Institute of Bio- and Geosciences- Forschungszentrum Jülich GmbH, IBG-1: Biotechnology, Jülich, Germany

Backgrounds

Pseudomonas aeruginosa is a Gram-negative opportunistic pathogen infecting immunocompromised humans with high mortality rates. Many virulence factors, among them phospholipases and lectins contribute to biofilm formation and high antibiotic resistance of *P. aeruginosa*.

Objectives

Phospholipases are involved in bacterial adaptation, host membrane damage and modulation of host lipid signaling. We have studied a novel phospholipase A which may contribute to the biosynthesis of lipid messengers related to virulence and biofilm formation. The lectin LecB is located at the cell surface and mediates bacterial attachment to human tissue during initial biofilm formation. We have tried to elucidate the so far unknown LecB secretion pathway.

Methods

PlbF as a novel phospholipase A of *P. aeruginosa* was shown to hydrolyze membrane phospholipids *in vitro* and *in vivo* releasing medium chain fatty acids. It acts as a virulence factor as shown by a *Drosophila melanogaster* infection model and is involved in biofilm formation. Screening of a transposon mutant library of *P. aeruginosa* using a high-throughput enzyme-linked lectin assay resulted in the identification of approximately 30 strains significantly affected in LecB secretion with targeted genes involved in the biogenesis of the flagellum and type-IV pili involved in cell attachment and biofilm formation.

Conclusions

The novel phospholipase PlbF may be linked to a virulence mechanism involving cell signaling in *P. aeruginosa*. The lectin LecB may be co-secreted with flagellin *via* a type-III secretion system. These data suggest that that lectin and phospholipase may represent potential targets for treatment of *P. aeruginosa* infections.

Pathogens / Pathogenicity - Part II

SELECTION OF AN ANTI-UBIQUITIN SSDNA APTAMER – A TOOL FOR STUDYING THE RELATIONSHIP BETWEEN UBIQUITINATION AND MICROBIAL INFECTIONS

E. Kowalska[1], K. Muszynska[1], F. Bartnicki[1], M. Bodaszewska-Lubas[1], W. Strzalka[1]
[1]Jagiellonian University, Plant Biotechnology, Krakow, Poland

Backgrounds

Ubiquitin is a well characterized conservative eukaryotic post-translational modifier (1). It was shown to be involved in signal transduction and to play a regulatory function in cellular processes. What is more ubiquitination turned out to be a key process in infectious disease responses in plants (2).

Objectives

To study the function of diverse ubiquitination patterns in plants, tools for detection and purification of ubiquitinated proteins are necessary. Therefore, the aim of this study was to develop a DNA aptamer recognizing ubiquitinated plant proteins.

Methods

GST-ubiquitin was overexpressed and purified to homogeneity from *E. coli* BL21 cells. The selection of a DNA aptamer was performed using the SELEX (*Systematic Evolution of Ligands by Exponential Enrichment*) method (3). The progress of the selection process was monitored using qPCR. After ten rounds of SELEX ssDNA molecules were cloned and sequenced. Among the selected ssDNA molecules five aptamer groups characterized by unique sequences were identified. The specificity and affinity of the identified aptamers were verified using qPCR and pull-down assays.

Conclusions

The developed aptamer may serve as a new tool for the study and analysis of the role of ubiquitination during plant microbial infections. This is crucial to better understand the molecular mechanisms of infectious diseases, since the modulation of host ubiquitination is a common mechanism of plant pathogen action.

SILVER NANOPARTICLES - NANOSIZED ENHANCERS OF THE ANTI-STAPHYLOCOCCAL ACTIVITY OF NAPHTHOQUINONES.

M. Krychowiak[1], *A. Kawiak*[1], *A. Królicka*[1]
[1]*Intercollegiate Faculty of Biotechnology UG&MUG, Department of Biotechnology, Gdansk, Poland*

Backgrounds

Staphylococcus aureus is a human pathogenic bacterium and a major cause of antibiotic-resistant infections. The failure of antibiotic-resistant therapies has driven the development of alternative approaches for combating microbial infections. Silver nanoparticles (AgNPs) and naturally occurring substances like naphthoquinones (NQs) represent antimicrobials with bactericidal potential towards *S. aureus*.

Objectives

The aim was to verify if silver nanoparticles enhance the anti-staphylococcal activity and decrease the cytotoxicity of selected naphthoquinones.

Methods

Antimicrobial potential of tested substances was determined by Broth Microdilutions Method (planktonic cultures) and MBEC Assay (bacterial biofilm). The Checkerboard Titration technique was employed to verify the impact of AgNPs on bactericidal potential of NQs. Cytotoxic effect of antimicrobials and their combinations was determined towards HaCaT cells with the use of the MTT Assay.

Conclusions

The overall results obtained during this study depicted the potential of AgNPs to enhance the bactericidal activity of NQs. The addition of AgNPs to culture medium lead to the reduction of NQs minimal bactericidal concentrations from 50 to 97%. Moreover, the decrease of NQs effective doses lead to a significant reduction of their cytotoxicity. What is most important, the enhancing effect of AgNPs was observed both for *S. aureus* strains resistant to antibiotics and staphylococcal biofilm.

Pathogens / Pathogenicity - Part II

SEX IN AN ASEXUAL YEAST: GENOMIC EVIDENCE OF A SEXUAL CYCLE AND ERROR-PRONE MATING TYPE SWITCHING IN THE OPPORTUNISTIC PATHOGEN CANDIDA GLABRATA

E. Ksiezopolska[1], L. Carreté[1], C. Pegueroles[1], C. Fairhead[2], T. Gabaldon[1]
[1]Centre for Genomic Regulation CRG, Bioinformatics and Genomics, Barcelona, Spain
[2]Paris-Sud University, Institute for the Diversity- Ecology and Evolution of the Living World, Paris, France

Backgrounds

Candida glabrata is considered an asexual species despite maintaing homolog genes to those involved in mating in *Saccharomyces cerevisiae*. Debates about its sexuality have arisen as some research indicates that *C. glabrata*, similarly to *Candida albicans*, might be able to mate (Muller *et al.,* 2008), other claims that the MLST-based clades show a strong bias in the presence of only one of the two mating types, suggesting a low incidence of mating type switching (Brisse *et al.,* 2009).

Objectives

We aim to address whether *C. glabrata* is able to mate using whole genome data and to perform for the first time a genome-wide characterization of the population structure in this species.

Methods

Comparative genomics methods were used to study the differences between *C.glabrata*, *C. albicans* and *S. cerevisae.* It involved calling SNPs, assessing the levels of gentetic variations, investigation of recombination rates and strength of purifying selection. What is more, PCR and Sanger sequencing were performed as a validation of computed results and switching of the mating-type.

Conclusions

We determined that *C. glabrata* is highly genetically structured. The existence of some form of sexual cycle is supported by similar patterns of evolutionary constraints in reproduction related genes in *C. glabrata, C. albicans,* and *S. cerevisiae*. Our results are consistent with previous reports of successful mating-type switching in MTL1 from a to alpha and also reveal frequent illegitimate recombination at the other MTL loci.

[3]Municipal Children's Infectious Hospital, intensive care unit, Astana, Kazakhstan
[4]The Pediatric Infectious Disease Unit Ben-Gurion University of the Negev Soroka University Medical Center, The Pediatric Infectious Disease Unit Ben-Gurion University, Beer-Sheva, Israel

Backgrounds

Topicality of research is defined the meningococcal disease is characterized by severity, high mortality and disability.

Objectives

To study the bacterial meningitis (BM) etiologic structure and sensitivity to antibiotics in children in Astana.

Methods

A prospective investigation of 30 patients with diagnosis of BM in Astana have been done during 2016, mean age was 36±3month. From it, meningitis of Meningococcal etiology 60%, pneumococcal meningitis 6,6%, meningitis caused by S. enteritidis 3,4%, other cases had unknown etiology.

Conclusions

The BM diagnosis was confirmed from testing the nasopharyngeal smear 30% of cases; in 27% cases the diagnosis was confirmed from investigation of liquor, blood testing in 10% of cases. Bacteriological analysis of nasopharyngeal smear found out that the etiology of the disease was N.meningitidis group A in 13%, in 6,6% cases was related to group B; the W135 group was in 3,46%, Streptococcus pneumoniae was revealed in 6,6 % cases. The analysis of cerebrospinal fluid confirmed the predominant etiologic role of N.meningitidis 17%, in which 10% cases belonged to the group A, in 3,4% cases to B, and to the group W135 3,4% of cases. The bacteriological sowing of liquor found Streptococcus pneumoniae 6.7% of cases and S. enteritidis in 3.4% of cases. N.meningitidis group in 3.4% of cases were identified due to blood analysis. In 56% of patients with Meningococcal disease and 70% of the BM bacteriological analysis results were negative and the diagnosis was based on clinical data. Antibiotics sensitivity analysis of major pathogens of BM showed that the sensitivity of the N.meningitidis had to the following antibiotics: levofloxacin,imipenem,meropenem, penicillin, amoxicillin, cefazoline. Isolated pure cultures Streptococcus pneumoniae demonstrated sensitivityto penicillin, cefazolin, cefuroxime, ceftriaxone, ceftazidime, amoksiklav, oxacillin, makrolidler, imipenem, vancomicin, ciprofloxacin and levofloxacinin 100% of cases and resistance to amixacinum in 50%($p \leq 0,05$).

CHANGES IN METABOLITES AND PROTEINS IN LEAVES OF EUCALYPTUS GRANDIS DURING THE INFECTION OF PUCCINIA PSIDII

M.V. Labate[1], F. Marques[1], T. Cataldi[1], A. Bini[1], I. Budizinski[1], F. Moraes[1], M. Quecine[1], C. Labate[1]
[1]University Of Sao Paulo / Luiz de Queiroz College of Agriculture, Departamento de Genética, Piracicaba, Brazil

Backgrounds

Eucalyptus is constantly exposed to pathogen attack with one of the most threatening diseases being rust caused by the fungus *Puccinia psidii* Winter which is rapidly spreading around the world and was recently described in Australia. To understand the molecular plant-microbe interaction between *E. grandis* and *P. psidii* we developed a model system by isolating the pathogen from a single pustle and select resistant and susceptible plants from half-sib population generated using Brasuz, as the pollen receptor. We performed light and epifluorescence microscopy analyses, identified all of the stages of the fungal development and recognized the moment which the resistant genotype blocks pathogen development. Based on these results we selected six time points to carry out proteomic amd metabolomic analysis of leaves.

Objectives

The aim of this work was to identify the changes in the proteome and metabolome of two contrasting genotypes when exposed to *Puccinia psidii*.

Methods

Qualitative and quantitative (*Label Free Proteomics*) changes of proteins, was evaluated by using an LC-MS/MS mass-spectrometer Synapt G2 HDMS from Waters, in line with a MClass Chromatographer. For metabolomics, a GC-TOF/MS from Leco was used for the identification of primary metabolites and a Q-TOF Ultima API in line with a Acquity chromatographer from Waters.

Conclusions

The results show that the resistant plants notice the presence of the pathogen shortly after being infected, producing immunity related proteins such as *HSP90, ILITYHIA, LRR Kinase, NB-ARC disease resistance protein*. This perception triggers the production of cell wall and oxidative burst proteins, also changing the primary and secondary metabolism. On the other hand, susceptible plants have its metabolism subverted, producing proteins responsible for the cell wall loosening, favoring *P. psidii* nutrient uptake, growth and spread. Metabolite biomarkers, Immune response biomarker molecules and infection signals triggered by *P. psidii* on *E. grandis* are also proposed on this work.

NEW ASPECTS OF TUBERCULOSIS IN PEOPLE WITH HIV: REPORT OF A COHORT OF 92 CASES.

M.E.H. Labdouni[1]
[1]*University of Oran, Scholar of Medecine, Oran, Algeria*

Backgrounds

Tuberculosis is one of the main factors of death among PLHIV, this co-infection has dramatically re-emerged in recent years in our climate. It clothed highly polymorphic aspects; therefore its diagnostic and therapeutic will be very difficult mainly in children.

Objectives

Is to raise the issue of the resurgence of TB in People living with HIV supported in a referent center in western Algeria, its epidemiological, clinical, biological and radiological new trends.

Methods

It was a prospective study during 36 months from the 01st /01/2013 to 31st /12/2015 in identifying and analyzing cases of TB / HIV co infection.

Conclusions

Co-infection TB / HIV reemerged in recent years in our patients taking a more invasive appearance with frequency and multifocal forms of liver disease thus causing relatively a high mortality.

ANTIBIOTIC-INDUCED STRINGENT RESPONSE IN ENTEROCOCCUS FAECALIS EVALUATED USING AN IN VITRO MODEL OF A CATHETERISED URINARY TRACT

S. Lang[1], R. Adeigbe[1]
[1]Glasgow Caledonian University, Department of Life Sciences, Glasgow, United Kingdom

Backgrounds

Enterococci exposed to environmental stresses of the urinary tract may undergo physiological changes leading to an overall switch from the expression of genes required for growth to those that will aid survival; a phenomenon known as the stringent response (SR).

Objectives

This study assessed the ability of antibiotics used in the treatment of *E.faecalis*-related catheter-associated urinary tract infection (CAUTI) to induce the SR and evaluate the impact of the induced-SR on virulence.

Methods

Gene expression of four clinical enterococcal strains was studied using real-time PCR during mid-exponential phase of growth in planktonic cells and biofilms in pooled human urine. Cultures exposed to the antibiotics trimethoprim, nitrofurantoin, ciprofloxacin and fosfomycin were assessed for induction of the SR (*relA* and *relQ*-markers of induction), changes in the expression of stress-related genes (*gls24, eep*), adhesins (*ebpA, ace, esp, efaA*), toxins (*cyl, hyl*), and proteases (*spr, enl, gelE*).

Conclusions

Exposure to trimethoprim or nitrofurantoin triggered the SR, during which all the adhesin, toxin, protease (except *spr* in one strain) and stress-related genes investigated showed significant up-regulation (≥2-fold change in gene expression). Neither ciprofloxacin nor fosfomycin induced the SR. Exposure to a combination of nitrofurantoin or trimethoprim with either fosfomycin or ciprofloxacin prevented the induction of the SR and the associated increase in the expression of virulence genes.

Under conditions mimicking CAUTI, treatment with commonly used antibiotics has the potential to increase the virulence of *E.faecalis*. Combination therapy however, has the potential to not only improve the treatment of these recalcitrant infections, but inhibit stress-responses and associated increased pathogenicity.

EFFECTS OF SUB-MICS OF COLISTIN ON ACINETOBACTER BAUMANNII BIOFILMS

M. Lázaro-Díez[1], I. CHAPARTEGUI-GONZÁLEZ[2], Z. Bravo-del Hoyo[1], T. Navascués-Lejarza[1], A. Ocampo-Sosa[1], J. Calvo[3], L. Martínez-Martínez[3], J. Ramos-Vivas[1]
[1]IDIVAL, Microbiology, Santander, Spain
[2]IDIVAL, Microbiolgy, Santander, Spain
[3]Hospital Universitario Marqués de Valdecilla HUMV, Microbiology, Santander, Spain

Backgrounds

Acinetobacter spp. are recognized as emerging nosocomial pathogens and a primary cause of Gram negative infections in many parts of the world. These bacteria, mainly *A. baumannii*, are particularly difficult to trait due to its propensity to develop resistances to many groups of antibiotics.

In *A. baumannii,* biofilm is increasingly recognized as an important bacterial virulence trait that encourages antibiotic resistance. Therefore, evaluation of antimicrobial agents against *Acinetobacter* should include an assessment of their ability to interfere with biofilms.

Objectives

The aim of this study was to investigate the responses of *Acinetobacter baumannii* biofilms to sub-inhibitory concentrations of colistin (one of the last choices to trait *A. baumannii* infections).

Methods

Ten *A. baumannii* strains were used in this study. Biofilm formation and disruption of preformed biofilms in presence of different concentrations of colistin were quantitatively assessed by crystal violet staining. We have also investigated the morphology of some of these strains challenged *in vitro* with sub-MICs by TEM. Biofilm cell viability was determined with Live/Dead staining using CLSM.

Conclusions

MICs of colistin ranged from 1 to 64 µg/ml. Four of 10 strains tested were designated as strong-biofilms formers. In these strains, our results showed that colistin affected the biofilm formation at MIC. However, 50% strains colistin was able to increases biofilm formation at certain sub-MICs. In some strains, colistin was unable to disrupt preformed biofilms. Electron micrographs taken from planktonic cells showed an array of deformations and structural changes in bacteria after exposure to this drug.

A NEW ENZYME WITH DUAL-FUNCTION FRUCTOSE/SEDOHEPTULOSE BISPHOSPHATASE SUSTAINS GLUCONEOGENESIS IN BRUCELLA SUIS BIOVAR 5

L. Lázaro[1], M.J. de Miguel[2], F. Baldin[3], E. Van Schaftingen[3], R. Conde-Álvarez[1], P.M. Muñuz[2], M. Iriarte[1], J.J. Letesson[4], A. Zúñiga-Ripa[1], I. Moriyón[1]
[1]Universidad de Navarra, Instituto de Salud Tropical. Microbiología y Parasitología, Pamplona, Spain
[2]Centro de Investigación y Tecnología Agroalimentaria CITA, Unidad de Sanidad Animal, Zaragoza, Spain
[3]Université Catholique de Louvain, Welbio and de Duve Institute, Brussels, Belgium
[4]UNAmur, Research Unit in Biology of Microorganisms Biology, Namur, Belgium

Backgrounds

Bacteria of the genus *Brucella* are facultative intracellular parasites causing brucellosis, a worldwide-extended zoonosis. The pathogenicity of these bacteria resides in their ability to adjust their metabolism to the nutrients available in the intracellular niche. Recently, we showed that a *B. suis* biovar 5 double mutant in the phosphoenolpyruvate carboxykinase (PckA) and the pyruvate phosphate dikinase (PpdK), two anabolic enzymes bridging the TCA cycle and the gluconeogenic pathway, is attenuated. Unexpectedly, a double mutant in the two genes (*fbp*, *glpX*) encoding a fructose-1,6-bisphosphatase (FBPase) was able to grow under gluconeogenic carbon sources.

Objectives

Since FBPases are essential for gluconeogenesis, this observation suggested that *B. suis* 5 remains gluconeogenically competent in the absence of Fbp and GlpX. The aim of this work was to identify the third FBPase or the metabolic bypass that sustains gluconeogenesis when Fbp and GlpX are absent.

Methods

Bibliographic and genomic analyses allowed us to identify the phosphatase Gpm. We constructed a triple mutant *fbp-glpX-gpm* and we tested the capability of the mutant to grow on gluconeogenic substrates. Finally, we studied the infection kinetics of the mutant in mice. Moreover, we expressed, purified and characterized Gpm.

Conclusions

The mutant lacking the three FBPases was not able to grow on gluconeogenic substrates and was attenuated in the mouse model, confirming that gluconeogenesis is essential during infection. Moreover, characterization of Gpm showed that i), it has dual-function fructose-1,6/sedoheptulose-1,7-bisphosphatase; ii), it does not require a metal cofactor and iii), it does not belong to any of the five types of FBPases.

Pathogens / Pathogenicity - Part II

VISUALIZATION OF THE ROLE OF HOST HEME ON THE VIRULENCE OF THE HEME AUXOTROPH STREPTOCOCCUS AGALACTIAE

D. Lechardeur[1], L. Joubert[1], J.B. Dagieu[1], F. Annabelle[2], A. Derré-Bobillot[1], E. Borezée-Durant[1], I. Fleurot[3], A. Gruss[1]
[1]INRA-Institut National de la Recherche Agronomique, Micalis, Jouy en Josas, France
[2]Bel, Fromagerie Bel, Vendôme, France
[3]INRA-Institut National de la Recherche Agronomique, Unité ISP, Nouzilly, France

Backgrounds

Heme is essential for several cellular key functions but is also toxic. Whereas most bacterial pathogens utilize heme as a metabolic cofactor and iron source, the impact of host heme during bacterial infection remains elusive. The opportunist pathogen *Streptococcus agalactiae* does not synthesize heme but still uses it to activate a respiration metabolism. Concomitantly, heme toxicity is mainly controlled by the HrtBA efflux transporter.

Objectives

Here we investigate how *S. agalactiae* manages heme toxicity *versus* benefits in the living host.

Methods

We used bioluminescent bacteria and heme-responsive reporters for *in vivo* imaging,

Conclusions

We show that the capacity of *S. agalactiae* to overcome heme toxicity is required for successful infection, particularly in blood-rich organs. Host heme is simultaneously required, as visualized by a generalized infection defect of a respiration-negative mutant. In *S. agalactiae*, HrtBA expression responds to an intracellular heme signal *via* activation of the two-component system HssRS. A *hssRS* promoter-driven intracellular luminescent heme sensor was designed to identify host compartments that supply *S. agalactiae* with heme. *S. agalactiae* acquires heme in heart, kidneys, and liver, but not in the brain. We conclude that the *S. agalactiae* response to heme is organ-dependent, and its efflux may be particularly relevant in late stages of infection.

Pathogens / Pathogenicity - Part II

GENOME-WIDE AND COMPARATIVE ANALYSIS OF SECRETED AND TRANSMEMBRANE PROTEINS IN BURKHOLDERIA SPECIES

H.H. Lee[1], N. Thao Thi[1], N. Kim[1], I. Kim[1], J. Park[1], I. Park[2], Y.S. Seo[1]
[1]Pusan National University, Microbiology, Busan, Republic of Korea
[2]Youngsan University, Oriental Culinary, Busan, Republic of Korea

Backgrounds

The *Burkholderia* genus is composed of not only important pathogens infecting plants, animals and humans but also non-pathogenic bacteria like endophytes. Secreted and transmembrane proteins of the *Burkholderia* genus especially play an essential role these various interactions.

Objectives

We tried to identify and compare the secreted proteins of six representative *Burkholderia* species consisting of plant pathogens (*B. glumae* BGR1, *B. gladioli* BSR3), human pathogens (*B. pseudomallei* K96243, *B. cepacia* LO6), and endophytes (*Burkholderia* sp. KJ006, *B. phytofirmans* PsJN) through the genome-scale computational identification.

Methods

The whole genome sequences of the six representative *Burkholderia* species were downloaded from the RefSeq database at the NCBI website. The secreted proteins were predicted and analyzed by SignalP, TatP, LipoP and TMHMM programs and the SecretomeP, EffectiveT3 and T3SS_prediction servers.

Conclusions

We found that the proportions of putative classically secreted proteins (CSPs) and transmembrane (TM) proteins of all species were significantly high up to approximately 20%, besides the lower proportions of putative type 3 non-classically secreted proteins (T3NCSPs) (~10%) and unclassified non-classically secreted proteins (NCSPs) (~5%). The fractions of TM proteins were separated but the distribution of the number of TM domains was conserved. In addition, the protein size distribution of the secreted protein groups was conserved among the species and species-specific differences in the functional characteristics of these proteins in CSPs, T3NCSPs, and unclassified NCSPs. This study could provide new insights into the relationship among plant-pathogenic, human-pathogenic, and endophytic bacteria.

Pathogens / Pathogenicity - Part II

QUORUM SENSING-DEPENDENT POST-SECRETIONAL ACTIVATION OF PROTEASE IV IN PSEUDOMONAS AERUGINOSA

J.H. Lee[1], J. Oh[1], X.H. Li[1], S.K. Kim[1]
[1]Pusan National University, Department of Pharmacy, Busan, Republic of Korea

Backgrounds

Protease IV (PIV), a key virulence factor of *Pseudomonas aeruginosa* is a secreted lysyl-endopeptidase whose expression is induced by quorum sensing (QS), a cell-density dependent cell to cell communication system. QS is very important in infection of pathogens.

Objectives

We found that PIV expressed in QS mutant has severe reduction of activity in culture supernatant (CS), even though it is overexpressed to high level. We intended to elucidate the underlying mechanism in this post-secretional activation of PIV by QS.

Methods

The PIV purified from the CS of QS mutant (M-PIV) had much lower activity than the PIV purified from the CS of wild type (P-PIV), although two PIVs has no difference. We found that the propeptide cleaved from prepro-PIV was always co-purified with M-PIV, but never with P-PIV. Since the activity of M-PIV could be restored by the addition of the CS prepared from a QS-positive and PIV-deficient strain, we hypothesized that the propeptide binds to and inhibits PIV, and is degraded to activate PIV by a QS-dependent factor. In fact, the CS of the QS-positive strain was able to degrade the propeptide. Since the responsible factor should be a QS-dependently expressed extracellular protease, we tested QS-dependent proteases of *P. aeruginosa* and found that LasB can degrade the propeptide and activate M-PIV. We purified the propeptide and confirmed the propeptide can bind to and inhibit PIV.

Conclusions

We suggest that PIV is post-secretionally activated through the extracellular degradation of the propeptide by LasB, a QS-dependent protease.

IDENTIFICATION OF NOVEL MYCOBACTERIUM TUBERCULOSIS ANTIGENS FOR IMMUNODIAGNOSIS BY A BIOINFORMATIC ANALYSIS

J.M. Ha[1], W.G. Yoo[2], S.H. Kim[1], M.S. Park[1], S. Lee[1]
[1]Korea National Institute of Health, Division of Tuberculosis and Bacterial Respiratory Infections, Cheongju, Republic of Korea
[2]Chung-Ang University College of Medicine, Department of Medical Environmental Biology, Seoul, Republic of Korea

Backgrounds

New biomarkers derived from *Mycobacterium tuberculosis* have been investigated for the accurate diagnosis of tuberculosis (TB). Especially, multifaceted approaches are required for finding diagnostic antigens related to the latent TB infection.

Objectives

To investigate new biomarkers for immunodiagnosis of tuberculosis, we performed an extensive analysis of the antigens and epitopes of *M. tuberculosis* K strain, coupled bioinformatics with reverse vaccinology.

Methods

Protein sequences (4,146 amino acids) of *M. tuberculosis* K strain were retrieved from National Center for Biotechnology and Information database. Sequences of BCG strains, non-tuberculoid *Mycobacteria*, and other tuberculoid *Mycobacteria* were extracted from MtbVeb. *M. tuberculosis* specific proteins were identified, comparing with sequences of BCG strains and other *Mycobacteria* spp. Protein localization was predicted by using 7-sub-cellular predictors. Antigen and epitope candidates having interferon-gamma secreting major histocompatibility complex class II peptides were predicted by using Immuno Epitope Database and Analysis Resources and IFNepitope.

Conclusions

One hundred and twenty eight unique proteins including 3 *M. tuberculosis* latency antigens were identified, which did not have any homology with those of 5 BCG vaccine strains and 34 species of non-tuberculoid *Mycobacteria*. Thirty seven secretory proteins were selected and then 17 secretory antigen candidates were predicted to induce IFN-γ secretion. Comparing our candidates with sequences of 1,036 antigens and 7,683 epitopes extracted from IEDB, 12 novel antigens were finally selected. And 4 to 16 sequences of human T cell epitopes were predicted for each antigen. Our results will provide new antigenic targets for the development of advanced immunodiagnostic tools.

Pathogens / Pathogenicity - Part II

INVERSE AUTOTRANSPORT: THE MECHANISM OF TYPE VE SECRETION

J.C. Leo[1], *P. Oberhettinger*[2], *M. Schuetz*[2], *D. Linke*[1]
[1]*University of Oslo, Department of Biosciences, Oslo, Norway*
[2]*University Clinics Tuebingen, Institute for Medical Microbiology and Hygiene, Tuebingen, Germany*

Backgrounds

Intimin and invasin are adhesins and central virulence factors of enterohaemorrhagic *E. coli* enteropathogenic *Yersiniae*, respectively. These proteins are prototypes of a large family of adhesins and represent a previously unrecognized autotransporter secretion system, termed type Ve secretion. Classical (type Va) autotransporters consist of a C-terminal β-barrel domain, or translocation unit, and an N-terminal extracellular region or passenger. According to the prevailing model of classical autotransport, the translocation unit exports the passenger C-terminus first, i.e. through a hairpin intermediate.

Objectives

In intimin and invasin, the domain order is reversed compared to classical autotransporters. We aimed to establish the topology and characterize the secretion process of these proteins.

Methods

We investigated the topology of intimin and invasin by introducing epitope tags at selected sites within the protein. Furthermore, we examined whether the passenger is transported through the pore of the translocator unit. We discovered that the insertion of an epitope tag into the membrane-proximal region of the Intimin passenger leads to a non-adherent phenotype, and closer examination showed that the passenger of this variant was still located in the periplasm despite the β-barrel domain being inserted into the outer membrane and correctly folded. This insertion disrupts folding of the proximal immunoglobulin-like domain.

Conclusions

Our results confirm the predicted topology of the translocation units of intimin and invasin and demonstrate that their passengers are exported via a hairpin intermediate in an N-to-C direction. Furthermore, passenger secretion is driven by protein folding. These findings have prompted us to use the moniker ‘inverse autotransporter’ for these proteins.

FEMS7-2531
Pathogens / Pathogenicity - Part II

A NOVEL CONJUGATIVE ELEMENT COMPOSED OF TN5801 AND A NEW TRANSPOSON: TRANSFER DYNAMICS BETWEEN ENTEROCOCCUS FAECALIS POPULATIONS

R. León-Sampedro[1], Á. San Millán[1], C. Novais[2], L. Peixe[2], F. Baquero[1], T.M. Coque[1]
[1]Instituto Ramón y Cajal de Investigación Sanitaria, Molecular Microbiology, Madrid, Spain
[2]UCIBIO/REQUIMTE - University of Porto, Microbiology Laboratory, Porto, Portugal

Backgrounds

Conjugative-transposon (CTn) Tn*5801*, a Tn*916-tet*(M) member conferring resistance to tetracycline, was detected in disparate Firmicutes genus, mainly Enterococcus. However, dynamics of transfer events still remains unexplored.

Objectives

To analyze the mechanism of transfer of Tn*5801* and the impact of acquiring this CTn in the bacterial fitness of *Enterococcus faecalis (Efs).*

Methods

Tn*5801* was transferred by filter mating using a clinical strain as donor, and different *Efs* laboratory recipient strains: JH2-2 (with a Tn*5801*-Δ*tet*M), OG1RF and OG1SSp. Secondary filter mating assays were performed using *Efs*-JH2-2 transconjugants as donors. Mating plates were supplement with 10mg/L of tetracycline. Whole genome sequencing (Illumina-HiSeq-2500) of primary JH2-2 and secondary OG1SSp transconjugants was performed to analyze conjugative events recombinations. Growth rate was estimated in a Synergy HTX Plate Reader in the absence and presence of sub-inhibitory tetracycline concentrations (0,5-2mg/L).

Conclusions

We describe the transmission of Tn*5801* among *Efs* using clonal backgrounds with/without a pre-existing Tn*5801* copy. Transference of a novel 50kb composite element-50CE (Tn-30kb+Tn*5801*-20kb) occurred in a in specific 11bp sequence at the chromosome of primary JH2-2 filter mating and secondary OG1SSp transconjugants carrying one or two 50CE copies. Transconjugants harboring two 50CE copies showed higher values of $MIC_{Tetracycline}$ and V_{max} of the growth curves than those with a single 50CE copy (24-48 vs 96vs1mg/L and 4.28 vs 5.97, respectively). The data suggest that widespread use of tetracycline might contribute for Tn916-elements transfer and bacterial fitness in tetracycline selective environments, which could facilitate the persistence and amplification of some pathogenic clones and mobile genetic elements.

Pathogens / Pathogenicity - Part II

UNRAVELING HOST CELLULAR FUNCTIONS EMPLOYED BY MRSA DURING INTRACELLULAR SURVIVAL

M. Letek[1], N. Bravo[1], V. Behrends[1]
[1]University of Roehampton, Life Sciences, London, United Kingdom

Backgrounds

As a facultative intracellular pathogen, Methicillin-resistant *Staphylococcus aureus* (MRSA) is able to invade and proliferate within mammalian cells, including professional and non-professional phagocytes. This intracellular survival may be used by the pathogen to evade host immune responses as well as exposure to antibiotics.

Objectives

While most studies have focused on the virulence factors of MRSA, host molecular factors exploited by the pathogen during intracellular survival remain mostly unknown. Our research aims to identify novel host-directed therapies against MRSA by studying the host molecular and metabolic factors exploited by the pathogen during infection.

Methods

We have employed shRNA-based genome-wide screens to identify novel host factors essential for the intracellular survival of MRSA. This has been complemented with a metabolomics approach based on Gas Chromatography Mass Spectrometry, in combination with stable isotope-labelling.

Conclusions

By employing shRNA screens, subsequent bioinformatics and *in silico* analysis, we have identified several host-cell genes that could be potentially involved in *S. aureus* pathogenesis. Our results show that silencing certain genes in HeLa cells increases host cell viability after MRSA infection whereas bacterial survival is significantly reduced. This suggests that *S. aureus* is able to modulate different molecular pathways of the host cell for its intracellular survival.

On the other hand, our metabolomics approaches indicate that the Tricarboxylic cycle and lower glycolysis pathway are affected by the presence of MRSA within the cell.

In our conference contribution, we will discuss these findings, which provide a better understanding of the MRSA-host cell interactions and may lead to novel treatments against this versatile pathogen.

Pathogens / Pathogenicity - Part II

P-113-DERIVED ANTIMICROBIAL PEPTIDES AGAINST CANDIDA ALBICANS

G.Y. Lin[1], W.C. Cheng[2], C.Y. Lan[1]
[1]National Tsing Hua University,
Institute of Molecular and Cellular Biology and Department of Life Sciences, Hsinchu, Taiwan R.O.C.
[2]General Biologicals Corporation, Department of Research & Development, Hsinchu, Taiwan R.O.C.

Backgrounds

Candida albicans is a commensal organism that is commonly found on the mucosal surfaces, nails and skin. However, *C. albicans* is also an opportunistic fungal pathogen that can infect immunocompromised patients and cause life-threatening infections. One of the reasons for the mortality is the emergence of antifungal-drug resistance in *C*. *albicans*. Therefore, it is important to develop new antifungal drugs.

Objectives

In this study, we studied the mechanisms of action for P-113-derived peptides to kill *C. albicans.* Particularly, the functions of these antimicrobial peptides on the cell wall of *C*. *albicans*.

Methods

We used a range of cell wall-defective mutants of *C. albicans* to investigate interactions between the fungicidal ability of the cationic antimicrobial peptides and the cell wall. In addition, we performed binding assay to determine the interaction between various cell wall components and the antimicrobial peptides.

Conclusions

We found a decreased binding and susceptibility of the antimicrobial peptides in different *C. albicans* mutants. The results showed that antimicrobial peptides need to recognize molecular patterns on the pathogens surface to enhance their activity and specificity against *C*. *albicans*.

CHARACTERIZATION OF BIOFILM PRODUCTION IN CLINICAL ISOLATES OF ACINETOBACTER BAUMANNII AND THE EFFECTS OF CHEMICAL COMPOUNDS ON BIOFILM FORMATION

M.F. Lin[1], Y.Y. Lin[2], C.Y. Lan[2]
[1]National Taiwan University Hospital Chu-Tung Branch, Department of Medicine, Hsinchu, Taiwan R.O.C.
[2]National Tsing Hua University, Institute of Molecular and Cellular Biology, Hsinchu, Taiwan R.O.C.

Backgrounds

Acinetobacter baumannii, an emerging important pathogen of nosocomial infection, is infamous for its ability to form biofilms. Biofilm formation increases the survival rate of *A. baumannii* on dry surfaces and may contribute to its persistence in the hospital environment, increasing the probability of causing nosocomial infections and outbreaks.

Objectives

This study was undertaken to characterize biofilm production of the clinical isolates of *A. baumannii* and the effects of chemical compounds, especially antibiotics, on biofilm formation.

Methods

We first determined biofilm formation of the wild type, mutant strains and clinical isolates of *A. baumannii* by XTT assay. The biofilm formation was also evaluated using scanning electron microscopy and confocal laser scanning microscopy. Moreover, the influence of amikacin, imipenem, colistin, tigecycline, LL-37 and tannic acid on biofilm formation was examined. Finally, the minimal planktonic and biofilm inhibitory concentrations of the above antibiotics to *A. baumannii* were determined.

Conclusions

The ability of biofilm formation in *A. baumannii* was various in different strains, involved many genes and could be influenced by many chemical compounds. The minimal biofilm inhibitory concentrations of all the tested antibiotics were increased for both the wild type and the clinical isolate of multidrug resistant *A. baumannii* VGH2.

Pathogens / Pathogenicity - Part II

RESISTANCE GENE TRANSFER: INDUCTION OF TRANSDUCING PHAGE BY SUB-INHIBITORY CONCENTRATIONS OF ANTIMICROBIALS IS NOT CORRELATED TO INDUCTION OF LYTIC PHAGE

K. Stanczak-Mrozek[1], K. Laing[1], J. Lindsay[1]
[1]St George's- University of London, Infection and Immunity, London, United Kingdom

Backgrounds

Horizontal gene transfer (HGT) of antimicrobial resistance genes (AMR) genes between clinical isolates via transduction is poorly understood. MRSA are opportunistic pathogens resistant to all classes of antimicrobial agents but currently no strains are fully drug resistant. AMR gene transfer between *S. aureus* isolates is predominantly due to generalized transduction via endogenous bacteriophage, and recent studies have suggested transfer is elevated during host colonization.

Objectives

The aim was to investigate whether exposure to sub-MIC concentrations of antimicrobials triggers bacteriophage induction and/or increased efficiency of AMR gene transfer.

Methods

Isolates from MRSA carriers were exposed to nine antimicrobials and supernatants compared for lytic phage particles and ability to transfer an AMR gene. A new technology, droplet digital PCR (ddPCR) measured the concentration of genes in phage particles.

Conclusions

All antibiotics tested induced lytic phage and AMR gene transduction, although the ratio of transducing particles to lytic particles differed substantially for each antibiotic. Mupirocin induced the highest ratio of transfer versus lytic particles. Gentamicin and novobiocin reduced UV-induced AMR transduction. The genes carried in phage particles correlated with AMR transfer or lytic particle activity, suggesting antimicrobials influence which DNA sequences are packaged into phage particles.

Sub-inhibitory antibiotics induce AMR gene transfer between clinical MRSA, while combination therapy with an inhibiting antibiotic could potentially alter AMR gene packaging into phage particles, reducing AMR transfer. In a continually evolving environment, pathogens have an advantage if they can transfer DNA while lowering the risk of lytic death.

Pathogens / Pathogenicity - Part II

SOLID-STATE NMR STUDIES OF YADA (YERSINIA ADHESIN A): FROM AUTOTRANSPORT TO DRUG SCREENING

N. Chauhan[1], M. Orwick-Rydmark[1], D. Linke[1]
[1]University of Oslo, Biosciences, Oslo, Norway

Backgrounds

Yersinia enterocolitica is a Gram-negative enteric pathogen that can cause diarrhea, and complications such as sepsis or reactive arthritis when passing from the gut into the blood stream and beyond. Adhesins that allow the initial adhesion in the gut are important pathogenicity factors for tissue invasion. One major adhesin of *Y. enterocolitica* is YadA, which binds to collagen of the extracellular matrix. It is the prototype of type Vc secretion systems, so-called autotransporters that form a pore in the bacterial outer membrane to transport their extracellular domain to the cell surface independent of external energy sources such as ATP.

Objectives

Understanding the autotransport process and the binding mode of this adhesin will help us to find small-molecule drugs that can inhibit initial adhesion to gut tissue.

Methods

We use a combination of solid-state NMR techniques and targeted mutagenesis to understand the autotransport process. We have recently published a full ssNMR structure of the YadA membrane anchor, and are now studying mutants stalled in the autotransport process. I will present structural details of such an autotransport intermediate, and will discuss possibilities how this conserved mechanism could be targeted with small-molecule drugs.

Conclusions

I will present structural details of such an autotransport intermediate, and will discuss possibilities how this conserved mechanism could be targeted with small-molecule drugs.

MYCOBACTERIUM ABSCESSUS AND THE HUNT OF THE CELL WALL COMPONENT RESPONSIBLE FOR CORDING

M. Llorens-Fons[1], M. Pérez-Trujillo[2], E. Julián[1], F. Alcaide[3], M. Luquín[1]
[1]Universitat Autònoma de Barcelona, Departament de Genètica i Microbiologia, Bellaterra, Spain
[2]Universitat Autònoma de Barcelona, Servei de Ressonància Magnètica Nuclear, Bellaterra, Spain
[3]Hospital Universitari de Bellvitge-IDIBELL, Departament de Microbiologia, L'hospitalet de Llobregat, Spain

Backgrounds

Many mycobacteria species have two morphotypes, the rough (R) that form winkled colonies and the smooth (S) that form even colonies. R morhotypes are more pathogenic than S morphotypes, which seems to be related with the organization of the bacilli. R morphotype bacilli dispose in parallel forming cords, in contrast, S morhotypes bacilli do not present any organization.

As cording is an important virulence factor, many studies have been performed in order to discover a compound responsible for the cord formation. In 1956 the trehalose dimycolate (TDM) from *Mycobacterium tuberculosis* was described as the “cord factor”. However, years later it has been detected TDM in no-cording mycobacteria.

Objectives

Our objective is to find the compound responsible for cording in *Mycobacterium absessus*, using this bacteria as a model of *M. tuberculosis*.

Methods

Different strains of *M. abscessus* were grown in Middlebrook 7H9 broth in order to obtain biopellicles in the surface of the media. An extraction of the superficial lipids was performed on the biopellicles using petroleum ether. Then, the delipidated biopellicles were observed under optical microscope and compared to the untreated biopellicles. The petroleum ether extracts were analysed by thin layer chromatography, nuclear magnetic resonance and mass spectrometry.

Conclusions

When treated with petroleum ether R morphotype bacteria lost its organization, cords seemed to be fraying. On the extracts, a lipidic compound was found only in R morphotypes, which seems to indicate a relation between this cell wall component and the cording.

BISTABLE EXPRESSION OF RELEVANT GENES FOR PSEUDOMONAS SYRINGAE VIRULENCE

N. López-Pagán[1], J.S. Rufián[1], D. López-Márquez[1], J. Ruiz-Albert[1], C.R. Beuzón[1]
[1]Instituto de Hortofruticultura Subtropical y Mediterránea "La Mayora" IHSM-UMA-CSIC, Departamento de Biología Celular- Genética y Fisiología. Facultad de Ciencias. Universidad de Mála ga. 29071, Málaga, Spain

Backgrounds

Heterogeneity or phenotypic variation has been known to take place in microbial clonal populations for decades. Under certain regulatory circuits, heterogeneity in gene expression can be enhanced leading to a bimodal expression profile in homogeneous environments. This process is known as bistability. The relevance of these processes has been demonstrated in *Salmonella enterica* and other human pathogen in the establishment of antibiotic persistence, and it has been shown to affect virulence genes, and to be linked to the establishment of chronic persistence. Nevertheless, little is known about the occurrence or impact of these processes in the adaptation of bacteria to non-animal host.

Objectives

To address the question of whether there is phenotypic heterogeneity in the expression of genes relevant for adaptation to a non-animal host of the model plant pathogen *Pseudomonas syringae*.

Methods

Transcriptional chromosome-located fusion to reporter genes encoding fluorescent protein were constructed in *P. syringae* pv. *phaseolicola*. Genes selected were several encoding different elements of a type III secretion system (T3SS) and flagellin, since motility has been reported as counter-regulated with the T3SS, Expression from these genes was analyzed using single-cell analysis methods, such as flow cytometry and fluorescent microscopy.

Conclusions

We recently showed expression of T3SS genes is phenotypically heterogeneous in planta and becomes bistable under certain laboratory conditions through the action of a double regulatory loop on the transcriptional activator HrpL. We present here single cell analyses of the gene encoding flagellin, as well as its responses to different regulatory proteins.

Pathogens / Pathogenicity - Part II

A NOVEL BIARYL AMIDE COMPOUND WITH INHIBITORY ACTIVITY AGAINST CANDIDA ALBICANS FILAMENTATION AND BIOFILM FORMATION AS AN ANTI-VIRULENCE AGENT FOR THE TREATMENT OF CANDIDIASIS

J. Romo[1], C. Pierce[2], A. Lazzell[1], S. Saville[1], J. Lopez-Ribot[1]
[1]The University of Texas at San Antonio, Biology, San Antonio, USA
[2]University of the Incarnate Word, Biology, San Antonio, USA

Backgrounds

Candida albicans is the most common fungal pathogen. The yeast-to-hyphae transition and biofilm formation represent two main virulence factors in *C. albicans.*

Objectives

Targeting functions essential for virulence constitutes an attractive, yet clinically unexploited alternative for the development of new antifungal agents.

Methods

We have performed high content screenings, with a total of 30,000 small molecule compounds from Chembridge's DIVERSet™ chemical library, in search for inhibitors of *C. albicans* filamentation and biofilm formation, and identified several hit compounds. Of these, a series of compounds with a common biaryl amide core demonstrated potent inhibitory activity against both filamentation and biofilm formation at low micromolar concentrations. The leading compound of this series was able to prevent filamentation under all liquid and solid media conditions tested, suggesting that it impacts a core component of the cellular machinery mediating hypha formation under different environmental conditions. The compound demonstrated *in vivo* activity in three different clinically-relevant murine models of invasive candidiasis, oral candidiasis and catheter-related candidemia. This compound displayed activity against a panel of azole resistant clinical isolates. RNA-Sequencing data revealed that treatment with this compound results in differential expression of key filamentation and biofilm genes. Current efforts are aimed at identifying its target at the molecular level. We have also embarked in a medicinal chemistry campaign to identify analogues with improved pharmacodynamic and pharmacokinetic properties.

Conclusions

Based on its *in vitro* and *in vivo* activities, this leading compound represents a promising candidate for the development of novel anti-virulence strategies against *C. albicans* infections.

Pathogens / Pathogenicity - Part II

PHENOTYPIC CHARACTERIZATION OF BERGEYELLA FROM THE NASAL MICROBIOTA OF SWINE

M. Lorenzo de Arriba[1], S. Lopez-Serrano[1], N. Galofre-Mila[1], V. Aragon[1]
[1]Centre de Recerca en Sanitat Animal CReSA-IRTA, Endemic diseases, Bellaterra, Spain

Backgrounds

Bacterial diseases in livestock are commonly treated with antimicrobials. However excessive use of antimicrobials has favoured the emergence of resistances to these drugs, in consequence reducing their effectiveness. Inappropriate administration of antimicrobials also produces dysbiosis of the microbiota, which can facilitate colonization by pathogens. In swine, nasal microbiota has been shown to have an effect on the predisposition to Glässer's disease, caused by *Haemophilus parasuis*. Among others, one of the most abundant genus in the nasal cavities of piglets at weaning was *Bergeyella*.

Objectives

The objective of this work was to characterize nasal isolates of *Bergeyella* and evaluate their virulence potential.

Methods

Nasal swabs from 3-4 week-old piglets from 8 commercial farms of domestic pigs and 1 farm of wild boars were cultured under aerobic conditions. Isolates were identified by 16S rRNA gene sequencing and later genotyped to assess different strains. *Bergeyella zoohelcum* and *Bergeyella porcorum* were identified within the 11 different strains. In general *Bergeyella* isolates showed resistance to serum complement and phagocytosis, showed poor biofilm formation capacity, and were able to adhere to epithelial cells. Maneval staining revealed that *Bergeyella* strains seemed to have capsule. Multiresistance to antimicrobials was found in 10 of the 11 strains, including one strain isolated from wild boar with no history of antimicrobial use.

Conclusions

In conclusion, *Bergeyella* strains from the nasal cavities of piglets showed some *in vitro* features indicative of virulence potential. Further studies are needed to identify the role of *Bergeyella* in disease and within the nasal microbiota of swine.

Pathogens / Pathogenicity - Part II

XYLELLA FASTIDIOSA, THE HIDDEN THREAT FOR THE MEDITERRANEAN AGRICULTURE

M.M. López[1], D. Olmo[2], A. Nieto[2], A. Monterde[1], M. Montes-Borrego[3], J. Peñalver[1], K. Ouertani[1], C. Morente[1], I. Navarro[1], M.T. Gorris[1], E. Marco-Noales[1], B.B. Landa[3]
[1]Instituto Valenciano de Investigaciones Agrarias, Bacteriología, Moncada Valencia, Spain
[2]Gobierno Islas Baleares, Sanidad Vegetal, Palma de Mallorca, Spain
[3]Consejo Superior de Investigaciones Científicas, Instituto de Agricultura Sostenible, Córdoba, Spain

Backgrounds

Xylella fastidiosa is a xylem limited bacteria, considered a quarantine organism. Originally circumscribed to America, it has been recently identified in Italy, France, Germany and Spain. Its economic importance is due to the large number of plant hosts, the severe symptoms induced, the long list of vectors and its difficult control. This pathogen represents a threat not only for European agricultural crops, but also for landscape trees and ornamentals.

Objectives

An update of the diseases caused by *X. fastidiosa*, new information about its biology and epidemiology in Europe and the role of accurate diagnostic protocols.

Methods

Following the identification in 2013 of *X. fastidiosa* subsp. *pauca* in southern Italy, rapid emergency measures have been implemented in the EU for its prevention. Available information suggests that the Italian strain could have been introduced with ornamental plants imported from Costa Rica. In addition, in Spain, the first detection in Mallorca island, in October 2016 using the EPPO protocol of diagnostic, was immediately followed by new detections in the nearby Ibiza island. Later on, the pathogen has been detected in 92 points in olive, almond, stone fruit trees and many ornamentals. There are several subspecies of *X. fastidiosa* involved and vectors are under study.

Conclusions

These two examples demonstrate that the global market could lead to dissemination of quarantine organisms. The prevention of this pathogen requires further investigations, as well as intensive surveys and accurate analytical methods (PonTE and XF-ACTORS projects financed by the H2020 Program of the European Union).

DETECTION OF BIOFILM FORMATION AMONG THE CLINICAL ISOLATES OF METYCILIN-RESISTANT STAPHYLOCOCCUS AUREUS

N. Łubowska[1], *L. Piechowicz*[1]
[1]*Medical University of Gdansk, Medical Microbiology, Gdańsk, Poland*

Backgrounds

Bacterial biofilms are associated with a majority of chronic human infections. They are a serious challenge for today's medicine. Treatment of infections caused by biofilm-growing cells is linked to a high risk of failure due to an extreme resistance to antimicrobial agents and increased capacity to evade the host defenses. A large number of biofilm-associated infections involve *Staphylococcus aureus*. The biofilm forming *S. aureus* strains are responsible for causing a number of diseases, including infective endocarditis, ventilator associated pneumonia, otitis media and infections of bones. *S. aureus* infections are becoming more worrisome with the emergence of antibiotic resistant strains in particular methicillin-resistant *S. aureus* (MRSA).

Objectives

The aim of the study was the determination of biofilm forming ability of MRSA clinical isolates.

Methods

The total 70 isolates of MRSA were chosen from the collection of the Department of Medical Microbiology, Medical University of Gdańsk. The isolates were collected from different sites of infection, including wound, pus, furuncle, bronchial tree, throat and nose. Biofilms were formed *in vitro* by 48 h incubation of bacteria in 96 wells microtiter plates. Biofilm biomass was quantified using a crystal violet staining, while MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide) assay assessed the number of viable cells.

Conclusions

All of the analyzed *S. aureus* isolates are able to form biofilms *in vitro*, but with different intensity. There was a correlation between the ability to form biofilm and the isolation site of *S. aureus*. Differences in a biofilm forming capacity may be caused by expression of various genes involved in biofilm formation.

[6]Univ. Grenoble, Alpes, Grenoble, France
[7]Universidad de Zaragoza-CSIC, Instituto de Ciencia de Materiales de Aragón ICMA, Zaragoza, Spain
[8]Universidad de Zaragoza, Instituto de Biocomputación y Física de Sistemas Complejos- BIFI, Zaragoza, Spain

Backgrounds

Antibiotic resistance in *Mycobacterium tuberculosis* is a global health emergency, and rising cases of MDR and XDR-TB are making increasingly difficult to treat tuberculosis. In 2012 the FDA approved the use of bedaquiline, the first drug designed to treat MDR-TB. It is very effective but shows serious side effects, so it can only be prescribed when no other options are available. Novel drug delivery systems based on nanocarriers are a promising strategy to overcome current therapeutic challenges. They improve drug solubility, protect the drugs, and allow a controlled release of the medication. Additionally they can be modified to allow selective transport to the sites of infection.

Objectives

The development of effective and safe nanotherapy is particularly relevant in the treatment of MDR-TB, as it requires very long treatments with highly toxic drugs. Therefore nanoencapsulation of bedaquiline is of special interest.

Methods

Chitosan based nanocapsules and Lipid NanoParticles, based on the Lipidots® technology, have been synthesized and optimized for the encapsulation of bedaquiline. upon quantification of drug loading efficiency, improvement of the drug payload, and nanoparticles stability amelioration in storage conditions. For the best candidates, drug release has been determined in biological media for in vitro assays. The antimycobacterial activity has been evaluated, and their cytotoxicity has been assayed in different cell lines.

Conclusions

Bedaquiline has been encapsulated in two different types of carriers, and the final nanoparticles have been totally characterized being found to be fully active as the free drug, and no cytotoxic.

Pathogens / Pathogenicity - Part II

IN VITRO BIOFILM FORMATION BY STREPTOCOCCUS PNEUMONIAE WITH DIFFERENT SEROTYPES

M. Luo[1], N. Barua[1], M. IP[1]
[1]The Chinese University of Hong Kong, Microbiology, Shatin, Hong Kong S.A.R.

Backgrounds

The use of the pneumococcal conjugate vaccine has resulted in an increasing in non-vaccine serotypes colonizing the human nasopharynx. An increase of serotypes 15B/C, 15A/F, 23A, 3, 6C and 19A in Hong Kong has been observed since 2009. Biofilm formation occurs in nasopharynx colonization and enables pneumococci to evade the human immune responses and facilitate genetic exchanges to increase their fitness in the nasopharynx.

Objectives

The study aims to evaluate the biofilm-forming capacity of pneumococcal clinical isolates with different serotypes.

Methods

Biofilm of ATCC strain R6 and 47 clinical isolates with different serotypes were grown in 24-well polystyrene plates at 35˚C, 5% CO2 for 24 hours without shaking. Biofilms were then stained with 0.5% crystal violet and dissolved with 95% ethanol. The OD595 values were measured using spectrophotometer. All samples were run in triplicates.

Conclusions

Non-encapsulated strains formed the strongest biofilms among all the strains, following by serotype 14 strains, whereas serotype 3 strains formed the least biofilm. Serotype 6C and 6D strains showed high biofilm formation capacity, and were greater than serotype 6A or 6B strains. Biofilm biomass of the serotype 15A strain was much stronger than the 15B/C strains, while biofilms of the serotype 23A strains were slight less than those of serotype 23F strains. Serotype 19A strains formed more robust biofilms than 19F strains. Pneumococcal biofilm formation capacity varied among serotypes (mean OD value of non-encapsulated(n=3) >14(n=2) >15A(n=1) >19A(n=7) > 6C(n=2) >23F(n=2) >6D(n=2) >15B/C(n=2) >23A(n=2) > 6A(n=2) > 6B(n=2) >19F(16) >3(n=5)).

RESISTANCE PROFILE, PRODUCTION OF EXOENZYMES AND HEMOLYSINS BY CLINICAL SAMPLES OF SERRATIA MARCESCENS

E. Lima Sousa[1], S. Alvares Martins[1], S.F. Rocha Constantino[1], W.D. Machado Maciel[1], I. Santos Sousa[2], N. Lisboa Camelo[2], S.C. Maia[2], F. Costa Moraes[3]
[1]Faculdade Estácio de São Luís, Biomedicina, São Luís, Brazil
[2]Faculdade Estácio de São Luís, Enfermagem, São Luís, Brazil
[3]Faculdade Estácio de São Luís, Enfermagem/Biomedicina, São Luís, Brazil

Backgrounds

The isolation of de *Serratia marcescens* in clinical samples of patients located in hospital reflects an unsatifying prognosis to these patients. Antimicrobial resistance and the production of diferente exoenzymes and hemolysins give this patogen virulence factors that lead to more severe affections of difficult treatment.

Objectives

To verify the resistance profile and the production of extracellular enzymes and hemolysins in clinical samples of *S. marcescens.*

Methods

21 strains of *S. marcescens* isolated from clinical samples from a laboratory in São Luís-MA were evaluated. The strains had their identification and resistance profile evaluated based on the automatized Vitek 2 method. The investigated exoenzymes were: amylase, phospholipase, protease and gelatinase. In order to do so, the Agar Muller Hinton was used with the addition of 1% of starch, 10% of egg yolk, 1% of olive oil, 10% of skim med milk and 4% of gelatine. The hemolisins were evidenced in Agar Blood 5% from lamb blood and human blood (A, B, O, AB). The formation of a light zone around the bacterial growth indicates positivity for hemolytic activity.

Conclusions

There was a predominance of strains from the tracheal secretion and all of them presented resistance to ampicilin, ampicilin sulbactam, cefuroxime and cefuroxime axetil. The strains didn't produce amylase or lipase. On the other hand, most of the strains presented gelatinase production capacity and only some of them were phospholips and protheolitical. According to the hemolytical pattern, the referred bacterial strains showed a stronger hemolytical capacity before human blood, specially type A group.

Pathogens / Pathogenicity - Part II

BIOMASS AND METABOLIC ACTIVITIES OF CANDIDA PARAPSILOSIS COMPLEX BIOFILMS

N. Pena-Fernández[1], C. Marcos Arias[1], E. Mateo[1], E. Cantón[2], J. Pemán[2], E. Eraso[1], G. Quindós[1]
[1]Universidad del País Vasco UPV/EHU, Inmunología- Microbiología y Parasitología, Bilbao, Spain
[2]Hospital Universitari i Politècnic La Fe, Servicio de Microbiología, Valencia, Spain

Backgrounds

Candida parapsilosis complex is a common cause of catheter related bloodstream infection and a pathogen well known for its ability to survive on abiotic and biotic surfaces. However, little is known about the biofilm forming ability of the cryptic species of this complex.

Objectives

To evaluate biofilm production of *Candida parapsilosis* complex by measuring biomass and metabolic activities.

Methods

Biofilm production of 26 *Candida parapsilosis sensu stricto*, 11 *Candida orthopsilosis* and 3 *Candida metapsilosis* clinical isolates from Hospital Universitario y Politécnico La Fe (Valencia, Spain) was evaluated. Biofilms were developed on 100-well polystyrene microplates after 24 and 48 h incubation at 37 ºC. Afterwards, planktonic cells were removed for evaluating biofilm metabolic activity by a XTT colorimetric method and biomass production by crystal violet staining.

Conclusions

Candida parapsilosis biofilms showed significantly higher metabolic activity than *Candida orthopsilosis* ones (p=0.018 and p=0.048 at 24 and 48 h, respectively). Conversely, there were no differences with the metabolic activity of *Candida metapsilosis* biofilms. *Candida parapsilosis* showed more biofilm biomass production than *Candida orthopsilosis* and *Candida metapsilosis* (p=0.009 and p=0.0001 at 24 and 48 h, respectively). More biomass production and higher metabolic activities were observed at 48 h, although differences were not statistically significant.

Species of the *Candida parapsilosis* complex show ability to produce biofilms being *Candida parapsilosis sensu stricto* the most efficient biofilm developer.

Funding: Fundación ONCE and projects GIC15/78 IT990-16 (Gobierno Vasco/Eusko Jaurlaritza) and UFI 11/25 (UPV/EHU).

Pathogens / Pathogenicity - Part II

EPIDEMICS OF MULTIDRUG-RESISTANT MYCOBACTERIUM TUBERCULOSIS HAARLEM GENOTYPE IN NORTHERN TUNISIA: A GENOTYPIC AND GENOMIC ANALYSIS

H. Mardassi[1]
[1]*Institut Pasteur de Tunis, Molecular Microbiology- vaccinology and Biotechnology development, TUNIS, Tunisia*

Backgrounds

Multidrug-resistant tuberculosis (MDR-TB) epidemics pose a great challenge for health-care authorities. Understanding how such rapidly transmitted forms of MDR-TB emerge is crucial to devise more appropriate intervention and surveillance strategies.

Objectives

Here we aim to explore thoroughly the transmission dynamics of the *Mycobacterium tuberculosis* Haarlem genotype in Northern Tunisia where it caused a major MDR-TB outbreak due to a Haarlem3-ST50 clone.

Methods

We ensured an 11-year (2001-2011) full coverage of the Haarlem genotype in the outbreak region by including all *M. tuberculosis* isolates displaying the Haarlem spoligotype signature (N = 253). We performed drug susceptibility testing and MIRU-VNTR24 (24-locus multiple interspersed repetitive unit-variable-number tandem repeat) typing for all isolates, as well as whole genome sequencing for 27 phylogenetically relevant isolates.

Conclusions

MIRU-VNTR24 typing revealed an exceptionally high clustering rate among both drug-susceptible and MDR-TB Haarlem isolates (78 % overall), suggesting rapid transmission. We identified a new MDR-TB Haarlem cluster, with no homolog (orphan) in the global spoligotype database, involving 7 patients. This minor MDR-TB cluster appears to have arisen from the same drug-susceptible progenitor as the major MDR-TB Haarlem clone (N = 48), a finding that was further confirmed by phylogenomics. Strikingly, in both MDR-TB clusters, pairwise genome comparisons uncovered much more genomic variation (14 to 83 single nucleotide polymorphism differences) than would usually be expected with a typical point source outbreak.

This study disclosed the ability of the Haarlem genotype to spread rapidly in Northern Tunisia, with evidence for an elevated mutation rate.

Pathogens / Pathogenicity - Part II

TLR-2, SIGLEC-3 AND CD163 EXPRESSION ON PORCINE PERIPHERAL BLOOD MONOCYTES IS INCREASED DURING THE SEPSIS CAUSED BY HAEMOPHILUS PARASUIS

Á. Álvarez-Estrada[1], S. Martínez-Martínez[1], E.F. Rodríguez-Ferri[1], B. Álvarez-Vega[2], T. Fernández-Caballero[2], J. Domínguez-Juncal[2], C.B. Gutiérrez-Martín[1]
[1]University of León, Animal Health, León, Spain
[2]Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria INIA, Biotechnology Department, Madrid, Spain

Backgrounds

Scavenger receptor CD163 binds complexes between haptoglobin and damage-associated molecular patterns, and also acts in the recognition of intact bacteria. Toll-like receptors (TLRs) recognize pathogen-associated molecular patterns. Most sialic acid-binding immunoglobulin-like lectins (Siglecs) recognize host sialic acid and act maintaining a balanced immune response. There is evidence that several bacterial pathogens, like genus *Haemophilus*, have developed different strategies for taking advantage of this interaction.

Objectives

To study the expression level changes of some of these molecules on peripheral blood (PB) monocytes from pigs suffering septicemia by *Haemophilus parasuis*.

Methods

Flow cytometry was used to evaluate TLR2, TLR4, Siglec-1, Siglec-3, Siglec-5 and CD163 expression level changes between PB monocytes from six pigs suffering experimental septicemia by *H. parasuis* and PB monocytes from the same pigs before infection.

Conclusions

Results showed a significant increase in the mean fluorescence intensity (ΔMFI) of TLR2 and Siglec-3 both on $CD163^+$ and $CD163^-$ monocytes during sepsis. A significant ΔMFI of CD163 during sepsis was also observed on these cells. No significant differences were seen for the remaining markers. We conclude that porcine monocytes show TLR-2, Siglec-3 and CD163 expression levels significantly higher during sepsis caused by *H. parasuis* than those of monocytes from healthy pigs. Further studies are required to know if these increases were due to changes in phenotype secondary to the interaction monocyte-bacteria or to release of monocytes with different maturation stages. Anyway, experimental infection by *H. parasuis* seems a good model to deepen in the knowledge of role of these molecules during sepsis.

COMPARATIVE IN VIVO STUDY OF THE VIRULENCE PHENOTYPE BETWEEN DIFFERENT SPECIES FROM THE MYCOBACTERIUM TUBERCULOSIS COMPLEX

E. Mata[1], S. Uranga[1], C. Martín[1], N. Aguiló[1]
[1]Universidad de Zaragoza, Microbiología- Medicina Preventiva y Salud Pública, Zaragoza, Spain

Backgrounds

Bovine tuberculosis disease, caused by *Mycobacterium bovis*, represents a big problem for cattle industry in some countries in Europe and mainly in Africa. The understanding of its pathogenesis is crucial to develop an effective vaccine against this disease.

It has been observed that *M. bovis* is more virulent than *Mycobacterium tuberculosis* in several animal models (DunnPL.InfectImmun,1995, NedeltchevGG.InfectImmun,2009). Despite they share more than 99.95 % of genome homology (GarnierT.PNAS,2003) the genomic differences that drive to such a strong disparity remain unknown.

Objectives

Our target is to study the virulence of *M. bovis* vs *M. tuberculosis* and to explore the molecular basis responsible for the differences observed.

Methods

We have studied virulence and dissemination *in vivo* of two *M. tuberculosis* strains and the *M. bovis* reference strain AF2122 in the mouse model. Mice were inoculated intranasally and we evaluated histopathology of infected lungs and bacterial replication in lungs, spleen, liver and kidneys. We used GFP-expressing strains to study the infectivity and to characterize the cell populations infected through the fluorescence of lung cells.

We also study the expression *in vitro* of dormancy genes under stress culture conditions through qRT-PCR analysis.

Conclusions

We found that *M. bovis* strain has more ability to cause lung pathology and dissemination than *M. tuberculosis* strains, as well as higher capacity to infect host cells *in vivo.* A differential induction of the dormancy genes expression under stress conditions was found *in vitro* between *M. tuberculosis* and *M. bovis*, which may have an implication in the infection profile of these strains.

LONG TERM INTRA-AMOEBAL SURVIVAL REDUCES VIRULENCE TRAITS OF PSEUDOMONAS AERUGINOSA

D. McDougald[1], C. Lutz[2], W. Leong[2], Y. Poh[2], B.Y.K. Yee[2], C.W. Qiang[2], M. Givskov[2]
[1]University of Technology Sydney, ithree Institute, Sydney, Australia
[2]Nanyang Technological University, Singapore Centre for Environmental Life Science Engineering, Singapore, Singapore

Backgrounds

The opportunistic pathogen, *Pseudomonas aeruginosa* is a major mortality factor for cystic fibrosis (CF) patients. Isolates of *P. aeruginosa* from CF patients show consistent genotypic and phenotypic changes compared to environmental and acute infection isolates, that are associated with the establishment of chronic infection. CF isolates often exhibit reduced virulence phenotypes, which are proposed to prevent host clearance, thus supporting their persistence in the lung.

Objectives

Here, we investigated the effects of long-term co-culture of *P. aeruginosa* with the amoeba *Acanthamoeba castellanii*.

Methods

Three independent co-cultures were established in low nutrient media, where naive *A. castellanii* were re-infected with amoeba-adapted *P. aeruginosa* populations every 3 days for 42 days. At days 3, 24 and 42, intracellular *P. aeruginosa* were isolated from *A. castellanii.* Control populations of *P. aeruginosa* that were not exposed to amoeba were also passaged for the same time period for comparison.

Conclusions

P. aeruginosa isolates exposed to *A. castellanii* for 42 days demonstrated decreased planktonic growth, reduced pyoverdine production and a reduction in twitching and swarming motilities. These differences were supported by genomic analysis that revealed single nucleotide polymorphisms in genes associated with pyoverdine synthesis and motility.

The phenotypic traits demonstrated by amoeba-adapted *P. aeruginosa* share similarities to *P. aeruginosa* isolates from CF lungs, suggesting that the selective factors experienced by the bacterium within amoeba are similar to those in the CF lung. Based on these data, we therefore suggest that the alteration of virulence may be a ubiquitous response of *P. aeruginosa* to survive the intra-host environment.

GALLERIA MELLONELLA AS AN IN VIVO INFECTION MODEL FOR PATHOGENESIS, ANTIMICROBIAL DRUG AND DRUG-COMBINATION TESTING IN MYCOBACTERIUM ABSCESSUS

M. Meir[1], T. Grosfeld[2], B. Daniel[2]
[1]The Ruth Rappaport Children's Hospital- Rambam Health Care Campus, Pediatric Infectious Diseases Unit, Haifa, Israel
[2]The Hebrew University- Rehovot Campus, Koret School of Veterinary Medicine, Rehovot, Israel

Backgrounds

Treatment of *Mycobacterium abscessus* infections is extremely challenging due to its intrinsic resistance to most antibiotics. Research of virulence factors and antimicrobial treatments of *M. abscessus* is highly limited due to a lack of a practical *in vivo* model of infection. *Galleria mellonella* has been recently established as an infection model in various bacteria.

Objectives

To establish an easily feasible *in-vivo* model for *M. abscessus* infection, virulence, genetics and drug treatment in *G. mellonella* larvae.

Methods

We inoculated larvae with *M. abscessus*, then homogenized and cultured larvae at set time points. We also treated infected larvae with antibiotics and examined the effect on CFU counts.

Conclusions

Larvae were inoculated with *M. abscessus* by injection on day 0. We injected meropenem, tigecycline or both to larvae in treatment groups on days 2 and 3. We demonstrated a consistent rise in mycobacterial counts on days 1-5 of infection, and a consistent time to mortality curve in untreated controls. On day 7, meropenem treated larvae had lower CFU counts by 1-2 logs compared to untreated controls. Mortality in the meropenem group was postponed by 48 hours compared to controls. The effect of tigecycline was neither additive nor synergistic to the effect of meropenem. These findings suggest *G. mellonella* to be an adequate *in vivo* model of *M. abscessus* infection that may be used for efficacy assessment of various antimicrobials and antimicrobial combination. The *G. mellonella* model may also be used for future studies of pathogenesis and virulence factors of *M. abscesssus*.

GENOMIC ANALYSIS OF DIFFUSELY ADHERENT ESCHERICHIA COLI AND ENTEROAGGREGATIVE ESCHERICHIA COLI STRAINS ISOLATED FROM PATIENTS WITH MODERATE TO SEVERE DIARRHOEA

M. Meza-Segura[1], A. Vera-Ponce de Leon[2], E. Martinez-Romero[2], M. Zaidi[3,4], J. Nataro[5], T. Estrada-Garcia[1]
[1]CINVESTAV, Molecular Biomedicine, Mexico City, Mexico
[2]UNAM, Center for Genomic Sciences, Cuernavaca, Mexico
[3]Hospital General O'Horan, Infectious Diseases Research Unit, Merida, Mexico
[4]Michigan State University, Department of Epidemiology and Biostatistics, Lansing, USA
[5]University of Virginia, Pediatrics, Charlottesville, USA

Backgrounds

Diarrhoea remains a major cause of morbidity and mortality among young children <5 years old in less developed countries. Diffusely adherent *Escherichia coli* (DAEC) and enteroaggregative *E. coli* (EAEC) are the main agents associated with acute diarrhoea in children requiring hospitalisation, in Mexico, surpassing *Salmonella* and *Shigella*.

Objectives

To establish the prevalence of virulence factor genes (VFG) in DAEC and EAEC genomes from cases of moderate to severe diarrhoea and to analyse the phylogenetic relationships between DAEC and EAEC isolates with other pathogenic (diarrheagenic and extraintestinal) and commensal *E. coli*.

Methods

Genomes of ten DAEC and nine EAEC isolated from young children and one EAEC from an adult with severe or moderate diarrhoea were sequenced using Illumina MiSeq. Genomes were analysed for the presence of VFG (encoding toxins, proteases, invasins, adhesins, flagella, type secretion systems (TSS), complement-resistance-factors, and iron acquisition systems) by BLAST. Pan-genome and core-genome phylogenetic trees were built including 86 previously reported genomes, using get-homologues and PhyML, respectively.

Conclusions

Significantly more VFG were identified among DAEC and EAEC genomes than in commensal strains ($p<0.05$). Toxins, proteases, and the Aai T6SS were the most prevalent VFG among EAEC strains, while in DAEC iron acquisition systems and complement resistance factor genes. Also, were identified two new DAEC Afa/Dr/Daa adhesin operons and the presence of the enterotoxigenic *E. coli* CS22 fimbria in two EAEC strains. EAEC and DAEC strains clustered in four and three phylogenetic groups, respectively, and three of these groups contained both DAEC and EAEC strains.

DETECTION OF H. PYLORI MICROEVOLUTION AND MULTIPLE INFECTION FROM GASTRIC BIOPSIES BY AMPLICON SEQUENCING

M. Palau[1], A.M. Comeau[2], N. Piqué[1], M.J. Ramírez-Lázaro[3], S. Lario[3], X. Calvet[3], M.G.I. Langille[2], D. Miñana-Galbis[1]
[1]Universitat de Barcelona- Facultat de Farmàcia i Ciències de l'Alimentació, Biologia- Sanitat i Medi Ambient- Secció de Microbiologia, Barcelona- Catalonia, Spain
[2]CGEB-Integrated Microbiome Resource IMR, Pharmacology- Dalhousie University, Halifax, Canada
[3]Institut Universitari Parc Taulí-UAB, Digestive Diseases Service- Hospital de Sabadell- Corporació Sanitària Parc Taulí, Sabadell- Catalonia, Spain

Backgrounds

Despite the extensive literature published on *H. pylori*, the exact mode of transmission (oral-oral, gastro-oral, and fecal-oral) and the role of *H. pylori* multiple infection are still controversial.

Objectives

The aim of this study was to evaluate the usefulness of amplicon sequencing methodology for the detection of *H. pylori* microevolution and multiple infection from gastric biopsies of patients with dyspeptic symptoms (from atrophy to gastric cancer).

Methods

DNA was extracted from five gastric biopsies (B508S and B508T belonging to the same patient – B508S from normal tissue and B508T from gastric adenocarcinoma–, B247S from normal tissue of a patient with gastric cancer, B373 with metaplasia, and B601A with atrophy). Housekeeping genes *luxS* (autoinducer-2 synthase) and *cgt* (cholesterol-α-glucosyltransferase) were amplified and sequenced following manufacturer instructions using the GS Junior system (Roche). Sequences were analysed with Mothur, aligned with Mega6, edited in BioEdit, and clustered at 97% identity.

Conclusions

The *luxS* sequences clustered into 12 unique OTUs (operational taxonomic units), with a range of 2–5 OTUs being present per gastric biopsy, and four OTUs representing 91% of all sequences and belonging to the samples B508S and B508T, B247S, B373 and B601A, respectively. Analysis of *cgt* sequences is in process.
Results suggest that gastric mucosa is infected with multiple *H. pylori* strains, where frequent microevolution events from a predominant *H. pylori* strain coexisting with other minority strains.

SERUM ALBUMIN BINDING OF BDELLOVIBRIO BACTERIOVORUS: INHIBITION OF PREDATORY ACTIVITY AGAINST HUMAN PATHOGENS

R. Mitchell[1], *C.M. Ghim*[1]
[1]*Ulsan National Institute of Science and Technology UNIST, School of Life Sciences, Ulsan, Republic of Korea*

Backgrounds

Bdellovibrio bacteriovorus is a bacterial predator that actively attacks and consumes other Gram-negative bacteria. The list of prey includes many human pathogens, including strains of *Salmonella*, *Escherichia*, *Yersinia* and *Acinetobacter*. As bacteria can also cause sepsis, we undertook this study to evaluate the ability of *B. bacteriovorus* to predate on *E. coli*, *S. enterica* and *Klebsiella pneumoniae* within human serum.

Objectives

This study sought to identify the factors present in human serum and their impact on the activity of *B. bacteriovorus*, particularly against human pathogens. These included the serum complement activity against each of the bacterial strains tested, the impact of the serum osmolality and the effect serum albumin had on the predatory activity against each of the prey strains.

Methods

The activity of the serum complement and predator were both evaluated by determining the bacterial viabilities under each condition. The osmolality tests were performed using various saline solutions and measuring the ability of the predator to attack *E. coli*. The serum albumin tests include using a bioluminescent prey as well as microscopic imaging techniques.

Conclusions

While serum complement was active against *E. coli*, *S. enterica* and *K. pneumoniae*, it was not against the predator, *B. bacteriovorus*. However, both the serum osmolality and albumin inhibited predation. The osmolality of serum was 268 mOsm/kg, a level that blocked the activity of *B. bacteriovorus*. As well, serum albumin coated the predator, effectively inhibiting it from attacking its prey. Consequently, predation does not seem to be a viable option to treat pathogens within human serum.

Pathogens / Pathogenicity - Part II

BDELLOVIBRIO BACTERIOVORUS: EFFECTIVE AGAINST BACTERIAL BIOFILMS, GENTLE TOWARDS HUMAN CELLS

R. Mitchell[1]
[1]*Ulsan National Institute of Science and Technology UNIST, School of Life Sciences, Ulsan, Republic of Korea*

Backgrounds

Bacteria in nature, including in and on the human body, are often found in biofilms, communities of cells connected to each other and a surface. Not only are biofilms naturally resilient, they also increase the antibiotic resistance of the members present within them. Consequently, a means to remove biofilms that is effective, yet gentle enough to use, is needed.

Objectives

Bacterial predators, including *Bdellovibio bacteriovorus*, are capable of attacking and consuming other Gram-negative bacteria, including numerous human pathogens. They have also be shown to effectively attack biofilms of these species, reducing their populations by several log. Here we sought to evaluate the activity of *B. bacteriovorus* against non-prey and polymicrobial biofilms, as well as in the removal of biofilms from the surface of human cells.

Methods

Biofilms were formed either on abiotic of biotic surfaces. For polymicrobial studies, the bacterial strains were mixed prior to incubation to generate the biofilms. We used various microscopic techniques to evaluate biofilm responses to predation, as well as the human response to the predatory bacteria. The cytokine responses were measured using ELISA.

Conclusions

Our results show that predatory bacteria can remove both single and polymicrobial biofilms from the surface through predation and secretion of proteases. However, they were not harmful to human cells, eliciting no or only weak cytokine responses but no cell death. Biofilms formed on human cells were also effectively removed by *B. bacteriovorus*, while the underlying MCF-10a cells were protected, showing its gentle nature towards human cells but tough character against bacterial biofilms.

EVALUATING THE ANTIMICROBIAL EFFECT OF THE BACTERIOCIN AS-48 ALONE AND IN COMBINATION WITH LYSOZYME AGAINST PROPIONIBACTERIUM ACNES

R. Cebrián[1], S. Arévalo[1], S. Ananou[1], M. Montalbán López[1], S. Arias-Santiago[2], C. Riazzo[3], M.D. Rojo[3], P. Bermúdez[4], E. Valdivia[1], M. Martínez-Bueno[1], M. Maqueda[1]
[1]University of Granada, Microbiology, Granada, Spain
[2]Hospital Universitario Virgen de las Nieves, Dermatology, Granada, Spain
[3]Hospital Universitario Virgen de las Nieves, Microbiology, Granada, Spain
[4]Hospital Regional Universitario, Microbiology, Malaga, Spain

Backgrounds

Propionibacterium acnes is involved in acne vulgaris and can be related to other infectious diseases. In the last years the multidrug resistant (MDR) isolates of this bacterium have increased alarmingly. AS-48 is a potent head-to-tail cyclized bacteriocin produced by some Enterococci.

Objectives

Our goal is to assess the activity of AS-48 against *P. acnes*.

Methods

We have evaluated the minimal inhibitory concentration of AS-48 and combinations with other antimicrobials on 23 different clinical isolates (from skin, bone, abscess or blood), some of which were resistant to erythromycin and clindamycin, the most commonly used antibiotics in the treatment of acne.

Conclusions

Our results show that AS-48 can effectively inhibit the clinical strains tested, including the MDR strains, at concentrations ranging between 2-12 µg/mL. We prove a bactericidal effect at concentrations above 1 µg/mL for one of the strains. Moreover, the combinations of AS-48 with either palmitic acid or lysozyme displayed a significant synergistic effect. The combined effect with lysozyme rendered the best reduction in MIC values (4-10 fold reduction against MDR strains). This combination was formulated in a cream and tested in a swine ear infection model causing a 4-log reduction of *P. acnes* in 1 h.

Our data prove the effectiveness of the enterocin AS-48 alone and in combination with lysozyme for the control of (MDR) *P. acnes* and highlight its potential in skin formulations, being particularly promising in light of emerging antibiotic resistance. The results confirm that this composition could be considered an approach for medical and pharmaceutical purposes against *P. acnes*.

Pathogens / Pathogenicity - Part II

EVALUATION OF THE ENTEROCIN AS-48 FOR THE CONTROL OF GARDNERELLA VAGINALIS

S. Arevalo[1], R. Cebrián[1], M. Montalbán López[1], J. Liebana Ureña[1], M. Martinez-Bueno[1], M. Maqueda[1], E. Valdivia[1]
[1]University of Granada, Microbiology, Granada, Spain

Backgrounds

Bacterial vaginosis (BV) is a common infectious disease characterized by an imbalance in the vaginal microbiota, where healthy lactobacilli are replaced by a proliferation of (facultative) anaerobic microorganisms, notably *Gardnerella vaginalis*. Antibiotic treatment of BV is not always effective and often leads to reoccurrence of the infection due, in many cases, to the arising of antimicrobial resistance.

The enterocin AS-48 is a circular cationic antimicrobial peptide produced by diverse *Enterococcus* species that selectively induces pore formation in bacterial membranes.

Objectives

Our research objectives were to reliably identify *G. vaginalis* using molecular techniques and to assay the inhibitory activity of the enterocin AS-48.

Methods

We employed PCR with designed specific primers (VG10F/534R) derived from the 16S rDNA of *G. vaginalis* for a quick identification of new isolates. The antimicrobial activity of AS-48 against the isolates was assessed by spot-on-lawn onto agar *Gardnerella* and by transmission electron microscopy.

Conclusions

We established that specific PCR is a reliable identification technique. We isolated 29 strains and 28 of them were sensitive to less than 75 ng of AS-48. TEM images of *G. vaginalis* treated with AS-48 (60 µg/ml for 1h) revealed the absence of lysis. Although the treated cells maintained the integrity of the cell wall, they presented evident citoplasmatic membrane retractions, due possibly to the loss of intracellular content.

These results reinforce the continuation of the studies on AS-48 for the control of *G. vaginalis*.

SEAGULLS, BIRDS OF PREY AND FOXES: IMPORTANT CARRIERS OF ESBL-PRODUCING ESCHERICHIA COLI IN THE NORTH-WEST OF SPAIN AND NOW PRESENCE OF COLISTIN-RESISTANCE

A. Mora Gutiérrez[1], S. Viso González[1], A.M. López Beceiro[2], L.F. Fidalgo Álvarez[2], M. Blanco Álvarez[1]
[1]Universidad de Santiago de Compostela, Microbioloxía e Parasitoloxía, Lugo, Spain
[2]Universidad de Santiago de Compostela, Anatomía- Producción Animal y Ciencias Clínicas Veterinarias, Lugo, Spain

Backgrounds

E. coli strains producing extended-spectrum beta-lactamases (ESBL-*E. coli*) and other beta-lactamases represent a major problem in both human and veterinary medicine. Wild animals can become colonized while sharing the same habitat as domestic animals and humans or through environmental pollution.

Objectives

The objective of this study was to define the role of wildlife populations that have undergone a significant increase over the last decades in the north-west of Spain as reservoir of ESBL-E. coli strains.

Methods

The faecal samples of 620 wild animals (390 birds and 230 mammals) obtained during 2012-2015 and belonging to 7 different groups were examined by PCR for the presence of ESBL and pAmpC-producing *E. coli*. As a result, 13,4% (83 of 620) were ESBL-carriers with isolation from the 7 animal groups analyzed. Seagulls (23,4%), foxes (16,3%) and birds of prey (15,5%) showed the highest significant prevalences. The 95 isolates recovered were typed as SHV-12 (29,5%), CTX-M-1 (26,3%), CTX-M-14 (18,9%), CTX-M-32 (12,6%), CTX-M-15 (5,3%), CTX-M-9 (4,2%), CTX-M-27 (2,1%), CTX-M-24 (1,0%), with 2 isolates being additionally CIT.

Furthermore, 1 strain isolated from a fox was positive for *mcr*-1. By conventional molecular characterization was O150:H20-A-ST1324 CTX-M-1. By whole genome sequencing, the mcr-1 was located on an IncX4 plasmid, and several additional resistant genes were detected (*floR*, *dfrA12*, *drfA17*, *sul1/2/3*, *cmlA1*, *mef(B)*, *aadA2*, *aadA5*, *tet(A)*, *tet(M)*, *aadA1*, $bla_{\text{TEM-1}}$).**Conclusions**

This is the first report of a plasmid-mediated colistin-resistant ESBL-*E. coli* in fox. We suggest seagulls, foxes and birds of prey as possible sentinels in surveillance programs on ESBL dissemination.

DIFFERENTIAL EFFECT OF THE AGGREGATIVE ADHERENCE FIMBRIA TYPE II ON THE INTESTINAL TRACT OF MICE INFECTED WITH ENTEROAGGREGATIVE ESCHERICHIA COLI WITH AN UNDISTURBED MICROBIOTA

N. Moran-Garcia[1], L.S. Catalina[1], G.G. Silvia[2], T. Victor[2], F.L. Alfonso[1], S. Michael[1], N. James P.[3], E.G. Teresa[1]
[1]CINVESTAV, Molecular Biomedicine, Cd. de México, Mexico
[2]CINVESTAV, Infectomic and Pathogenesis, Cd. de México, Mexico
[3]University of Virginia School of Medicine, Pediatrics, Charlottesville, USA

Backgrounds

Enteroaggregative *Escherichia coli* (EAEC) is one of the major agents causing diarrhoea in young children from developing countries and adults from industrialised regions. EAEC adherence fimbria (AAF) are responsible for the EAEC characteristic aggregative phenotype.

Objectives

To evaluate *in situ* the role of AAF/II fimbria using a recently developed mouse model of EAEC infection with an undisturbed microbiota.

Methods

Six week old, C57BL/6 mice, without previous antibiotic treatment, were orally inoculated with $5x10^9$ CFU of 042 EAEC archetype strain that express the AAF/II fimbria, while another set of mice were infected with the same dose of an 042 AFF/II mutant strain. Control mice were only given saline. Colon and Ileum paraffin sections were analyzed for morphological changes by H&E staining and for β-catenin and Muc1 expression by immunofluorescence.

Conclusions

On H&E stain, no apparent histopathologic changes were observed in the intestines of animals infected with 042 or ΔAAF/II-042. However, in 042-infected mice, β-catenin was partially delocalized from the enterocyte basolateral location in ileal sections, and was apparently more abundant in the cytoplasm, appearing along the apical enterocyte surface at both days 3 and 4 post-inoculation; concurrently, the Muc1 was highly expressed on ileal enterocytes at 3 days post-infection. In ΔAAF/II-042 infected mice, β-catenin was not delocalized, nor was Muc1 expressed. Noteworthy, Muc1 was not expressed nor was β-catenin delocalized to the cytoplasm in colonic enterocytes of mice infected with either strain. EAEC AAF/II fimbria plays a role in β-catenin delocalization and expression of Muc1 in ileal enterocytes of 042 infected mice.

Pathogens / Pathogenicity - Part II

SIZE REALLY MATTERS: O-ANTIGEN FINAL LENGTH HAS AN ESSENTIAL ROLE DURING MICROBIAL PATHOGENESIS

C. Moreira[1]
[1]*School of Phamaceutical Sciences, Biological Sciences, Araraquara, Brazil*

Backgrounds

Salmonella Typhimurium is a major foodborne pathogen responsible for gastroenteritis. The LPS is employed to protect themselves against host defenses, more specifically the O-antigen (OAg) portion plays an essential role during the infection and as immunogenic defensive shield. The O-Ag assembly in Salmonella Typhimurium has the Wzz system to determine the O-antigen final chain length and it presents a tri-modal distribution. Therefore the chain length may be Short (16units), Long (35units), and Very-Long O-Ag forms (more than 100 unit repeats). The WzzST and WzzfepE proteins regulate respective the L O-Ag and VL O-Ag synthesis. Recently we have reported the role of VisP (Virulence and stress related Periplasmic protein) and LpxO enzyme in chemical signaling during pathogenesis (Moreira et al, 2013). Whereas the VisP prompts Salmonella Typhimurium to survive upon stress factors, and LpxO-mediated Lipid A hydroxylation helps the bacteria to adapt itself to host defenses and different colonization niches.

Objectives

A better understanding of the Salmonella Typhimurium chemical signaling during pathogenesis. Moreover, elucidate how the O-antigen, flagella, T3SS, and the periplasmic VisP protein converge to help bacteria to survive and infect their hosts.

Methods

We have assessed epithelial cell invasion, J774 macrophages intracellular replication, and flagella motility differences employed the λ Red single and double-mutants of the wzzST, wzzfepE, visP, and lpxO genes to compared with Salmonella Typhimurium WT levels. The VL-OAg has shown to be detrimental to invasion, intracellular replication and flagella motility, independent of the L-OAg form presence. The VL-OAg diminished flagella motility by 65%, decreased cells invasion, and slightly reduced intracellular survival compared to the WT levels.

Conclusions

How bacteria adapt themselves to these changes and regulate their membrane to interact with the host are essential aspects to microbial-host relationships. The complete elucidation of all these mechanisms will be essential to understand their relationship, develop novel technologies and therapies

18S RRNA AMPLICON-BASED METAGENOMICS FOR MULTIPLE IDENTIFICATION OF WATERBORNE PROTOZOA IN IRRIGATION WATER

Y. Moreno[1], R. Pérez[1], L. Moreno-Mesonero[1], I. Amoros[1], J.L. Alonso[1]
[1]University Research Institute of Water and Environmental Engineering. UPV, Water Chemistry and Microbiology division, VAlencia, Spain

Backgrounds

The contamination of drinking and bathing water with protozoan pathogens and the usage of sewage water for agricultural purposes poses a serious threat to millions of people worldwide. Among the waterborne pathogens, *Giardia* and *Cryptosporidium* are the most common causes of major diarrheal outbreaks globally. In contrast, insufficient information is available for *Toxoplasma gondii*, *Blastocystis hominis*, , *Entamoeba histolytica* and other free-living amoebae.

Molecular techniques are the most promising methods in comparison with conventional methods, which much benefit the water industry and public health. 18S rRNA amplicon-based next generation sequencing could be a powerful tool to investigate the presence of protozoan pathogens in the environment**Objectives**

The aim of this study has been to use 18S rRNA amplicon- sequencing to identify simultaneously the presence of important waterborne protozoa in irrigation water.

Methods

Five irrigation water samples were collected. DNA was extracted using UNEX protocol (homogenization using the FastPrep-24® Instrument at speed setting 6.5,120 s). PCR was performed as described by Illumina guide. A pair of primers were designed to target the V4 region of the18S rRNA gene of the protozoa. DNA sequencing data was processed using QIIME™ 1.8.0 open – source bioinformatics pipeline (http://qiime.org).

Conclusions

Pathogenic protozoa identified by 18S rRNA sequencing included *Blastocystis* (32 OTUs) and *Entamoeba* (38 OTUs). Other identified genus, such as *Giardia* (12 OTUs), *Acanthamoeba* (3 OTUs) and *Toxoplasma* (5 OTUs), had a lower representation.

Then, this technique could be established as a useful and cost-effective method to identify simultaneously, within a single analysis important pathogenic protozoa in water samples.

Pathogens / Pathogenicity - Part II

GENETIC DISSECTION OF THE SIGNALING CASCADE THAT CONTROLS ACTIVATION OF THE SHIGELLA TYPE III SECRETION SYSTEM FROM THE NEEDLE TIP

I. Murillo[1], I. Martinez Argudo[2], A. Blocker[1]
[1]University of Bristol, Cellular and Molecular Medicine, BRISTOL, United Kingdom
[2]Universitdad de Castilla-La Mancha-, Área de Genética, Toledo, Spain

Backgrounds

Many Gram-negative bacterial pathogens use type III secretion systems (T3SSs) for virulence. The *Shigella* T3SS consists of a hollow needle, made of MxiH and protruding from the bacterial surface, anchored in both bacterial membranes by multimeric protein rings. Atop the needle lies the tip complex (TC), formed by IpaD and IpaB. Upon physical contact with eukaryotic host cells, T3S is initiated leading to formation of a pore in the eukaryotic cell membrane, which is made of IpaB and IpaC. Through the needle and pore channels, further bacterial proteins are translocated inside the host cell to meditate its invasion. IpaD and the needle are implicated in transduction of the host cell-sensing signal to the T3S apparatus. Furthermore, the sensing-competent TC seems formed of 4 IpaDs topped by 1 IpaB. However, nothing further is known about the activation process.

Objectives

To investigate IpaB's role during T3SS activation and whether IpaB is directly involved in host sensing by isolating and characterising *ipaB* mutants unresponsive to activation signals.

Methods

Isolation of secretion-deregulated IpaB mutants using random mutagenesis and a genetic screen.

Conclusions

We found *ipaB* point mutations in leading to defects in secretion activation, which sometimes diminished pore insertion and host cell invasion. We also demonstrated IpaB communicates intramolecularly and intermolecularly with IpaD and MxiH within the TC because mutations affecting these interactions impair signal transduction.

PATHOGENICITY GENES FROM PLASMIDS OF PSEUDOMONAS SYRINGAE PV. SAVASTANOI ARE MAINTAINED IN THE POPULATION BY DIFFERENT EVOLUTIONARY FORCES

M. Añorga[1], A. Pintado[2], L. Bardaji[1], C.J. Ramos[2], J. Murillo[1]
[1]Universidad Pública de Navarra, Departamento de Producción Agraria, Pamplona, Spain
[2]Instituto de Hortofruticultura Subtropical y Mediterránea «La Mayora»- Universidad de Málaga-CSIC, Área de Genética, Málaga, Spain

Backgrounds

Pseudomonas syringae pv. savastanoi NCPPB3335 is a plant pathogen that naturally causes aerial tumours on olive (*Olea europaea*). Pathogenicity is dependent on several determinants, including a functional type III secretion system and the production of phytohormones.

Objectives

We sought to investigate the role of native plasmids in pathogenicity and virulence, as well as the mechanisms involved in their genetic and structural stability.

Methods

By functional inactivation of stability determinants and spontaneous curing, we obtained a derivative of strain NCPPB3335 cured of its three native plasmids (strain UPN912) and unable to induce disease symptoms. Pathogenicity and virulence were tested in micropropagated and lignified olive plants cv. Arbequina.

Conclusions

Genes *ptz* and *ipt* are both essential for the production of tumours in plantlets, and probably involved in the biosynthesis of cytokinins. Gene *ptz* codes for an isopentenyl transferase and is located in plasmid pPsv48A whereas *ipt* codes for a putative isopentenyl diphosphate isomerase and is located in pPsv48C. Insertion sequence IS*801* promoted the occurrence of deletions (average frequency of $1.8\pm0.7 \times 10^{-4}$) by one-ended transposition in plasmid pPsv48C, of which half resulted in the loss of gene *ipt*. Functional inactivation of the three toxin–antitoxin systems from pPsv48C increased three times the frequency of deletions, with 80% of them losing gene *ipt*. Together, our results indicate that maintenance of pathogenicity genes in bacterial populations of *P. syringae*, and their allocation to plasmids, results from the combination of diverse antagonistic evolutionary forces that are unrelated and independent of the pathogenicity process.

FEMS7-1146
Pathogens / Pathogenicity - Part II

DECIPHERING THE TRANSCRIPTIONAL REPROGRAMMING OF YERSINIA FOR PERSISTENCE

R. Navais[1], *M. Fällman*[1]
[1]*Umeå University, Molecular Biology, Umeå, Sweden*

Backgrounds

Yersinia pseudotuberculosis is an enteropathogen causing gastroenteritis, which usually is self-limiting in humans. This enteropathogen provides a suitable mouse model system for persistent bacterial infections. It invades and persist in extracellular foci in lymphoid follicles in cecum where it is surrounded by polymorphonuclear leukocytes. An *in vivo* RNA-seq approach was recently used to identify the genes whose expression is increased during *Y. pseudotuberculosis* persistence. This approach revealed that *Y. pseudotuberculosis* reprograms it transcriptome for persistence, involving repression of T3SS and induction of flagella and genes encoding proteins involved in anaerobiosis, chemotaxis and protection against oxidative and acidic stress, indicating the influence of and adaptation to different environmental cues. All this suggests a model for the life cycle of this enteropathogen with reprogramming from a virulent phenotype during early infection to an adapted phenotype during late infection or persistence. The observed transcriptional reprogramming has become a major focus of attention in our research group.

Objectives

We aim to identify the genes that control this novel regulation as well as the environmental cues that induce persistence.

Methods

Reporter strains harbouring a transcriptional fusion between the selected promoter (up- or down-regulated during persistence) and a chloramphenicol resistance gene have been generated. These reporter strains have been subjected to transposon mutagenesis and the resulting transposon mutant libraries have been screened for the phenotype of interest.

Conclusions

Two promoters that are downregulated during persistence seem to be calcium-sensitive. Further studies are needed to assess whether calcium plays a role in triggering the transcriptional reprogramming of *Yersinia* for persistence.

BIOLOGICAL FEATURE OF E. COLI STRAINS ISOLATED FROM PIGLETS WITH ENTERITIS

O. Nechypurenko[1], D. Dreval[2], T. Ponomarenko[3], I. Sobko[4], A. Pastyria[5]
[1]D.K. Zabolotny Institute of Microbiology and Virology NAS of Ukraine, Antibiotics department, Kyiv, Ukraine
[2]Centre of Veterinary Diagnostics, Bacteriology, Kyiv, Ukraine
[3]Centre of Veterinary Diagnostics, Molecular diagnostics, Kyiv, Ukraine
[4]Centre of Veterinary Diagnostics, Director, Kyiv, Ukraine
[5]Centre of Veterinary Diagnostics, Research, Kyiv, Ukraine

Backgrounds

Escherichiosis is a currently distributed worldwide disease. *E. coli* is a representative of opportunistic microbiota of gastrointestinal tract of humans and animals, but pathogenic strains have virulence factors that induce the development of enteritis, edema disease and septicemia. Such bacterial isolates are the main cause of intestinal disorders in porcine farming of Ukraine. Besides the pathogenic *E. coli* strains could affect human, be the source of food poisoning and transmission of antibiotic resistance to clinical isolates.

Objectives

Investigate the biological features of *E. coli* strains isolated from piglets with enteritis and determine the dynamics of their antibiotic resistance development through 2011-2015 years in Ukraine.

Methods

Routine autopsy of piglets with intestinal disorders at the age up to 60 days, isolation of bacteria from the small intestine and identification of isolates using Api 20E test, PCR detection of pathogenic strains, disk-diffusion determination of antibiotic resistance (13 antimicrobials), standard histological examination of affected organs.

Conclusions

During 2011-2015 years we analyzed 357 piglets from 135 farms of Ukraine. From the small intestine of 311 animals 336 strains were isolated among which 317 were identified as pathogenic *E. coli*. The amount of 66 enteropathogenic, 233 enterotoxigenic, and 18 enterohemorrhagic bacterial strains have been differentiated based on histopathology and PCR detection of STa, STb, LT, Stx toxins and intimin genes. It was determined that colistin, gentamicine, enrofloxacine and florfenicol were the most effective antibiotics because of 71%, 66%, 53% and 55% of isolated *E.coli* strains were susceptible to these medications respectively. However 5 strains of *E.coli* were resistant to all of used antimicrobials. Also in 2015 the increasement of number of resistant strains was found to colistin, enrofloxacine and florfenicol in 1.5-2.0 times comparatively to 2011 year. Therefore it was determined the distribution of pathogenic *E.coli* strains and the dynamics of their antibiotic resistance development in Ukraine.

Pathogens / Pathogenicity - Part II

MOLECULAR CHARACTERIZATION OF PSEUDOMONAS SYRINGAE STRAINS FROM SERBIA BY USING MULTI-LOCUS SEQUENCE TYPING METHOD

I. Nikolić[1], T. Popović[2], T. Berić[1], J. Lozo[3], I. Dimkić[1], D. Fira[3], S. Stanković[1]
[1]Faculty of Biology - University of Belgrade, Department of Microbiology, Belgrade, Serbia
[2]Institute for Plant Protection and Environment, Department of Plant Disease, Belgrade, Serbia
[3]Faculty of Biology - University of Belgrade, Department of Biochemistry and Molecular Biology, Belgrade, Serbia

Backgrounds

Pseudomonas syringae represent a phylogenetic complex of plant pathogenic strains, which affect different host plants such as fruits trees, field crops, vegetables and ornamental plants. During 2013, leaf spot disease of sugar beet caused by *P. syringae* was detected for a first time in Serbia.

Objectives

Objectives of our research were to characterize *P. syringae* strains from Serbia by using multi-locus sequence typing (MLST) method, in order to estimate intra-species genetic diversity.

Methods

Twenty five strains of *Pseudomonas syringae,* out of 104 identified, from fourteen commercial fields in province Vojvodina in Serbia were tested. Multi-locus sequence typing was performed with strains of *P. syringae* from Serbia and the three reference strains on four housekeeping genes (*gyrB*, *rpoD*, *gapA*, *gltA*). Sequences were analyzed in MEGA 6 software package and phylogenetic tree was constructed by using Neighbor-Joining clustering method.

Conclusions

Genetic differences among tested strains of *P. syringae* obtained by MLST method, show high level of genetic diversity by analyzing *gyrB* and *gapA* genes, which includes existence of four and three genetic groups, respectively. In contrast, genes *rpoD* and *gltA* did not show genetic variations among tested strains. Obtained genetic diversity demonstrates that infection of sugar beet with *P. syringae* in Vojvodina was not clonal and there were at least three different lines of infection. According to obtained results, analysis of *gyrB* and *gapA* genes was shown as reliable and suitable for determination of genetic diversity of *P. syringae*.

FIRST DESCRIPTION OF METHICILLIN-LINEZOLID RESISTANT STAPHYLOCOCCUS EPIDERMIDIS WITHOUT PREVIOUS LINEZOLID EXPOSURE, TURKISH EAST BLACKSEA REGION 2016

A.R. Freitas[1], A.R. Dilek[2], L. Peixe[1], C. Novais[1]
[1]REQUIMTE/UCIBIO- Faculty of Pharmacy- University of Porto, Microbiology, Porto, Portugal
[2]Recep Tayyip Erdoğan University. Medical Faculty Hospital, Microbiology, Rize, Turkey

Backgrounds

Linezolid is a critical option for multidrug-resistant Gram-positive infections. Emergence of resistant strains is occasionally described, mostly associated with previous therapies with linezolid.

Objectives

Here we characterize the first methicillin-linezolid-resistant (LinR) *S.epidermidis* from a patient without previous linezolid exposure.

Methods

A hypertensive 70-year-old male attended the emergency service (October-2016; Rize/Turkey; day-1) with syncope and was hospitalized. Clinical meningitis diagnosis was established in the following days but cultural+microscopic CSF analysis was negative. Antibiotic therapy was initiated and included ceftriaxone, netilmicin and vancomycin. Patient condition deteriorated and *S.epidermidis* (VitekII identification) from a hemoculture was recovered (day-14). Patient died (day-16) with multiple organ failure. Linezolid was never given to the patient and it has been scarcely used in the hospital. No other patients presented LinR-*S.epidermidis* infections. Susceptibility to linezolid and vancomycin was evaluated by microdilution, to daptomycin by Etest and to other 12 antibiotics by disk diffusion (EUCAST). The search of *cfr*/*cfr(B)*/*optrA*/*mecA*/*mecC* genes and mutations in the 23S-rRNA-V-domain were done by PCR/sequencing and clonality by MLST.

Conclusions

S.epidermidis-ST22 was resistant to linezolid (MIC≥256mg/L), cefoxitin (*mecA* gene), gentamicin, tobramycin, ciprofloxacin, chloramphenicol, erythromycin, clindamycin, tetracycline, cotrimoxazol and fusidic acid but not to quinuspristin-dalfopritin, rifampicin, tigecycline, vancomycin (MIC=4mg/L) and daptomycin (MIC=0,38mg/L). The previous identified T2530A, C2560T and the new T2834C mutations in 23S-rDNA-V-domain were detected (GenBankreference:CP000029), but not the often described G2576U or *cfr*/*optrA* genes.This is the first description of a linezolid-resistant *S.epidermidis* without previous linezolid treatment. Understanding the driving factors behind this phenomenon is critical for antimicrobial stewardship.

FREQUENCY AND PROFILE OF SENSITIVITY OF MICROORGANISMS ISOLATED FROM PATIENTS CARRIED OUT AT A PRIVATE HEALTH INSTITUTION OF SAO LUIS- MA

T. Novais[1], D. Sousa[2], G. Cabral[2], S. Maia[2], N. Camelo[3], F. Moraes[3], E. Fonseca[2], A. Carvalho[1]
[1]Universidade Federal do Maranhão, Hospital Universitário, São luis, Brazil
[2]Faculdade Estacio São Luis, Curso Biomedicina, São Luís, Brazil
[3]Faculdade Estacio São Luis, Curso Enfermagem, São Luís, Brazil

Backgrounds

Hospital infections have been drawing attention in recent decades, as they represent a serious public health problem. Antibiotics are used for the treatment of these infections, but the abusive use of these drugs contributes to increase the selective pressure of these drugs, creating a favorable environment for the bacteria, facilitating their proliferation and developing bacterial resistance, even though in the presence of these drugs.

Objectives

To evaluate the frequency and sensitivity profile of microorganisms isolated from patients attended at a private health institution in São Luís - Maranhão.

Methods

It was analyzed the results of the main microorganisms isolated from clinical samples and the sensitivity profile of these pathogens from the institution's clinical laboratory database from July 2013 to 2016. For the identification of the sensitivity profile, the test was performed using the disk diffusion method according to CLSI, 2015 (Institute of Clinical and Laboratory Standards).

Conclusions

It was verified that the sector with the highest frequency of isolation of microorganisms in clinical samples was the Intensive care unit (ICU). The most frequent microorganism was Escherichia coli; The uroculture presented a higher prevalence of the clinical samples. The group of beta-lactams presented greater microbial sensitivity. However, the highest percentage of the drug isolated as sensitivity was polymyxin B. Regarding microbial resistance, a higher percentage of antibiotics in the beta - lactam group was also observed. In isolation, ampicillin was the drug that showed less efficacy against the five most frequent microorganisms.

Pathogens / Pathogenicity - Part II

STUDY OF RESISTENCE PHENOTYPES AND GENOTYPES IN STREPTOCOCCUS AGALACTIAE ISOLATED FROM NEONATES AND ADULTS WITH INVASIVE INFECTIONS IN ARGENTINA

M.G. Novosak[1], F.J. Bobadilla[1], R.F. Derna[2], I.J. Cortese[1], M.E. Laczeski[1]
[1]Instituto de Biotecnología de la Provincia de Misiones Dra. María Ebe Recca, Microbiología, Posadas, Argentina
[2]Laboraorio Müller, Bacteriología, Encarnación, Paraguay

Backgrounds

Streptococcus agalactiae (GBS) is responsible for severe invasive infections in neonates and adults with or without underlying chronic diseases. Penicillin is the drug of election for treatment, however, in allergic to β-lactams patients, erythromycin (ERI) and clindamycin (CLI) are the recommended drugs. In the last years, increased macrolide resistance has been reported. Mechanisms include changes in target site mediated by *erm* genes leading to resistance to macrolide-lincosamides-streptogramin B (MLS_B - phenotype expressed in inducible or constitutive form) or mechanisms by efflux encoded by *mef* genes leading to macrolide resistance of 14-15 members (M phenotype). The knowledge of these phenotypes allows to adapt the treatment.

Objectives

The objective was to study the mechanisms of resistance to ERI and CLI in GBS recovered from patients with invasive diseases.

Methods

Twenty six strains isolated from blood cultures and cerebrospinal liquid from neonates and adults were investigated. MLS_B resistance phenotypes was determined by the double-disc test (D-Test) and *ermB* and *mefA* genes by PCR technique.Two GBS strains (7.69%) presented resistance phenotypes, one constitutive MLS_B phenotype and the other M phenotype. The presence of *ermB* and *mefA* genes was demostrated by PCR. This showed a correlation between the phenotype and genotype detected.

Conclusions

The results indicate the importance of D-Test technique for monitoring of the resistance to these antibiotics and to implement treatment strategies. In addition, these results confirm the presence of associated genes that can be transmitted between bacteria and disseminate the mechanisms of resistance involved.

Pathogens / Pathogenicity - Part II

CLINICAL FORMS OF CYTOMEGALOVIRUS IN CHILDREN

A. Kushugulova[1], A. Altynbekova[2], D. Bayesheva[2], V. Chudinovskikh[2], S. Zhamukova[3], Z. Abdikadyr[2], G. Tulegenova[2]
[1]Kazakhstan Association of Human Microbiome researchers, head, Astana, Kazakhstan
[2]JSC Medical University Astana, Department of Pediatric Infectious Diseases, Astana, Kazakhstan
[3]City Children's Hospital №1, City Children's Hospital, Astana, Kazakhstan

Backgrounds

CMV infection is widespread and is characterized by diverse manifestations from asymptomatic to severe with damage to internal organs and the central nervous system

Objectives

To investigate clinical forms of CMV infections in children who had cured in City Children's Hospital №1 during the time frame 2015-1016 in Astana

Methods

It were analyzed 38 clinical cases with the diagnosis "cytomegalovirus" in children, who had the treatment during 2015-1016 in City Children's Hospital №1 in Astana. Design of research is retrospective. SPSS Statistics 20 was used for statistical analysis.

Conclusions

During examination of 38 cases, where the 38 children had treatment of CMV, the most frequent cases were in the age range 0-3 months children and represent 55,26%(n=21); at the age of 4-6 months and 7-9 month the morbidity represents the equal numbers – 21.08%(n=8); from 10 till 12 months the percentage was – 2.67%(n=1). The male represented by 52,63%(n=20) and the female by 47,37%(n=18). During examination the history cases 55,26%(n=21) had congenital generalized form of CMV; 21,05% had recurrence and 23.68%(n=9) had latent form of CMV. The presence of CMV in the body was revealed by ELISA test in 60,5 %; in 7,89% by PCR; complex ELISA+PCR represented in 7,8% and in 23,68% the presence of CMV was revealed postmortem. It should be noted that 76,32 % had congenital malformations and 55,26 % of mothers had problematical obstetric history. The minimal hospital stay represented from 1 to 7 days in 34.21% and maximal hospital stay 61-86 days in 5,26% .

Conclusion: The study found that the maximal morbidity of CMV was indicated in children from 0-3 months in 55,26%, among the clinical forms congenital generalized form is revealing more frequent and represent 55.26 %.

Pathogens / Pathogenicity - Part II

DEVELOPMENT AND APPLICATION OF A THREE-DIMENSIONALLY DIFFERENTIATED AIRWAY EPITHELIAL CELL MODEL OF THE OVINE RESPIRATORY TRACT TO STUDY HOST-PATHOGEN INTERACTIONS

N. O'Boyle[1], *E. Sutherland*[1], *C. Berry*[2], *R. Davies*[1]
[1]*Infection- Immunity and Inflammation, Bacteriology, Glasgow, United Kingdom*
[2]*Institute of Molecular Cell and Systems Biology, Cell Engineering, Glasgow, United Kingdom*

Backgrounds

Respiratory tract infections are one of the principle causes of mortality and economic loss in the livestock industry. *Mannheimia haemolytica* is the most common bacterial pathogen associated with respiratory disease in cattle and sheep. While some information regarding the virulence factors of this organism has been obtained from large animal infections, such experiments are costly and ethically questionable. The process of airway tissue colonisation also remains poorly understood.

Objectives

Through extensive characterisation and optimisation, we aimed to develop a well-differentiated *in vitro* model of the sheep airway epithelium. This model was subsequently employed to investigate epithelial colonisation and host-specificity of a panel of *M. haemolytica* isolates.

Methods

Following growth at an air-liquid interface, optimal conditions for differentiation of airway epithelial cell (AEC) cultures were determined by carrying out extensive time-course studies and comparing a wide variety of growth parameters. Histological analysis, immunofluorescence microscopy and scanning electron microscopy confirmed that the AEC cultures contained the full repertoire of relevant cell types present in the *in vivo* airway epithelium and therefore represent a highly suitable model for infection studies. Pathogenic strains of *M. haemolytica* were capable of colonising ovine AEC cultures *in vitro* and interesting insights into temporal aspects of this process were revealed. A panel of virulent and avirulent isolates from cattle and sheep were used to demonstrate patterns of colonisation and tissue invasion that were specific to the pathogenic isolates.

Conclusions

These findings reveal previously unseen pathogenic mechanisms of this important respiratory tract pathogen.

Pathogens / Pathogenicity - Part II

UNDERSTANDING THE MECHANISM OF ACTION OF THE PRODRUG TP053

B.S. Orena[1], L.R. Chiarelli[1], G. Mori[1], V. Makarov[2], F. Gosetti[3], M. Manfredi[3], J. Madacki[4], J. Kordulakova[4], M. Guerin[5], K. Mikušová[4], E. Marengo[3], G. Riccardi[1], M.R. Pasca[1]
[1]University of Pavia, Biology and Biotechnology "Lazzaro Spallanzani", Pavia, Italy
[2]Russian Academy of Science, 2A. N. Bakh Institute of Biochemistry-, Moscow, Russia
[3]University of Piemonte Orientale, Department of Science and Technological Innovation, Alessandria, Italy
[4]Comenius University Bratislava, Department of Biochemistry-, Bratislava, Slovak Republic
[5]CIC bioGUNE- Bizkaia Technology Park, Structural Biology Unit, Derio, Spain

Backgrounds

Tuberculosis, caused by *Mycobacterium tuberculosis*, remains one of the leading public health problems worldwide. Considering the worrying spread of *M. tuberculosis* drug-resistant strains, it is urgently needed the development of antitubercular compounds with novel mechanisms of action. The thienopirimidine (TP) derivative TP053 is a new compound active against both replicating and non-replicating *M. tuberculosis* bacilli, with an MIC *in vitro* of 0.125 µg/ml. TP053 has been characterized as a prodrug activated by the reduced form of the thioredoxin-like enzyme Rv2466c.

Objectives

The study aims to characterize the mechanism of action of the prodrug TP053.

Methods

To identify the TP053 target, several *M. tuberculosis* TP053 resistant mutants were isolated harboring the mutation L240V in Rv0579, protein with unknown function. By recombineering method, it was demonstrated that Rv0579 has a role in TP053 resistance. To verify if Rv0579 is the TP053 target, the protein was expressed and purified in *Escherichia coli*, but additional improvements are needed. To clarify the mechanism of action of TP053 and to identify its active metabolite(s), *M. tuberculosis* cellular extracts treated with TP053 were analysed by proteomic and metabolomic approaches. Moreover, to demonstrate if there is a direct interaction between the TP053 active metabolite and Rv0579, innovative click chemistry experiments are *in progress*.

Conclusions

Preliminary results obtained by proteomic and metabolomic approaches suggest that TP053 could interfere with the protein synthesis pathway. These experiments will be repeated in order to confirm the results that will be validated by genetic, microbiological and biochemical approaches.

Pathogens / Pathogenicity - Part II

PROPIONIC ACID INDUCES RAPID EVOLUTION OF CROHN'S DISEASE ASSOCIATED AIEC

M. Ormsby[1], L. Meikle[1], A. Mcintosh[1], S. Johnson[1], R. Goldstone[2], C. Edwards[3], D. Smith[2], D. Wall[1]
[1]Infection- Immunity and Inflammation, Bacteriology, Glasgow, United Kingdom
[2]Biological Chemistry- Biophysics and Bioengineering, Heriot-Watt University, Edinburgh, United Kingdom
[3]School of Medicine, Human Nutrition, Glasgow, United Kingdom

Backgrounds

Crohn's Disease (CD) is a multi-factorial disease that occurs in genetically susceptible individuals, resulting in inflammation of the digestive tract. Concurrently, the use of antibacterial compounds, particularly short chain fatty acids (SCFAs), has increased dramatically in recent years in both agriculture and human food. One such SCFA, propionic acid (PA), inhibits *Salmonella* and *Campylobacter* colonisation of poultry. Here we show that the bacterial pathotype adherent and invasive *Escherichia coli* (AIEC), that has been isolated in increased numbers from CD patients, can use PA as a carbon source for growth.

Objectives

Our work aims to elucidate the adaptation that pre-exposure to PA may have on the ability of AIEC to colonise the human intestinal tract, outcompeting the native microflora.

Methods

Continued growth of the AIEC type strain LF82, in PA, resulted in; an increased rate of growth; greater adherence to Caco-2 intestinal epithelial cells; and a greater propensity to form biofilms under anaerobic conditions. PA use was also seen to induce shedding of inflammatory bacterial micro-compartments, with upregulation of both the *pdu* and *eut* operons, for 1,2-propanediol and ethanolamine use, respectively. Both metabolites are known to allow pathogens such as *Salmonella* Typhimurium to out-compete the native microflora during intestinal inflammation.

Conclusions

As antibiotic use has previously been implicated in the horizontal transmission of *E. coli* between poultry and humans, this work highlights the risk associated with using alternative antimicrobials such as PA in both agriculture and human food potentially evolving *E. coli* strains that are specifically adapted to life in the inflamed CD gut.

Pathogens / Pathogenicity - Part II

AN INNOVATIVE NEXT GENERATION SEQUENCING-BASED APPRAISAL OF THE EUKARYOTIC MICROBIOME IN AUSTRALIAN TICKS

A. Paparini[1], A. Codello[1], C. Oskam[1], U. Ryan[1], P. Irwin[1]
[1]Murdoch University, Vector- and Water-Borne Pathogen Research Group School of Veterinary and Life Sciences, Murdoch WA, Australia

Backgrounds

After mosquitoes, ticks are the second most important vector of pathogens to humans, and the chief cause of vector-borne diseases in domestic animals and wildlife. Tick-borne pathogens include viruses, bacteria and protozoa of medical significance and can be successfully audited by high-throughput next generation sequencing (NGS). Tick internal tissues and organs, however, are also colonized by highly abundant groups of other symbionts. Their high dominance can hamper the detection of rare pathogens of interest, especially when universal PCR primers are used for NGS.

Objectives

We present an innovative approach to analyse the tick microbiome by selectively retrieving DNA from protozoan parasites, in the presence of highly abundant genomic DNA, from the tick and the vertebrate host. The objective was to use this approach, to audit the eukaryotic microbiome in Australian ticks, with a focus on potential pathogens.

Methods

DNA from Australian ticks of various species and genera, sex, instar, location and feeding status was processed by NGS (Miseq, Illumina). Amplicons were generated using universal PCR primers, used in conjunction with novel tick- and mammalian-blocking primers.

Conclusions

A novel approach was developed to prevent the undesired amplification of eukaryotic sequences from the tick and mammalian host. This allowed the detection, identification and quantification of various blood-borne parasites, including *Babesia*, *Theileria* and *Trypanosoma*. A number of Bacterial taxa were also identified, including two potentially new species of *Francisella* sp. Statistical analyses revealed novel insights onto the biogeography of Australian ticks and their associations with potential pathogens.

Pathogens / Pathogenicity - Part II

EXCISION OF SALMONELLA ENTERICA SEROVAR ENTERIDIS PATHOGENICITY ISLAND ROD21 PLAYS A KEY ROLE DURING SYSTEMIC INFECTION IN MICE

C. Pardo-Roa[1,2], G.A. Salazar[1,2], L. Noguera[1,2], F.J. Salazar-Echegarai[1,2], C.A. Riedel[1,3,4], A.M. Kalergis[1,2,5,6], M. Alvarez-Lobos[1,7], S.M. Bueno[1,2,6]
[1]Milleniumm Institute on Immunology and Immunotherapy, IMII, Santiago, Chile
[2]Pontificia Universidad Católica de Chile,
Facultad de Ciencias Biológicas- Departamento de Genética Molecular y Microbiología, Santiago, Chile
[3]Universidad Andrés Bello, Facultad de Medicina, Santiago, Chile
[4]Universidad Andrés Bello, Facultad de Ciencias Biológicas-Departamento de Ciencias Biológicas, Santiago, Chile
[5]Pontificia Universidad Católica de Chile, Facultad de Medicina- Departamento de Endocrinología, Santiago, Chile
[6]INSERM, U1064, Nantes, France
[7]Pontificia Universidad Católica de Chile, Facultad de Medicina- Departamento de Gastroenterología, Santiago, Chile

Backgrounds

ROD21 is a Pathogenicity Island (PAI) present in the chromosome of *S.* Enteriditis (SEn). ROD21 harbors genes encoding virulence associated proteins and is an excisable PAI. The excision of ROD21 is a dynamic process related to environmental conditions. In mice, strains unable to excise ROD21 show reduced ability to colonize the liver and spleen. These results suggest that the excision may regulate virulence mechanisms during infection.

Objectives

To determine the effect of ROD21 excision during SEn infection *in vivo*.

Methods

C57BL/6 mice were intragastrically infected with SEn PT4 (SEn WT) or SEn strain unable to excise ROD21 (SEnDintDxis). Stomach, ileum, ceaecum, colon, mLN, blood, spleen, liver, gallbladder and feces were recovered at different times after infection **(**between 1 h and 10 days) and CFU counting and gDNA extraction were performed to evaluate bacterial load and ROD21 excision frequency, respectively. **Results:** SEn WT and SEnDintDxis were detected during the 10 days of infection in the gut. The transit of *S.* Enteritidis across the small intestine occurs rapidly for both strains, although the mutant strain was not detected in colon after 24 h of infection. SEn WT was able to colonize internal organs such as spleen, liver and gallbladder faster and more efficiently as compared to SEnDintDxis. Finally, the frequency of ROD21 excision showed differences in organs during the different phases of the infective cycle

Conclusions

Our data show that ROD21 excision is an important process to regulate SEn mechanisms involved in virulence during the systemic stages of infection.

TYPE III SECRETION SYSTEM OF PSEUDOMONAS AERUGINOSA AFFECTS MUCIN GENE EXPRESSION VIA NF-KB SIGNALING IN HUMAN CARCINOMA EPITHELIAL CELLS AND A PNEUMONIA MOUSE MODEL

J.W. PARK[1], J.H. Lee[2], S.R. Oh[1], U.H. Ha[2], K.S. Ahn[1]
[1]Korea Research Institute of Bioscience & Biotechnology, Natural Medicine Research Center, Cheongju-si, Republic of Korea
[2]Korea University, Department of Biotechnology and Bioinformatics, Sejong, Republic of Korea

Backgrounds

Pseudomonas aeruginosa is a ubiquitous soil bacterium and versatile opportunistic pathogen, capable of causing life-threatening acute and chronic infections in a variety of patient populations. Many clinical isolates of P. aeruginosa have a specialized apparatus for injecting toxins into eukaryotic cells, namely, the type III secretion system (T3SS). The P. aeruginosa T3SS is a syringe-like apparatus on the bacterial surface, with 4 effector toxins: ExoS, ExoT, ExoY, and ExoU.

Objectives

Here, we investigated the effect of ExoS and ExoT of the T3SS of P. aeruginosa K strain (PAK). We aimed to investigate whether the ExoS and ExoT effector proteins of P. aeruginosa affect the expression of mucin gene via NF-κB signaling pathways.

Methods

To understand the T3SS, we used ΔExoS, ΔExoT, and ExsA::Ω mutants, as well as PAK-stimulated A549 cells. We investigated the effects of ΔExoS, ΔExoT, and ExsA::Ω on the development of pneumonia in PAK-infected mouse models. We also examined the effects of ΔExoS, ΔExoT, and ExsA::Ω on mucin gene production in A549 cells. ΔExoS and ΔExoT reduced NF-κB phosphorylation, together with mucin gene expression in PAK-infected mouse models and A549 cells.

Conclusions

To conclude, P. aeruginosa infection induced the expression of mucus gene, and P. aeruginosa T3SS appeared to be a key player in mucin gene expression, which is further controlled by NF-κB signaling. These findings might be useful in devising a novel therapeutic approach for the treatment of chronic and acute pulmonary infections.

Pathogens / Pathogenicity - Part II

TRICHOMONAS VAGINALIS A-ACTININ 2, AN ADHESIN FOR HOST CELLS, MODULATES HOST IMMUNE RESPONSES BY INDUCING TOLEROGENIC DENDRITIC CELLS VIA IL-10 PRODUCTION FROM REGULATORY T CELLS

S.J. Park[1], H.Y. Lee[1], Z. Kim[1]
[1]Yonsei University College of Medicine, Environmental Biology, Seoul, Republic of Korea

Backgrounds

Trichomonas vaginalis is a protozoan pathogen that induces severe immune responses in hosts. *T. vaginalis* α-actinin 2, Tvα-actinin 2, has been used for diagnosis of trichomoniasis both in men and women.

Objectives

This study was undertaken to examine a role of Tvα-actinin 2 as an antigenic molecule to induce immune response from humans.

Methods

An immunofluorescence microscopy was used to observe localization of Tvα-actinin 2 upon contacts of *T. vaginalis* with vaginal epithelial cells (VEC) and prostate cell lines (RWPE-1). Antibody blocking experiments was performed to examine the role of Tvα-actinin 2 in *T. vaginalis*-host cell interaction. Flow cytometry, ligand-binding immunoblotting assay, and observation by fluorescence microscopy were used to detect the binding of Tvα-actinin 2 to these cell-lines. ELISA was employed to measure cytokine production by VEC, RWPE-1, mouse dendritic cells (DCs), or T-cells stimulated with *T. vaginalis* or Tvα-actinin 2 protein.

Conclusions

Surface localization of Tvα-actinin 2 was observed in *T. vaginalis* incubated with human epithelial cell-lines. Pretreatment of *T. vaginalis* with anti-rTvα-actinin 2 Abs resulted in reduction in cytoadherence and cytotoxicity. Direct binding of Tvα-actinin 2, especially the truncated N-terminal portion of Tvα-actinin 2 to VECs was demonstrated. Both *T. vaginalis* and rTvα-actinin 2 induced cytokine production from epithelial cell lines which includes IL-10. Moreover, CD4+CD25- regulatory T-cells (Treg cells) incubated with rTvα-actinin 2-treated DCs produced high levels of IL-10. These data suggested that α-actinin 2 plays a role in the pathogenesis of *T. vaginalis* by serving as one of the adhesins to the host cells. In addition, this surface molecule modulates immune responses via the IL-10 production by Treg cell. Therefore, *T. vaginalis* may use its surface protein, α-actinin 2 to evade excess immune responses which occurred frequently in trichomoniasis.

Pathogens / Pathogenicity - Part II

EXPRESSION PROFILE OF EMRKY EFFLUX PUMP DURING SHIGELLA'S INTRACELLULAR LIFE

M. Pasqua[1], M. Grossi[1], L. Aussel[2], F. Barras[2], M.L. Di Martino[3], G. Prosseda[1], B. Colonna[1]
[1]Sapienza - Università di Roma, Department of Biology and Biotechnologies "C. Darwin", Roma, Italy
[2]Aix-Marseille Université - CNRS- Institut de Microbiologie de la Méditerranée, Laboratoire de Chimie Bactérienne, Marseille, France
[3]Biomedical Center- Uppsala University, Department of Medical Biochemistry and Microbiology, Uppsala, Sweden

Backgrounds

In several bacterial pathogens, efflux pumps, besides exporting antimicrobial agents, play a role in bacterial pathogenicity.
Shigella, the causative agent of bacillary dysentery, has conserved 14 out of 20 operons encoding efflux pumps systems present in the genome of its commensal ancestor *Escherichia coli*.

Objectives

The aim of this work was (i) to analyze the regulation of *Shigella's* efflux pumps during the infection of macrophages and epithelial cells and (ii) to identify and characterize those that are required for bacterial pathogenesis.

Methods

The expression of efflux pumps was monitored by qRT-PCR during infection of macrophages and epithelial cells. Strains defective for efflux pump encoding genes were used in infection assays to investigate the existence of interplays between them. Competition assays were conducted to compare the importance of these genes in *Shigella*'s fitness. To better understand the regulative network, transcriptional fusions were monitored in the presence of different stimuli which reflect the intracellular environment.

Conclusions

Our results allowed us to identify efflux pump encoding genes up- or downregulated in macrophages and epithelial cells. Among them, *emrK*, encoding the membrane subunit of the EmrKY multidrug efflux pump, was specifically up-regulated within macrophages. Moreover, an *emrK* mutation was shown to affect *Shigella*'s fitness.
Our observations also reveal that its role, still unknown, and its modulation during infection are dependent upon pH and ion concentrations.

Pathogens / Pathogenicity - Part II

NASAL SELF-ADJUVANTED VACCINE AGAINST SHIGELLA FLEXNERI

Y. Pastor[1], A.I. Camacho[1], A.G. Gil[2], R. Ramos[3], A. López de Ceráin[2], I. Peñuelas[3], J.M. Irache[4], C. Gamazo[1]
[1]Universidad de Navarra, Microbiology, Pamplona, Spain
[2]Universidad de Navarra, Toxicology, Pamplona, Spain
[3]Clínica Universidad de Navarra, Radiopharmacy, Pamplona, Spain
[4]Universidad de Navarra, Pharmacy and Pharmaceutical technology, Pamplona, Spain

Backgrounds

Shigellosis is one of the leading causes of diarrhea in developing countries. *Shigella flexneri* is estimated to cause more than 80 million dysenterial episodes each year but no vaccine is available yet. Since non-living vaccines seem to be the safest option, our group has focused on liposome-like outer membrane vesicles.

Objectives

The aim was to improve the yield and safety in the isolation process of the outer membrane vesicles, and evaluate toxicity, biodistribution and protection after nasal administration in mice.

Methods

Outer membrane vesicles were obtained by two different methods: either from the supernatant of growing bacteria (OMV), or from bacteria treated at 100 ºC, 15 min (HT). Cytotoxicity and immunostimulating properties were studied in Raw 264.7 macrophage cell line *in vitro.* Acute and chronic toxicity studies and biodistribution studies were performed in rat and mice, respectively. Finally, protection against an infection with *S. flexneri* was evaluated in mice.

Conclusions

Heat treatment simultaneously achieves the inactivation of bacteria, leading a safe working process, as well as an increase in the yield the vaccine product (HT) in four times with respect OMV. In addition, HT appeared to be non-cytotoxic, induced expression of main differentiation markers of antigen presenting cells and did not elicit adverse effects *in vivo*. Finally, the HT vaccine product was as effective as OMV in protection against an experimental infection with *S. flexneri* in mice. These findings support the use of the new HT product as a new vaccinal candidate to face shigellosis.

Pathogens / Pathogenicity - Part II

TLRS DIFFERENTIALLY INDUCE IG SYNTHESIS FOLLOWING PAMPS STIMULATION IN THE CARP CATLA CATLA BY ACTIVATING MAPK AND NF-KB SIGNALING CASCADE

B. Patel[1], M. Samanta[2], S. Das[3]
[1]National Institute of Technology, Life Science, Rourkela, India
[2]ICAR-Central Institute of Freshwater Aquaculture, Fish Health Management Division, Bhubaneswar, India
[3]National Institute of Technology- Rourkela, Life Science, Rourkela, India

Backgrounds

The extracellular-signal regulated kinases have emerged as highly conserved signal transducers of mitogen activated protein kinase family across vertebrates. These serine/threonine kinases participate in propagating intracellular signals initiated by ligand stimulated cellular receptors to transcription factors eliciting cytokine release. Although ERK signaling has been extensively studied in mammalian counterparts, very little is known about its existence in carps and its role in augmentation of Ig synthesis.

Objectives

To gain insights into the efficacy of MAPkinase cascade in orchestrating fish antigen receptor generation, *Catla catla* fingerlings were induced with various TLR agonists or pathogen associated molecular patterns (PAMPs).

Methods

Analysis of upstream signaling events revealed that PAMPS stimulated tissues led to a significant upregulation ($P<0.001$, Two-way ANOVA) of different TLRs (TLR2, TLR3, TLR4 and TLR5) followed by activation of MyD88 dependent and independent pathway. Consequent activation of ERK, triggered NF-kB mediated cytokine production and enhanced expression of circulating IgZ and IgM in a time dependent manner as was evident by qRTPCR analysis, flow cytometry and ELISA. Pretreatment with ERK inhibitor (UO126) antagonized PAMPs mediated TLR stimulation leading to sequential downregulation of MyD88/NF-kB/cytokines via interrupting ERK/NF-kB signaling axis.

Conclusions

Together these results demonstrate that TLR triggering stimulates IgZ and IgM production via activation of ERK and NF-kB in *C. catla* indicating that NF-kB mediated cytokine production and ERK1/2 signaling is not only functional in fish, but may be crucial for generation of Ig repertoire in lower vertebrates.

FEMS7-1064
Pathogens / Pathogenicity - Part II

CHARACTERIZATION OF THE LUNG MICROBIOME IN LEGIONELLA-ASSOCIATED PNEUMONIA AND ITS EVOLUTION DURING ANTIBIOTIC TREATMENT

A.E. Pérez Cobas[1,2], C. Ginevra[3,4], C. Rusniok[1,2], J. Sophie[3,4], C. Buchrieser[1,2]

[3]Centre National de Référence des Légionelles, Hospices Civils de Lyon, Lyon, France
[4]Centre International de Recherche en Infectiologie- Université Lyon 1- UMR CNRS 5308- U1111 Ins erm, Ecole Normale Supérieure de Lyon, Lyon, France

Backgrounds

Pneumonia represents a major public health problem with a high rate of morbidity and mortality worldwide. Despite the explosion of microbiome (MC) analyses, very little is known about the lung MC, especially with respect to bacterial pneumonia. The lung MC seems to contribute to the stimulation of the immune system and to inflammation. It thus plays possibly a role in the response to lung infections.

Objectives

Here we characterized the dynamics of the lung MC during bacterial infection and antibiotic therapy.

Methods

We collected broncheoalveolar samples from patients with pneumonia caused by *Legionella pneumophila* during around two months of hospitalisation and performed a longitudinal analysis of their lung MC. We characterized the bacterial and fungal diversity of these samples by deep sequencing (Illumina) of the 16S rRNA gene (bacteria) and the ITS region (fungi).

Conclusions

During infection the bacterial fraction of the lung MC was characterized by a low diversity and a dominance of the pathogen, as *L. pneumophila* represented more than 50% of the identified bacteria. Antibiotic treatment led to a strong change in the MC as we observed a marked decrease in the abundance of *L. pneumophila* and an increase in the bacterial diversity. The commonly identified bacteria of the lungs such as *Prevotella*, *Fusobacterium* or *Staphylococcus* were recovered. In contrast, the composition and diversity of the fungal fraction was more homogeneous. However, the fungal diversity was higher during infection probably because of a colonization advantage of fungi due to the loss of the bacterial MC during antibiotics treatment.

Pathogens / Pathogenicity - Part II

PSEUDOMONAS PROTEGENS AND PSEUDOMONAS CHLORORAPHIS: SWITCH BETWEEN ROOT- AND INSECT-ASSOCIATED LIFESTYLES

P. Vesga[1], P. Flury[1], M. Péchy-Tarr[2], C. Keel[2], M. Maurhofer[1]
[1]Institute of Integrative Biology- Federal Institute of Technology Zurich ETHZ, Plant Pathology, Zurich, Switzerland
[2]University of Lausanne, Fundamental Microbiology, Lausanne, Switzerland

Backgrounds

Insect pests are a major agricultural problem and very difficult to control. Root-colonizing fluorescent pseudomonads are known for their ability to promote plant growth and to protect plants against soilborne fungal pathogens, but some of them belonging to the species *Pseudomonas protegens* and *P. chlororaphis* additionally have insecticidal activity. They can colonize the gut of insect larvae and invade the hemocoel causing systemic infection and death. These bacteria produce an insect toxin termed Fit, which contributes to insecticidal activity.

Objectives

To answer the question whether *P. protegens* and *P. chlororaphis*, which were so far thought to be mostly associated with plants and soil, are naturally associated with insects.

Methods

In order to answer this question, bacteria were isolated from insects collected from the field. Isolates were assessed for presence of the Fit insect toxin gene and insecticidal activity and were phylogenetically characterized. So far, we found that Fit-harbouring pseudomonads are common in different insect species, which indicates that insects are an additional ecological niche for *P. protegens* and *P. chlororaphis*. Currently, we are performing a RNA-sequencing analysis with *P. protegens* CHA0 to determine the genes it needs to switch between a root- and an insect-associated lifestyle. In addition, we have demonstrated, in insect backgrounds, the expression of known insecticidal factors as well as factors involved in suppression of plant pathogens and competition.

Conclusions

Altogether, this knowledge will contribute to a better understanding of *Pseudomonas*-insect interactions and to develop future biocontrol strategies for insects on top of diseases.

Pathogens / Pathogenicity - Part III

HOST-MICROBIOTA INTERACTIONS IN INFLAMMATORY ARTHRITIS

L. Lam[1], D. Regan-Komito[1], J. Faith[2], T. Griseri[1], F. Powrie[1]
[1]University of Oxford, Kennedy Institute of Rheumatology, Oxford, United Kingdom
[2]Mount Sinai School of Medicine, Genetics and Genomic Sciences, New York, USA

Backgrounds

The gut is the primary site of host-commensal symbiosis, but disequilibrium can drive inflammatory disease and damaging systemic immune responses. Spondyloarthropathies are a form of inflammatory arthritis, the most common of which is ankylosing spondylitis (AS), characterized by joint deformation and fusion throughout the body. Intriguingly, over 70% of AS patients have subclinical intestinal inflammation and 15-25% develop inflammatory bowel disease. Additionally, arthritis is the most common extraintestinal manifestation of IBD. Together, these findings suggest a gut-joint connection in AS pathogenesis.

Objectives

While microbial dysbiosis is strongly associated with inflammatory arthritis, it is unclear how altered intestinal community composition modulates systemic immune responses. IgA secreted at mucosal surfaces coats different species of intestinal bacteria and is a critical mediator of homeostasis. While commensal microbiota may be coated with IgA, pathogens elicit high-affinity responses, making IgA coating a powerful metric for identifying specific bacteria that trigger inflammation.

Methods

The proposed research will use differential immunoglobulin A coating of fecal bacteria coupled with 16S rRNA sequencing (IgA-SEQ) to identify immunopathogenic members of the microbiota. IgA+ and IgA- bacteria from will be collected by fluorescence-activated cell sorting in both ankylosing spondylitis (AS) patients and healthy controls.

Conclusions

In parallel with IgA-seq, patient libraries of bacterial isolates will be generated using high-throughput cultivation platforms. To identify immunomodulatory microbes, IgA+ and IgA- bacterial consortia will be screened in gnotobiotic mouse models of AS. This work has the potential to identify host-microbiota interactions that drive local intestinal inflammation and systemic joint disease.

Pathogens / Pathogenicity - Part III

CHEMICAL COMPOSITION, ANTICANDIDAL AND ANTIOXIDANT ACTIVITY OF STAR ANISE ESSENTIAL OIL

S. Patil[1]
[1]*Shri Shivaji Science College- Amravati, Department of Microbiology & Biotechnology, Amravati, India*

Backgrounds

Plant based medicines are in use ever since the antiquity and still a large population of the world is relying on the herbal based products in controlling the various ailments. Star anise is the dried, star shaped fruit of *Illicium verum* and is indigenous to South Eastern China and also produced to a small extent in India. Star anise essential oil (EO) is used as a fragrance in soaps, cosmetics, perfumes, and toothpaste, and to mask undesirable odors in drug products.

Objectives

The objective of the present study was to evaluate the antimicrobial potential of star anise essential oil against *Candida* species along with chemical constituents, free radical scavenging potential and possible synergism with commonly used antifungal drugs.

Methods

Sensitivity of 50 clinical isolates of *Candida* to star anise oil was determined by agar disc diffusion method. Minimum inhibitory concentrations (MIC) were evaluated by broth microdilution method. GC-MS analysis of essential oil components was performed by using JEOL, GC-MS, Japan. The synergic efficacy of antifungal drugs with EO was assessed by using checkerboard assay.

Conclusions

Majority of *C. albicans* and *C. glabrata* isolates were sensitive to star anise EO at all the concentrations tested. The broth microdilution assay gave MIC values ranging from 1.25- >5.00 µg/ml and *C. krusei* exhibited higher sensitivity to star anise oil than other isolates with mean MIC of 1.86 µg/ml. GC-MS studies showed presence of *trans*-anethole (22.34%), limonene (14.63%), α-trans-bergamotene (14.28%), estragole (12.24%), a-cubebene (10.86%). However, a-pinene (9.57%), and 4-terpineol (8.84%) were present comparatively in lower quantities. At 500 µg/ml concentrations the scavenging activity of both star anise EO and ascorbic acid was same (8.68%). The combinational effects of EOs with antifungal drugs showed varying degrees of interactions. The results suggest that star anise oil possess active anticandidal components and synergistic interactions for the management of fungal infections.

Pathogens / Pathogenicity - Part III

SURVIVAL OF RESISTANCE PLASMID IN A BACTERIAL POPULATION EXPOSED TO PLASMID-DEPENDENT PHAGES, PREDATORS AND/OR ANTIBIOTICS

T. Patinen[1], J. Cairns[2], R. Penttinen[1], T. Hiltunen[2], M. Jalasvuori[1]
[1]University of Jyväskylä, The Department of Biological and Environmental Science, Jyväskylä, Finland
[2]University of Helsinki,
Department of Food and Environmental Sciences/Microbiology and Biotechnology, Helsinki, Finland

Backgrounds

Resistance plasmids are common among hospital bacterial pathogens, therefore horizontal gene transfer as mediated by these mobile elements plays a critical role in the evolution of antibiotic resistance.

Objectives

In this study, we set to investigate how predation, plasmid-depended bacteriophages and antibiotics in both inhibiting and sub-inhibiting concentrations affects the persistence of plasmids in bacterial populations.

Methods

Bacteria carrying a resistance conferring conjugative plasmid were let to interact in daily refreshed cultures for 50 days in a factorial experiment setup containing (A) predator Tetrahymena thermophila, (B) plasmid-dependent phage PRD1 and (C) aminoglycosides and beta-lactams. Evolved populations were studied for their presence of plasmids as well as for various other phenotypic attributes.

Conclusions

Plasmid-dependent phages are effective in removing antibiotic resistance plasmids from bacteria. Interestingly, conjugation appears to be necessary for a plasmid to maintain itself in a bacterial population under predation. On the other hand, simultaneous exposure to phages and antibiotics cause plasmids to become conjugation defective. These results suggest that various biological interactions play a crucial role in determining whether bacteria retain their plasmids.

Pathogens / Pathogenicity - Part III

UNIQUE STRUCTURAL FEATURES REVEAL THE BINDING MECHANISM FOR A LARGE FAMILY OF BACTERIAL HOST CELL ADHESINS

J. Paxman[1], A. Lo[2], S. Panjikar[3], M. Kuiper[4], S. Nocadello[5], D. Moriel[2], C. Gee[3], M. Schembri[2], B. Heras[1]
[1]La Trobe Institute for Molecular Science, Biochemistry and Genetics, Melbourne, Australia
[2]The University of Queensland, Australian Infectious Diseases Research Centre, Brisbane, Australia
[3]Australian Synchrotron, Macromolecular Crystallography, Melbourne, Australia
[4]The University of Melbourne, Victorian Life Sciences Computation Initiative, Melbourne, Australia
[5]Northwestern University, Department of Biochemistry and Molecular Genetics, Chicago, USA

Backgrounds

Autotransporters (type V secretion pathway) are the largest family of outer membrane and secreted proteins in Gram-negative bacteria. Despite their prevalence, there are few crystal structures of autotransporters and their definite mechanisms of action remain largely unknown. Most autotransporters are associated with colonisation for many medically important bacterial pathogens. Their β-helical structures are thought to remain associated with the bacterial cell surface where they function as adhesins.

Objectives

We have investigated the UpaB autotransporter adhesin that is critical for uropathogenic *E. coli* (UPEC) colonisation of the urinary tract[1].

Methods

Determination of the UpaB crystal structure revealed a significant deviation from previous autotransporter β-helical structures[2], to accommodate two very different host cell binding sites. We found that the UpaB β-helix forms a long deep groove to interact with epithelial glycosaminoglycans. The second UpaB binding site was found to form a completely new type of interaction with human fibronectin. This is very significant considering that most of the 100 bacterial fibronectin binding proteins follow a single and very different type of interaction with fibronectin. Following initial attachment of UPEC to the urinary tract by fimbrial adhesins, the UpaB binding activities likely work in unison to promote more intimate and higher affinity interactions at a later stage of colonisation.

Conclusions

We are the first to show how the large autotransporter family interacts with host cell surfaces to facilitate bacterial colonisation/pathogenesis. The unique UpaB structure also reveals unprecedented structural plasticity in the autotransporter β-helices, which should lead to a re-evaluation of the current autotransporter classification.

Pathogens / Pathogenicity - Part III

DAM OVEREXPRESSION IMPACTS MOTILITY AND VIRULENCE OF THE ENTOMOPATHOGENIC BACTERIUM PHOTORHABDUS LUMINESCENS

A. Payelleville[1], A. Givaudan[1], J. Brillard[1]
[1]Université de Montpellier, Diversité Génome Interactions Microorganismes Insectes DGIMI, Montpellier cedex 5, France

Backgrounds

Photorhabdus luminescens is an entomopathogenic bacterium symbiotically associated with nematodes of the genus *Heterorhabditis*. The nemato-bacterial complex is able to kill a broad range of insect's crop pest and is therefore use in biocontrol. Dam is the most described DNA-methyltransferase and is widespread in gamma-proteobacteria. Dam DNA methylation can play a role in gene expression and in virulence of several bacterial species but has never been studied in *P. luminescens*.

Objectives

We studied the functionality of a *dam* ortholog identified in *P. luminescens* and its involvement in bacterial phenotypes and virulence.

Methods

The *dam* gene was cloned on a plasmid under the control of a strong promoter. This construction complemented DNA methylation of an *E. coli dam* mutant. It also allowed the overexpression of Dam protein in *P. luminescens* and different phenotypes were assayed.

Conclusions

Overexpression of Dam protein in *P. luminescens* did not impair growth ability nor mutation rates relative to a control harboring an empty plasmid. In contrast, it drastically reduced swimming motility. Similarly, *dam* overexpression in the closely related bacterium *Xenorhabdus nematophila* also impaired motility. In addition, the *dam*-overexpressing *P. luminescens* strain showed a delayed virulence compared to that of the control strain after injection in larvae of the lepidopteran *Spodoptera littoralis*. These results reveal that Dam plays a major role during *P. luminescens* insect infection. To go further, the analysis of the DNA methylation pattern of the whole *P. luminescens* genome will be performed by SMRT sequencing.

MULTILOCUS SEQUENCE TYPES PREDICT PHYLOGENY AND GENE CONTENT BUT NOT ISOLATION SOURCE FOR BURKHOLDERIA MULTIVORANS

C. Peeters[1], V.S. Cooper[2], P.J. Hatcher[3], B. Verheyde[1], A. Carlier[1], P. Vandamme[1]
[1]Ghent University, Laboratory of Microbiology - Department of Biochemistry and Microbiology, Gent, Belgium
[2]University of Pittsburgh School of Medicine, Department of Microbiology and Molecular Genetics, Pittsburgh, USA
[3]University of New Hampshire, Department of Computer Science, Durham, USA

Backgrounds

Burkholderia multivorans is an important pathogen in people with cystic fibrosis (CF) in many countries including Belgium, and the continued emergence of unique *B. multivorans* strains (as defined by multilocus sequence typing) in CF patients suggests acquisition from nonhuman sources, such as the natural environment. Because environmental pressure can select for traits that confer virulence, the natural environment may serve as a reservoir of opportunistic pathogens.

Objectives

The aim of the present study was to examine whether the isolation source (CF or environment) or the multilocus sequence type (ST) of *B. multivorans* better predicted their genomic content and functionality.

Methods

We identified four pairs of *B. multivorans* isolates, representing distinct STs and consisting of one CF and one environmental isolate. All genomes were sequenced using the PacBio SMRT sequencing technology, which resulted in eight high-quality *B. multivorans* genome assemblies.

Conclusions

The present study demonstrated that the genomic structure of *B. multivorans* is highly conserved and that the *B. multivorans* genomic lineages are defined by their ST. Orthologous protein families were not uniformly distributed among chromosomes, with core orthologs being enriched on the primary chromosome and ST-specific orthologs being enriched on the second and third chromosome. The ST-specific orthologs were enriched in genes involved in defense mechanisms and secondary metabolism, corroborating the strain-specificity of these virulence characteristics. Finally, the same *B. multivorans* genomic lineages were isolated from CF and environmental samples and on different continents many years apart, demonstrating the evolutionary persistence and ubiquity of these strains in different niches and on different continents.

Pathogens / Pathogenicity - Part III

DECTIN-1 PLAYS A CRITICAL ROLE DURING THE MICROGLIAL PHAGOCYTOSIS OF THE FILAMENTOUS PATHOGENIC FUNGUS LOMENTOSPORA PROLIFICANS

A. Pellon[1], A. Ramirez-Garcia[1], I. Buldain[1], A. Antoran[1], A. Arbizu-Delgado[1], C. Matute[2], A. Rementeria[1], F.L. Hernando[1]
[1]University of the Basque Country UPV/EHU,
Fungal and Bacterial Biomics Research Group. Dept. of Immunology- Microbiology & Parasitology, Leioa, Spain
[2]University of the Basque Country UPV/EHU, Neuroscience, Leioa, Spain

Backgrounds

The filamentous ascomycete *Lomentospora* (*Scedosporium*) *prolificans* is an emerging pathogen that is able to invade the Central Nervous System (CNS). Unfortunately, little is known about its neurotropism and how microglia, the resident immune cells in the CNS, manages these infections.

Objectives

To study the interactions between *L. prolificans* and microglia, and to analyze the role of the macrophage receptors Dectin-1 (Dc-1) and Mannose Receptor (MR) in this interplay.

Methods

Conidia were co-cultivated with two microglial cellular models, the BV-2 cell line and primary cultures, or with J774A.1 monocytes. Then, we characterized these co-cultures by measuring phagocytosis and survival rates, production of reactive oxygen and nitrogen species (ROS and RNS), and pro-inflammatory cytokines. Moreover, the role of Dc-1 and MR was studied using specific inhibitors.

Conclusions

We showed that both microglial models were able to phagocytize *L. prolificans* but in very low rates, being microglial survival rates also low. Additionally, TNF-α, IL-6, and ROS production was also deficient in microglia. Finally, we observed that Dc-1 was the most important since its inhibition blocked up to 84% of the phagocytic events, while only 71% inhibition was induced when MR was blocked. In summary, this study delves into *L. prolificans* pathobiology, and shed light on its neurotropism. This process might be, at least in part, a consequence of microglial deficiencies, contributing to the fatal outcomes of these mycoses.

Funding: GIU15/36 from the Basque Government. AP (postdoctoral), IB and AA (predoctoral) are recipients of fellowships from the UPV/EHU or the Basque Government, respectively.

Pathogens / Pathogenicity - Part III

INDUCED REARRANGEMENT OF PASA5 PLASMID IN AEROMONAS SALMONICIDA

R. Farto[1], L. Rivera[1], N. Serrano[1], T. Pérez Nieto[1]
[1]Universidad de Vigo, Biología Funcional y Ciencias de la Salud, Vigo, Spain

Backgrounds

Quorum system (QS) appears to be involved in regulating expression of Type Three Secretion System (T3SS). However, it has not been confirmed its direct association with the regulation of specific genes of this system associated with virulence such as *ascC* or *ascV*.

Objectives

The main purpose of this study was to give a broader understanding on how QS system AsaI/R, in *A. salmonicida* subspecies *salmonicida*, influences the expression of T3SS.

Methods

The effect of *asaR* and *asaI* genes on expression of T3SS genes were studied by qPCR in the strain RIM 33.1, its mutants and complemented strains for genes of QS system AsaI/R, and control strains.

Conclusions

The *asaR* gene activated the expression of *ascV*, this regulation might also occurs for *ascC.* On the other hand, *asaI*, could be also causing activation of them. However the regulatory role was not confirmed, since absence of expression was detected in complemented or control strains. Negative amplification for *ascC* and *ascV* and other genes of T3SS locus (*ati2, exsD, aopN*) was detected by PCR; by contrast it was positive for genes located upstream and downstream of T3SS locus (*traD*, *aopO*), showing the loss of T3SS locus, but not the pAsa5 plasmid.

Recent studies have shown that insertion sequences, which are abundant in *A. salmonicida* pAsa5 plasmid, are involved in rearrangement events that lead to the loss of *ascC* and *ascV* genes or other changes also in the chromosome. Since, we are introducing a new plasmid in the cell, it induced interactions with pAsa5 plasmid being affected expression of genes.

DE NOVO ANALYSIS OF THE HAUSTORIAL TRANSCRIPTOME OF THE CUCURBIT POWDERY MILDEW FUNGUS PODOSPHAERA XANTHII REVEALS NEW CANDIDATE SECRETED EFFECTOR PROTEINS

A. Polonio[1], P. Seoane[2], A. de Vicente[1], A. Pérez-García[1]
[1]Universidad de Málaga, Microbiología, Málaga, Spain
[2]Universidad de Málaga, Plataforma Andaluza de Bioinformática, Málaga, Spain

Backgrounds

Cucurbit crops are affected, among other pathogens, by the obligate biotrophic fungus *Podosphaera xanthii*, the main causal agent of powdery mildew in cucurbits. This fungus develops a specialized structure of parasitism termed haustorium. Haustoria are developed into epidermal cells and are responsible for nutrients uptake and effectors delivery.

Objectives

The aim of this study was to obtain the haustorial transcriptome of *P. xanthii* to complete the panel of effector candidates of this fungal pathogen.

Methods

To obtain the haustorial transcriptome, we have developed an effective method for isolation of haustoria without contaminants by flow cytometry. The cDNA library was built using a combination of dT primers and random primers followed by a depletion of ribosomal sequences. Sequencing was carried out by Illumina NextSeq550.

Conclusions

After bioinformatic analysis, we were able to identify 25 new effector candidates secreted by the classic pathway (with signal peptide) and 269 new candidates secreted by the non-classic pathway (without signal peptide). Most proteins had no functional annotation. By protein modelling and ligand predictions, we are now being able to assign putative functions to some of these candidates to select those with potential roles in pathogenesis for subsequent functional *in vivo* analysis by HIGS (host-induced gene silencing). By these approaches, we are starting to shed some light into the molecular mechanisms of pathogenesis in this very important pathogen of cucurbits.

This work was supported by a grant from the Ministerio de Economía y Competitividad (AGL2013-41938-R), co-financed with FEDER funds (EU).

CARBAPENEMASE GENES AND CLONAL RELATEDNESS OF CARBAPENEM RESISTANT KLEBSIELLA PNEUMONIAE CLINICAL ISOLATES FROM UNIVERSITY HOSPITAL IN NORTHERN THAILAND

K. Phannachet[1], *N. Khamprom*[1], *M. Deeudom*[1]
[1]*Chiang Mai University, Microbiology, Muang, Thailand*

Backgrounds

During April 2014 to December 2015, clinical isolates of *Klebsiella pneumoniae* were collected from patients in university hospital in Northern Thailand. The results of imipenem, meropenem and ertapenem disc diffusion tests and minimal inhibitory concentration of meropenem indicated that 23 isolates were carbapenem resistant *K. pneumoniae.*

Objectives

The aim of this study is to identify carbapenemase genes, determine carbapenemase expression and investigate clonality of carbapenemase gene-harboring *K. pneumoniae* clinical isolates from university hospital in Northern Thailand.

Methods

The identification of carbapenemase genes, bla_{NDM}, bla_{IMP}, bla_{VIM}, bla_{KPC} and $bla_{OXA48\text{-}like}$, in 23 isolates of *K. pneumoniae* was done by multiplex PCR. The expression of carbapenemase was determined by using modified carbaNP method. The clonal relatedness of carbapenemase gene-harboring isolates was performed by repetitive extragenic palindromic-PCR (rep-PCR) using $(GTG)_5$ primer and interpreted based on >80% similarity index as a cut off.

Conclusions

Among 23 isolates of carbapenem resistant *K. pneumoniae*, carbapenemase genes were identified in 19 isolates in which bla_{NDM} and $bla_{OXA48\text{-}like}$ were found in 6 and 9 isolates, respectively. Furthermore, 2 isolates of *K. pneumoniae* co-harboring bla_{NDM} and $bla_{OXA48\text{-}like}$ genes and 2 isolates co-harboring bla_{IMP} and $bla_{OXA48\text{-}like}$ genes identified in this study has not been reported in Thailand. Carbapenemase production determined by modified carbaNP revealed that 14 isolates expressed carbapenemase whereas 5 isolates were negative for this test. Clonality study showed that *K. pneumoniae* carried carbapenemase genes were classified in 14 distinct clusters.

Pathogens / Pathogenicity - Part III

EVALUATION OF THE ANTIMICROBIAL POTENTIAL OF THE ETHANOLIC EXTRACT OF PIPER UMBELLATUM

V. Greatti[1], R. Sorrechia[1], R. Pietro[1]
[1]School of Pharmaceutical Sciences- São Paulo State University´UNESP, Drugs and Medicines, Araraquara, Brazil

Backgrounds

Piper umbellatum is popularly known as Pariparoba and has a secondary metabolite with expressive antimicrobial capacity, 4-Nerolidylcatechol. Among microorganisms that cause infections, there are *Candida krusei*, *Enterococcus faecalis* and *Escherichia coli* that have several virulence factors, causing difficulties of treatment. On the other hand, marine microorganisms are of great interest, since they are a source of new compounds, however, they are still unknown as to their antimicrobial activities.

Objectives

The aim of this study was to search for new potential antimicrobial agents derived from *P umbelatum* against pathogenic microorganisms and marine organisms.

Methods

Candida krusei (ATCC 6258), *Escherichia coli* (ATCC 25922), *Bacilus antrophaeus* (ATCC 9372), *Enterococcus faecalis* (ATCC 29212) and two marine fungi (F12, F22) were evaluated against the ethanolic extract 70% of the aerial parts of *P umbelatum*. Minimum inhibitory concentrations (MIC) were determined by the microdilution technique. The controls were amphotericin B and fluconazole (initial concentrations of 16 and 640 µg/mL) respectively for fungi and yeast; and ampicillin (initial concentration of 12.5 µg/mL) for bacteria. The extract was used at the initial concentration of 1250 µg/mL. The results showed that the ethanolic extract had a higher activity against *B. antrophaeus* at MIC of 156.25 µg/mL followed by *C. krusei* at 312.5 µg/mL and *E. faecalis* at 625 µg/mL while the others microorganisms presented MICs of 1250 µg/mL. The marine fungi evaluated in this study showed resistance to fluconazole.

Conclusions

The extract of *P. umbellatum* shows great potential as source of new molecules with antimicrobial activity.

EVALUATION OF ALTERNATIVE IAA BIOSYNTHETIC PATHWAYS IN THE BACTERIA FROM THE PSEUDOMONAS SYRINGAE COMPLEX

A. Pintado[1], *I. Pérez-Martínez*[1], *M. Cerezo*[2], *V. Flors*[2], *C. Ramos*[1]
[1]*Universidad de Málaga, Biología Celular- Genética y Fisiología Animal, Málaga, Spain*
[2]*Universitat Jaume I, Departament de Ciències Agràries i del Medi Natural, Castelló de la Plana, Spain*

Backgrounds

Indole-3-acetic acid (IAA) is a phytohormone belonging to the auxin group which production is widely distributed among plant-associated bacteria. In phytopathogenic bacteria, several IAA biosynthetic pathways have been described. The best characterized is the indole-3-acetamide (IAM) pathway, where tryptophan is initially converted into IAM by a monooxygenase (*iaaM* gene), and later transformed to IAA in a reaction catalysed by a hydrolase (*iaaH* gene). *Pseudomonas savastanoi* pv. savastanoi NCPPB 3335 (Psv), which synthesizes IAA through IAM, encodes two paralogs of these two genes organized in two operons (*iaaMH-1* and *iaaMH-2*). Previously, we have demonstrated that a Psv mutant in the *iaaMH-1* operon produces an amount of IAA significantly lower than that synthesized by the wild type strain. This strain, shows a reduced virulence in olive plants. In contrast, a mutant in the *iaaMH-2* operon (which encodes a *iaaM-2* pseudogene), produces IAA levels similar to those of the wild type strain and is not affected in virulence. Unexpectedly, the *iaaMH-1* mutant and the double mutant *iaaMH-1/iaaMH-2* synthesize a residual amount of IAA, suggesting the existence of an alternative route for the production of this compound in Psv.

Objectives

Identification of the alternative IAA biosynthetic pathway active in the Psv mutant devoid of the IAM pathway.

Determination of the IAA biosynthetic pathway encoded by other strains of the *P. syringae* complex with different host spectrum.

Methods

Candidate genes search, directed mutagenesis and functional analysis.

Conclusions

Besides the IAM pathway, bacteria from the *P. syringae* complex encode other pathways for the biosynthesis of IAA.

FEMS7-2160
Pathogens / Pathogenicity - Part III

PROTEOMICS AND METABOLOMICS TOWARDS A BETTER UNDERSTANDING OF VIRULENCE OF STREPTOMYCES SCABIES, THE PLANT PATHOGEN

S. Planckaert[1]
[1]*Ghent University, WE-10, Gent, Belgium*

Backgrounds

Streptomyces species are known for their ability to produce a variety of medically and agriculturally important secondary metabolites. Unfortunately, several species are plant pathogens. *Streptomyces scabies* is recognized as the main causal agent of common scab. This plant disease affects root and tuber crops, especially potatoes. The symptoms are variable and can range from corky surface lesions to deep pits. Scab lesions are aesthetic unappealing, thereby reducing the marketability of both fresh-market and processed potatoes.

The actual causative of the disease is the secondary metabolite thaxtomin A, an inhibitor of plant cellulose biosynthesis. The genes responsible for the thaxtomin A biosynthesis are located on a pathogenicity island. Expression of these genes is mainly controlled by the TxtR regulator which is responsive to short cello-oligosaccharides, but recently other regulators are discovered (Bignell et al 2014). Also CebR, a cellobiose sensor, seems to be important in the pathogenicity of *Streptomyces scabies.* The details of this complex regulation are not fully understood.

Objectives

The combination of proteomics (LC-MS^E and MRM) and metabolomics should provide a solid basis for the further elucidation of the complex virulence mechanism of *Streptomyce*s scabies. The determination of proteins involved in virulence and their corresponding known or unknown metabolites could lead to a better understanding of *Streptomyce*s scabies' pathogenicity.

Methods

Label-free proteomics (LC-MS^E)
Targeted proteomics (LC-MRM)
Targeted metabolomics (LC-MRM)

Conclusions

The combination of proteomics (both discovery as targeted) and metabolomics reveals new insights in the regulation mechanism of the secondary metabolites involved in the virulence of Streptomyces scabies.

Pathogens / Pathogenicity - Part III

INVESTIGATING FLAVESCENCE DOREE PHYTOPLASMA EMERGENCE AND THE PATHS OF SPREAD BY MLST IN CROATIA

J. Plavec[1], Ž. Budinšćak[1], I. Križanac[1], D. Škorić[2], M. Šeruga Musić[2]
[1]Institute for Plant Protection, Department for Diagnostics and Analytics, Zagreb, Croatia
[2]University of Zagreb- Faculty of Science, Department of Biology, Zagreb, Croatia

Backgrounds

Phytoplasmas are plant-pathogenic bacteria with a complex two-kingdom-host life cycle involving plants and insect vectors. Flavescence dorée (FD) phytoplasma is a quarantine pathogen associated with severe and epidemic grapevine yellows disease that represents great threat for grapevine cultivation in Europe.

Objectives

From the first report in Croatia (2009) for restricted continental area, FD phytoplasma has been detected in other winegrowing regions of the country with clear epidemic trend of the disease spread. The main objective of this study was to trace FD phytoplasma emergence, to study the prevalence and distribution of FD strains and determine their epidemiological significance by multilocus sequence typing (MLST).

Methods

In the 6-year period over 600 samples of grapevine, other wild/reservoir plants, *Scaphoideus titanus* and other potential vectors from different regions of Croatia were collected countrywide and analysed. Triplex real-time PCR was performed for detection together with PCR/RFLP of 16S rDNA. Detected FD phytoplasma isolates were characterised by MLST of *secY*, *map* and *uvrB-degV* genes.

Conclusions

FD-related phytoplasmas were found for the first time in alder, invasive tree species *Ailanthus altissima* and leafhopper *Phlogotettix cyclops*. Phylogenetic analyses of FD phytoplasma isolates revealed the existence of 3 mapFD strain clusters: mapFD1, mapFD2 and mapFD3, with the mapFD2 being prevalent. In addition, 7 *uvr*B-*deg*V and at least 5 *sec*Y genotypes have been detected. Finding of all 3 mapFD clusters and different distribution of genotypes based on MLST suggests separate routes of the disease introduction and propagation origins in Croatia. Tentative role of *P.cyclops* in transmission of FD phytoplasma is also indicated.

COMPARISON OF TIGECYCLINE SUSCEPTIBILITY TESTING METHODS FOR MULTIDRUG-RESISTANT ACINETOBACTER BAUMANNII

S. Popovic[1], N. Opavski[1], I. Gajic[1], V. Mijac[1], D. Kekic[1], S. Jovanovic[2], A. Smitran[3], M. Lopicic[4], L. Ranin[1]
[1]Institute of Microbiology and Immunology Medical Faculty- University of Belgrade, Department of Microbiology and Immunology, Belgrade, Serbia
[2]Clinical center of Serbia, Department of Microbiology-, Belgrade, Serbia
[3]Faculty of medicine- University of Banja Luka, Department of Microbiology and Immunology, Banja Luka, Bosnia - Herzegovina
[4]Insitute for public health, Department for microbiology, Podgorica, Montenegro

Backgrounds

Multidrug-resistant (MDR) *Acinetobacter baumannii* is increasing worldwide, raising the necessity of finding effective therapies.

Objectives

The aim of this study was to compare broth microdilution (BMD) method and E test for tygecycline susceptibility testing of MDR *A. baumannii*.

Methods

A total of 133 MDR isolates of *A. baumannii* collected from hospital's intensive care units from Serbia, Montenegro and Bosnia and Herzegovina in 2016 were studied. Bacterial identification was done by Vitek-2 (bioMérieux®), while the minimal inhibitory concentrations (MICs) of tygecycline were determined by BMD and E test (Liofilchem®). Interpretation to susceptible, intermediate or resistant category was performed according to Enterobacteriaceae breakpoints (no tigecycline breakpoints available for A. baumannii) from both EUCAST (≤1, 2, ≥4) and FDA (≤2, 4, ≥8).

Conclusions

The MIC_{50}/MIC_{90} for BMD and E test were 4/8mg/L and 0.5/4, respectively. MIC range for BMD and E test were 0.25–32mg/L and 0.25-12mg/L. Essential agreement (EA, MIC difference ≤1 double dilution step) for BMD and E test amounted to 88%. With EUCAST breakpoints, categorical agreement (CA) for MBD and E test was achieved in 38% of isolates. Major discordance (MD, false susceptibility/false resistance) and minor discordance (mD, false categorization involving intermediate results) were thereby observed in 10%/57% of isolates. With FDA breakpoints, CA for BMD and E test was achieved in 44%, while MD and mD were observed in 16% and 47% of isolates.Our study highlights the differences between BMD and E test, which sometimes may lead to the restriction of the available treatment options or inappropriate therapy.

COMPARATIVE PREVALENCE OF STAPHYLOCOCCAL ENTEROTOXIN GENE IN METHICILLIN-RESISTANT STAPHYLOCOCCUS PSEUDINTERMEDIUS ISOLATED FROM DOG, HUMAN, AND ENVIRONMENT IN A VETERINARY HOSPITAL

N. Prapasarakul[1], *N. Phumthanakorn*[1]
[1]*Chulalongkorn university, Veterinary Microbiology, Bangkok, Thailand*

Backgrounds

Methicillin-resistant *S. pseudintermedius* (MRSP) isolated from dogs can occasionally colonizes on nasal carriage in human and persists in environment. The source of bacterial isolation may be a factor related to bacterial-host adaptation that leads to genetic variation encoding viability and function.

Objectives

To detect and compare staphylococcal enterotoxin (*se*) family genes in MRSP divided by lineage sequence types that isolated from dogs, human, and the environment in veterinary hospital.

Methods

A total of 93 MRSP were isolated from dogs (n = 43), human (n = 18) and in a veterinary hospital (n = 32) in Thailand during 2009-2014. The detection of 17 *se* and toxic shock syndrome toxin (*tst*) genes was carried out by the single and multiplex PCR. Multi-locus sequence typing (MLST) and pulsed-field gel electrophoresis (PFGE) were used as DNA fingerprinting platform. The representatives of MRSP belonging to ST45 (n= 18), ST181 (n=8) and ST112 (n=8) were further selected for the comparison of *se* gene profiles within these clone types.

Conclusions

MRSP from human apparently possessed the most variation genes (12/14; *sea, sec, seg, sei, sek, sel, sem, sen, seo, sep, seq* and *tst-1*) followed by dog MRSP (5/14; *sec, sel, sem, seq* and *tst-1*) and the veterinary hospital (3/14; *sec, seq* and *tst-1*), respectively. The clone types seemed not to relate to number and type of *se* family gene profile. In contrast, the source of isolation might have a linkage to virulent genes. This finding highlights a higher pathogenicity potential of human MRSP than in the other sources.

MULTILOCUS SEQUENCE TYPING OF MYCOPLASMA AGALACTIAE TO STUDY ITS GENETIC VARIABILITY IN A CONTAGIOUS AGALACTIA ENDEMIC AREA

M. Prats-van der Ham[1], J. Tatay-Dualde[1], Á. Gómez-Martín[1], A. Paterna[1], J.C. Corrales[1], A. Sánchez[1], A. Contreras[1], C. de la Fe[1]
[1]University of Murcia, Animal Health, Murcia, Spain

Backgrounds

M. agalactiae (Ma) is the main causative agent of contagious agalactia (CA), a serious disease of small ruminants. In endemic areas, the lack of effective strategies against this disease highlights the need of using molecular typing tools, such as multilocus sequence typing (MLST), to obtain epidemiological information which allows tracing the source of disease outbreaks and understanding the genetic distribution and evolution of pathogens, favouring disease surveillance and control.

Objectives

The aim of the present work was to assess the genetic variability of Ma isolates from a CA-endemic area considering all the epidemiological determinants associated to this disease, such as small ruminant host (sheep and goats) and separate geographical areas.

Methods

Sixty-three Ma isolates from 39 different ovine and caprine herds, retrieved between 2009 and 2016, were subjected to a previously described MLST scheme, which is based on the study of housekeeping genes *dnaA*, *gltX*, *gyrB*, *metS* and *tufA*. Distinct allelic numbers and subsequent sequence types (STs) were assigned according to the pubMLST database of Ma (http://pubmlst.org/magalactiae/), and STs were grouped in clonal complexes.

Conclusions

Although Ma is genetically more stable than other CA-causing mycoplasmas, genetic diversity appeared, mainly between caprine isolates. This variability could be explained by the coexistence of different CA-causing mycoplasma species infecting the same host, especially considering the possibility of horizontal gene transfer. The existence of different genetic profiles of Ma within a CA-endemic area affects the design of effective preventive and control strategies against this disease.

MOLECULAR CHARACTERIZATION OF MYCOPLASMA AGALACTIAE FIELD ISOLATES WITH ACQUIRED RESISTANCE TO TYLOSIN

M. Prats-van der Ham[1], J. Tatay-Dualde[1], Á. Gómez-Martín[1], A. Paterna[1], J.C. Corrales[1], A. Sánchez[1], A. Contreras[1], C. de la Fe[1]
[1]University of Murcia, Animal Health, Murcia, Spain

Backgrounds

Mycoplasma agalactiae (Ma) is the main causative agent of contagious agalactia (CA), a serious disease of small ruminants. Antimicrobials are the main strategy applied when clinical outbreaks of this disease occur. The development of effective therapeutic strategies depends upon an accurate understanding of the antibiotic resistance mechanisms. However, the specific molecular mechanisms of acquired resistance of Ma to 16-membered macrolides have not yet been elucidated.

Objectives

The aim of the present work was to determine the minimum inhibitory concentration (MIC) values of different field isolates of Ma to tylosin, and to investigate the association between the obtained MICs and mutations in the *23S rRNA* genes and ribosomal proteins L4 and L22 of the studied isolates.

Methods

Fifty Ma field isolates, retrieved between 2009 and 2016, were analysed. Their antimicrobial susceptibility to tylosin (Tyl) was tested by determining their MIC, following previously recommended guidelines for mycoplasmas. Subsequently, partial genome sequences of domains II and V of both *23S rRNA* genes and ribosomal encoding sequences *rplD* (L4) and *rplV* (L22) were studied.

Conclusions

Nearly 40% of the studied field isolates of Ma were resistant to Tyl, showing a remarkable decrease in their susceptibility in comparison to previous works performed on this mycoplasma species. This increase in MIC values was associated to the presence of mutations in ribosomal protein L22 (Ser89Leu and Gln90Lys/His) and in domain V of the *23S rRNA* genes (A2058G) (*Escherichia coli* numbering). This is the first report of the molecular mechanisms involved in macrolide resistance of Ma.

Pathogens / Pathogenicity - Part III

ISOLATION OF GASTROINTESTINAL YEAST STRAINS AS POTENTIAL PROBIOTICS

D. Prieto[1], *E. Roman*[1], *R. Alonso-Monge*[1], *J. Pla*[1]
[1]*Dept. Microbiología II- School of Pharmacy- Universidad Complutense de Madrid, Microbiología II, Madrid, Spain*

Backgrounds

Most *Candida albicans* systemic infections arise from endogenous origin. This microbe is present in the majority of the human population, colonizing the gut as a harmless commensal. Some bacteria and a few fungi species have been proposed as probiotic to reduce the candidiasis originated in the gastrointestinal tract; however, the mechanisms are still not clear and continuous administration is required. A stable colonization would be needed to improve the probiotic effect.

Objectives

Isolation and analysis of non-pathogenic yeast strains in a mouse model of gut colonization and test their potential as probiotics against *C. albicans*.

Methods

Mouse gut colonization by fungal species was established by the administration of an antibiotic combination in the drinking water. Fungal isolates were identified from the gut of C57B/6 mice and identified through 16S rDNA sequencing. The ability to colonize and to prevent *C. albicans* colonization was tested by CFUs analysis from stools. Nystatin sensitivity was also assessed *in vitro* and *in vivo*. This work was supported by the grant from the Ministry of Economy and Competitiveness PCIN-2014-052 (INFECT-ERA).

Conclusions

Cyberlindnera fabianii was identified as a frequently yeast isolate from mouse gut under antibiotic treatment. In this mouse model, this specie reaches a very high and stable fungal levels in the gut (around 10^8 cells/g) for a prolonged time (>6 weeks) and shows resistance to Nystatin treatment. Although *C. fabianii* does not prevent *C. albicans* colonization in this model, it can be considered a good candidate to design future strategies to its prevention.

ITRACONAZOLE IN COMBINATION WITH A MONOCLONAL ANTIBODY SPECIFIC TO NEUTROPHIL REDUCES THE EXPRESSION OF GENES RELATED TO PULMONARY FIBROSIS IN AN EXPERIMENTAL MODEL OF PARACOCCIDIOIDOMYCOSIS

J.D. Puerta Arias[1], P.A. Pino Tamayo[2], J.C. Arango[1], L.M. Salazar Pelaez[3], A. Gonzalez[4]
[1]Corporación para Investigaciones Biológicas, Medical and Experimental Micology Group, Medellín, Colombia
[2]Weill Cornell Medical College, Microbiology and Immunology, New York, USA
[3]Universidad CES, Basic Sciences Group, Medellín, Colombia
[4]Universidad de Antioquia, Basic and Applied Microbiology Research Group MICROBA, Medellín, Colombia

Backgrounds

Itraconazole (ITC) is the drug of choice for treating paracoccidioidomycosis (PCM); nonetheless, most patients with the chronic form of PCM develop fibrosis, even after treatment. Recently, we observed that the depletion of neutrophils with a specific monoclonal antibody (anti-Ly6G) during the chronic phase of PCM was associated with a decrease in the fungal burden and the inflammatory response as well as with a reduction of fibrosis.

Objectives

To evaluate the effect of ITC in combination with the anti-Ly6G mAb using an experimental model of pulmonary PCM.

Methods

BALB/c male mice were challenged with *Paracoccidioides brasiliensis* yeasts, treated with the mAb and/or ITC at 4th week p.i. and then sacrificed at 12th week p.i. to assess neutrophil subpopulations, fungal load, expression of pro-inflammatory and pro-fibrotic genes, collagen levels, and pulmonary histopathological changes.

Conclusions

We observed that combination of mAb/ITC favored the control of infection and diminished the inflammatory response. Of note, such combined therapeutic strategy reduced synergistically the expression of IL-1β, IL-6, IL-17, TNF-α, TGF-β1, TGF-β3, GATA-3, RORc, Ahr, MMP-1α, MMP-8, MMP-15, TIMP-1 and TIMP-2 genes in comparison with those mice treated with the mAb or ITC alone. Interestingly, ITC induced an increase of type-II neutrophils, even in those mice treated with the antibody. These results indicate that combination anti-Ly6G mAb/ITC synergistically reduced the infection and pulmonary fibrosis through down-regulation of pro-inflammatory- and pro-fibrotic genes. This work emphasizes the importance of exploring new potential combination therapies to treat fungal infections.

SPINASES – SECRETED SERINE PROTEASES FROM STAPHYLOCOCCUS PSEUDINTERMEDIUS

K. Pustelny[1], M. Wisniewska[2], P. Mak[3], J. Worwa[1], W. Rut[4], P. Golik[1], M. Drag[4], B. Wladyka[3], G. Dubin[1]
[1]Jagiellonian University, Department of Microbiology, Krakow, Poland
[2]Malopolska Centre of Biotechnology, Department of Structural Biology, Krakow, Poland
[3]Jagiellonian University, Department of Analytical Biochemistry, Krakow, Poland
[4]Wroclaw University of Technology, Faculty of Chemistry, Wroclaw, Poland

Backgrounds

Staphylococcus pseudintermedius, a member of *Staphylococcus* genus, is the most frequent bacterial pathogen isolated from canine clinical specimens. Staphylococci are known to produce a wide variety of exoproteins that promote host-pathogen interaction and eventually lead to infection. Since knowledge about *S.pseudintermedius* secretome is limited and almost all predictions concerning its role are mostly based on extrapolation to *S.aureus*, the pathogen calls for specific attention.

Objectives

This study presents a comprehensive analysis of recently identify *S.pseudintermedius* secreted proteases – Spinases, and aims at understanding of their role in pathogenesis.

Methods

The PCR analysis reveals the presence of eight ***spinases'*** genes (*spinaseA-H)* in all tested *S.pseudintermedius* isolates recovered from skin abscess lesions in dogs. The semi-quantitative RT-PCR demonstrates that Spinases are translated from individual gene transcripts controlled by independent promoters. Spinases' genes are mainly expressed during the transition into a stationary phase and a level of transcripts depends on culture condition. To conduct the biochemical and structural characteristic of SpinaseA, we produce and purify an active recombinant enzyme. The P4-P1 substrate specificity of the enzyme is next determined with a combinatorial library of synthetic peptide substrates. Crystallography and molecular modeling, were applied to explain the substrate specificity is explained at a molecular level.

Conclusions

Spinanes constitute a group of proteolytic enzyme with a potential role in staphylococcal infection. The proteases expression is tightly regulated in a response to environmental stimuli. The Spinase A reveals a restricted substrate specificity, similarly to staphylococcal V8 protease and epidermolytic toxins, well defined by arrangement of substrate binding pockets.

IDENTIFICATION OF THE SIDEROPHORE ACINETOBACTIN EXPORTER IN AEROMONAS SALMONICIDA SUBSP. SALMONICIDA

D. Rey Varela[1], M.C. Afonso Lages[1], M. Balado Dacosta[1], M.L. Lemos Ramos[1]
[1]Institute of Aquaculture, Microbiology and parasitology, Santiago de Compostela, Spain

Backgrounds

Aeromonas salmonicida subsp. *salmonicida* is the aetiological agent of furunculosis, a disease that affects a great variety of fish cultures worldwide. To obtain iron from its hosts, *A. salmocida* produces two siderophores: acinetobactin and amonabactin(s). The genes encoded the synthesis and transport of both siderophores have been previously described by our group. However the proteins involved in the secretion of these siderophores to the external medium are unknown.

Objectives

The main objective of this work was to identify and characterize the genes encoding the siderophores secretion function.

Methods

An *in silico* analysis of the genomes of different strains revealed the existence of 3 candidate genes to encode the corresponding efflux proteins: *asbH* and *asbJ*, which could encode the acinetobactin exporter, and *amoS* which could encode the amonabactins exporter. To test the function of these genes, we generated by allelic exchange single and combined mutants of all them, using a previously generated biosynthetic mutant for each siderophore. Using bioassays, under iron-restricted conditions, we tested the ability of each mutant to export the siderophores.

Conclusions

The results showed that only the mutants defective for *asbH* were unable to export acinetobactin to the medium, whereas the a*moS* mutant did not show any growth impairment in iron-deficiency conditions. In addition, the double mutant *asbH-amoS*, also kept the ability to secrete amonabactins to the medium. These results confirm our initial hypothesis that AsbH could be the acinetobactin exporter, but we still ignore the pathway followed by amonabactins to be secreted to the external medium.

GENOMIC CHARACTERIZATION OF ENTEROAGGREGATIVE ESCHERICHIA COLI (EAEC) CLINICAL ISOLATES FROM CHILDREN IN AHVAZ

H. Helalat[1], S.E. Rezatofighi[1], M. Roayaei Ardakani[1]
[1]Shahid Chamran University of Ahvaz, Biology, Ahvaz, Iran

Backgrounds

Enteroaggregative *Escherichia coli* (EAEC) is identified as the emerging cause of pediatric diarrhea in developed and developing countries.

Objectives

Our study investigated the genetic characteristics of EAEC strains isolated from children with diarrhea in Ahvaz, Iran.

Methods

EAEC strains were identified using *agg*R primers which are specific for the pathotype. Thirty three EAEC strains were detected and examined for virulence genes of *aggA, aaF, aap, and pcvD by PCR.*

Conclusions

The *pcv*D was found in all of strains. The *agg*A gene was present in 24.24% of isolates and 87.9% of strains had the *aap* gene. However, the *aaf* gene was found in the any of strains. Combination of the genetic markers was different among the EAEC strains. However, the most prevalent combination was *pcv*D/*agg*A/*aap* that found in 24.24% of strains. Our data suggest that *pcvD and aggR* may serve as a valuable marker for the detection of EAEC pathotype and genetic heterogeneity is common in EAEC strains.

MORPHOLOGICAL AND MOLECULAR IDENTIFICATION OF PUCCINIA PORRI ON LEEK IN SERBIA

D. Ristic[1], I. Vucurovic[1], M. Stevanovic[1], S. Stosic[1], K. Gasic[1], S. Zivkovic[1]
[1]Plant Protection and Environment, Plant Disease, Belgrade, Serbia

Backgrounds

Leek rust, caused by *Puccinia porri* (Sow.) Winter is an economically important disease of the leek crop in Serbia. The bright orange urediniospores appear on young leaves and the disease spreads under warm damp conditions, resulting a reduction in plant growth and crop quality.

Objectives

Consequently, the objectives of this study were to identify the rust fungi on leek based on morphological and molecular characteristics.

Methods

Leaves samples infected with a rust fungus were collected from commercial leek crops (*Allium porrum*) in the locality Medveđa (Rasina district) during 2016. Small lesions on leaves with uredinia were present. Based on morphological characteristics and molecular diagnostics the pathogen was identified as *Puccinia porri.* The light brown urediniospores were ellipsoidal to obovoid and measured 24-32 × 20-25 µm. Morphological identification was confirmed by amplification and sequencing of the internal transcribed spacer (ITS) region. Total DNAs were extracted directly from fungal tissue with a DNeasy Plant Mini Kit (Qiagen, Hilden, Germany) and PCR amplification was performed with primers ITS1F/RUST1. Sequence analysis of ITS region revealed that representative isolate 22-16 (GenBank Accession No. KY492366) shared 100% identity with sequences of *P. porri* deposited in the GenBank.

Conclusions

Further characterization and research on diversity of rust fungi on *Allium* species in Serbia are needed. Increase of rust inoculum could lead to a higher incidence of the disease on leek and other *Allium* species and high yield looses.

This research was supported by the projects TR31018 funded by the Ministry of Education, Science and Technological Development, Republic of Serbia.

Pathogens / Pathogenicity - Part III

IDENTIFICATION OF NEW INTESTINAL PATHOGENIC E. COLI ANTIGENS BY REVERSE VACCINOLOGY APPROACH

M. Rojas Lopez[1], *M. Pizza*[2], *M. Desvaux*[1], *R. Rosini*[2]
[1]*Institute Nationale pour la Recherche Agronomique, UR454 Microbiologie, Site de Theix, France*
[2]*GSK, Vaccines, Siena, Italy*

Backgrounds

The need for a vaccine development against Intestinal Pathogenic *Escherichia coli* (InPECs), lies in the increasing burden of the *E. coli*-diarrheal diseases; the emergence of hybrids and antibiotic resistance strains; and the heighten annual cost of the health care systems. Previous studies have shown the utility of the Reverse Vaccinology (RV) approach to identify new antigens as promising vaccine candidates in Extraintestinal Pathogenic *E. coli*.

Objectives

To identify novel antigens against InPECs

Methods

We applied the RV approach in two complete, annotated reference InPEC genomes: ETEC and EHEC. First, we selected CDSs mainly encoding extracellular and OMPs by predicting their cellular localization with the PSORT algorithm and further structures or protein features using the InterProScan server. To predict their expression in a transcriptional level, we went through RNA-seq reported experiments performed in different growth conditions and selected those expressed with >10 RPKM. To select antigens that have more than one target strain, we performed a gene distribution and variability analysis by BLAST among a panel of 47-*E. coli* complete genomes strains, using as cut-off criteria a query coverage of >90% and >80% of sequence identity. From this *in silico* analysis, we identified 31 potential antigens present in more than 5 pathogenic and fecal *E. coli* isolates, but not previously reported. The prospective antigens were cloned, expressed as recombinant proteins, and used to immunize mice to obtain specific sera. The specific sera were used in western blot analysis to detect the real expression of these proteins in total extracts preparations from standard laboratory conditions. The final selection panel includes 4 potential candidates

Conclusions

In conclusion, our study identified new potential vaccine candidates by their putative function, cellular exposure, expression, and genetic diversity in the different *E. coli* pathotypes, for the further development of a vaccine against InPECs strains infections, currently in immunological tests.

FEMS7-2207
Pathogens / Pathogenicity - Part III

PNEUMOCYSTIS CARINII INDUCES MUC5B HYPERSECRETION THROUGH STAT6/FOXA2 PATHWAY ACTIVATION IN IMMUNOCOMPETENT INDIVIDUALS.

D.A. Rojas[1], P. Iturra[1], A. Méndez[1], C. Ponce[1], R. Bustamante[1], S.L. Vargas[1]
[1]Facultad de Medicina- Universidad de Chile- ICBM, Programa Microbiología y Micología, Santiago, Chile

Backgrounds

Mucus hypersecretion is associated to respiratory diseases and is induced via several pathways such as STAT6/FoxA2 or EGFR. We have reported increased mucus associated to *Pneumocystis* infection in autopsied lungs of infants dying in the community. MUC5AC was tested as a marker of mucus because this protein is believed to be the most abundant mucin in airways. However, because *Pneumocystis* is likely the most frequent and consistent infection during early infancy, pathways and expression of other mucins such as MUC5B, essential in defense, need to be characterized.

Objectives

To study the role of MUC5B and STAT6/FoxA2 pathway during *Pneumocystis* primary infection in infants and immunocompetent *Pneumocystis*-infected rats.

Methods

Lungs from *Pneumocystis*-infected infants and rats were analyzed by qRT-PCR and western blot to evaluate mucins and STAT6/FoxA2 pathway members. STAT6/FoxA2 pathway was evaluated using Kaempferol on infected animals. Binding of FoxA2 to MUC5B promoter was evaluated by ChIP. Mucus hypersecretion was analyzed in fixed-airway sections.

Conclusions

MUC5B levels were elevated in *Pneumocystis*-infected compared to non-infected infants. The expression of MUC5AC and MUC5B was found increased in infected rats compared with non-infected animals. MUC5B mRNA and protein levels were higher than MUC5AC in infected animals suggesting MUC5B plays a role in defense against *Pneumocystis*. These increments were dependent on STAT6 pathway induction. Analysis of MUC5B promoter showed that FoxA2 occupancy decreased during infection in a STAT6 pathway-dependent manner. These results are showing that *Pneumocystis* primary infection induces mucus hypersecretion through STAT6/FoxA2 pathway suggesting a new mechanism and proposing a new pharmacological target for *Pneumocystis* infection.

OVERPRODUCTION OF CYTOSOLIC CATALASE COUNTERBALANCES THE FUNGICIDAL ACTION OF DIFFERENT ANTIFUNGALS IN CANDIDA ALBICANS

E. Román[1], A.D. Prieto[1], E. Varea[1], R. Alonso-Monge[1], O. Zaragoza[2], J. Pla[1]
[1]Universidad Complutense de Madrid, Microbiología II, Madrid, Spain
[2]Instituto de Salud Carlos III, Micología, Majadahonda- Madrid, Spain

Backgrounds

Amphotericin B is a polyene type antifungal that interacts with fungal membranes leading to their loss of functionality and eventual cell death. The mechanism of action of this antifungal has been also shown to involve the production of reactive oxygen species (ROS). Mitogen activated kinases (MAPK) are involved in the response to ROS in the fungal pathogen *Candida albicans* and mutants defective in the *hog1* MAPK are sensitive to oxidants

Objectives

Determine the role that overproduction of cytosolic catalase (encoded by *CAT1*) has on the resistance of this fungus to antifungals and other drugs, morphogenesis and virulence

Methods

Strains overexpressing the *CAT1* under the control of the under the control of the tetracycline regulated system TET-ON/TET-OFF were constructed in a wild type and *hog1* background

Conclusions

Cells overexpressing *CAT1* are more resistant to certain oxidants such as hydrogen peroxide but not others, such as menadione. In addition, they were found to be more resistant to amphotericin B or ciclopirox olamine but not fluconazole. Overexpression of catalase also protected cells against mammalian phagocytic cells in both backgrounds. Virulence studies showed that *CAT1* overproduction was sufficient to suppress the avirulent phenotype of *hog1* mutants. Finally, we observed that MAPKs activation pattern under hydrogen peroxide, amphotericin B and fluconazole was diminished in *CAT1* overproducing cells

Our results indicate the important role for ROS in antifungal resistance and show that the production of catalase counterbalances the effects of certain antifungals, phagocyte-mediated killing and virulence in a systemic mouse model of candidiasis

[6]Université Paris Diderot / Assistance-Publique des Hôpitaux de Paris / CEA Genoscope, INSERM IAME UMR 1137 / APHP / LABGeM, Paris, France

Backgrounds

Bloodstream infection (BSI) is one of the most common infectious diseases worldwide, leading to important health expenditure. *Escherichia coli* is the major causative agent but also the most abundant species among facultative anaerobic bacteria in the human gut. To explain this paradox, many traits seem to be associated with pathogenicity including host factors, portal of entry, genetic and metabolic diversity of the strains. Furthermore, the worldwide epidemiology of *E. coli* BSI shows a dramatic shift since 2000 with the emergence of highly virulent and resistant clones, both from hospital and community settings. A large multicenter prospective study, “Septicoli”, has been launched by the IAME laboratory (Inserm-UMR1137) across 7 hospitals in Paris. Through 500 adults with *E. coli* BSI, accurate clinical data are collected and bacterial strains are isolated and sequenced (Illumina 2x150bp).

Objectives

We present here the bioinformatics workflow that is used to analyze *E. coli* genomes in order to find genetic determinants that may be associated to BSI severity.

Methods

For each strain, an extensive genome analysis is conducted using the MicroScope platform for comparative genomics and also: Mash pairwise comparison and phylogroup assignation, virulence (VFDB, VirulenceFinder) and antimicrobial resistance (CARD) gene prediction. Furthermore, a pangenome-based approach will be conducted focusing on strain metabolic capacities that could paly a role in strain pathogenicity

Conclusions

This bioinformatics analysis should help the interpretation of clinical data with the objective to identify new microbiological risk-factors for severe or fatal *E. coli* BSI.

ANTIMICROBIAL ACTIVITY OF STREPTOCOCCUS MUTANS CULTURE FILTRATE AGAINST CANDIDA ALBICANS

L. Ruano de Oliveira Fugisaki[1], J. Diane dos Santos[1], M. Sa Alves[1], R. Previate Medina[2], A. Olavo Cardoso Jorge[1], D. Helena Siqueira Silva[2], J. Campos Junqueira[1]
[1]Universidade Estadual Paulista / UNESP, Departamento de Biociencias e Diagnostico Bucal, Sao Jose dos Campos, Brazil
[2]Universidade Estadual Paulista / UNESP, NuBBE – Nucleo de Biossintese- Bioensaios e Ecofisiologia de Produtos Naturais- Instituto de Quimic a, Araraquara, Brazil

Backgrounds

Streptococcus mutans, recognized as the main cause of dental caries in the world, can be found along with *Candida albicans* in the dental biofilm. Products of the secondary metabolism of the human microbiota are being increasingly investigated because of their direct impacts on the host and other microorganisms.

Objectives

Here, we evaluated the effects of the crude extract obtained from *S. mutans* culture filtrate on *in vitro* biofilm formation and morphogenesis of *C. albicans.*

Methods

Firstly, *S. mutans* was grown in brain-heart infusion broth for 24h at 37°C under 5% CO_2. After, the standardized suspension of *S. mutans* containing 10^7 cells/mL was inoculated in brain-heart infusion broth for 4 h at 37ºC under 5% CO_2, and then, the culture was centrifuged and the supernatant was filtered through a 0.22 µm membrane filter. Then, the crude extract was obtained by extraction with EtOAc (3 x 50% of culture filtrate volume each) and dried in rotatory evaporator. Next, the biofilms were formed on the bottom of a 96-well microtiter plate for 48 h and the number of colony-forming units (CFU) was determined. The *C. albicans* filamentation study was performed in 24-well plate and analyzed by light microscopy.

Conclusions

The results showed a statistically significant reduction in biofilm viable cells ($p < 0.05$) and significant inhibition of hyphae formation of *C. albicans* when in contact with 5 mg/mL of the crude extract. These findings suggest that *S. mutans* secretes subproducts capable to inhibit the biofilm formation and morphogenesis of *C. albicans*.

CONSTRUCTION OF AN EFFECTORLESS CITROBACTER RODENTIUM STRAIN TO STUDY THE IN VIVO COMBINATORIAL CONTRIBUTION OF TYPE III SECRETION SYSTEM EFFECTORS

D. Ruano-Gallego[1], *L.Á. Fernández*[2], *G. Frankel*[1]
[1]*Centre for Molecular Bacteriology & Infection CMBI, Life Sciences, London, United Kingdom*
[2]*Centro Nacional de Biotecnología - CSIC, Biotecnología microbiana, Madrid, Spain*

Backgrounds

The attaching and effacing (A/E) pathogens enteropathogenic *Escherichia coli* (EPEC) and enterohaemorrhagic *E. coli* (EHEC) are major global causes of intestinal infections. Through the Type III Secretion System they inject virulence factors (effectors) into enterocytes, altering the homeostasis of the host. Since EPEC is a human-restricted pathogen and EHEC colonises only large farm animals apart from humans, the mouse-restricted pathogen *Citrobacter rodentium* has been used as a surrogate model to study A/E pathogens *in vivo*. *C. rodentium* infection provides useful insights to the contribution of individual effectors by single gene mutations, but this approach does not consider redundancy and dependency of the effectors.

Objectives

The aim of this project is to deconstruct the function of the effectors *in vivo* using the *C. rodentium* model.

Methods

To address this, we have generated a set of *C. rodentium* strains, with accumulating sequential genomic deletions of the effector genes, using a scarless mutation system that leaves no antibiotic resistance.

Conclusions

Through this method, we have generated an effectorless *C. rodentium* strain (CR-0) that lacks all known effector genes and is unable to colonise mucosal surfaces, but retains the functionality of the T3SS, as demonstrated by reinserting effector genes into their original loci. Using this approach, we expect to generate CR-0 expressing the minimal number of effectors needed for the colonisation of the gastrointestinal tract.
This study will provide a new level of understanding of diseases caused by A/E pathogens and the fundamental biology of bacterial infections of mucosal surfaces, with direct relevance to host responses to infection and the alteration of the intestinal microbiota.

EVADING DECONTAMINATION STRATEGIES; GENETIC BASIS OF THE PERSISTENCE OF LISTERIA MONOCYTOGENES IN FOOD PROCESSING INDUSTRIES AND THE KNOCK-ON EFFECTS ON VIRULENCE

J.K. Rudkin[1], E.M. McCabe[2], C. Hill[1], C.G.M. Gahan[1]
[1]University College Cork, APC microbiome Institute. Microbiology Department., Cork, Ireland
[2]University College Cork, Microbiology Department, Cork, Ireland

Backgrounds

Listeria monocytogenes is an important foodborne pathogen which is present ubiquitously within the environment, representing a major source of food contamination. Methods to prevent contamination are often averted by *L. monocytogenes* due to high tolerance to many of the stresses which it is exposed to, persisting in the face of decontamination challenges. The genetic mechanisms underpinning this, and the evolutionary consequences of repeated stress exposure are not understood.

Objectives

This project aims to phenotypically characterise a large collection of strains isolated from food processing industries for tolerance to decontamination stresses. We shall assess the effects of repeated stress exposure on the evolution of strains to determine if high tolerance to stress conditions has any knock-on effects on virulence.

Methods

The effects of repeated stress exposure on survival, biofilm formation, and cellular invasion capacity shall be presented.

Conclusions

Both the stress response and the major virulence regulator (*prfA*) are co-regulated by the sigB operon, suggesting a link between stress tolerance and virulence in *L. monocytogenes*. We assessed the effect of environmental selection upon stress survival, and look at the linked effects on evolutionary adaptation and virulence of *L. monocytogenes* to answer the question; In trying to inhibit the growth of *L. monocytogenes* do we inadvertently drive pathogen evolution towards persistence, increased resistance and ultimately altered pathogenicity and virulence?

TRANSCRIPTION ACTIVATOR LIKE EFFECTORS ARE INVOLVED IN THE HOST ADAPTATION OF XANTHOMONAS STRAINS RESPONSIBLE FOR COMMON BACTERIAL BLIGHT OF BEAN

M. Ruh[1], S. Bonneau[2], J. Foucher[2], A. Préveaux[2], L. Gagnevin[3], B. Szurek[4], L. Noël[5], M.A. Jacques[2], N.W.G. Chen[1]
[1]Agrocampus Ouest, Institut de Recherche en Horticulture et Semences IRHS, Beaucouzé Cedex, France
[2]INRA, Institut de Recherche en Horticulture et Semences IRHS, Beaucouzé Cedex, France
[3]CIRAD, Interactions Plantes Micro-organismes Environnement IPME, Montpellier, France
[4]IRD, Interactions Plantes Micro-organismes Environnement IPME, Montpellier, France
[5]CNRS, Laboratoire des Interactions Plantes Micro-organismes LIPM, Toulouse, France

Backgrounds

Transcription Activator Like Effectors (TALE) are type III effectors able to induce the expression of susceptibility genes to promote infection. To achieve this, TALE are able to get into the nucleus of the host cells, then specifically bind to the promoter region of targeted plant genes, resulting in the overexpression of these genes. Common bacterial blight of bean is caused by *Xanthomonas axonopodis* pv. *phaseoli* and *Xanthomonas fuscans* subsp. *fuscans* (*Xap-Xff*). *Xap-Xff* strains are spread across four phylogenetically distant lineages. Despite this genetic distance, these four genetic lineages have the ability to infect common bean. This leads us to hypothesize that these strains acquired common genetic determinants of adaptation to common bean, either by convergent evolution or by horizontal transfer.

Objectives

Our phylogenetic analyses indicate that *tal* genes have been transferred horizontally between distant *Xap-Xff* genetic lineages, suggesting that TALE would have been involved in the functional convergence of common bacterial blight agents.

Methods

In order to confirm this hypothesis, we undertook the functional validation of TALE shared by different *Xap-Xff* lineages. For this, we constructed *tal* deletion mutants and performed comparative analyses of transcripts from plants inoculated with bacterial strains containing TALE or not. Also, we performed phenotyping experiments including dynamics of bacterial population sizes and monitoring of symptom development by chlorophyll fluorescence Imaging.

Conclusions

Altogether, our results highlight how TALE impact common bean transcriptome and *Xap-Xff* pathogenicity, and confirm that TALE are involved in the adaptation of *Xap-Xff* to common bean.

GENOMIC ANALYSIS OF PSEUDOMONAS AERUGINOSA INTRAPATIENT EVOLUTION IN NON-CF PATIENTS

P. Ruiz-Hueso[1], L. Sánchez-Busó[2], S. Harris[2], J. Parkhill[2], N. Tormo Palop[3], C. Gimeno Cardona[3], F. González-Candelas[1]
[1]FISABIO-Universidad de Valencia, Unidad Mixta Infección y Salud Pública, Valencia, Spain
[2]Wellcome Trust Sanger Institute, Pathogen Genomics, Cambridge CB10 1SA, United Kingdom
[3]Consorcio Hospital General Universitario Valencia, Servicio de Microbiología, Valencia, Spain

Backgrounds

Pseudomonas aeruginosa is a very dynamic bacterium, characterized by a highly variable genome. This trait, coupled with the complicated infections it causes, such as chronic lung infections in individuals with respiratory problems, and the high number of antibiotic resistance genes exchanged between species, make this bacterium a serious threat to public health. A better understanding of how these processes occur would help in the research of new treatments.

Objectives

To analyse genomic variations that could lead to adaptation in different body locations in non-cystic fibrosis patients.

Methods

We have analysed 92 samples taken at different time intervals and body locations from 15 patients. *P. aeruginosa* samples were isolated mainly from blood, urine, wounds and sputum. Pure cultures were sequenced with Illumina MiSeq 2x300bp. Genome assembly was performed with VelvetOptimiser, annotation of each genome with Prokka and preliminary analysis of the pangenome with Roary. Additionally, the reads were mapped to a reference strain with BWA. Putative recombinant regions were identified and removed with Gubbins and RAxML was used to reconstruct a phylogenetic tree.

Conclusions

Our results revealed a core of 1908 genes (present in >95% of the samples), from a total of 20818 detected genes. There is very large variability in the accessory genome as expected from the range of times and multiple sources sampled. Nevertheless, 80% of the samples belonged to ST244, a global *P. aeruginosa* clone which is associated with VIM-2 carbapenemase. Possible co-infection or re-infection with different clones was detected in 5 patients.

BACTERIAL-DERIVED CELL-PENETRATING PEPTIDES DELIVER GENTAMICIN TO KILL INTRACELLULAR PATHOGENS

C. Rüter[1], M. Gomarasca[1], T. F.C. Martins[1], L. Greune[1], P. Hardwidge[2], M.A. Schmidt[1]
[1]Center for Molecular Biology of Inflammation, Infectiology, Münster, Germany
[2]College of Veterinary Medicine, Kansas State University, Manhattan, USA

Backgrounds

Commonly used antimicrobials show poor cellular uptake and often have limited access to intracellular targets, resulting in low antimicrobial activity against intracellular pathogens. An efficient delivery system to transport these drugs to the intracellular site of action is needed. Cell-penetrating peptides (CPPs) mediate the internalization of biologically active molecules into the cytoplasm.

Objectives

Here we characterized two CPPs, α1H and α2H, derived from the *Y. enterocolitica* YopM effector protein. These CPPs, as well as Tat, were used to deliver the antibiotic gentamicin to target intracellular bacteria.

Methods

The YopM-derived CPPs penetrated different endothelial and epithelial cells to the same extent as Tat. CPPs were covalently conjugated to gentamicin and CPP-gentamicin conjugates were used to target infected cells to kill multiple intracellular Gram-negative pathogenic bacteria, such as *E. coli* K1 RS218, *Salmonella enterica* serovar Thyphimurium, and *Shigella flexneri*.

Conclusions

Taken together, CPPs show great potential as delivery vehicles for antimicrobial agents and could contribute to the generation of new therapeutic tools to treat infectious diseases caused by intracellular pathogens.

VIRULENCE STUDIES OF KLEBSIELLA PNEUMONIAE ISOLATED FROM NEONATAL NASOGASTRIC FEEDING TUBES

M. Saad[1], K. Dahmani[1], P. Ogrodzki[1], T. Osaili[2], J. Winter[1], S. Forsythe[1]
[1]Nottingham Trent University, School of Science and Technology, Nottingham, United Kingdom
[2]Jordan University of Science and Technology, Nutrition and Food Technology, Irbid, Jordan

Backgrounds

The rate of neonatal infections due to *Enterobacteriaceae* has increased in neonatal intensive care units, particularly in those born with low birth weights (< 2000g) and fed via nasogastric tubes.

Objectives

The aim of this study was to evaluate the potential virulence of *Klebsiella pneumoniae* isolated from neonatal nasogastric enteral feeding tubes (NEFT) from two Jordanian hospitals.

Methods

Seventy-six *K. pneumoniae* strains were isolated from NEFT, from May to Dec 2011. The isolates were genotyped using pulsed-field gel electrophoresis with *XbaI* and *SpeI* restriction digestion. Potential pathogenicity and biofilm-associated traits were determined using specific PCR probes, genome analysis, and *in vitro* tissue culture assays.
The *K. pneumoniae* strains were genotyped as sequence types (ST)111, 247 and 526. These isolates clustered into five pulsotypes (Kp 1-5) according to *XbaI,* which were confirmed using *SpeI* as the second restriction enzyme. *K. pneumoniae* Kp1 ST111 strains (n = 76) were obtained from 21 neonates, of 5 to 39 days old, from two hospitals. *K. pneumoniae* ST111 strains 1681 and 1725 exhibited various virulence traits associated with neonatal sepsis and extracellular matrix formation. The majority of isolates showed the ability to attach to and invade human bladder carcinoma cells(T24). Antibiogram analysis revealed that most strains were resistant to 3rdgeneration cephalosporins and produced ESBLs, whereas high susceptibility to ciprofloxacin was observed.

Conclusions

K. pneumoniae strains exhibited features that allow them to invade and survive within certain eukaryotic cells, and survive on feeding tubes. Therefore, NEFT are an important risk factor to consider with respect to neonatal infections.

THE TRANSCRIPTION FACTOR ARCA MODULATES SALMONELLA TYPHIMURIUM RESPONSE TO THE CONDITIONS FOUND INSIDE NEUTROPHILS

C. Pardo-Esté[1], C. Cabezas[1], C. Aguirre[1], A. Briones[1], V. Cuevas[1], C. Salinas[1], M.S. Baquedano[1], J. Castro-Severyn[1], A. Hidalgo[2], M.C. Opazo[3], C.A. Riedel[3], C.P. Saavedra[1]
[1]Universidad Andres Bello, Molecular Microbiology Laboratory - Faculty of Biological Sciences, santiago, Chile
[2]Universidad Andres Bello,
Laboratory of Molecular and Antimicrobial Pathogenesis - Faculty of Medicine, santiago, Chile
[3]Universidad Andres Bello,
Millennium Institute of Immunology and Immunotherapy - Faculty of Biological Sciences, santiago, Chile

Backgrounds

Our study model *Salmonella enterica* serovar Typhimurium (*S*. Typhimurium) is a Gram-negative and intracellular pathogen that is able to avoid numerous defense mechanisms from the host´s immune response, here we focus on the phagocytes from the innate immune response like neutrophils. Inside these phagocytic cells, it faces several different kinds of stress; among the most relevant we found that highly toxic Reactive Oxygen Species (ROS), which inside neutrophils is mainly hypochlorous acid due to the myeloperoxidase action. In this context we have found that the ArcAB two-component system is also involved in ROS resistance to both hydrogen peroxide and hypochlorous acid.

Objectives

We proposed to determine the role of ArcA on the bacteria capacity to overcome the conditions inside the neutrophils.

Methods

To achieve this goal we set out to measure the transcriptional levels of relevant genes such as *sipC*, *sifA*, *sptP*, *sseI, cadB, pagC* and *manY* that are known to the up regulated during infection and in the presence of HOCl, as well as damage indicators such as lipid peroxidation and protein carbonylation in *S.* Typhimurium 14028s and *S.* Typhimurium D*arcA* strains harvested from infected murine neutrophils.

Conclusions

The ArcA regulon includes relevant genes for the bacterial survival inside neutrophils.

MONOCLONAL ANTIBODIES DIRECTED TOWARD ACTINOMYCES NAESLUNDII POLYSACCHARIDE

A. Saeed[1], M. Pasciak[1], J. Szkudlarek[1], M. Drab[1], A. Gamian[1]
[1]Institute of Immunology and Experimental Therapy - Polish Academy of Sciences, Department of Immunology of Infectious Disease, Wroclaw, Poland

Backgrounds

Actinomycosis is a rare chronic disease caused by *Actinomyces* spp which are normal commensal flora of the oral cavity, gastrointestinal and urogenital tracts. In some cases this commensal flora becomes pathogenic when the mucosa barrier is breached.

Objectives

The goal of the study was to isolate and resolve the composition of polysaccharide antigens extracted from *Actinomyces naeslundii* to generate monoclonal antibodies reactive with them.

Methods

***Actinomyces naeslundii* were grown on liquid thioglycolate medium at 37 ºC for 120 hours in anaerobic atmosphere. Exopolysaccharide antigens were extracted by using trichloroacetic acid. The extracts were further purified by ion-exchange chromatography (DEAE Sephadex A25) and gel filtration (Toyopearal HW 55 S). The composition of pure exopolysaccharide was determined by gas-liquid chromatography–mass spectrometry of sugar alditol acetates. Monoclonal antibodies were produced by the hybridoma technique with whole cell mass immunization. The evaluation of specificity of monoclonal antibodies was carried out by ELISA method.**

Scanning electron microscopy showed rod-shaped bacteria, some of which had clubbed ends. Exopolysaccharide isolated from *A. naeslundii* consists mainly of glucose and traces of ribose and mannose. Two hybridomas named, mAbs 6 and mAbs 88, producing mAbs against exopolysaccharide antigen were selected. Both mAbs were of IgM class. The ELISA test allowed to detect cross reactivity of these monoclonal antibodies with different *Actinomyces* spp antigens, probably as a consequence of the common epitope present on the cell wall.

Conclusions

These preliminary results show *Actinomyces naeslundii* as rod-shaped bacteria with expolysaccharide antigen coat common among other Actinomycetes. We progress with the experimental work aimed to characterize the epitope detected by the monoclonal antibodies mAbs 6 and mAbs 88.

Pathogens / Pathogenicity - Part III

IMMUNE EVASION MEDIATED BY A PSEUDOMONAS AERUGINOSA TIR DOMAIN-CONTAINING EFFECTOR

P. Imbert[1], A. Louche[1], J.B. Luizet[1], S. Bigot[1], S. Salcedo[1]
[1]CNRS UMR5086, Molecular Microbiology and Structural Biochemistry, Lyon, France

Backgrounds

Bacterial pathogens have developed numerous strategies to subvert the innate immune system to establish an infection. Several bacterial pathogens take advantage of TIR domain-containing proteins for blocking Toll-like receptor (TLR) signalling but the mechanisms that enable these proteins to interfere with receptor proximal events are still poorly characterized.

Objectives

We focused on a previously uncharacterized TIR domain-containing protein of the multi-drug resistant pathogen *Pseudomonas aeruginosa* PA7, that we called PumA. We aimed at identifying its cellular targets and characterize its role during infection.

Methods

By combining microbial genetics with cell biology and biochemistry approaches we have found PumA inhibits NFκB translocation into the nucleus during infection of A549 cells, a property transferable to non-PumA strain PA14. PumA directly interacts with the TLR adaptors MyD88 and TIRAP. Consistently, high-resolution microscopy imaging shows ectopically-expressed PumA co-localizing with both adaptors. More interestingly, PumA was found to directly interact with the ubiquitin-associated protein 1 (UBAP1), an important modulator of cytokine receptor sorting. Endogenous co-immunoprecipitation assays confirmed that PumA is associated with the endosomal-sorting complex required for transport I (ESCRT-I) of which UBAP1 is a major constituent.

Conclusions

By targeting UBAP1 and TLR adaptors via its TIR domain, PumA enables *P. aeruginosa* PA7 modulation of both cytokine and TLR signalling pathways, highlighting a novel strategy for bacterial innate immune evasion.

FEMS7-2172
Pathogens / Pathogenicity - Part III

WADD, A NEW GLYCOSYLTRANSFERASE ACTING ON BRUCELLA LIPOPOLYSACCHARIDE CORE SYNTHESIS, ITS INTERACTION WITH INNATE IMMUNE SYSTEM AND VIRULENCE

M. Salvador[1], *I. Moriyón*[1], *M. Iriarte*[1], *R. Conde-Álvarez*[1]
[1]*Universidad de Navarra, Microbiology and Parasitology, Pamplona, Spain*

Backgrounds

Brucellosis is a zoonotic disease caused by *Brucella*. The lipopolysaccharide (LPS) of *Brucella* plays a major role in virulence as impairs normal recognition by the innate immune system, and delays the immune response. The LPS core is involved in the resistance to complement and polycationic peptides. Mutants in glycosyltransferases involved in its synthesis are attenuated and good vaccine candidates against brucellosis. The chemical structure of the *Brucella* LPS core suggests that, in addition to the already identified WadB and WadC, other glycosyltransferases should also be implicated in its biosynthesis.

Objectives

Identification of new genes encoding glycosyltransferases involved in synthesis of *Brucella* LPS core and analysis of their role in virulence.

Methods

We constructed mutants in 7 not yet identified ORFs putatively encoding core glycosyltransferases in *B. abortus*. We analysed their LPS structure, sensitivity to different components of innate immune system and virulence.

Conclusions

All mutants kept the O-chain in their LPS. Interestingly, mutant in ORF BAB1_0953 (named wadD) lost reactivity against the antibodies that recognize the core section. This suggest that WadD is a new glycosyltransferase adding one or more sugars to the core ramification of *Brucella* LPS that is not linked to the O-chain. WadD mutants were more sensitive than the parental strain to components of the innate immune system. *In vivo* studies suggest that WadD plays a role in chronic stages of infection. This opens new perspectives for the design of new *Brucella* vaccines since it is known that mutants in the core branch protect against brucellosis.

Instituto de Investigação e Inovação em Saúde- Centre of Biological Engineering, Porto, Portugal
[4]University of Porto, Faculdade de Medicina Dentária- I3S-
Instituto de Investigação e Inovação em Saúde- INEB-Instituto de Engenharia Biomédica, Porto, Portugal

Backgrounds

Factors influencing the occurrence of peritoneal dialysis (PD) related infections, namely peritonitis and catheter exit-site infections, are still far from being fully understood. Presently there is no data regarding the existence of a microbiome in the peritoneum.

Objectives

To understand if the peritoneum of end-stage renal disease (ESRD) patients harbours a unique microbiome and determine the influence of PD catheter insertion and PD technique in the peritoneal microbiome.

Methods

Peritoneal tissue from ESRD patients with intact peritoneal cavity (ESRD-nonPD, n=10) and ESRD in PD program with PD catheter (ESRD-PD, n=10) were collected under sterile conditions. Metagenomic approach included PCR amplification of V3-V4 region of 16S ribosomal gene using MiSeq Illumina® technology.

Conclusions

The peritoneum tissue of ESRD patients presents a unique microbiome dominated by the phyla Proteobacteria, Firmicutes and Actinobacteria. The catheter insertion for PD therapy may induce slight changes in the microbiome composition revealed by a non-statistically significant decrease in species richness after PD catheter insertion (α-diversity, $p = 0.056$) as well as a decrease in the prevalence of Lactobacillaceae, Peptococcaceae and Carnobacteriaceae families and an increase in the number of reads in Pseudomonadaceae, Bradyrhizobiaceae and Xanthomonedaceae families in the peritoneum tissue. Also, LEfSe analysis showed enrichment of *Halomonas* and *Mesorhizobium* and decrease in *Lactobacillus*, *Peptococcus* and *Facklamia* in ESRD with catheter insertion.

Pathogens / Pathogenicity - Part III

EVOLUTION OF POXA-48-MEDIATED CARBAPENEM RESISTANCE IN A HOSPITAL SETTING

J. de la Fuente[1], *J. Rodríguez-Beltrán*[1], *R. León-Sampedro*[1], *M. Hernández*[1], *R. Cantón*[1], *Á. San Millán*[1]
[1]*Ramon y Cajal Institute for Health Research, Microbiology, Madrid, Spain*

Backgrounds

Plasmids mediate the horizontal transmission of genetic information between bacteria by conjugation, playing a pivotal role in the evolution of antibiotic resistance in pathogenic bacteria. Some of these plasmid-bacterium associations become particularly successful, creating superbugs that spread uncontrollably in clinical settings. The rise of these clones is mainly constricted because plasmids entail a fitness cost when they arrive in a new bacterial host. This cost can be subsequently alleviated through compensatory adaptation during plasmid-bacterium coevolution. Despite the importance of this cost-compensation dynamic in the evolution of plasmid-mediated antibiotic resistance, it remains completely unexplored in clinical contexts.

Objectives

In this work we analyse the spread and evolution of enterobacteria clones carrying the carbapenemase-coding plasmid pOXA-48 in the hospital Ramon y Cajal in Madrid.

Methods

We used molecular epidemiology and genome sequencing to characterized the inter-patient spread of enterobacteria clones carrying pOXA-48 over a two-year period in four different wards in the hospital. Moreover, we tracked the events of conjugation of pOXA-48 in the gut of hospitalized patients and analysed the fitness effects produced by the plasmid and the subsequent intra-patient evolution of plasmid carrying clones.

Conclusions

Klebsiella pneumoniae drives the dissemination of pOXA-48 among patients in the hospital. Once *K. pneumoniae*/pOXA-48 colonises a new patient pOXA-48 spreads horizontally towards other resident enterobacteria in the gut microbiome. The fitness effects of the plasmid in the new bacterial hosts determine the fate of these associations in the bacterial community.

Pathogens / Pathogenicity - Part III

QUANTITATIVE ANALYSIS OF BISTABILITY IN SALMONELLA INVASION: A RE-INTERPRETATION

M.A. Sánchez-Romero[1], *J. Casadesús*[2]
[1]*University of Seville, Genetics, Sevilla, Spain*
[2]*University of Seville, Genetics, Seville, Spain*

Backgrounds

Salmonella enterica pathogenicity island 1 (SPI-1) is a gene cluster that encodes a type 3 secretion apparatus and effectors involved in invasion of human epithelial cells. A well known trait of SPI-1 is bistable expression, which generates SPI-1 ON and SPI-1 OFF subpopulations. The biological significance of SPI-1 bistability has been adressed by previous, insightful studies. Bistability has been viewed, for instance, as a division of labour involving self-destructive altruism by the SPI-1 OFF subpopulation (Ackermann et al. *Nature* 454, 987-90, 2008). Another study, however, has envisaged that the SPI-1 OFF subpopulation might benefit from inflammation triggered by the SPI-1 subpopulation (Stecher et al. *PLOS Biology* 5:2177-89, 2007).

Objectives

In this communication we describe an additional, unsuspected feature of SPI-1 bistability.

Methods

To do this, we have used a wide array of single cell assays to study the phenotypic heterogeneity during Salmonella virulence.

Conclusions

We show that relatively pure SPI-1 ON and OFF subpopulations obtained by bacterial cell sorting are observed non invasive, indicating that both subpopulations play an essential role in invasion. When individual Salmonellae are visualized inside epithelial cells, the intracellular bacterial populations are made of ON and OFF cells. These observations propose that the OFF subpopulation is able to invade, and can benefit from the activity of the invasion machinery of the ON cells. In support of this view, we also show that a small number of ON cells is sufficient for epithelial cells invasion, suggesting an uneven distribution of labor between ON and OFF cells.

Pathogens / Pathogenicity - Part III

GENOME-WIDE IDENTIFICATION OF GENES REQUIRED FOR THE INTRACELLULAR SURVIVAL OF SALMONELLA TYPHIMURIUM IN THE AMOEBA DICTYOSTELIUM DISCOIDEUM

B. Labra[1], A. Sabag[1], C. Valenzuela[1], Í. Urrutia[1], S. Riquelme[1], S. Porwollik[2], M. McClelland[2], S.A. Álvarez[1], C.A. Santiviago[1]
[1]Universidad de Chile,
Departamento de Bioquímica y Biología Molecular- Facultad de Ciencias Químicas y Farmacéuticas, Santiago, Chile
[2]University of California, Department of Microbiology and Molecular Genetics- School of Medicine, Irvine, USA

Backgrounds

Salmonella spends a substantial part of its life cycle in the environment living in close contact with predatory organisms that feed on bacteria, such as protozoa. Recently, we described that *S.* Typhimurium can survive intracellularly in the social amoeba *Dictyostelium discoideum*. However, no in-depth study has been conducted to elucidate the molecular mechanisms used by *Salmonella* to survive within Dictyostelia.

Objectives

In this work, we performed a high-throughput analysis of mutants under selection to identify genes that contribute to *S.* Typhimurium survival in *D. discoideum*.

Methods

We infected *D. discoideum* AX4 with a transposon library containing ~200,000 mutants of *S.* Typhimurium 14028s. After co-incubation for 1 h, extracellular bacteria were removed and intracellular bacteria were recovered immediately (t0) and after 6 h of infection (t6). Total DNA from recovered bacteria was amplified across specific barcodes present in the transposon and sequenced to measure the relative amount of each transposon in the population of bacteria at t0 and t6.

Conclusions

Analysis of the sequencing data identified mutants in 185 genes that were under negative selection after 6 h of infection. These genes encoded products whose functions included lipopolysaccharide synthesis and modification (*wbaPKMNU, wbaICD*, *waaK*, *waaL*, wzz_{fepE}, *eptA*, *pmrAB*, *pmrD*, *arnEF*), metabolism (*aroA*, *aroC*, *gnd*, *fabF*, *pgpA*), and transport (*acrAB*, *mgtCB*, *trkD*), among others. Predictions from our high-throughput screening are being confirmed for a selected group of genes using competition assays between individual single-gene deletion mutants and the wild-type strain.

Supported by FONDECYT grants 1140754 and 1171844, and CONICYT fellowships 22140758, 21140615 and 21150005.

CHEMOTAXONOMIC AND MOLECULAR CARACTERIZATION OF TENACIBACULUM MARITIMUM

B. S. Torres[1], N. Buján[1], A. E. Toranzo[1], B. Magariños[1]
[1]CIBUS- Facultad de Biología & Instituto de Acuicultura, Microbioloxía e Parasitoloxía- Universidade de Santiago de Compostela, Santiago de Compostela, Spain

Backgrounds

Tenacibaculum maritimum, a Gram negative and filamentous bacterium, has been described as the etiological agent of tenacibaculosis in marine fish. Until now, tenacibaculosis is one of the most threatening bacterial infections limiting the culture of many species of commercial value in distinct geographical areas of the world.
At serological and molecular level, previous studies revealed the existence of intraspecific variability within this pathogen. In the last years, new outbreaks of tenacibaculosis occurred in different fish species which makes necessary in deep studies of this pathogen.

Objectives

The objective of this work is to study the existence of genetic and chemotaxonomic variability among different strains of *T. maritimum* isolated between 2007-2016 from several marine fishes with the aim to determine a possible association between genogroups and origin or serotype.

Methods

A total of 20 strains of *T. maritimum* were used in this work. All strains were identified by 16S rRNA gene sequencing and specific PCR. The molecular analysis was performed using ERIC, REP and RAPD PCR methodologies and the fatty acid composition was determined with the Sherlock Microbial Identification System.

Conclusions

The molecular results confirmed the existence of genetic variability within *T. maritimum* strains but not associations with the host and/or serogroups were found. With regard to the analysis of the fatty acid profiles, a low variability in their composition was observed among the strains analysed.

SEARCH FOR POLYMORPHISMS IN THE ESPB AND ESPD PROTEINS AND THEIR EFFECT ON THE ADHERENCE OF ATYPICAL ENTEROPATHOGENIC ESCHERICHIA COLI TO HELA CELLS

F. Fernandes dos Santos[1], D. Yamamoto[1], R. Tavanelli Hernandes[2], R.M. Fontes Piazza[3], W. Pereira Elias[3], T. Aparecida Tardelli Gomes[1]
[1]UNIFESP - Universidade Federal de São Paulo, Departamento de Microbiologia- Imunologia e Parasitologia, São Paulo, Brazil
[2]UNESP - Universidade Estadual Paulista, Departamento de Microbiologia e Imunologia, Botucatu, Brazil
[3]Instituto Butantan, Laboratório de Bacteriologia, São Paulo, Brazil

Backgrounds

Intimin (encoded by *eae*) is the main adhesin of atypical enteropathogenic *Escherichia coli* (aEPEC). However, we have previously shown that an *eae* mutant of the aEPEC 1551-2 strain maintains its adherence efficiency by virtue of EspB and EspD, the components of a Type Three-Secretion System (T3SS) translocon.

Objectives

This study aimed to investigate whether polymorphisms in EspB and EspD could result in differences in the aEPEC efficiency to adhere to epithelial cells.

Methods

SDS-PAGE and Immunoblotting were used to determine the sizes of EspB and EspD of all eight strains studied. Intimin mutants were constructed from all strains, two of which were tested regarding any modification in their adherence efficiency on HeLa cells. The *espB* and *espD* genes were sequenced, translated into protein sequences and compared to those of the 1551-2 and EPEC prototype E2348/69 strains, using ExPasy and Clustal Omega. EspB and EspD molecular weights differed among the eight strains. Of the two mutants tested for adherence, one became non-adherent (BA4095), while the other (2012-1) remained adherent. Subsequently, the later mutant was used to generate an *eae*/*escN* (encoding the T3SS-ATPase) double mutant that was non-adherent, thus suggesting that its T3SS-translocon contributed to its adherence. The analyses of the EspD transmembrane domains have shown three identical aminoacids between the non-adherent *eae* mutant and the tEPEC strain, which were different from those present in the adherent 2012-1 and 1551-2 mutant strains.

Conclusions

Our preliminary analyses suggested that specific polymorphisms could contribute to the efficient adherence of aEPEC intimin mutants.

Pathogens / Pathogenicity - Part III

STRUCTURE-FUNCTION RELATIONSHIP IN BACTERIAL ADHESINS

A. Saragliadis[1], *D. Linke*[1]
[1]*University of Oslo, Department of Biosciences, Oslo, Norway*

Backgrounds

Bacterial adhesion is a crucial step in bacterial pathogenesis. Adhesion prevents microbial clearance from host by mechanical forces and also contributes to successful colonization of cells and tissues. The specialized surface proteins that mediate bacterial adhesion are called adhesins. They recognize specific binding partners on surfaces of host cells, leading subsequently to attachment, biofilm formation and pathogenesis. For the optimal control of bacterial adhesion and biofilm formation it is important to pinpoint the means to prevent and inhibit the adhesion and therefore the formation of biofilms.

Objectives

The aim of this project is to obtain a better understanding of individual adhesins and of their binding modes, and of their biogenesis. The ultimate goal of this research is the development of antimicrobial compounds, i.e. direct or indirect inhibitors of bacterial adhesion.

Methods

In order to identify novel antimicrobial compounds we are developing assays in our labs that will allow us to screen for molecules with the desired functionality. Subsequently we will transfer our developed assay to the High-Throughput Chemical Biology Screening Platform, located at the Biotechnology Center in Oslo. There, we are aiming to set up the necessary pilot screen that will lead us to a target based screen against a diversity library containing at least 28500 compounds.

Conclusions

As soon as we have identified lead compounds and after a verification process, the successful candidates will be used to expand on the understanding of adhesion structure and function.

LISTERIA SENSU STRICTU SPECIFIC GENES ARE IMPORTANT FOR IN VIVO COLONIZATION OF LISTERIA MONOCYTOGENES IN A FOODBORNE MOUSE MODEL

J. Schardt[1], G. Jones[2], S. Müller-Herbst[1], S. D'Orazio[2], T. Fuchs[3]
[1]Zentralinstitut für Ernährungs- und Lebensmittelforschung, Mikrobiologie, München, Germany
[2]College of Medicine University of Kentucky, Microbiology- Immunology & Molecular Genetics, Lexington- Kentucky, USA
[3]Friedrich-Loeffler-Institut, Institut für molekulare Pathogenese, Jena, Germany

Backgrounds

Listeria monocytogenes is the causative agent of listeriosis. Consumption of contaminated foods may lead to colonization of the gastrointestinal tract and a subsequent systemic infection.

The genus *Listeria* consists of 17 species, among them the two pathogens *L. monocytogenes* and *L. ivanovii*. Together with four other species, they form the so called "*Listeria sensu strictu*" group. All its members have been found in feces and the gastrointestinal tract of mostly symptom-free animals. The species of the second group in the genus, the "*Listeria sensu lato*", are thought to be solely environmental bacteria without the ability for colonization.

Objectives

To identify novel colonization determinants of *L. monocytogenes*, we applied a genome comparison approach between the two groups, and identified a list of candidate genes conserved in the *Listeria sensu strictu* species of which two were analyzed in more detail.

Methods

A mutant of a gene-pair encoding an ABC-Transporter exhibited a defect in adhesion and invasion of Caco-2 cells. Using a novel mouse model of foodborne infections (Bou Ghanem *et al*., 2013), a reduced number of the mutant strain was observed in the tissue of the small intestine. A mutant of a gene involved in propanediol metabolism showed reduced persistence in the stool of infected mice, pointing to a role of propanediol as carbon and energy source.

Conclusions

Taken together, these data revealed the presence of yet unknown colonization genes of *L. monocytogenes*. Both factors are also found in non-pathogenic *Listeria* species of the *sensu strictu* group, suggesting their potential to interact with mammalian hosts.

Pathogens / Pathogenicity - Part III

INFLUENCE OF BACTERIAL STATE ON CRONOBACTER SAKAZAKII VIRULENCE

K. Schauer[1], *J. Stecklum*[1], *E. Märtlbauer*[1]
[1]*Ludwig-Maximilians-Universität München, Lehrstuhl für Milchhygiene, Oberschleißheim, Germany*

Backgrounds

Cronobacter sakazakii are Gram-negative, facultative anaerobic bacteria of the family *Enterobacteriaceae* that have been implicated in rare but severe cases of illnesses predominantly in premature and newborne infants. This opportunistic pathogen has been isolated from clinical as well as from a range of food and environmental sources. The ability to form biofilm increases the persistence of *C. sakazakii* under different harsh environmental conditions and delays the entering of bacteria in a VBNC (***v****iable* ***b****ut* ***n****on-****c****ulturable*) state.

Objectives

Although progress has been made during the last years, there is still a lack of knowledge on the virulence-associated factors and processes involved during pathogenesis.

Methods

In order to investigate the importance of biofilm formation for *C. sakazakii* pathogenicity and to examine the virulence of VBNC cells, bacteria cells from stationary growth phase were desiccated under standardized conditions, resuscitated and analyzed in a gentamycin protection assay in Caco-2 cells.

Conclusions

The results showed that two bacterial populations with distinct functions are present in the biofilm: aggregated cells form and conserve the biofilm in contrast to planktonic cells which are more virulent and swarm to build new aggregates. VBNC cells generated from planktonic cells are also more virulent compared to the VBNCs from aggregates.

This work was supported by the Federal Ministry of Education and Research (BMBF) of Germany (Food Supply and Analysis [LEVERA], funding code 13N12611).

FEMS7-0246
Pathogens / Pathogenicity - Part III

ASSAY DEVELOPMENT: ADHESIN INTERACTION WITH IMPLANT MATERIALS

K. Schneider[1], D. Linke[1], H.J. Haugen[2]
[1]University of Oslo, Department of Biosciences, Oslo, Norway
[2]University of Oslo, Institute of Clinical Dentistry - Department of Biomaterials, Oslo, Norway

Backgrounds

Dental implants have been optimised with rough surfaces for bone integration; however, such surfaces also promote the unwanted adhesion of pathogens. This results in an inflammatory response (peri-implantitis) in 28-56 % of patients, causing the loss of supporting bone, and ultimately leads to implant failure.

The first step during bacterial infection is the adhesion to host cells or other surfaces, mediated by adhesins (cell surface proteins). Adhesins require suitable receptors or material surfaces to function. Consequently, bacterial adhesion to implant surfaces can be regulated in two ways; surface modification with antagonistic or supporting molecules, or by targeting the biogenesis of the adhesins.

Objectives

A bottom-up approach, starting with molecular biology studies of bacterial adhesion factors, is necessary, so that strategic implant surface modifications can be developed. We therefore develop assays that can mimic the host environment and that deliver time-resolved data regarding the performance of various implant surfaces.

Methods

We are creating a feedback loop between a materials-science and a molecular biology laboratory by testing wild type, knockouts and overexpressed adhesins. This improves both the surface modifications and the assays, and guarantees direct translation of fundamental research into application. Aggregatibacter actinomycetemcomitans (Aa) serves as model organism as it is associated with the destructive inflammatory process surrounding infected dental implants (peri-implantitis), which can also cause inflammation of the aortic valve of the heart (mortality rate: 18%).

Conclusions

We expect answers to adhesin expression pathways and adhesin function, enabling us to target particular cell-substrate interactions in our modifications of implant surfaces.

Pathogens / Pathogenicity - Part III

THE BEAT-AMR CONSORTIUM: PARTNERSHIP AGAINST BIOFILM-ASSOCIATED EXPRESSION, ACQUISITION AND TRANSMISSION OF ANTIMICROBIAL RESISTANCE

F. Schreiber[1], H.J. Kunte[1], Q. Ren[2], M. Buhmann[2], H. van der Mei[3], H. Busscher[3], S. Faust[4], J. Webb[5]
[1]Federal Institute for Materials Research and Testing BAM, Materials and Environment, Berlin, Germany
[2]EMPA - Swiss Federal Laboratories for Materials Science and Technology, Laboratory for Biointerfaces, St. Gallen, Switzerland
[3]University Medical Center Groningen, Department of Biomedical Engineering, Groningen, The Netherlands
[4]University of Southampton, Pediatric Immunology and Infectious Diseases and NIHR Wellcome Trust Clinical Research Facility, Southampton, United Kingdom
[5]University of Southampton, Biological Sciences, Southampton, United Kingdom

Backgrounds

Here, we introduce the BEAT-AMR consortium, which is recommended for funding within the 3rd call of the Joint Programming Initiative on Antimicrobial Resistance (JPIAMR).

Objectives

The aim of the consortium is to investigate fundamental mechanisms that shape antimicrobial resistance in biofilms in relation to the surface and then translate those findings into clinical practice. We thereby aim to generate clinical recommendations on the combinatorial use of biomaterials coated with antimicrobials and antibiotics that avoid the occurrence and transmission of nosocomial biofilm infections with bacteria insusceptible to antibiotics.

Methods

We established a Europe-wide network of experts in biofilm research, antimicrobial resistance, material sciences, and translational medicine that allows us to investigate those aspects in a coherent framework.

Conclusions

Biofilms are structured communities of bacteria found on surfaces that become embedded within a self-produced extracellular polymeric matrix. Bacteria living in biofilms can tolerate much higher antibiotic concentrations compared to planktonic bacteria and survive long enough to evolve antimicrobial resistance (AMR). They form persistent, hard-to-treat infections and exhibit an intrinsic biology that promotes the development and transmission of AMR. The goal of our consortium is to determine how bacteria adapt to antimicrobials during biofilm formation on surfaces coated with antimicrobials, how AMR mutations are acquired and evolve within mature biofilms, and how population dynamics within biofilms affect the transmission of AMR. Our team provides facilities and clinical research governance for experimental and translational medicine. Our synergy of laboratory, clinical and translational research across Europe will ensure the development of novel and successful interventions and therapeutic outcomes.

Pathogens / Pathogenicity - Part III

PRODUCTION OF PORCINE CIRCOVIRUS NUCLEOCAPSID PROTEIN IN SACCHAROMYCES CEREVISIAE

S.H. Seo[1], K.M. Park[1], Y.J. Shim[2], C.S. Kim[2], S.S. Yoo[2], E.S. Choi[1]
[1]Korea Research Institute of Bioscience & Biotechnology, Bio Process Engineering Center, Cheongju-si, Republic of Korea
[2]ChoongAng Vaccine Laboratories Co.- Ltd., Manufacture & Research, Daejeon, Republic of Korea

Backgrounds

Porcine circoviruses are associated with postweaning multisystemic wasting syndrome (PMWS). The nucleocapsid protein of porcine circovirus type 2 (PCV2) encoded by ORF2 is a promising subunit vaccine against porcine circovirus. Recombinant production of PCV2 ORF2 was studied in *Saccharomyces cerevisiae*.

Objectives

To develop a high-efficacy subunit vaccine of porcine circovirus using yeast.

Methods

For intracellular expression of ORF2, the gene was chemically synthesized according to yeast codon preference, was placed under GAL10 promoter and the resulting plasmid was transformed into *S. cerevisiae* Y2805 and Y2805Δgal80 strains. The ORF2 protein formed virus-like particle (VLP) in the cytoplasm of *S. cerevisiae* as observed by electron microscopy. The secretion of capsid protein into the culture supernatant was, however, unsuccessful. Purification of the VLP using various column chromatography was almost impossible due to the formation of large aggregates. Whole yeast containing ORF2 was immunized to guinea pigs and then serum titer was measured by ELISA. The antibody titer T/C values were higher than 2.0.

Conclusions

The ORF2 gene of porcine circovirus was expressed in yeast and it was observed that the VLP was efficiently formed. The feasibility of use of whole yeast cells containing the VLP as vaccine was tested in guinea pig experiments. In the ELISA test, the whole yeast cell containing VLP was found to be immunogenic. The recombinant ORF2 expressed in yeast is expected to be a candidate for a subunit vaccine for porcine circovirus.

FEMS7-0829
Pathogens / Pathogenicity - Part III

RECOMBINANT PRODUCTION OF SPAA, A SUBUNIT VACCINE FOR SWINE ERYSIPELAS, IN SACCHAROMYCES CEREVISIAE

S.H. Seo[1], K.M. Park[1], Y.J. Shim[2], S.S. Yoo[2], J. Ahn[1], E.S. Choi[1]
[1]Korea Research Institute of Bioscience & Biotechnology, Bio Process Engineering Center, Cheongju-si, Republic of Korea
[2]ChoongAng Vaccine Laboratories Co.- Ltd., Manufacture&Research, Daejeon, Republic of Korea

Backgrounds

A surface protein of *Erysipelothrix rhusiopathiae*, SpaA is a promising subunit vaccine against swine erysipelas. Recombinant production of SpaA was studied in yeast *Saccharomyces cerevisiae*. *S. cerevisiae* is a GRAS (generally regarded as safe) microorganism that has been exploited for thousands of years for fermentation, thus proven to be safe.

Objectives

To efficient produce SpaA for use as a subunit vaccine for swine erysipelas, using yeast expression systems including intracellular and surface-display expression.

Methods

For intracellular expression of SpaA, the SpaA gene that was chemically synthesized according to yeast codon preference, placed under GAL10 promoter and the resulting plasmid was transformed into *S. cerevisiae* Y2805 and Y2805Δgal80 strains. Since SpaA is a surface protein in *E. rhusiopathiae*, rSpaA was also expressed as surface-displayed protein. For surface display, SpaA gene was fused to the mating-factor alpha secretion signal sequence and an anchor-motif of a cell wall protein gene was fused at C-terminus of SpaA. The expression was confirmed by Western blot and the localization of the surface-displayed protein was monitored by fluorescence microscopy. The vaccine efficacy was evaluated by challenging mouse with virulent strain of *E. rhusiopathiae*.

Conclusions

The SpaA gene was expressed successfully both in cytoplasm and at the cell surface. The surface-display of the protein was confirmed by fluorescence microscopy. In mouse experiment, the crude preparation of SpaA from yeast lysate leads to 80% survival of mouse against lethal challenge with *E. rhusiopathiae*. The recombinant SpaA expressed in yeast is expected to be a useful candidate for a subunit vaccine for erysipelas.

MOSAICISM OF HORIZONTALLY TRANSFERRED POTENTIAL MOBILE UNITS IN THE GENOME OF 'CANDIDATUS PHYTOPLASMA SOLANI' STRAIN SA-1

M. Seruga Music[1], I. Samarzija[1], S.A. Hogenhout[2], M. Haryono[3], C.H. Kuo[3]
[1]University of Zagreb, Department of Biology, Zagreb, Croatia
[2]John Innes Centre, Department of Cell and Developmental Biology, Norwich, United Kingdom
[3]Academia Sinica, Institute of Plant and Microbial Biology, Taipei, Taiwan R.O.C.

Backgrounds

Small and repeat-rich genomes are characteristic for the members of the genus '*Candidatus* Phytoplasma', endocellular phytopathogens transmitted and hosted by phloem-feeding insects. While phytoplasma economical importance is increasing, experimental studies are still lagging due to the inability to grow a pure phytoplasma culture. For most phytoplasma species, one of the hallmarks of their behaviour is the adaptability to different plant and insect hosts, especially in '*Ca*. P. solani' that has a broad host range as is transmitted by polyphagous insects.

Objectives

The aim of this work was to learn about the background of its plasticity and adaptability by sequencing the genome of '*Ca.* P. solani' strain SA-1.

Methods

Whole plant samples of infected periwinkle were used for generation of libraries sequenced on the Illumina MiSeq platform. *De novo* assembly generated the draft genome of 19 contigs with a total size of 821,322 bp. Repetitiveness and abundance of potential mobile units (PMUs) was confirmed and found responsible for the incomplete genome assembly. Moreover, a mosaicism of PMUs and PMU-like regions was found, corroborated both by the analyses of PMU organization and gene content as well as the molecular phylogeny of PMU-related genes *(dnaB, dnaG, hflB, tmk, fliA, tra5*).

Conclusions

This finding suggests a horizontal transfer of PMUs from related ('*Ca*. P. australiense') and more distant ('*Ca*. P. asteris' and '*Ca*. P. mali') phytoplasmas. We hypothesize that SA-1 strain gained a mosaic of PMUs, a trait not previously described for phytoplasma genomes, allowing high genome plasticity and successful adaptation to various plant and insect hosts.

FEMS7-0830
Pathogens / Pathogenicity - Part III

PATHOGENICITY FACTORS IN ACHROMOBACTER RUHLANDII ADAPTATION TO THE AIRWAYS OF CYSTIC FIBROSIS PATIENTS

N. Sharapova[1], M. Kunda[1], O. Voronina[1], A. Gintsgurg[1]
[1]N.F. Gamaleya Federal Research Centre for Epidemiology and Microbiology, Ministry of Health of the Russian Federation, Moscow, Russia

Backgrounds

Achromobacter ruhlandii SCCH3:Ach33-1365 (Aruh ST36) is Russian epidemic strain especially dangerous for cystic fibrosis (CF) patients because of transmissibility, multi-drug resistance and failure of eradication. Comparative analysis of virulence factors involved in adhesion, invasion and biofilms formation (pili, flagellar and bacterial capsule) could explain the extraordinary Arul ST36 pathogenicity.

Objectives

Aruh ST36 (Accession Number CP017433) was compared with two *Achromobacter* strains isolated from a CF patient: *A. xylosoxidans* MN001 (CP012046.1), USA, and *A. xylosoxidans* NH-44784-1996 (NC_021285.1), Denmark. According to MLST analysis MN001 was *A. ruhlandii* ST36 too. In each genome we revealed 18 pili formation genes assembled in the single *tad-rcp* operon; 56 flagellar genes organized in 8 operons and 10 bacterial capsule biosynthesis genes. 88% of all detected virulent factors were identical in the *A. ruhlandii* pair and only 9.5% - in the pair Aruh ST36 - NH-44784-1996. 13 proteins participated in *A. ruhlandii* ST36 adaptation to the local environmental conditions: ten flagellar proteins (4 chemotaxis, 3 regulatory proteins, M-ring protein, motor rotation protein MotA and secretion system III protein), one pili formation protein (peptidase TadV) and two proteins involved in bacterial capsule biosynthesis (polyketide synthase and WcbD).

Methods

454 Roche technology was used for Arul ST36 whole genome sequencing and assembling; RAST v.2.0 server – for genome annotation; VFDB (Virulence Factor DataBase) – for the virulence factors revealing. *Burkholderia cenocepacia* strain J2315 (NC_011000.1) has the closest taxonomic relationship with *Achromobacter* in VFDB.

Conclusions

Flagellar proteins are the most important virulence factors in adaptation of *A. ruhlandii* epidemic strain.

Pathogens / Pathogenicity - Part III

PREVALENCE OF INTESTINAL PARASITIC INFECTIONS AMONG GENERAL POPULATION IN NORTH OF IRAN

M. Sharif[1], A. Ahmad Daryani[1], M. Mohtaram Nasrolahei[2], S. Shahabeddin Sarvi[1], A.S. Abdol Sattar Pagheh[1]
[1]Toxoplasmosis Research Center- Mazandaran University of Medical Sciences- Sari- Iran, Parasitology and Mycology, Sari, Iran
[2]Microbiology Department- Faculty of Medicine- Mazandaran University of Medical Sciences- Sari- Ira n, microbiology, Sari, Iran

Backgrounds

Intestinal parasitic infection (IPIs) is one of the most important health problems in developing countries. The prevalence of these infections is different among various communities; hence, there is a need for the periodical prevalence evaluation to develop public health strategies.

Objectives

The study aimed to investigate the prevalence and risk factors of intestinal parasites among the general population of Mazandaran province in north of Iran, as the first comprehensive research in this region.

Methods

This cross-sectional study was conducted in general population in Mazandaran province, north of Iran from December 2015 to December 2016. Faecal samples were selected from 17 urban areas (2515 samples) and 34 rural areas (2273 samples). 4788 specimens from 2579 males and 2579 females were examined by direct wet mounting, formalin-ether concentration, and Ziehl–Neelsen and trichrome permanent staining methods.

Conclusions

Intestinal parasites were found in 680 (14.2%) of the studied samples. Blastocystis hominis (5.2%) and Giardia lamblia (4.6%) were the most frequent parasites. Protozoa, helminthes and mix infections were observed in 12.32%, 1.03% and 0.85 of specimens, respectively. A significant association was observed with household income, place of residence, kind of washing vegetables, contact with soil and season. But neither age and nor gender were correlated to parasite infection.These findings emphasized that IPIs are a health concern in this area, so programs including screening and treatment of patients, improving sanitary conditions and public education for preventing the spread of intestinal parasitic are required.

FEMS7-0195
Pathogens / Pathogenicity - Part III

ALCOHOL AND TOBACCO CONSUMPTION AFFECT THE ORAL CARRIAGE OF CANDIDA ALBICANS AND MUTANS STREPTOCOCCI

C. Sheth[1], M.D.M. Jovani-Sancho[2], R. Gonzalez[2], V. Veses[3]
[1]Universidad CEU Cardenal Herrera, Medicine, Alfara de Patriarca, Spain
[2]Universidad CEU Cardenal Herrera, Dentistry, Alfara de Patriarca, Spain
[3]Universidad CEU Cardenal Herrera, Biomedical Sciences, Moncada, Spain

Backgrounds

The consumption of alcohol and tobacco is widespread in modern society. This study defines the relationship between the consumption of these social stimulants and the oral colonization by mutans streptococci and Candida species. Both species are common commensals in the oral cavity and both are implicated in disease processes (Candida; oropharyngeal candidiasis, denture-related stomatitis and Streptococcus; caries, infective endocarditis).

Objectives

The study had two main objectives:
1. Investigate changes in oral flora in males vs females induced by the consumption of alcohol and tobacco
2. Compare the differences in oral flora composition as a result of long versus short term consumption of alcohol and tobacco

Methods

Subjects were recruited from the University Dental Clinic of CEU Cardenal Herrera University (Moncada, Valencia). Information about alcohol and tobacco consumption was obtained by questionnaire. Individual stimulated saliva samples were obtained and selective media was used to isolate and quantify the colony forming units per mililiter of saliva (CFU / ml) of mutans streptococci and Candida spp.

Conclusions

Alcohol consumption statistically significantly decreased oral carriage of mutans streptococci ($p= 0.005$). Tobacco users were found to harbour elevated levels of C. albicans ($p= 0.03$). We observed changes in the levels of microbial colonization in response to the consumption of alcohol and tobacco in a species-specific manner. Whereas smoking increases the levels of Candida albicans in the oral cavity, drinking alcohol reduces the levels of mutans streptococci. Other species investigated, such as Candida krusei, Candida tropicalis and Lactobacilli, do not show a response to the consumption of the stimulants analyzed.

Pathogens / Pathogenicity - Part III

IL-6 AMELIORATES ACUTE LUNG INJURY IN INFLUENZA VIRUS INFECTION

A.L. Shiau[1], Y. Mei-Lin[1], W. Chao-Liang[2]
[1]National Chen Kung University Medical College, Department of Microbiology and Immunology, Tainan, Taiwan R.O.C.
[2]National Chen Kung University Medical College, Department of Biochemistry and Molecular Biology, Tainan, Taiwan R.O.C.

Backgrounds

Interleukin 6 (IL-6) is involved in innate and adaptive immune responses to defend against pathogens. Although the role of IL-6 in influenza pathogenesis has been documented, to date no studies have investigated its role in modulating lung repair responses necessary for recovery from influenza.

Objectives

We studied the role of IL-6 in lung repair from influenza-induced lung injury in mice.

Methods

We used IL-6 knockout and wild-type C57BL/6 mice to establish an influenza-induced acute lung injury model. We investigated the effects of IL-6 on the functions of lung fibroblasts, epithelial cells, and macrophages, as well as the interplay among these cell types during influenza infection. Immunohistochemical, immunological, apoptotic, migration, and phagocytosis assays were employed.

Conclusions

IL-6-deficient mice infected with influenza virus exhibited higher lethality, lost more body weight, and had higher fibroblast accumulation, and lower extracellular matrix (ECM) turnover in the lung than their wild-type counterparts. Deficiency in IL-6 enhanced proliferation, migration, and survival of lung fibroblasts, as well as increased virus-induced apoptosis of lung epithelial cells. IL-6-deficient lung fibroblasts produced elevated levels of TGF-β, which may contribute to their survival. Macrophage recruitment to the lung and phagocytic activities of macrophages during influenza infection were reduced in IL-6-deficient mice.

Our results indicate that IL-6 is crucial for lung repair after influenza-induced lung injury through reducing fibroblast accumulation, promoting epithelial cell survival, increasing macrophage recruitment to the lung, and enhancing phagocytosis of viruses by macrophages. This study suggests that IL-6 may be exploited for lung repair during influenza infection.

EPIDEMIOLOGICAL STUDY OF MULTIDRUG-RESISTANT PSEUDOMONAS AERUGINOSA ISOLATES IN HAMAD MEDICAL CORPORATION, QATAR

M. Sid Ahmed[1], J. Jass[1], E. Ibrahim[2], B. Söderquist[3]
[1]Örebro University, School of Science and Technology, Örebro, Sweden
[2]Hamad Medical Corporation, The Department Laboratory Medicine and Pathology- Microbiology, Doha, Qatar
[3]Örebro University, School of Medical Sciences, Örebro, Sweden

Backgrounds

Nosocomial infections affect millions of patients yearly. Gram-negative bacteria (GNB) deserve special attention as some have inherited resistance to all available antibiotics, leaving only the more toxic agents (e.g. polymyxins) for treatment. *Pseudomonas aeruginosa* is the second most common GNB isolated from health care infection. There is insufficient data about the epidemiology of multidrug- and pandrug-resistant *P. aeruginosa* (MDR-PA) in Qatar.

Objectives

The aim of the present study was to determine antimicrobial susceptibility patterns and epidemiology of MDR-PA from patients from Hamad Medical Corporation, Qatar

Methods

A total of 2552 *P. aeruginosa* isolates were identified from 5 hospitals in Qatar and antimicrobial susceptibility testing was performed according to Clinical and Laboratory Standards Institute. Clinical data were collected prospectively, including electronic medical records

Conclusions

The overall prevalence of MDR-PA isolates was 8% (n=205). Majority of the patients were male (75%), aged >50 years (64%) and recently hospitalized (74%). Among the infected patients with MDR-PA, 85% of were exposed to antibiotics during the last 90 days and 97% were hospital acquired while 3% were community acquired. However, of the MDR-PA, 56% were due to colonization, while 44% were infections. Most of the MDR-PA (96.6%) isolates were resistant to cefepime, 91% to ciprofloxacin, 91% to piperacillin/tazobactam and 90% to meropenem. Majority of MDR-PA isolates also exibited universal sensitivity to colistin, the drug of last resort treatment, thus considered pan-resistant. Our study showed a higher incidence of MDR-PA in comparison to neighboring countries, providing insight into the current situation in Qatar.

Pathogens / Pathogenicity - Part III

STUDYING THE ROLE OF CGMIP1 IN THE EVOLUTION OF CANDIDA GLABRATA DURING ADAPTION TO THE HUMAN HOST

S. Siscar Lewin[1], *S. Brunke*[1], *B. Hube*[1,2,3]
[1]*Department of Microbial Pathogenicity Mechanisms,*
Leibniz Institute for Natural Product Research and Infection Biology, Hans Knöll Institute (HKI), Jena, Germany
[2]*Center for Sepsis Control and Care, Jena University Hospital, Jena, Germany*
[3]*Friedrich Schiller University, Jena, Germany*

Backgrounds

Candida glabrata is the second most prevalent cause of candidemia worldwide, which is largely due to its high intrinsic and rapidly acquired resistance to azole antifungals. Phylogenetically, *C. glabrata* is more closely related to *Saccharomyces cerevisiae* than to the most common *Candida* species, *C. albicans*. Recent evolutionary studies have shown that the gene *CgMIP1* may have been under positive selection during the evolution of *C. glabrata* as human pathogen. The ortholog *MIP1* in *Saccharomyces cerevisiae* encodes a mitochondrial polymerase. Defects in mitochondrial functions lead to respiratory deficiency, as described in *petite* mutants, and increased resistance against azole antifungals.

Objectives

We studied the possible role of *CgMIP1* in *C. glabrata* pathogenicity compared to the non-pathogenic species *S. cerevisiae.*

Methods

We created *MIP1* knock-out mutants of both species and analyzed their growth under different stress conditions, such as oxidative stress, osmotic stress, endoplasmic reticulum (ER) stress and cell wall stress.

Conclusions

MIP mutants (*mip1Δ*) of both species showed *petite*-like phenotype. Interestingly, the *C. glabrata* mutant showed steady growth under ER stress conditions, whereas the growth of the wild type and *S. cerevisiae* strains was notably slower. Hence, deletion of *MIP1* conferred a species-specific increased resistance to these stressors for *C. glabrata*.

These adaptations might originally be due to frequent exposure to noxious substances, e.g. originating from the mucosal flora, which made selection pressure on *CgMIP1*. This could allow loss of function upon certain stressors and better survival in *petite*-like growth. Further studies are underway to verify this hypothesis.

MOLECULAR CHARACTERIZATION OF VANCOMYCIN-RESISTANT ENTEROCOCCI AT UNIVERSITY HOSPITALS IN BRNO (CZECH REPUBLIC)

M. Sittová[1], M. Röderová[2], M. Dendis[1], O. Holý[3], F. Růžička[4]
[1]GeneProof a.s., Research and Development, Brno, Czech Republic
[2]Faculty of Medicine and Dentistry- Palacký University Olomouc, Microbiology, Olomouc, Czech Republic
[3]Faculty of Medicine and Dentistry- Palacký University Olomouc, Preventive Medicine, Olomouc, Czech Republic
[4]Faculty of Medicine- St. Anne's University Hospital- Masaryk University, Microbiology, Brno, Czech Republic

Backgrounds

Enterococci are Gram-positive bacteria occurring as part of the natural microflora in the gastrointestinal tract. Vancomycin-resistant enterococci (VRE) represent a growing threat in hospital-acquired infections.

Objectives

The aim of this study was to monitor the incidence of VRE at the particular university hospitals in Brno (Czech Republic) in the period January-September 2015 where the increasing trend of VRE has occurred. Determination of virulence factors, detection of genes for antimicrobial resistance and assessment of their clonality were also part of this study.

Methods

Enterococci were isolated from various kinds of clinical specimens. They were identified using standard microbiological methods and MALDI-TOF MS. Determination of antibiotic susceptibility was performed by disk diffusion test. Real-time PCR was used for *vanA* gene and *vanB* detection. Genes for virulence factors were examined by end-point PCR: gelatinase (*gel*), surface protein (*asp*) cytolyzin (*cylA*), aggregation substance (*asa1*) and hyaluronidase (*hyl*). The clonality of individual strains was determined by pulsed-field gel electrophoresis (PFGE) of *Sma*I-digested DNA.

Conclusions

In the reporting period 32 VRE isolates from 26 patients were collected. All isolates were identified as *Enterococcus faecium* with *vanA* gene. The most common clinical material was urine (17). Only *esp* and *hyl* were detected from virulence factors. *Esp* gene was detected in eight samples (25%), *hyl* gene in 13 samples (41 %) and both genes (*esp*, *hyl*) in nine samples (28%). None of virulence factors was detected at two samples (6%). All isolates were resistant to vancomycin and aminopenicillin. Sensitivity to linezolid and tigecycline remained in all specimens. PFGE revealed identical strains with possible clonal spreading only in four patients (5 strains). Although, there is an increasing trend in incidence of VRE, PFGE results did not reveal any significant distribution of identical strains within selected hospitals in Brno. We assume that it is due to correct hospital infection control.

THE IMPACT OF PUTATIVE VIRULENCE GENES ON PATHOGENICITY DISPLAYED BY CLINICAL ACINETOBACTER BAUMANNII STRAINS

J. Skerniskyte[1], E. Karazijaite[1], J. Deschamps[2], R. Briandet[2], C. Pechoux[3], S. Kulakauskas[2], R. Krasauskas[1], J. Armalyte[1], E. Suziedeliene[1]
[1]Life Sciences Center- Vilnius University, Institute of Biosciences, Vilnius, Lithuania
[2]INRA- AgroParisTech- Universite Paris-Saclay, Micalis Institute, Jouy-en-Josas, France
[3]INRA- AgroParisTech- Universite Paris-Saclay, GABI, Jouy-en-Josas, France

Backgrounds

Acinetobacter baumannii is one of the major infection agents causing nosocomial pneumonia. Bacterium displays a high degree of genome plasticity which is thought to enable its successful adaptation to clinical environment and within the host. The impact of genome features on the virulence-associated properties of clinical *A. baumannii* strains is little investigated.

Objectives

To access virulence properties displayed by clinical *A. baumannii* strains and to investigate the role of putative virulence genes in bacterium pathogenicity with an emphasis on the bacterial surface-related properties.

Methods

Clinical *A. baumannii* strains (n=140) were screened for the genome presence of candidate virulence genes. Representative strains were further tested for biofilm formation, hydrophobicity, serum resistance, adhesion to mucin and to lung epithelial cells, virulence in *Caenorhabditis elegans* model. *A. baumannii* deletion mutants of putative virulence genes were generated by natural recombination. Biofilm structure was analyzed by confocal laser microscopy, cell wall changes were accessed by transmission electron microscopy.

Conclusions

Of the 10 *A. baumannii* candidate genes tested, the distribution of genes coding for bacterial surface-related proteins *blp1*, *smpA*, *epsA*, *bap*, *acfC* showed specific association with the genomes of pandemic clonal lineages I or II suggesting that alternative mechanisms might contribute to the environmental fitness of most successful *A. baumannii* clones. Moreover, the significant variation in virulence phenotypes was observed among individual *A. baumannii* strains. *blp1* and *ompA* gene mutants showed the most attenuated expression of virulence-associated features including changes in biofilm and cell wall structures.

Pathogens / Pathogenicity - Part III

CONTRIBUTION OF CARBAPENEMASES AND EFFLUX PUMPS TO CARBAPENEM RESISTANCE IN ACINETOBACTER BAUMANNII CLINICAL ISOLATES FROM POLAND

A. Słoczyńska[1], *A.E. Laudy*[1], *S. Tyski*[1,2]
[1]*Medical University of Warsaw, Department of Pharmaceutical Microbiology, Warsaw, Poland*
[2]*National Medicines Institute, Department of Antibiotics and Microbiology, Warsaw, Poland*

Backgrounds

Acinetobacter baumannii is recognized as important cause of nosocomial infections worldwide.

Objectives

The aim of the study was to determine carbapenem resistance mechanisms of Polish *A.baumannii* clinical isolates.

Methods

A total of 62 *A.baumannii* clinical isolates from Polish hospitals were analyzed for mechanisms of carbapenem resistance. Species identification was confirmed by *gyrB* PCR. All isolates were defined as imipenem resistant/non-susceptible by disk diffusion method. PCR was used to detect carbapenem hydrolyzing class D carbapenemases (CHDL) genes (*bla*$_{\text{OXA-51-like}}$, *bla*$_{\text{OXA-23-like}}$, *bla*$_{\text{OXA-24-like}}$, *bla*$_{\text{OXA-58-like}}$) with insertion sequences (IS). All isolates were subjected to CarbAcineto test. MICs for imipenem and meropenem, also in the presence of efflux pump inhibitor PAβN (50 µg/ml), were determined using broth dilution method.

Conclusions

All 62 isolates possessed the intrinsic *bla*$_{\text{OXA-51}}$ gene, while 57 (91,9%) harbored simultaneously also one of the acquired CHDL genes. 40/62 isolates (64,5%) harbored *bla*$_{\text{OXA-24}}$, 14/62 (22,6%) *bla*$_{\text{OXA-23}}$ and 3/62 (4,8%) *bla*$_{\text{OXA-58}}$. IS were detected upstream of all *bla*$_{\text{OXA-23}}$ and *bla*$_{\text{OXA-58}}$ genes. Highest meropenem and imipenem MICs (up to 128 µg/ml and 64 µg/ml, respectively) were observed for OXA-24-positive isolates. In the case of OXA-58 and OXA-51-positive isolates the lowest carbapenem MIC (4 µg/ml) was observed, which was concordant with negative CarbAcineto test results for these isolates. PAβN reduced by at least 4-fold meropenem MIC of 10 (71,4%) OXA-23 positive isolates, 4 (10%) OXA-24 and 1 (33,3%) OXA-58 positive isolate. Obtained results suggest that carbapenem resistance of Polish *A.baumannii* isolates is mainly mediated by acquired carbapenemases, however efflux pump activity may also play a role in this resistance profile.

[3]Carlos Chagas Institute, FIOCRUZ, Curitiba, Brazil
[4]Bioinformatics and Systems Biology, Justus-Liebig-University, Giessen, Germany
[5]Research Group Environmental Genomics and Systems Biology- IUNR, Life Sciences and Facility Management, Wädenswil, Switzerland

Backgrounds

Twenty-five clonal Gram-negative, rod-shaped, non-spore-forming bacteria were isolated from total parenteral nutrition during a 2013 multistate sepsis outbreak in Brazil. Standard clinical identification protocols pointed to the former *Erwinia herbicola-Enterobacter agglomerans* complex (EEC), but yielded contradictory results.

Objectives

Taxonomic description of the outbreak organism.

Methods

Multi-locus sequence analysis (MLSA) of representative isolate 5110RM suggested that the latter was closely related to *Phytobacter diazotrophycus* DSM 17806^T, the type strain of a non-validly described species isolated from wild rice in China, and to a number of clinical strains isolated in the United States in the 1970's that, based on DNA similarity, were previously assigned to Biotype XII of the EEC.

Conclusions

Both MLSA and whole-genome sequence data analysis supported the existence of two separate species within the genus *Phytobacter* as well as the distinctiveness of the latter from nearby genera such as *Kosakonia* or *Citrobacter*. The name *Phytobacter ursingii* sp. nov. was proposed for the second species. While both species contain plasmid-based multidrug resistant isolates, their relevance for clinical surveillance is given, moreover that isolates from this genus were repeatedly misidentified as *Pantoea agglomerans* in the past. We are currently designing assays to detect the genus *Phytobacter* from clinical samples. This will enable to study its diversity, spread and will help to prevent further septicaemia outbreaks by their implementation in surveillance programs.

ANTIBIOTIC SENSITIVITY OF BACTERIA CONTAMINATING BOAR SEMEN EXTENDED SAMPLES AND EFFICACY OF COMMERCIAL COLLECTION EXTENDER

P. Soler-Llorens[1], R. Ausejo[1], N. Mendoza[1], J. Miguel[1]
[1]Magapor S.L., R&D - Veterinary service, Ejea de los Caballeros, Spain

Backgrounds

Artificial Insemination (AI) is the predominant form for breeding in swine. Semen is diluted in extender in order to preserve its viability for a period of time. Bacterial contamination of extended porcine semen occurs frequently in AI centers, and may occur during whole semen processing.

Objectives

The aims of this study were to check the main bacterial species isolated from seminal doses; to assess the activity of antibiotics and the appropriate combination to control bacteria; and to evaluate the efficacy of a collection extender, Dicol®, in controlling contamination.

Methods

Samples were collected from different Spanish AI centers. Bacterial culture, isolation, identification and antibiogram of the isolated bacteria were performed. Antibiotic-free extender containing semen samples were aliquoted and infected with 10^6 ufc/ml of *Serratia marcescens* (Gram-negative), and *Micrococcus spp*. (Gram-positive). Infected semen samples were and incubated with 4 concentrations of 10 antibiotics and cultured for bacterial content. Ejaculates from five different boars were collected and divided into 3 groups which were initially diluted (1:1) with Dicol, Vitasem or Duragen extender, aliquoted and infected with 10 multi-resistant bacterial isolates. After 25 or 50 min, final dilution was carried out and stored at 16ºC and bacterial load determined at 24 hours post-infection.

Conclusions

Most frequent bacteria present on samples were: *Proteus vulgaris* (3.5%), *Serratia marcescens* (6.19%), *Serratia liquefaciens* (12.39%), *Stenotrophomonas maltophilia* (7,96%), *Staphylococcus spp.* (9.4%), Cedea (4.4%), *Micrococcus spp*. (5.3%), *Morganella mornanii* (4.4%). Dicol® treated samples showed almost no growth (<1cfu/ml), even when the final dilution was in with antibiotics-free extender.

CHARACTERIZATION OF AN ATYPICAL BRUCELLA SPP. ISOLATE FROM A PAC-MAN FROG (CERATOPHRYS ORNATA) SHOW CHARACTERISTICS DEPARTING FROM CLASSICAL BRUCELLAE

P. Soler-Lloréns[1,2], C.R. Quance[3], S.D. Lawhon[4], T.P. Stuber[3], J.F. Edwards[4], T.A. Ficht[5], S. Robbe-Austerman[3], D. O'Callaghan[1,2], A. Keriel[1,2]
[1]Institut National de la Santé et de la Recherche Médicale, U1047- UFR de Médecine, Nîmes, France
[2]Université de Montpellier, U1047, Nîmes, France
[3]Animal and Plant Health Inspection Service- United States Department of Agriculture-, Mycobacteria and Brucella Section- National Veterinary Services Laboratories, Ames- IA, USA
[4]College of Veterinary Medicine and Biomedical Science- Texas A&M University, Clinical Microbiology- Department of Veterinary Pathobiology, College Station- TX, USA
[5]Texas A&M University, Department of Veterinary Pathobiology, College Station- TX, USA

Backgrounds

Brucella are highly infectious bacterial pathogens responsible for brucellosis, a frequent worldwide zoonosis. The *Brucella* genus has recently expanded from 6 to 11 species, all of which were associated with mammals; The natural host range recently expanded to amphibians after some reports of atypical strains from frogs.

Objectives

Here we describe the first in depth phenotypic and genetic characterization of a *Brucella* strain isolated from a frog. Strain B13-0095 was isolated from a Pac-Man frog (*Ceratophyrus ornate*) at a veterinary hospital in Texas and was initially misidentified as *Ochrobactrum anthropi*.

Methods

Whole genome sequencing was performed for B13-0095. The result was assembled and annotated. *In Silico* analysis of the sequence revealed several specific features, which were evaluated by several methods (motility assays, growth under different conditions, SDS-PAGE, or *in vitro* infections).

Conclusions

B13-0095 belongs to a group of early-diverging brucellae that includes *Brucella inopinata* strain BO1 and the *B. inopinata*-like strain BO2. B13-0095 genome sequence revealed specific features that suggest that this isolate represents an intermediate between a soil associated ancestor and the host adapted "classical" species. Like strain BO2, B13-0095 does not possess the genes required to produce the perosamine based LPS found in classical Brucella, but has a set of genes that could encode a rhamnose based O-antigen. B13-0095 has a very fast intracellular replication rate in epithelial cells and macrophages. Finally, the study also shows that B13-0095, BO1, and BO2 are motile strains, which is remarkable for this bacterial genus.

Pathogens / Pathogenicity - Part III

ECTOPIC EXPRESSION OF PAR-4 LEADS TO INDUCTION OF APOPTOSIS IN MYCOBACTERIA-INFECTED MACROPHAGES

Y.J. Lim[1], J.A. Choi[1], J.H. Lee[1], S.N. Cho[1], S.M. Oh[1], D. Go[1], S.H. Kim[1], C.H. Song[1]
[1]Chungnam National University - School of Medicine,
Department of Microbiology- Department of Medical Science, Daejeon, Republic of Korea

Backgrounds

Immunotherapy with mycobacteria has been used successfully as a treatment for bladder and prostate cancers. Bacillus Calmette-Guérin (BCG) is a strain of *Mycobacteria bovis* that effectively induces an immune response against tumor cells, leading to a reduction of risk factors associated with tumor recurrence and progression. However, the exact mechanisms of mycobacterial immunotherapy are not fully understood. Prostate apoptosis response-4 (Par-4) is a protein that was first identified in prostate cancer cells undergoing apoptosis. Although Par-4 is incapable of directly inducing apoptosis in normal cells, Par-4 overexpression is sufficient to induce apoptosis in most cancer cells. Secretion of Par-4 follows the conventional ER-Golgi secretory pathway, and is associated with ER stress.We hypothesize that *Mtb*-induced GRP78 production coordinates with Par-4 to induce apoptosis of *Mtb*-infected macrophages.

Objectives

The aim of this study was to investigate the role of ectopic expression of Par-4 during mycobacterial infection.

Methods

In this study, we measured Par-4 levels by Western blot analysis of RAW 264.7 macrophages infected with the H37Ra strain of *Mtb*. We examined Par-4 production in *Mtb* H37Ra-infected macrophages treated with the chemical chaperone and inhibitor of ER stress. To investigate the role of ectopic exressed Par-4, we visualized Par-4 localization in *Mtb*-infected macrophages and analyzed apoptotic cell death.

Conclusions

Par-4 is associated with ER stress-induced apoptosis resulting in reduced intracellular survival of mycobacteria. BCG treatment increases Par-4-dependent caspase activation in prostate cancer cells. Therefore, ER stress-induced Par-4 acts as an important defense mechanism against mycobacterial infection and regulates cancer.

BACTERIAL PATHOGENS DETECTED IN CYSTIC FIBROSIS PATIENTS

V. Spendal[1], *N. Fajfar*[1], *D. Luznik*[1], *V. Tomic*[1]
[1]*University Clinic of Respiratory and Allergic Diseases Golnik, Laboratory for respiratory microbiology, Golnik, Slovenia*

Backgrounds

Cystic fibrosis (CF) is the most common genetic disease. In CF a defect (mutation) in a gene changes a protein that regulates the movement of salt in and out of cells. The result is thick, sticky mucus in the lungs which provides an ideal breeding ground for bacteria.

Objectives

The objective of this study was to characterize the bacterial pathogens colonizing lungs of patients with CF during ten-year period.

Methods

In the Laboratory for Respiratory Microbiology 471 clinical isolates were collected from 31 patients with CF, who were admitted to University Clinic of Respiratory and Allergic Diseases Golnik between 2006 and 2016. In 31 patients (21 female, 10 male) we found 13 different potentially pathogenic bacteria. The most commonly isolated pathogen was *Staphylococcus aureus* found in 77,4% of patients (90 % male, 77 % female), followed by *Pseudomonas aeruginosa* 54,8 % of patients (40% male, 62 % female). *Haemophilus influenzae* and *Bulkholderia cepacia complex* were isolated in 16,1 % of patients. *Stenotrophomonas maltophilia* was isolated from 9,7 % patients. *Moraxella catarrhalis*, *S. pneumoniae, Streptococcus group C, Klebsiella pneumoniae* and *Escherichia coli* were found in 3,2 % patients. In two cases we isolated methicillin-resistant *S. aureus* (MRSA).

Conclusions

The results showed that *Pseudomonas aeruginosa* and *Staphylococcus aureus* are the most commonly isolated organisms from the respiratory tract of these CF patients. Multidrug resistant organisms were uncommon.

FEMS7-1865
Pathogens / Pathogenicity - Part III

THE EXTRACELLULAR ACID TREHALASE ENCODED BY THE ATH1 GENE IS REQUIRED FOR VIRULENCE OF CANDIDA GLABRATA

R.G. Lopes[1], J.E. Muñoz[2], L.M. Barros[1], C.P. Taborda[2], B.U. Stambuk[1]
[1]Universidade Federal de Santa Catarina- Centro de Ciências Biologicas, Bioquímica, Florianopolis, Brazil
[2]University of São Paulo- Institute of Biomedical Sciences, Microbiology, São Paulo, Brazil

Backgrounds

Both the incidence of invasive fungal infections and rates of multidrug resistance associated with the fungal pathogen *Candida glabrata* have increased in recent years, accounting for as many as 10-25% of all candidaemias. The carbon utilization spectrum of this yeast is extremely narrow when compared with other yeasts (only consumes glucose and the disaccharide trehalose), and has been suggested to be consequence of an adaptation for its life and success as a commensal pathogen. Indeed, rapid identification tests for this species are based on the ability of this yeast to rapidly hydrolyze trehalose, but not other disaccharides.

Objectives

We have recently characterized the extracellular trehalase encoded by the *CgATH1* gene of *C. glabrata* (Microbiol. Res. 179: 12-19, 2015), which allows efficient hydrolysis and fermentation of this sugar by this yeast. One intriguing point is why this yeast has retained the ability to utilize extracellular trehalose as carbon source, since this sugar is not found easily in the environment or mammalian host.

Methods

Thus, we decided to delete this gene from the genome of *C. glabrata* using the promoter-dependent disruption of genes (PRODIGE) method.

Conclusions

Our results show that the *C. glabrata CgATH1*Δ::*ScURA3* mutant strain is, as expected, unable to consume and ferment extracellular trehalose. However, our results also show that deletion of this gene also led to a significant ($p<0.01$) reduction in virulence in a murine model of infection, using normal or immunocompromised (treated with cyclophosphamide) mice, indicating that trehalose metabolization is important for virulence in the mammalian host of this fungal pathogen.

GENOME ANALYSIS OF NINE TREPONEMA PALLIDUM SUBSP. PERTENUE STRAINS

M. Strouhal[1], L. Mikalová[1], J. Haviernik[1], D. Čejková[2], P. Tenti[1], D. Šmajs[1]
[1]Masaryk University- Faculty of Medicine, Department of Biology, Brno, Czech Republic
[2]Veterinary Research Institute, Department of Immunology, Brno, Czech Republic

Backgrounds

Treponema pallidum subsp. *pertenue* (TPE) is the causative agent of yaws, a multistage disease endemic in tropical regions in Africa, Asia, Oceania, and South America. To date, only four TPE strains were completely sequenced and analyzed including three TPE strains of human origin (Samoa D, CDC-2, and Gauthier) and one TPE strain isolated from the baboon (Fribourg-Blanc).

Objectives

The aim of this study was genome analysis of five TPE strains of African and Indonesian origin (CDC-1, CDC2575, Ghana-051, Kampung Dalan, and Sei Geringging) and comparison of these complete genome sequences with other available TPE genomes.

Methods

The genomes were determined using the pooled segment genome sequencing method combined with Illumina sequencing platform. Whole genome nucleotide alignment of nine TPE strains was used for determination of genetic relatedness using several approaches including single nucleotide variants (SNV) determination, calculation of nucleotide diversity and construction of a phylogenetic tree.

Conclusions

There were a total of 443 identified SNV among TPE genomes (excluding *tprK* and *tprD* genes and 16S-23S rDNA intergenic regions). Most of them represented strain-specific SNV. No larger genome rearrangements were found. The nucleotide sequences of strains CDC2575 and Ghana-051 were found to be identical differing only in intra-strain heterogenic sites. The nucleotide diversity (π) ranged between 0,00006±0,00003 – 00040±0,00020. Phylogenetic tree showed no identifiable subgroups among analyzed TPE strains suggesting unique ancestor of TPE strains.

Pathogens / Pathogenicity - Part III

TOPOLOGICAL MODEL FOR THE SEARCH OF NEW ANTIBACTERIAL COMPOUNDS. FIRST ASSAYS

B. Suay[1], J.I. Bueso-Bordils[1], M.T. Perez-Gracia[1], G. Anton-Fos[1], L. Lahuerta-Zamora[1], R. Martin-Algarra[1], P. Aleman-Lopez[1]
[1]University CEU Cardenal-Herrera, Pharmacy, Valencia, Spain

Backgrounds

Due to the increasing detection of multi-drug resistant bacteria, the arsenal of antibacterial compounds has to be constantly evolving. We developed a topological model to predict antibacterial activity.

Objectives

To verify experimentally our topological model by assaying a group of theoretically active compounds, randomly selected from said model. Moreover, the results obtained will allow verification and further optimization of this model as well as the identification of new lead compound.

Methods

Of the 158 theoretically active compounds, 14 were randomly selected to be assayed against four bacteria (*Staphylococcus aureus*, *Streptococcus agalactiae,* E*scherichia coli* and *Serratia marcescens*). All 14 compounds were tested for antibacterial activity using the Kirby-Bauer method, having impregnated the disks with a saturated solution of each compound. After obtaining these results, the compounds showing an inhibition zone were assayed following the CLSI standards to determine their Minimum Inhibitory Concentration (MIC).

Conclusions

Of the 14 compounds assayed, 4 presented bactericidal activity at saturated concentrations. Of these, only 1 showed a MIC below 512µg/mL, therefore becoming possible lead compound candidates. Furthermore, the negative results obtained provide information necessary to improve our topological model in order to obtain better results in the future. Therefore, we consider molecular topology to be a cost-effective, powerful and useful tool for the identification of new antibacterial compounds, which could be of interest against multi-drug resistant bacteria.

Pathogens / Pathogenicity - Part III

BACTERIOPHAGES IN AGRICULTURE: OVERVIEW OF A PROGRAM TO DEVELOP A HIGH EFFICACY BIOPESTICIDE FOR CONTROL OF ERWINIA AMYLOVORA

A. Svircev[1], *A. Castle*[2]
[1]*Agriculture and Agri-Food Canada, STB, Vineland Station, Canada*
[2]*Brock University, Department of Biological Sciences, St. Catharines, Canada*

Backgrounds

Commercial biologicals are available for the control of *Erwinia amylovora*, the fire blight pathogen, in apple and pear orchards. In the blossom, the biologicals suppress the pathogen on the pistil by competing for nutrients and/or through the production of antimicrobial compounds. In contrast, lytic bacteriophages have the ability to infect the pathogen and destroy the infected host cells through cell lysis. In agricultural applications, bacteriophages are restricted by the adverse environmental conditions such as UV light and dry conditions.

Objectives

We have developed a biological that incorporates lytic phages inside the epiphytic bacterium, *Pantoea agglomerans*. The *P. agglomerans* performs as biological control agent and a bacteriophage the carrier.

Methods

Once applied to the blossom under optimal conditions results in an increase in both the phage and the carrier populations. In this phage-carrier mediated biological control system, both the bacteriophage host range and the development of bacterial resistance need to be considered. Phages were collected and screened for efficacy against the pathogen using detached flower bioassays, screen house and field trials. Ten phages demonstrated high field based efficacy.

Conclusions

This presentation will focus on the impact of bacterial resistance mechanisms on phage efficacy, specifically, the role of bacterial exopolysaccharides (amylovoran and levan) in phage infection and growth, the possible roles of lysogeny, and CRISPR/Cas systems on phage-host interaction and resistance.

FEMS7-1808
Pathogens / Pathogenicity - Part III

THE EFFECT OF PROTEOLYTIC ENZYMES INHIBITORS ON PSEUDOMONAS AERUGINOSA AND STAPHYLOCOCCUS AUREUS CELLS

K. Szałapata[1], *M. Osińska-Jaroszuk*[1], *A. Jarosz-Wilkołazka*[1]
[1]*Maria Curie Sklodowska University, Department of Biochemistry, Lublin, Poland*

Backgrounds

Pseudomonas aeruginosa and *Staphylococcus aureus* are one of the main pathogens which cause postoperative prosthesis infections in many patients. Late detection or improperly treating of these infections leads to the need of a repeated surgery and sometimes even ends up the death of the patients. Currently we are looking for new substances which are more effective in action than the antibiotics. The efficient competition may be a group of natural and synthetic inhibitors of proteolytic enzymes, which are very important as homeostasis regulators.

Objectives

The aim of this study was to investigate the selected proteolytic enzyme inhibitors (AEBSF and α-1-antitrypsin) affecting the viability of two pathogenic strains - *Pseudomonas aeruginosa* and *Staphylococcus aureus.*

Methods

For two strains of pathogenic microorganisms - *Staphylococcus aureus* ATCC 25923 and *Pseudomonas aeruginosa* ATCC 27853 - analysis of Minimal Inhibitory Concentration (MIC) and Minimal Bactericidal Concentration (MBC) were carried out in accordance with applicable guidelines from Clinical and Laboratory Standards Institute.

Conclusions

The results obtained under conducted experiments showed that the AEBSF can affect the growth of both tested bacterial strains in the range of tested concentrations. For α-1-antitrypsin we showed the inhibitory effect on the production of coloured substances by the strain of *Pseudomonas aeruginosa,* which are its virulence factors.

This work was partially supported by National Science Centre (**2014/15/N/NZ7/04092**).

Pathogens / Pathogenicity - Part III

THE MECHANISMS OF THE ANTIMICROBIAL EFFECT OF ISOTHIOCYANATES ON VIBRIO CHOLERAE

K. Krause[1], D. Nowicki[1], A. Herman-Antosiewicz[2], A. Szalewska-Palasz[1]
[1]Uniwersity of Gdańsk, Department of Bacterial Molecular Genetics, Gdańsk, Poland
[2]Uniwersity of Gdańsk, Department of Biological and Medical Genetics, Gdańsk, Poland

Backgrounds

Plant secondary metabolites, as a group of compounds of natural origin, are the object of research interest due to their beneficial effects, including antimicrobial action. This is of particular importance nowadays, when the antibiotic resistance became a global medical problem. Isothiocyanates (ITC) are secondary metabolites produced by plants of the *Brassicaceae* family, of known chemopreventive and anticancer effects. We already presented their bactericidal effects against enterohaemorrhagic *Escherichia coli.*

Objectives

The main aim of our studies was the evaluation of the mechanisms of three ITCs, sulforaphane (SFN), benzyl isothiocynanate (BITC) and phenethyl isothiocyanate (PEITC) against *Vibrio cholerae*.

Methods

We used broth microdilution method to determine minimum inhibitory concentrations (MIC) and bactericidal concentrations (MBC). To assess ITCs effect on DNA/RNA synthesis, the experiment of incorporation [^{3}H]-labelled nucleotides was employed. The induction of the stringent response upon ITC treatment was evaluated using [^{32}P]-labelling and thin layer chromatography separation.

Conclusions

Our studies revealed that PEITC has the strongest antimicrobial effect against *V. cholerae,* while SFN effect was rather moderate. All ITCs inhibited significantly DNA, and to even higher extent, RNA synthesis. In concert with this observation, the exposure of the bacteria to all tested ITCs resulted in the strong induction of the stringent response and the accumulation of its alarmon, unusual nucleotide, ppGpp. This effect was reversed by the excess of particular amino acids. Our studies show strong antimicrobial potential of ITCs against *V. cholerae* which would be of great importance for designing future efficient therapy of infection by bacterial pathogens.

FEMS7-3066
Pathogens / Pathogenicity - Part III

DISRUPTION OF COTH1 AND COTH2 GENES OF MUCOR CIRCINELLOIDES BY USING A CRISPR/CAS9 SYSTEM

C. Szebenyi[1], *N. Gábor*[2], *V. Amanda*[1], *T. Eszter*[1], *K. Sándor*[1], *V. Csaba*[1], *P. Tamás*[2]
[1]*University of Szeged, Department of Microbiology, Szeged, Hungary*
[2]*MTA-SZTE "Lendület" Fungal Pathogenicity Mechanisms Research Group, Department of Microbiology, Szeged, Hungary*

Backgrounds

A CRISPR/Cas9 system has been developed and established as a robust and versatile genetic modification tool for site-specific mutagenesis of *Mucor circinelloides*. In this study, a transformation system was optimized without using plasmids to disrupt the spore cote protein H-like genes *CotH1* and *CotH2*, in *M. circinelloides*. Our transformation strategy was to use the crRNA and trans-activating crRNA (tracrRNA) together (gRNA) to guide the CRISPR-associated nuclease Cas9 to cleave double-strand breaks in the targeted DNA sequence. In parallel, deletion cassettes were constructed by PCR for the two genes and used as template DNAs for HR repair.

Objectives

M. circinelloides is one of the most studied Mucorales species and frequently used model organism in different molecular and genetic studies. Genetic modification of *Mucor* is still problematic, because the template DNA used for the transformation barely integrates in the genome and the mitotic stability of transformants is generally low.

Methods

In this study, CRISPR/Cas9 was used to disrupt the *CotH1* and *CotH2* genes in *M. circinelloides.* PEG mediated protoplast transformation was used to introduce the nuclease and the synthesized *CotH1* and *CotH2* gene specific gRNAs with the appropriate deletion cassette into the fungus.

Conclusions

Co-transformation of the Cas9 and gRNA with the deletion cassette resulted double-strand breaks of DNA, which was repaired by the own homologous recombination system of *M. circinelloides*. Molecular analysis revealed the presence of the *pyrG* gene, used as a selection marker, in the coding sequence of *CotH1* and *CotH2* genes.

The study was supported by the grants LP2016-8/2016 and GINOP-2.3.2-15-2016-00035.

ANTIMICROBIAL AND INHIBITORY EFFECTS OF THERAPEUTIC-GRADE ESSENTIAL OILS AGAINST THREE ENVIRONMENTAL ISOLATED BACTERIAL STRAINS

T. Szoke-Nagy[1,2], N.E. Dina[1], S. Porav[1,2], C. Tripon[1]
[1]National Institute for Research and Development of Isotopic and Molecular Technologies, Department of Molecular and Biomolecular Physics, Cluj-Napoca, Romania
[2]Babes-Bolyai University - Faculty of Biology and Geology, Department of Molecular Biology and Biotechnology, Cluj-Napoca, Romania

Backgrounds

Evaluation of the antimicrobial effects of four essential oils against three environmental isolated bacterial strains.

Objectives

Determination of MIC, and evaluation of the antimicrobial effects for four EOs (clove, peppermint, bergamot, elemi) using disk diffusion assay.
Assessment of the bacteria structural features before and after EOs addition, using SEM.

Methods

Bacterial strains were isolated from environment by cultivation on selective media and further identified based on 16S rRNA molecular markers, using 27FB-1492R primer pair.
MIC were determined using 96-well microplates. The crude EOs were dissolved in Muller-Hinton medium with DMSO and Tween-20. Bacterial inoculum was prepared to obtain 10^6 CFU/mL bacterial suspensions. A series of two fold dilutions of each EO were prepared in each well and added the bacterial suspension. After incubation, the optical density of each well was measured at 630nm by a Microplate Reader.
An overnight culture of bacteria were adjusted to obtain 10^6 CFU/mL bacterial suspensions and spread on MH-agar medium. Paper disk with EOs was added afterwards. The inhibition zone was measured after incubation.
For SEM analysis, bacterial samples were fixed with 4% glutaraldehyde in medium for 2 hours, followed by dehydration in graded acetone series. After dehydration samples were dried on a 3 mm copper grid and coated with a 10 nm gold layer.

Conclusions

The EOs tested in this study exhibit promising antimicrobial and inhibitory effects against selected bacteria, possibly due to the presence of their bioactive constituents.

Financial support from the National Authority for Scientific Research and Innovation - ANCSI, Core Programme, Project PN16-30 02 03 is gratefully acknowledged.

GENOMIC CHARACTERIZATION OF BORDETELLA PERTUSIS 0134, A VACCINE STRAIN WITH HISTORIC VALUES

K. Tadayon[1], R. Ghaderi[1], M. Noofeli[2], E. abbasi[2], P. khaki[3], M. sekhavati[1]
[1]Razi Vaccine & Serum Research Institute- Agricultural Research- Education and Ex, Aerobic Bacterial Vaccine, Karaj, Iran
[2]Razi Vaccine & Serum Research Institute- Agricultural Research- Education and Ex, Human Bacterial Vaccine, Karaj, Iran
[3]Razi Vaccine & Serum Research Institute- Agricultural Research- Education and Ex, Microbiology, Karaj, Iran

Backgrounds

The earliest serious attempts to protect Iranian citizens against pertussis were initiated in 1952 when a domestically-developed vaccine was licensed for public use.

Objectives

This study was designed and conducted to get a deeper genomic insight toward molecular characteristics of current Razi Vaccine strain of *Bordetella pertusis,* 0134.

Methods

In order to characterize the genomic properties of the exotic strain Razi Bp 0134 currently used in manufacturing the whole cell pertussis vaccine, an 8-locus multiple-locus variable-number tandem repeat analysis (MLVA) was selected. This system uses VNTR1,VNTR2,VNTR3,VNTR5,VNTR7,VNTR8,VNTR9 and VNTR10. Technically, the PCR primers and amplification cycles were designed to enable simultaneous amplification of all the 8 loci in a single round using any traditional thermocycler.

Conclusions

The sequencing-supported observations displayed that there were 8.9 copies of a 15 bp unit repeat (UR), 3.3 copies of a 12 bp UR, 7.2 copies of a 5 bp UR, 12.5 copies of a 6 bp UR, 3 copies of a 9 bp UR, 2 copies of a 12 bp UR, 5 copies of a 6 bp UR, 3.8 copies of a 9 bp UR at VNTR1,VNTR2,VNTR3,VNTR5,VNTR7,VNTR8,VNTR9 and VNTR10, respectively.
The MLVA genotyping pattern of the BP134 strain was then compared with that of the nineteen BP strains currently available at http://www.ncbi.nlm.nih.gov/genome/genomes/1008 from rest of the world. Considering the dynamic nature of Bordetella pertussis in human hosts we assume a systematicMLVA genotyping of clinical isolates is necessary to improve the currently poor epidemiological knowledge of pertussis in Iran.

LEVELS OF LIPOTEICHOIC ACID (LTA), LIPOPOLYSACCHARIDE (LPS) AND MICROORGANISMS IN ROOT CANALS OF TEETH WITH PULP NECROSIS AND PERIAPICAL LESION

C.A.T. CARVALHO[1], F.E. OLIVEIRA[2], M.V.P. LEÃO[3], G. BACK BRITO[2], R. SANTANA[1], F.G. cardoso[1], M.C. VALERA[1], L.D. OLIVEIRA[2]
[1]São Paulo State University UNESP- Institute of Science and Technology, Restorative Dentistry, São Jose dos Campos, Brazil
[2]São Paulo State University UNESP- Institute of Science and Technology, Biosciences and Oral Diagnosis, São Jose dos Campos, Brazil
[3]Taubaté University, Medicine, Taubaté, Brazil

Backgrounds

Lipoteichoic acid (LTA) and lipopolysaccharide (LPS) play an important role in the etiology of pulpal and periapical alterations.

Objectives

Evaluating the levels of LTA, LPS and microorganisms in root canals of teeth with pulp necrosis and periapical lesion during endodontic treatment.

Methods

Tweenty teeth needing endodontic treatment were evaluated. The contents of canals were collected immediately after coronary opening (S1), preparation with 2.5% NaOCl (S2), use of 17% EDTA (S3) and 14 days after intracanal medication of calcium hydroxide with chlorexidine gel 2% (S4). Microorganisms were identified and quantified by Real Time PCR, LPS was quantified by chromogenic kinetic test of limulus amebocyte lysate (LAL) and LTA by enzyme-linked immunosorbent assay (ELISA). Data were analyzed by ANOVA and Tukey test ($p<0.05$). The most prevalent bacterial species in the S1 collection were *P. intermedia* (9/20), *F. nucleatum* (9/20) and *T. forsythia* (8/20). LTA and LPS were detected in 100% of the initial samples, with the highest values in samples S1 and S2. Samples S3 and S4 presented the lowest values of LTA and LPS, being statistically similar ($p>0.05$) and different from samples S1 and S2 ($p<0.05$).

Conclusions

LTA and LPS are present in 100% of the initial collections of the root canals and, during treatment, their levels only significantly reduced after the use of EDTA and intracanal medication (calcium hydroxide with chlorhexidine gel 2%). The most prevalent species were *P. intermedia*, *F. nucleatum* and *T. forsythia*.

Pathogens / Pathogenicity - Part III

ALLELIC VARIATION, BUT NOT GENE GAIN, MAY EXPLAIN MULTI-HOST VIRULENCE IN S. DERBY ISOLATES

M. Tambassi[1], C. Bracchi[2], M. Morganti[1], S. Erika[1], L. Bolzoni[1], S. Pongolini[1], G. Casadei[1]
[1]Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna, Risk Assessment Unit, Parma, Italy
[2]Università degli Studi di Parma,
Department of Chemistry- Life Sciences and Environmental Sustainability, Parma, Italy

Backgrounds

Multi-host virulence among *Salmonella* serotypes is usually attributed to specific genes while the role of Single-Nucleotide-Polymorphisms (SNPs) is not yet well understood. Data from our Regional Enteropathogens surveillance network show that the two most prevalent serotypes isolated from swine are *S.* Derby and *S.* Typhimurium monophasic variant (28.2% and 34.7%) but *S.* Derby is rarely found in human (2.6%) compared to *S.* monophasic (46.1%). *S.* Derby isolates seem therefore adapted mostly to swine with few exceptions which might have gained genetic traits responsible for multi-host virulence.

Objectives

Our work aimed to identify molecular determinants responsible for host-range broadening in S. Derby.

Methods

S. Derby isolates (n=240) were genotyped by Pulsed-Field Gel Electrophoresis (PFGE) and grouped in: A) genotypes found in isolates of swine only origin; B) genotypes found in isolates from both human and swine. We tested the virulence of 45 isolates from group A and B by invasion and replication assays in human INT-407 and swine IPEC-J2 cell lines. Group A isolates infect only IPEC-J2 cell-line while group B isolates infect both INT-407 and IPEC-J2. Whole-genome-sequencing analysis revealed 28 SNPs and 73 genes (56 chromosomal and 17 plasmidic) only present in group B isolates, but genes knockout or plasmid curing could not restrict the observed multi-host virulence. SNPs-based phylogenetic analysis showed that group A isolates cluster separately from group B, indicative of different evolutionary paths.

Conclusions

Our results suggest that multi-host virulence in S. Derby is not caused by gene gain, but more probably by SNPs allelic variation.

Pathogens / Pathogenicity - Part III

MUSHROOM HEALTH: A SYSTEMS APPROACH

T. Taparia[1,2], M. Krijger[1], M. Hendriks[1], C. Coipan[1], W. de Boer[2], J. van der Wolf[1]
[1]Wageningen University, Biointeractions and Plant Health, Wageningen, The Netherlands
[2]Neherlands Institute of Ecology, Department of Microbial Ecology, The Netherlands

Backgrounds

Mushroom cultivation is done on a substrate of sterilized compost over which a layer of casing soil is applied. It comprises of peat, limestone and chalk, and is rich in organic matter. Fruiting of mushroom bodies relies heavily on the dynamic interactions between Agaricus bisporus and other microbes present in this casing layer. However, various Pseudomonas species present in it cause bacterial blotch on the mushrooms caps, leading to severe economic losses.

Objectives

This study aims to identify key factors determining blotch outbreaks in mushroom cultivation. It involves development of diagnostic tools to study pathogen thresholds and population dynamics in the soil. It also aims to determine suppressiveness indicators of different casing soils against these pathogens.

Methods

Taqman PCRs were developed as quantitative detection methods for various blotch pathogens. Microbiome analysis of different casing soils was performed using amplicon targeted sequencing of the 16S and ITS regions. Mushrooms cultivation bioassay were performed to check blotch prevalence under varied biotic and abiotic conditions.

Conclusions

P. gingeri is a more aggressive pathogen for bacterial blotch than P. tolaasii. Their infection and population dynamics differ significantly in casing soils. Higher microbial biodiversity in casing soil seems to lead to lower native blotch prevalence. Microbiome analysis shows that physio-chemical properties of peat, and the other raw materials used in preparation of casing affect the inherent microflora of the casing soil.

Pathogens / Pathogenicity - Part III

IDENTIFICATION AND CHARACTERIZATION OF MYCOPLASMA FERIRUMINATORIS ISOLATES FROM ALPINE IBEXES: A NEW SPECIES VERY CLOSE TO MAJOR PATHOGENS OF DOMESTICATED RUMINANTS

C. Ambroset[1], C. Pau-Roblot[2], P. Gaurivaud[3], F. Tardy[3]
[1]VetAgro Sup, UMR Mycoplasmoses des ruminants, Marcy l'étoile, France
[2]Université de Picardie Jules Verne, Unité de Biologie des Plantes et innovation- EA 3900, Amiens, France
[3]Anses- Laboratoire de Lyon, UMR Mycoplasmoses des ruminants, Lyon, France

Backgrounds

The genus *Mycoplasma,* a group of free-living, wall-less prokaryotes gathers more than 100 species of which dozens are primary pathogens of humans and domesticated animals. Species isolated from wildlife are often understudied despite their potential role in mycoplasma overall evolutionary history. In 2013 several isolates from wild caprinae were tentatively assigned to a new species, *M. feriruminatoris*, characterized by an unusual fast growth in vitro and an important genetic proximity to ruminant pathogenic species. Recently in France, atypical isolates collected from Alpine ibexes were suspected to be *M. feriruminatoris.*

Objectives

This study was undertaken to check whether French ibexes isolates actually belong to the *M. feriruminatoris* species and further characterize them.

Methods

Phylogenetic analyses were performed to identify the isolates and explore their taxonomic position. The population diversity was characterized by genomic macrorestriction and by examining the capacity of different strains to produce capsular polysaccharides, a feature now known to vary amongst ruminant pathogenic species.

Conclusions

We reported the first isolation of *M. feriruminatoris* from Alpine ibexes in France. Phylogenetic analyses suggested that *M. feriruminatoris* might constitute the 4th species of a genetic cluster that contained so far only important ruminant pathogens. Despite their collection in a restricted region of the Alps, French isolates were not clonal, signifying an important diversity of the new species. Strains were able to produce concomitantly two types of capsular polysaccharides, β-(1→6)-galactan and β-(1→6)-glucan, with variation in their respective ratio, a feature never described so far in mycoplasmas.

Pathogens / Pathogenicity - Part III

CHARACTERIZATION OF MOLECULAR MECHANISMS ASSOCIATED WITH FLUOROQUINOLONE RESISTANCE IN MYCOPLASMA AGALACTIAE

J. Tatay-Dualde[1], M. Prats-van der Ham[1], C. de la Fe[1], A. Paterna[1], A. Sánchez[1], J.C. Corrales[1], A. Contreras[1], Á. Gómez-Martín[1]
[1]University of Murcia, Animal Health, Espinardo Murcia, Spain

Backgrounds

M. agalactiae is the main causative agent of contagious agalactia, a disease affecting small ruminants whose importance is due to its economic impact, mainly caused by a drop in milk production. Antimicrobial treatment is the main applied control measure against this disease. Quinolones are an effective group of antimicrobials inhibiting the growth of *M. agalactiae*, but in the last years, various reports have demonstrated an increase of resistance in field isolates due to its massive use. In this context, previous studies have proved the importance of *gyrA, gyrB, parC* and *parE* genes modifying quinolone susceptibility in other mycoplasma species. Nevertheless, the molecular mechanisms involved in the acquisition of quinolones resistance in *M. agalactiae* have not been elucidated yet.

Objectives

The aim of this study was to analyze the DNA variations which affect quinolone susceptibility in *M. agalactiae*.

Methods

Two field isolates (Ag280 and Ag310) and the reference strain of *M. agalactiae*, PG2 (NCTC 10123) were selected to obtain *in vitro* resistant mutants by serial passes at subinhibitory enrofloxacin, marbofloxacin and moxofloxacin concentrations. Afterwards partial sequences of their *gyrA, gyrB, parC* and *parE* genes were analyzed.

Conclusions

Changes related to variations in quinolones susceptibility were found in *gyrB, parC* and *parE*. Besides, *parC* was the first gene showing alterations when changes in susceptibility to quinolones occurred. Thus, this gene is the most suitable target for a rapid study of quinolone resistance in field isolates of *M. agalactiae***.**

Pathogens / Pathogenicity - Part III

MOLECULAR CHARACTERIZATION OF MYCOPLASMA MYCOIDES SUBSP. CAPRI FIELD ISOLATES FROM SPAIN

J. Tatay-Dualde[1], M. Prats-van der Ham[1], C. de la Fe[1], Á. Gómez-Martín[1], A. Paterna[1], J.C. Corrales[1], A. Contreras[1], A. Sánchez[1]
[1]University of Murcia, Animal Health, Espinardo Murcia, Spain

Backgrounds

Mycoplasma mycoides subsp. capri (Mmc) is one of the main causative agents of caprine contagious agalactia. Besides, the absence of accurate control methods eases its spread between different herds within endemic areas. In this context, the possible dispersion of the agent towards different herds due to asymptomatic carriers highlights the need of molecular typing schemes which offer robust and reproducible epidemiological
information. From all the methods available nowadays, multilocus sequence typing (MLST) is the most suitable technique for genotyping bacterial isolates,
as it allows unambiguous and highly reproducible strain discrimination.

Objectives

The aim of this study was to assess the genetic variability of different strains of Mmc from a contagious agalactia endemic area through multilocus sequence typing.

Methods

For this purpose, five house-keeping genes (*fusA, glpQ, gyrB, lepA, rpoB*) from 39 field isolates were analyzed. These isolates were obtained from different geographic areas of Spain, between the years 2004 and 2015. The partial sequences of the reference strain PG3,
which are available at GenBank, were also studied.

Conclusions

Our study proved a higher
genetic variability in Mmc populations than in other contagious agalactia causing mycoplasmas, such as *M. agalactiae*. Despite the significant differences found between
the assessed field isolates, they could be classified according to their geographical origin. Moreover, it was also possible to detect genetic differences between Mmc strains coming from the same herd at the same sampling time, which may need to be taken into consideration when designing or arranging prophylactic strategies.

Acknowledgements

This study was funded by project AGL2013-44771-R awarded by the Spanish Ministry of Economy, government of Spain, and co-financed by FEDER funds.

Pathogens / Pathogenicity - Part III

HELICOBACTER PYLORI SECRETED PROTEIN HP1286 TRIGGERS APOPTOSIS IN MACROPHAGES VIA ERK-MAPK-DEPENDENT PATHWAYS

R. Tavares[1], *S. Pathak*[1]
[1]*Stockholm University, Molecular Biosciences- The Wenner-Gren Institute, Stockholm, Sweden*

Backgrounds

Helicobacter pylori is a Gram-negative bacterium known to selectively colonize the human gastric mucosa of more than 50% of the world's population. Considering the non-invasive nature of *H. pylori*, secreted proteins are believed to play an important role in the bacterial survival and ultimately disease development.
Macrophages constitute a powerful line of defense against *H. pylori*. The final disease outcome is highly dependent on the bacterial ability to modulate the effector functions of activated macrophages.

Objectives

Investigate the role of *H. pylori* secreted protein HP1286 in the regulation of macrophage responses.

Methods

Eight different *H. pylori* strains were tested for recombinant purified HP1286 (rHP1286) expression. Primary human monocyte-derived macrophages (MDM) and macrophage cell lines (RAW 264.7, THP-1) were used for the cell assays. Binding assays and measurement of apoptosis were determine using LSRFortessa flow cytometer. Caspase 3 activation was measured using the Caspase 3/7 activity assay. Activation of TNF and ERK MAPK signalling pathways were verified by immunoblotting.

Conclusions

Exposure to rHP1286 induced apoptosis in macrophages in a time-and dose-dependent manner. Although interaction of rHP1286 was observed for several other cell types, rHP1286 failed to induce apoptosis under similar conditions, indicating a macrophage-specific effect of the protein. rHP1286 induced activation of caspase 3 and ERK MAPK signaling pathways. These results provide functional insight into the potential role of HP1286 during *H. pylori* infection. Considering the ability of HP1286 to induce macrophage apoptosis, the protein could possibly help in the bacterial escape from activated macrophages and persistence in the stomach.

Pathogens / Pathogenicity - Part III

EFFECTS OF LEMONGRASS OIL ON MULTISPECIES ORAL BIOFILM FORMATION IN VITRO

S. Taweechaisupapong[1], W. Pinsuwan[2], W. Suwannarong[3], W. Khunkitti[4]
[1]Faculty of Dentistry- Khon Kaen University,
Biofilm Research Group and Department of Oral Diagnosis, Khon Kaen, Thailand
[2]Faculty of Dentistry- Khon Kaen University, Biofilm Research Group, Khon Kaen, Thailand
[3]Faculty of Dentistry- Khon Kaen University,
Department of Periodontology and Biofilm Research Group, Khon Kaen, Thailand
[4]Khon Kaen University, Faculty of Pharmaceutical Sciences, Khon Kaen, Thailand

Backgrounds

Cymbopogon citratus (lemongrass) oil is a volatile oil obtained from the lemongrass leaves. Lemongrass oil (LG) is mainly composed of citral, a natural mixture of geranial and neral and some myrcene, geraniol and geranyl acetate which is a potential natural biocide for use as a disinfectant. It was reported to exhibit antibacterial activity towards periodontal pathogens, such as *Porphyromonas gingivalis* and *Aggregatibacter actinomycetemcomitans*. However, there is no report on inhibitory effects of LG against subgingival biofilm formation.

Objectives

The purpose of this study was to investigate the inhibitory effects of LG on subgingival biofilm formation using an *in vitro* model.

Methods

Subgingival plaque samples from 5 periodontitis patients were cultivated in saliva-coated 96-well microtiter plates in the presence of LG at concentrations 1 - 6 µl/ml under anaerobic atmosphere at 37°C for 2, 4 and 8 days by replacing every 2 days with fresh medium alone or LG-containing medium. Biofilm formation was determined quantitatively by crystal violet staining.

Conclusions

The results showed that LG exhibited more than 70% anti-biofilm activity at 6 µl/ml. These results revealed that LG is able to inhibit *in vitro* subgingival biofilm formation and suggest potential for developing LG as a natural oral hygiene product against oral infection in people.

SUBCELLULAR LOCATION OF CANDIDATE EFFECTOR PROTEINS FROM SPORISORIUM SCITAMINEUM, THE CAUSAL AGENT OF SUGARCANE SMUT

N. Teixeira-Silva[1], P. Schaker[1], S. Dinesh-Kumar[2], C. Monteiro-Vitorello[1]
[1]University Of Sao Paulo / Luiz de Queiroz College of Agriculture, Genetics Department, Piracicaba, Brazil
[2]University of California - Davis, Department of Plant Biology, Davis, USA

Backgrounds

Sugarcane is one of the most valuable crops worldwide mostly due to the great economic value of its subproducts. The production of sugarcane can be affected by many diseases including smut, caused by the biotrophic fungus *Sporisorium scitamineum*. Disease establishment is fully dependent on the environmental conditions and the sugarcane genotype, leading to the emission of a whip like structure responsible for teliospores spreading in the late stages. A previous analysis of the pathosystem using dual RNAseq-based transcriptome uncovered the expression of genes coding for candidate effectors.

Objectives

This work aimed to determine the subcellular plant compartment targeted by four *S. scitamineum* candidate effectors most expressed in early interaction using transient expression assay in *N. benthamiana*.

Methods

The coding sequence of mature protein was cloned to obtain candidate effector-green fluorescent protein (Citrine) fusions downstream of a 35S promoter in an *Agrobacterium tumefaciens* binary vector. The fusion proteins were transiently expressed by agroinfiltration and their accumulation in leaf cells was determined by confocal microscopy and immunoblots.

Conclusions

All proteins accumulated at detectable levels. Results revealed that *S. scitamineum* candidate effectors encode proteins which target various plant compartments, such as cytosol, membrane and nucleus, and some of them seems to undergo post-translational modifications. Further analysis will be performed in order to define the potential role of these proteins within host cells during disease establishment.

Pathogens / Pathogenicity - Part III

STREPTOCOCCUS SUIS WITH HAEMOLYTIC ACTIVITY INDUCES CASPASE-1-DEPENDENT PYROPTOSIS IN HUMAN MONOCYTES

H. Thananchai[1], *J. Khikhuntod*[1], *K. Duangsonk*[1], *M. Deeudom*[1]
[1]*Faculty of Medicine - Chiang Mai University, Microbiology, Chiang Mai, Thailand*

Backgrounds

Pyroptosis is an inflammatory cell death which play an essential role in controlling intracellular infection. Recently, there are several studies reported that pore-forming toxin from gram positive bacteria can induce pyroptosis in many cell types. However, the pyroptotic induction by *Streptococcus suis* that also produce pore-forming toxin namely suilysin has not been identified.

Objectives

To investigate whether *S.suis* can induce pyroptosis in U937 human monocytic cell line.

Methods

U937 cell line was infected with nine clinical *S. suis* serotype 2 strains isolated from infected Northern Thai individuals and one reference stain from diseased pig (P1/7). Pyroptotic cells were determined by using fluorescent labeled inhibitors of caspase (FLICA)-1 flow cytometry assay.

Conclusions

We found that three live *sly*+ *S. suis* strains and P1/7 strain could activate caspase-1 and induce pyroptosis in U937 cell line. In addition, the activation of caspase 1 by *S.suis* was not resulted from K+ efflux. Although the level of suilysin production was not measured, we observed that the ability to induce pyroptosis by *S. suis* was correlated with their haemolytic activity. Taken together, our results suggested that *S. suis* with haemolytic activity can induce pyroptosis in U937 human monocytic cell line. It is likely that suilysin or other components might be involved in caspase 1 activation. Further identification of the effector mechanism that play a role in pyroptotic induction may contribute to better understanding of the pathogenesis of *S. suis* infection.

Pathogens / Pathogenicity - Part III

COMPETITIVE FITNESS OF CLOSTRIDIUM DIFFICILE STRAINS

V. Tkalec[1], *M. Rupnik*[1,2]
[1]*National Laboratory of Health- Environment and Food, Department for Microbiology Research, Maribor, Slovenia*
[2]*University of Maribor- Faculty of Medicine, Department of Microbiology, Maribor, Slovenia*

Backgrounds

Clostridium difficile is the leading cause of nosocomial gastrointestinal infections. There are currently over 500 *C. difficile* PCR ribotypes known and some, including 014/020, are more frequently encountered than others. Common PCR ribotypes have been associated with certain phenotypic properties, however data on their competitive fitness are sparse.

Objectives

The objective of our study was to evaluate growth competition between 014/020 strains and strains of less common and rare PCR ribotypes.

Methods

Altogether five *C. difficile* strains of 014/020 (n=2), less common 002 (n=1) and rare PCR ribotypes (n=2) were included. Differences in levofloxacin minimal inhibitory concentrations (mg/L) were used to differentiate strains after co-culturing. Pairs of strains were mixed in 1:1 ratio and diluted in fresh BHIS broth. Dilution was repeated after every 24 hours for up to ten cycles. The number of viable cells for each of two strains was determined by selective plating at the end of every cycle. Competitive indices (CI) were calculated by standard methodology.

Conclusions

In this study, no apparent competitive advantage was observed for 014/020 strains in comparison to other less endemic strains. Interestingly, an oscillatory pattern in proportion of two strains was observed for some co-cultures while in one pair of strains no differences in CI were observed during first few passages, but later rare strain always outcompeted 014/020 strain.

DEVELOPMENT AND VALIDATION OF A BIOLUMINESCENT BSL2 SURROGATE MODEL FOR EARLY ANTITUBERCULOSIS DRUG SCREENING

E. Torfs[1], M. Bidart de Macedo[1], F. Cools[1], B. Vanhoutte[1], L. Maes[1], G. Caljon[1], P. Delputte[1], P. Cos[1], D. Cappoen[1]
[1]University of Antwerp, Laboratory of Microbiology- Parasitology and Hygiene LMPH, Wilrijk - Antwerp, Belgium

Backgrounds

Tuberculosis (TB), an ancient infectious disease caused by *Mycobacterium tuberculosis*, still remains a major threat for global health. In 2015, there were an estimated 10.4 million new TB cases worldwide and an estimated 1.4 million people died from TB. Despite the intensive efforts to eradicate TB, there is still an urgent need for the development of novel TB drugs to address the current TB epidemic in an efficient manner. To facilitate early drug screening by avoiding the use of the highly infectious and slow-growing pathogen, a less pathogenic and faster growing surrogate model could be used instead.

Objectives

In this study, we compared different *in vitro* characteristics of a panel of seven *Mycobacterium* species and developed a luminescent reporter strain to generate a rapid and convenient surrogate model for early screening processes.

Methods

The strains were compared for their (a) *in vitro* growth, (b) *in vitro* susceptibility to a range of first- and second-line TB drugs, and (c) potential to survive and multiply inside macrophages using a RAW246.7 cell line as a surrogate for primary immune cells. Finally, a bioluminescent reporter strain was developed by electroporation of the mycobacterial strains with the pSMT1 plasmid, containing the *luxAB* genes of *Vibrio Harveyi*, for a more convenient readout of screening processes.

Conclusions

Based on the comparison of the *in vitro* characteristics of the different *Mycobacterium* species, a faster growing, bioluminescent surrogate model was developed and validated for the early screening of compounds and compound libraries with potential anti-TB activity.

DISTRIBUTION OF TRIMETHOPRIM RESISTANCE GENES IN CHILEAN SHIGELLA SONNEI ISOLATES

C. TORO[1], C. García[1], L. Cádiz[1], M.T. Ulloa[1], G. Hermosilla[1], J.C. Salazar[1]
[1]Facultad de Medicina- Universidad de Chile- ICBM, Programa de Microbiología y Micología, Santiago, Chile

Backgrounds

The most common mechanism of trimethoprim (TMP)-resistance is the acquisition of dihydrofolate reductase enzyme insensitive to this drug. Previous molecular characterization of TMP-genes resistance in Chilean isolates of *S. sonnei* looking for *dfrA1*, *dfrA8* and *dfrA14*, showed solely the presence of *dfrA8* in strains isolated before 2009. However, during this year *dfrA14*-positive strains were detected, and after that between 2010-2013 *dfrA1* were detected mostly associated to class 2 integron. These genetic markers were absent in one TMP-resistance *S. sonnei* strain. Sequencing the genomic DNA of this strain allowed to identify the *dfrA15* allele.

Objectives

To identify the distribution of *dfrA1*, *dfrA8*, *dfrA14* and *drfA15* TMP-resistance genes in chilean *S. sonnei* strains isolated between 2009-2013.

Methods

Presence of TMP resistance genes was determined in 212 *S. sonnei* isolates, 28 from them were TMP-sensitive strains. Conventional PCR was conducted to detect the four TMP-resistance genes mentioned above, and class integron. Tiling PCR was used to characterize the genetic organization of class 2 integron. Clonality was analyzed by PFGE.

Conclusions

dfrA14 was present as the only TMP-resistance marker in 52% of strains, *dfrA15* was present in 33% (71/212) and 52 of them coded for *dfrA1* and *dfrA15*, meanwhile 13% do not harbour TMP resistance genes, being all of them sensitive to TMP. Strains harboured *dfrA1-dfrA15* linked to the presence of class 2 integron and most of them clustered in a nearly clonal group by PFGE. This distribution also correlated with the isolation period, showing a dynamics of trimethoprim genetic markers prevalent in Chilean *S. sonnei* strains.

THE SEARCH FOR NEW TREATMENT OPTIONS AGAINST BURKHOLDERIA PSEUDOMALLEI

A. Torres[1], *B. Ross*[1], *J. Myers*[1], *G. Pradenas*[1], *L. Muruato*[1], *D. Tapia*[1]
[1]*UTMB, Microbiology and Immunology, Galveston, USA*

Backgrounds

Burkholderia pseudomallei is the causative agent of melioidosis. Aside from being a Tier 1 select agent due to its availability and ease to be aerosolized, it is a multidrug-resistant pathogen that was estimated to cause human infections and deaths worldwide. Treatment of *B. pseudomallei* usually involves long and tedious antibiotic treatment that last several weeks/months. However, even with treatment, infection relapse occurs in approximately 1 in 16 patients as *B. pseudomallei* is able of establishing a latent infection.

Objectives

Here, we used a library of 400 FDA approved compounds as part of the Pathogen Box to screen for compounds that can inhibit or kill *B. pseudomallei.*

Methods

After identifying six inhibitory compounds (Levofloxacin, Rifampicin, Auranofin, Miltefosin, and two pentaminidine analogs MMV688271 and MMV688179, we determined their MIC and MIC_{50} and determined their bacteriostatic or bactericidal properties. We also tested the ability of the bacteria to persist a supralethal dose of each compound. Further, we tested the effectiveness of the compounds in a murine model of melioidosis infection monitoring colonization and dissemination using *B. pseudomallei* K96243 strain.

Conclusions

Although the compounds did not provide as much protection as current treatments, there is evidence to suggest that improving route, dose, and solubility of MMV68827 and MMV68817 will result in more viable treatments that could help combating melioidosis infections.

COMPARISON AND ENZYMATIC CHARACTERIZATION OF TYPE VD PATATIN-LIKE LIPASES

T. Trunk[1], J.P. Morth[2], D.J. Slade[3], J.C. Leo[1]
[1]University of Oslo, Department of bioscience, Oslo, Norway
[2]University of Oslo, Centre for Molecular Medicine, Oslo, Norway
[3]Virginia Polytechnic Institute and State University, Department of Biochemisttry, Blacksburg, USA

Backgrounds

Type V secretion systems and lipases of the patatin-like family have been shown to be important virulence factors in certain bacteria. *Pseudomonas aeruginosa* expresses a recently described type Vd secretion system with a C-terminal β-barrel for transmembrane transport and a N-terminal passenger domain, called patatin-like protein D (PlpD). The PlpD passenger domain displays an α/β hydrolase fold common for lipases with a catalytic Ser-Asp dyad. Once transported across the outer membrane, the passenger domain is cleaved of and forms homodimers in the extracellular space.

Objectives

The objective of this study is the characterization of the patatin-like lipase of *P.aeruginosa*, investigating the role of PlpD during *Pseudomonas* infection as well as the role of PlpD dimerization in enzyme activity and its comparison to PlpD homologues found in other bacteria (*Aeromonas hydrophila, Burkholderia pseudomallei, Fusobacterium nucleatum, Ralstonia solanacearum*, *Vibrio cholera*).

Methods

PlpDs role in the infection process will be tested via leaf infiltration assays in *Arabidopsis thaliana*, as well as in the zebrafish embryo model, employing light, fluorescence and electron microscopy. The potential direct toxic effect on mammalian cells will also be tested. The role of dimerization will be investigated using crosslinking, size exclusion chromatography and by disruption of the dimerization interface via targeted mutagenesis.

Conclusions

Characterization of the lipase and its role in infection will contribute to understanding and counteracting the pathogenesis of *Pseudomonas*. Furthermore, comparison of the activities and specificities of PlpD homologues will reveal functional differences between the lipases of the individual pathogens and contribute to understanding differential mechanisms of pathogenesis.

TO DISCUSS THE VANCOMYCIN MINIMAL INHIBITORY CONCENTRATION DATA ON METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS IN BACTEREMIA

S.Y. Tsai[1], C. Fu-Chieh[2], L. Chon-Fu[3], L. I-Hong[1], H. Cheng-Wei[1], H. Yan-Jiun[1], C. Yi-Ting[1], K. Chien-Feng[4]
[1]Mackay Memorial Hospital, Department of Laboratory Medicine, Taipei, Taiwan R.O.C.
[2]Mackay Memorial Hospital, Infection control center, Taipei, Taiwan R.O.C.
[3]Macao Centro Hospitalar Conde de Sao Januario, Centro Hospitalar Conde de Sao Januario, Macau, Macau
[4]Mackay Memorial Hospital, Department of Infectious Disease, Taipei, Taiwan R.O.C.

Backgrounds

Vancomycin, the first line antibiotic for Methicillin-resistant Staphylococcus aureus(MRSA) bacteremia, is indicated inappropriate to administer when MIC greater than 2ug/mL, including 'susceptible' strains. Therefore, MIC should be accurately identified to avoid inappropriate antibiotic use.

Objectives

The study aims to investigate if other tests are necessary to improve the accuracy of a MIC result.

Methods

We collected 216 strains of MRSA since 2009 to 2015 and then used three methods, including auto-machine method (Vitek II), E-test and microdilution to assess the MICs of Vancomycin for the different strains of MRSA. The chi-squared test is used to determine whether there is a significant difference between the two different methods.

Conclusions

According to the MICs detected by Vitek II, 28, 95, and 93 strains had MICs of 2, 1, and 0.5 respectively. Using E-test and microdilution, only 198 strains and 195 strains showed consistent MICs, respectively. Only 15 of 28 strains, whose MIC was 2 as per Vitex II, were consistent with the results in E-test and microdilution. The proportion of MIC=2 detected from the Microdilution test was only 6.94% whereas the proportion from the Vitek II was 12.96%. The difference in proportions is significant, $\chi^2(1, N = 216) = 4.37$, $p = 0.037$. But the detection rate between E test (6.94%) and Microdlilution test(6.94%) were not statistically significant ($p = 1.00$).
Sum up, we suggest that in the setting of MRSA bacteremia, a Vancomycin MIC of 2ug/ml by Vitek II analysis should be confirmed by E-test and microdilution to avoid improper use of antibiotics.

Pathogens / Pathogenicity - Part III

RV0089: DOES IT HAVE A ROLE IN GROWTH AND PATHOGENESIS OF M. TUBERCULOSIS?

G. Tyagi[1], P. Singh[1], R. Sinha[1], N. Sharma[1], M. Bose[1], M. Varma-Basil[1]
[1]Vallabhbhai Patel Chest Institute- University of Delhi, Microbiology, Delhi, India

Backgrounds

Biotin is an essential micronutrient required by all domains of life. In *Mycobacterium tuberculosis* it acts as a cofactor for many essential enzymes. It has been shown that exogenous biotin present in the host serum is not sufficient for bacterial growth, hence *M. tuberculosis* synthesizes biotin on its own.

Objectives

To understand the role of *Rv0089* gene in biotin biosynthesis & its effect on lipidomic profile, pathogenicity and biotin concentration in *Mycobacterium tuberculosis.*

Methods

pKO vector was used for the construction of a knockout strain *Mtb∆Rv0089* using allelic replacement method. It was grown on Sauton's medium with or without biotin for growth kinetic, stress, colony morphology & electron microscopic studies. Lipid quantification and lipidomic profiles were studied using the phosphovanillin assay and Thin Layer Chromatography (TLC) respectively. RAW 264.7 cell line was infected with *Mtb∆Rv0089* and H37RV. Immunoprecipitation was performed to quantify the biotinylated proteins in recombinant strain.

Conclusions

Deletion of *Rv0089* gene rendered the bacteria with a stationary phase growth defect and altered colony morphology. *Mtb∆Rv0089* had lower lipid content as compared to H37Rv. Addition of biotin improved the lipid composition and cell wall dynamics of *Mtb∆Rv0089*. The mutant was attenuated in macrophages and had a lower concentration of biotinylated proteins. **The results suggest that *Rv0089* gene facilitates the survival of *M. tuberculosis* during stationary phase and is required when there is no exogeneous biotin present in the medium.**

Pathogens / Pathogenicity - Part III

SALMONELLA TYPHIMURIUM VIRULENCE FACTORS SOPB, SPTP AND PPHB CONTRIBUTE TO EVASION OF AUTOPHAGY IN THE AMOEBA DICTYOSTELIUM DISCOIDEUM AND RAW264.7 MACROPHAGES

I.M. Urrutia[1], B. Salas[1], C. Valenzuela[1], P. Fernandez[1], S.A. Álvarez[1], R. Escalante[2], C.A. Santiviago[1]
[1]Laboratorio de Microbiología- Universidad de Chile,
Departamento de Bioquímica y Biología Molecular, Santiago, Chile
[2]Instituto de Investigaciones Biomédicas "Alberto Sols" CSIC-UAM,
Departamento de Modelos Experimentales de Enfermedades Humanas, Madrid, Spain

Backgrounds

Autophagy plays a crucial role during infection acting as a defense mechanism against intracellular pathogens. As a consequence, many bacterial pathogens have developed the ability to evade this process. Autophagy is regulated by several intracellular signaling pathways, such as those linked to MAPK and PI3K/AKT/mTORC1. In these pathways, activation of MAPK and/or mTORC1 results in the repression of autophagy.

Objectives

In these work, we evaluated the contribution of *S*. Typhimurium virulence factors SopB, SptP and PphB in the evasion of autophagy in *Dictyostelium discoideum* and RAW264.7 macrophages. SopB is a phosphatidylinositol phosphatase that activates AKT, SptP has a tyrosine phosphatase domain that inactivates Erk, and PphB is a non-characterized hypothetical serine-threonine phosphatase.

Methods

We constructed mutant strains Δ*sopB*, Δ*sptP* and Δ*pphB* derived from *S*. Typhimurium 14028s, and performed infection assays using *D. discoideum* and RAW264.7 macrophages at a multiplicity of infection of 1000 bacteria/cell. After 1 h of infection, total protein fractions obtained from infected cells were subjected to western blot using antibodies against mTOR, p-mTOR and LC3 proteins, classic autophagy markers.

Conclusions

Our results in RAW264.7 suggest that virulence factors SopB and PphB contribute to *S*. Typhimurium evasion of autophagy, while SptP promotes this process. We are currently evaluating the contribution of SopB, SptP and PphB in the *S*. Typhimurium evasion of autophagosome-lysosome fusion in *D. discoideum* and RAW264.7 by confocal microscopy using cells expressing RFP-GFP-LC3 constructs.

COMPARATIVE GENOTYPING AND PHENOTYPING OF ASPERGILLUS FUMIGATUS ISOLATES FROM HUMANS, DOGS AND THE ENVIRONMENT

I. Valdes[1], J. van den Berg[1], A. Haagsman[2], N. Escobar[1], F. Hagen[3], P.J. Haas[4], J. Houbraken[5], H. Wösten[1], H. de Cock[1]
[1]Utrecht University, Microbiology, Utrecht, The Netherlands
[2]Utrecht University, Veterinary Medicine, Utrecht, The Netherlands
[3]Canisius-Wilhelmina Hospital, Medical Microbiology and Infectious Diseases, Nijmegen, The Netherlands
[4]UMC Utrecht, Medical Microbiology, Utrecht, The Netherlands
[5]CBS-KNAW Fungal Biodiversity Centre, Applied and Industrial Mycology, Utrecht, The Netherlands

Backgrounds

Aspergillus fumigatus is a ubiquitous saprotrophic fungus and an opportunistic pathogen in humans and dogs and because of its ubiquity, hundreds of *A. fumigatus* spores are inhaled on a daily basis. In most cases, the inhalation of spores is harmless but in humans, with an immunodeficiency, an invasive form of pulmonary aspergillosis (IPA) can develop which have a mortality rate of 50% or higher. *A. fumigatus* can cause also non-invasive sino-nasal aspergillosis (SNA) in immunocompetent dogs.

Objectives

Here a comparative phenotypic and genetic analysis of *A. fumigatus* isolates from canine SNA, clinical isolates from humans and environmental isolates from the air was performed to find out if inherent differences between the three groups can be found and to possibly determine what characteristics enable strains of *A. fumigatus* to infect dogs or humans.

Methods

Tandem repeats in the cyp51A gene, sequencing of calmodulin (*caM*),beta-tubulin(*benA*) genes as well as microsatellite(STR*Af*) analysis were performed in order to detect genetic differences within isolates. Results showed that that dogs with SNA are infected by one genotype only whereas human patients are infected by various genotypes.Interestingly, phenotypic analysis indicated that the isolates from dogs are most variable in growth speed and morphology as compared to human and environmental isolates. K-means clustering of the measurements of colony growth in several media showed three different clusters, one of then contain mainly *A.fumigatus* isolates from dog patients while the other two were composed by a mixture of human and environmental isolates

Conclusions

Our observation shows that canine isolates are phenotypically more diverse that their environmental and human counterparts. The basis of this heterogeneity might be due to genomic differences or epigenetic variations that occur during the infection process in dogs. Our results suggest that the canine isolates might represent a subgroup of *A. fumigatus* that are responsible for SNA.

Pathogens / Pathogenicity - Part III

METHYLOME OF RALSTONIA SOLANACEARUM AND TRANSCRIPTOMIC CHANGES DURING POTATO INFECTION

M. Puigvert[1], N. Sánchez-Coll[1], R. Guarischi[2], I. Erill[3], A. Macho[4], J. Setubal[2], M. Valls[1]
[1]Universitat de Barcelona, CRAG, BARCELONA, Spain
[2]Universidade de Sao Paulo, Biochemistry, Sao paulo, Brazil
[3]University of Maryland Baltimore County, Biological Sciences, Baltimore, USA
[4]Shanghai Center for Plant Stress Biology, PSC, Shangai, China

Background

Ralstonia solanacearum is a ß-proteobacterium that causes bacterial wilt on important crops such as tomato and potato. *R. solanacearum* survives in soil and waterways, infects plants through the roots, migrates apoplastically and finally multiplies extensively in the xylem vessels causing plant death.

Objectives/Methods

Here, we have determined and compared the methylomes of two *R. solanacearum* strains. We have also analyzed the transciptome of strain UY031 at diffferent stages of potato colonisation.

Conclusions

Novel methylation motifs were identified, one of them associated with a DNA methylase unique to strain UY031. In addition, some virulence loci were hyper- or hypo-methylated, suggesting that methylation may modulate their expression.

We detected expression for >90% *R. solanacearum* genes both from isolated bacteria or *in silico* selected transcripts sequenced from infected plant tissues. Global transcriptional profiling provided insight into the intercellular environment encountered by this plant pathogen and the carbon and energy sources it utilizes during plant infection. Differential expression of the type three secretion system and its associated effectors was observed at various potato colonization stages. In addition, we identified several *R. solanacearum* genes that are significantly up-regulated during infection but had not been previously identified as virulence factors. This work will help identifying bacterial genes that are key for successful plant infection, which can be targets for novel antibacterial drugs.

GENOMIC, METABOLIC AND IN PLANTA TRANSCRIPTOMIC COMPARISON OF THE POTATO SOFT ROT ENTEROPATHOGENS DICKEYA SOLANI AND DICKEYA DIANTHICOLA

F. Van Gijsegem[1], J. Pédron[2], D. Faure[3], Y. Raoul des Essart[4]
[1]INRA, iEES - Institute of Ecology and Environmental Sciences, PARIS, France
[2]UPMC, iEES-Institute of Ecology and Environmental Sciences of Paris, PARIS, France
[3]CNRS, Institute for Integrative Biology of the Cell - I2BC, Gif-sur-Yvette, France
[4]CNRS, Institute for Integrative Biology of the Cell - I2BC, Gif-sur-Yvette, France

Backgrounds

In potato cultures, the 4th main food crop worldwide, blackleg and soft rot caused by soft rot enterobacteria is one of the most devastating diseases. In addition to the endemic *Pectobacterium* populations, two *Dickeya* species (*D. dianthicola* and *D. solani*) emerged successively and recently in potato cultures in Europe though *Dickeya* populations were, initially, considered to be restricted to tropical and subtropical areas.

Objectives

To explore the role of the *D. dianthicola* and *D. solani* species traits in their ecological fitness and to acquire knowledge on the regulation of virulence in these pectinolytic enterobacteria, we undertook comparative genomic, metabolic and in planta transcriptomic analyses of one potato field-isolate of each species.

Methods

Definition of common and strain-specific genes was achieved using Blast analysis, metabolic capabilities using Biolog plates. Gene expression profiles after in vitro growth or tuber infection were determined by RNAseq.

Conclusions

D. solani and *D. dianthicola* genomes are highly syntenic. Both genomes only harbour a few hundred genes present in only one of the two species. These species-specific genes are often clustered in genomic regions and most of them regroup genes that are predicted to be involved in metabolism/transport. The expression of several of these species-specific genes is modulated *in planta* as compared to *in vitro* bacterial growth pointing to an involvement in plant-bacteria interactions. A differential modulation of several genes that are common to both species was also observed *in planta*. This highlights the importance of regulatory networks in the diversity of related strains/species in their interaction with their hosts.

Pathogens / Pathogenicity - Part III

ESSENTIAL OIL AND POSTDISTILLATION WASTE OF JUNIPERUS COMMUNIS IN BIOCONTROL OF OPPORTUNISTIC PATHOGEN CANDIDA ALBICANS

B. Vasilijević[1], A. Paunkov[1], J. Knežević-Vukčević[1], D. Mitić-Ćulafić[1], S. Cvetković[1], D. Orčić[2], M. Franciškovič[2], B. Nikolić[1]
[1]University of Belgrade- Faculty of Biology, Chair of Microbiology, Belgrade, Serbia
[2]University of Novi Sad Faculty of Sciences,
Department of Chemistry- Biochemistry and Environmental Protection, Novi Sad, Serbia

Backgrounds

Candida albicans is a benign member of the gut microbiome of healthy individuals. However, the disturbance of balance in gut microbiome in immunocompromised patients can result in uncontrolled growth of *C. albicans* and lead to invasion of deeper mucosal tissue or dissemination to other organs; eventually it can enter to the bloodstream and induce systemic infections. The increasing resistance to antifungal compounds directed investigation to search for therapeutic alternatives among aromatic and medicinal plants. Among others, *Juniperus communis* is interesting for its antimicrobial properties but its anticandidial activity was only scarcely investigated.

Objectives

The aim of this study was to examine the anticandidial and antiadhesive properties of Serbian wild-growing *J. communis* var. *saxatilis* essential oil (EO) and postdistillation waste (PDW).

Methods

MIC assay on *C. albicans* ATCC10231 was used to determine MIC/MFC values, while checkerboard assay was used to determine the mode of action in binary combinations of EO/PDW with commercial fungicide bifonazole. The *in vitro* adhesion assay with EO and PDW was performed using human colon epithelial cancer HT-29 cell line.

Conclusions

MIC and MFC values of EO were determined at 12.5mg/mL, while binary combination of EO with bifonazole showed additive effect. Although effect of PDW was weaker (MIC at 25 mg/mL), in checkerboard assay it induced synergistic effect with bifonazole. In adhesion assay only EO showed notable potential to reduce pathogen colonization (72% inhibition). This preliminary work showed that *J. communis* EO and PDW could inhibit growth and adherence of *C. albicans*.

Pathogens / Pathogenicity - Part III

ANTIFUNGAL EFFECT OF JUNIPERUS COMMUNIS ESSENTIAL OIL AND POSTDISTILLATION WASTE AGAINST SELECTED MICROMYCETES

B. Vasilijević[1], A. Paunkov[1], B. Nikolić[1], D. Orčić[2], M. Franciškovi[2], A. Džamić[3], D. Mitić-Ćulafić[1], J. Knežević-Vukčević[1], A. Ćirić[4]
[1]University of Belgrade- Faculty of Biology, Chair of Microbiology, Belgrade, Serbia
[2]University of Novi Sad Faculty of Sciences,
Department of Chemistry- Biochemistry and Environmental Protection, Novi Sad, Serbia
[3]University of Belgrade - Faculty of Biology, Institute of Botany and Botanical Garden "Jevremovac", Belgrade, Serbia
[4]University of Belgrade - Institute for Biological Research "Siniša Stanković",
Department of Plant Physiology, Belgrade, Serbia

Backgrounds

Taking into account the occurrence of micromycetes in the environment and food products, their potential toxicity and pathogenicity, the importance of their control is evident. Synthetic substances targeting plant fungal pathogens frequently produce toxic residues which contaminate environment and poison foodstuff and feedstuff. In addition, occurrence of fungicidal resistance to conventional antimycotics is growing. To overcome the problem biological control systems frequently based on phytochemicals are developing. Literature data indicate that *Juniperus communis* essential oil (EO) possesses antifungal capacity, but its postdistillation waste (PDW) has not been previously tested.

Objectives

The aim of this study was to compare the antifungal effect of Serbian wild-growing *Juniperus communis* var. *saxatilis* EO and PDW against *Aspergillus*, *Trichoderma* and *Penicillium* species.

Methods

The chemical composition of EO and PDW was determined using GC-MS and LC-MS/MS analyses, respectively. *In vitro* microdilution assay was used to determine the minimal inhibitory (MIC) and minimal fungicidal (MFC) concentrations.

Conclusions

Chemical analysis revealed α-pinene, sabinene and δ-cadinene as dominant constituents of EO. On the other hand rutin, quinic acid, catechin and epicatechin were abundantly presented in PDW. EO possessed only inhibitory activity with MIC of 12.5 mg/mL for all tested strains. However, antifungal potential of PDW was remarkably higher, with MIC and MFC values obtained in the ranges 0.112-0.9 mg/mL and 0.225-0.9 mg/mL, respectively. The most sensitive was *Aspergillus versicolor*. Obtained results showed high antifungal potential of PDW and direct research to its further investigation as potent antimycotic agent.

CSL2, A NOVEL CHIMERIC LYSIN TO FIGHT INFECTIONS CAUSED BY THE EMERGING ZOONOTIC PATHOGEN STREPTOCOCCUS SUIS

R. Vázquez[1], M. Domenech[1], M. Menéndez[2], P. García[1]
[1]Centro de Investigaciones Biológicas CSIC, Molecular Microbiology and Infection Biology, Madrid, Spain
[2]Instituto de Química Física Rocasolano IQFR-CSIC, Química Física Biológica, Madrid, Spain

Backgrounds

Abuse and misuse of antibiotics have favored the selection and spread of multiresistant bacterial strains, leading to an alarming situation for severe infections treatment. Thus, development of alternative antimicrobial agents, such as bacteriophage –encoded endolysins (or enzybiotics), should nowadays be a priority. *Streptococcus suis* is an emerging zoonotic pathogen that infects both pigs and humans. The economic importance of swine and the severity of *S. suis* infections in humans taken together with the facts that there is no effective vaccine and multiresistant strains have already been reported, justify the development of an endolysin-based antimicrobial against *S. suis*.

Objectives

The aim of this work was the design, production and characterization of a novel chimeric endolysin specifically directed towards *S. suis*, taking advantage of our knowledge on the modular nature of bacteriophage lytic enzymes.

Methods

Chimeric enzyme Csl2 was produced in *Escherichia coli*, purified, and its activity tested *in vitro* against different *S. suis* strains and other Gram-positive bacteria. In addition, a *S. suis* biofilm model was set up for testing the ability of this enzyme to disaggregate biofilms. Finally, *in vivo* assays of Csl2 activity against *S. suis* infection were carried out in an adult zebrafish model.

Conclusions

Csl2 displayed a narrower lytic spectrum than that of its parental enzyme, focusing mainly on *S. suis* and some other streptococci from mitis group. Our new enzyme was able to both disaggregate and kill *S. suis* cells forming biofilms, and total protection of *S. suis* infected adult zebrafish was achieved by microinjecting 2 mg Csl2/kg.

Pathogens / Pathogenicity - Part III

IDENTIFICATION OF BACTERIAL GENES INVOLVED IN THE RECOGNITION OF ESCHERICHIA COLI P4 BY BOVINE MAMMARY EPITHELIAL CELLS

M. VEDRINE[1], C. BERTHAULT[1], C. LEROUX[1], M. REPERANT[1], F.B. GILBERT[1], P. RAINARD[1], P. GERMON[1]
[1]INRA - Centre Val de Loire, 37, NOUZILLY, France

Backgrounds

Mastitis remains a major infection of dairy cows and an important issue for the dairy industry, in particular infections due to *Escherichia coli* strains. During infection, the immune response that takes place in order to eliminate infectious agent, requires recognition of bacteria by host cells, including mammary epithelial cells (MEC).
In a mouse model, infections induced by strain *E. coli* P4 show a strong colonisation of the mammary gland, while this strain has a low stimulating power on MEC.

Objectives

Our objective was to identify the genes responsible for this weak stimulation.

Methods

We screened a library of 2 000 P4 transposon mutants to identify mutants with increased ability to stimulate MEC.

Conclusions

The transposon insertion sites for thirteen mutants were identified and grouped into two classes of mutants: (i) mutants with an altered lipopolysaccharide (LPS) and (ii) others mutants which mechanism of action are at present unknown. LPS represents a highly active stimulus of the innate immune system. It has an O-polysaccharide moiety, a core oligosaccharide, and a lipid A domain. Some mutants in LPS biosynthesis genes have lost the O-polysaccharide region, while others have an altered composition. In parallel to complementation analyses of a set of selected mutants, inflammation triggered by LPS molecules with or without an altered O-antigen will be further studied in a bovine model.
This project will thus provide new knowledge about the pathways activated during the recognition of the pathogen, and which could then be modulated to improve the host response to intramammary infection by *E. coli*.

ELEVATED TEMPERATURE EFFECT ON PSEUDOMONAS SYRINGAE-TOMATO PLANT INTERACTION

L. Scalschi[1], E. Fernandez-Crespo[1], M. Pitarch[1], A. Gonnzález-Hernandez[1], E. Llorens[1], L. lapeña[1], P. García-Austín[1], G. Camañes[1], B. Vicedo[1]
[1]Universitat Jaume I, Ciències Agràries i del Medi Natural, Castellón de la Plana, Spain

Backgrounds

Nowadays climate change is having numerous impacts on plants. Simultaneously this change can also have direct effects on many plant pathogens therefore affecting pathogen development and survival rates and modifying host susceptibility, resulting in changes in the impact of diseases on crops.Understanding how plants and pathogens respond to this change is essential to conserve the former ones.

Objectives

One of the components of climate change are the elevated temperatures. In order to understand how this component affects both plant and pathogen response as well as their interaction,

Methods

Studies were carried out using the Pseudomonas syringae-tomato pathosystem. Two experimental conditions were compared. The first one consists in growing and inoculating the plants at 26 ° C while for the second one plants were grown at 31 °C and further inoculated with a bacteria acclimatized at 31 °C.

Conclusions

Subsequently, both plant and bacterial response was analyzed, demonstrating that, under the later conditions, the plant acclimatizes faster than the bacteria. The results showed that elevated temperatures not only reduced the infection by 50%, but also modified the infection phenotype since greater chlorosis and less necrosis was observed in these plants. This was accompanied by a significant reduction in the number of colony forming units. Our study also revealed that plants are able to adapt to elevated temperatures by undergoing physiological changes such as increases in chlorophyll content and photosynthetic rate.

In view of these results, plant response as well as bacterial response to increased temperatures are being characterized at both transcriptomic and metabolomic level.

INITIAL EVALUATION OF THE ROLE OF MUCR IN VIRULENCE AND OUTER MEMBRANE PROPERTIES OF BRUCELLA OVIS PA

R.S. Sidhu-Muñoz[1], R. Losa-Rodríguez[2], N. Vizcaíno[1]
[1]Edificio Departamental and IBSAL. Universidad de Salamanca, Dpto. Microbiología y Genética, Salamanca, Spain
[2]Edificio Departamental. Universidad de Salamanca, Dpto. Microbiología y Genética, Salamanca, Spain

Backgrounds

Brucella ovis provokes contagious epididymitis in rams and consequently important economic loses in the livestock sector. The virulence of this rough *Brucella* (without O-polysaccharide chains in the lipopolysaccharide) has been scarcely studied when compared to that of smooth *Brucella* (bearing O-polysaccharide). Additionally, there is no specific vaccine for *B. ovis* infection and heterologous *B. melitensis* Rev1, considered the best available vaccine against *B. ovis*, displays several important drawbacks.

Objectives

The aim of this work was the construction and initial characterization the Δ*mucR* mutant of *B. ovis* PA. MucR was previously found to be involved in cell envelope modifications and to be necessary for the virulence of smooth *B. melitensis*.

Methods

mucR was deleted by homologous recombination with a plasmid bearing the gene inactivated by overlapping PCR. Characterization of *B. ovis* Δ*mucR* included growth characteristics, outer membrane-related properties and intracellular behaviour in professional and nonprofessional phagocytes.

Conclusions

Compared to the parental strain, the Δ*mucR* mutant showed delayed growth in solid and liquid rich medium and a smaller colony size. It exhibited autoagglutination ability in static liquid culture medium and higher susceptibility in a disc assay to sodium deoxycholate and sodium dodecyl sulphate. Internalization of Δ*mucR* in HeLa cells and J744 murine macrophages was similar to that of the parental strain. However, its intracellular survival over time was impaired in a similar way to that of an attenuated mutant in the type IV secretion system. These results encourage the evaluation of the virulence and vaccine properties of *B. ovis* PA Δ*mucR* in animals.

INITIAL CHARACTERIZATION OF THE BRUCELLA OVIS PA ΔZNTR MUTANT DEFECTIVE IN A TRANSCRIPTIONAL REGULATOR INVOLVED IN ZINC HOMEOSTASIS

R.S. Sidhu-Muñoz[1], R. Losa-Rodríguez[2], N. Vizcaíno[1]
[1]Edificio Departamental and IBSAL. Universidad de Salamanca, Dpto. Microbiología y Genética, Salamanca, Spain
[2]Edificio Departamental. Universidad de Salamanca, Dpto. Microbiología y Genética, Salamanca, Spain

Backgrounds

Brucella ovis causes ram contagious epididymitis, an infectious disease for which specific vaccines are not available. Previous works with *B. abortus* identified *zntR* as a gene involved in zinc homeostasis and required to maintain a chronic infection in mice. Deletion of *zntR* in *B. ovis* would allow to analyse its role in virulence and led to the development of a specific recombinant attenuated vaccine.

Objectives

In this work we describe the construction of the Δ*zntR* mutant of *B. ovis* PA and its initial evaluation aiming to determine the role of ZntR in zinc homeostasis and virulence of *B. ovis* PA.

Methods

zntR was deleted by homologous recombination with a plasmid bearing the gene inactivated by overlapping PCR. Characterization of *B. ovis* Δ*zntR* included growth characteristics, susceptibility to $ZnCl_2$ and a zinc chelator, outer membrane-related properties and intracellular behaviour in professional and nonprofessional phagocytes.

Conclusions

Growth of *B. ovis* PA and its derived Δ*zntR* mutant in solid an liquid rich medium was similar. Addition of a zinc chelator to the culture medium abolished growth of Δ*zntR* and *B. ovis* PA but it was restored in both strains after addition of $ZnCl_2$. Susceptibility to compounds conventionally used to evaluate outer membrane properties was not modified by *zntR* deletion. Internalization and survival in murine macrophages and HeLa cells of the Δ*zntR* mutant and *B. ovis* PA were also similar. However, according to the results described for *B. abortus* Δ*zntR*, evaluation of the *B. ovis* mutant in mice must be performed before discarding its lack of attenuation.

VISIBLE AND UVA LIGHT AS A POTENTIAL MEANS OF PREVENTING ESCHERICHIA COLI BIOFILM FORMATION IN URINE AND ON MATERIALS USED IN URETHRAL CATHETERS

T. Vollmerhausen[1], A. Conneely[2], C. Bennett[2], V. Wagner[3], J. Victor[4], C. O'Byrne[1]
[1]National University of Ireland Galway, Bacterial Stress Response Group Microbiology, Galway, Ireland
[2]National University of Ireland Galway, National Centre for Laser Applications, Galway, Ireland
[3]Teleflex, Cambridge, Cambridge, USA
[4]Teleflex, Reading, Reading, USA

Backgrounds

Catheter-associated urinary tract infections are the most common hospital-acquired infection, for which *Escherichia coli* is the leading cause.

Objectives

This study investigated the efficacy of 385 nm and 420 nm light for inactivation of *E. coli* attached to the silicone matrix of a urinary catheter.

Methods

Using urine mucin media, inactivation of planktonic bacteria and biofilm formation was monitored using silicone coupons.

Conclusions

Continuous irradiance with both 385 nm and 420 nm wavelengths with starting cell density population 10^3 CFU ml^{-1} reduced planktonic suspensions of *E. coli* to below the detection level after 2h and 6h, respectively. Bacterial attachment to silicone was successfully prevented during the same treatment. Inactivation by 385 nm and 420 nm was found to be dependent on media, cell density and oxygen, with less inhibition on planktonic suspensions when higher starting cell densities were used. In contrast to planktonic suspensions in PBS, continuous irradiance of pre-established biofilms showed a greater reduction in survival compared to urine mucin media after 24 hours. Enhanced inhibition for 385 nm and 420 nm light in urine mucin media was associated with increased production of reactive oxygen species. These findings suggest 385 nm and 420 nm light as a promising antimicrobial technology for the prevention of biofilm formation on urethral catheters.

MOLECULAR EPIDEMIOLOGY OF TUBERCULOSIS IN KALININGRAD, RUSSIAN EXCLAVE ON BALTIC SEA

A. Vyazovaya[1], N. Solovieva[2], G. Akhmedova[3], E. Turkin[3], A. Gerasimova[1], O. Narvskaya[1], V. Zhuravlev[2], I. Mokrousov[1]
[1]St. Petersburg Pasteur Institute, Laboratory of Molecular Epidemiology and Evolutionary Genetics, St. Petersburg, Russia
[2]Research Institute of Phthisiopulmonology, Department of Etiological Diagnostics, St. Petersburg, Russia
[3]Regional Anti-Tuberculosis Dispensary, Bacteriology Laboratory, Kaliningrad, Russia

Backgrounds

Kaliningrad (former Koenigsberg) is the westernmost Russian region and makes an exclave on the Baltic Sea separated from mainland Russia by Lithuania and Poland. Despite some decline in tuberculosis (TB) incidence (50.6/100000 in 2015), the rate of primary multidrug resistance (MDR) in the last five years increased from 23.9% to 31.8%.

Objectives

We aimed to assess current structure of *Mycobacterium tuberculosis* population in the Russian/EU borderline Kaliningrad region and see how the situation has changed since our previous study in 2006.

Methods

The 93 *M. tuberculosis* isolates were recovered from newly-diagnosed pulmonary TB patients in 2015. Drug susceptibility testing was done by absolute concentrations method. DNA was subjected to spoligotyping; spoligotypes were compared to SITVIT_WEB. LAM isolates was detected by testing specific *Rv0129c* SNP and were further tested for RD-Rio, RD115, LAM-RUS markers. Beijing B0/W148 cluster was identified by detection of *Rv2664-Rv2665*::IS*6110*.

Conclusions

Most of isolates were drug resistant (32.3% pansusceptible, 51.6% MDR). Beijing genotype predominated in the collection (61/93). Russian epidemic clone Beijing B0/W148 was detected in 22/93 isolates and was mainly MDR (21/22). Non-Beijing families included T, LAM, Ural, S, and X (32 isolates in total) and presented 16 spoligotypes. *M. tuberculosis* population in Kaliningrad region is dominated by the Beijing (65.6%), T (14%) and LAM (12%) families. The MDR-associated Beijing genotype increased its rate in the last 10 years from 44% to 65%; its circulation continues to critically influence the adverse epidemiological situation of MDR-TB here and bears an impact on the EU neighbors.

CHARACTERISTIC OF LOW-1 MOLECULAR-MASS PENICILLIN-BINDING PROTEINS, NAGZ AND AMPR IN AMPC B-LACTAMASE EXPRESSING YERSINIA ENTEROCOLITICA

X. WANG[1], *H. Jing*[2]
[1]*National Institute for Communicable Disease Control and Prevention - China CDC, Beijing, China*
[2]*National Institute for Communicable Disease Control and Prevention- China CDC, Laboratory of Emergency, Beijing, China*

Backgrounds

Yersinia enterocolitica encodes a chromosomal AmpC β-lactamase under the regulation of the classical *ampR-ampC* system.

Objectives

To obtain a further understanding of the regulation characteristics of the AmpC expression of *Y. enterocolitica*. Elucidate the characteristics of LMM PBPs (PBP4, PBP5a, PBP5b and PBP7), NagZ and AmpR in the regulation of *ampC* in *Y. enterocolitica*.

Methods

We investigate the roles of low-molecular-mass penicillin-binding proteins (LMM PBPs) in the expression of AmpC β-lactamase by monitoring the ampC promoter activity in a series of LMM PBP mutants. PBP5b is involved in the process of *ampC* regulation, and the effects of PBP4, PBP5a and PBP7 were relatively low. Additionally, the quadruple deletion strain YEΔ4Δ5aΔ5bΔ7 (*pbp4, pbp5a, pbp5b* and *pbp7* inactivated) possessed the highest ampC promoter activity. Then, we explored the role of NagZ in *ampC* regulation and found that nagZ inactivation caused two completely different results in YEΔD123 (*ampD1, ampD2* and *ampD3* inactivated) and YEΔ4Δ5aΔ5bΔ7, indicating that two *ampC* regulation pathways exist in *Y. enterocolitica*.

Conclusions

We found that NagZ is essential for AmpC hyperproduction through the Δ*pbps* pathway, while in the Δ*ampD* pathway, NagZ was displaced by an unknown enzyme which could not hydrolyze the p-nitrophenyl-β-Nacetyl-D-glucosaminide. The inactivation of AmpR reduced the *ampC* expression in both YEΔD123 and YEΔ4Δ5aΔ5bΔ7, indicating that AmpR is necessary in the AmpC hyperproduction in these two pathways.

[11]Centre National de Référence des Streptocoques, Hôpital Cochin, Paris, France

Backgrounds

The strictly human pathogen *Streptococcus pyogenes*, also known as Group A Streptococcus (GAS), is a Gram-positive bacterium responsible for non-invasive and invasive diseases, including endometritis, and post streptococcal sequelae, leading altogether to 517,000 deaths yearly. Postpartum endometritis refers to infection of the decidua and is responsible for puerperal sepsis, a leading cause of peripartum maternal death. GAS presents various virulence factor repertoires and *emm28* strains are associated with endometritis. Models recapitulating early stages of tissue invasion are lacking.

Objectives

To set up an *ex vivo* model of human tissue GAS colonization and invasion, to decipher the cellular and molecular mechanisms involved in GAS invasive infections.

Methods

The decidua contains uterine stromal cells, derived from maternal endometrial cells, and resident immune cells. Human decidual samples are obtained from cesarean delivery at term of an uncomplicated pregnancy. These samples are infected *ex vivo* with an *emm28* GAS fluorescent relevant clinical isolate and mutant strains. Infection is monitored by confocal microscopy to follow the time-course of bacterial colonization and invasion of the tissue. Thorough image analysis is performed to precisely localize bacteria within the tissue and to quantify invasion kinetic and breadth. Cytotoxicity of the different strains is measured by analyzing nuclear damages.

Conclusions

Within the first four hours, GAS forms biofilm-like structures at the surface of the decidua with an extended colonization surface. In contrast to mutant strains, the wild-type strain kills a notable proportion of cells. This non-motile bacterium penetrates several micrometers deep into the tissue in a previously undescribed manner.

CONDITIONALLY PATHOGENIC GUT MICROBES PROMOTE LARVAL GROWTH BY INCREASING REDOX-DEPENDENT FAT STORAGE IN HIGH SUGAR DIET-FED DROSOPHILA

T.W. Whon[1], N.R. Shin[1], M.J. Jung[1], D.W. Hyun[1], H.S. Kim[1], P.S. Kim[1], J.W. Bae[1]
[1]Kyung Hee University,
Department of Life and Nanopharmaceutical Sciences and Department of Biology, SEOUL, Republic of Korea

Backgrounds

Changes in the composition of the gut microbiota contribute to the development of obesity and subsequent complications associated with metabolic syndrome. However, the role of increased numbers of certain bacterial species during the progress of obesity and factor(s) controlling the community structure of gut microbiota remain unclear.

Objectives

The present study aimed to identify the inter-relationship between *Drosophila melanogaster* and their resident gut microbiota under chronic high sugar diet (HSD) conditions.

Methods

Chronic feeding of a HSD to *Drosophila* resulted in a predominance of resident uracil-secreting bacteria in the gut. Axenic insects mono-associated with uracil-secreting bacteria or supplemented with uracil under HSD conditions promoted larval development. Redox signaling induced by bacterial uracil promoted larval growth by regulating sugar and lipid metabolism via activation of p38a mitogen-activated protein kinase.

Conclusions

The present study identified a new redox-dependent mechanism by which uracil-secreting bacteria (previously regarded as opportunistic pathobionts) protect the host from metabolic perturbation under chronic HSD conditions. These results illustrate how *Drosophila* and gut microbes form a symbiotic relationship under stress conditions, and changes in the gut microbiota play an important role in alleviating deleterious diet-derived effects such as hyperglycemia.

TRIGGERING THE ACTIVITY OF THE H2-T6SS OF PSEUDOMONAS AERUGINOSA IN VITRO AND CHARACTERISATION OF A COGNATE EFFECTOR

T.E. Wood[1], L.P. Allsopp[1], S. Wettstädt[1], A. Förster[2], P.S. Freemont[2], A. Filloux[1]
[1]Imperial College London, Life Sciences, London, United Kingdom
[2]Imperial College London, Medicine, London, United Kingdom

Backgrounds

The type VI secretion system (T6SS) is an important virulence determinant of many pathogenic Gram-negative bacteria and is often also vital in inter-bacterial competition. *Pseudomonas aeruginosa* PAO1 encodes three such systems, of which the H2- and H3-T6SS contribute to bacterial fitness during infection.

Objectives

In this work we sought to establish expression conditions in which the H2-T6SS could be studied *in vitro*, and probe the roles of effector proteins linked with this system.

Methods

We present conditions for detection of a functional H2-T6SS and associated effector proteins by western blot.

Conclusions

We characterise one such effector and demonstrate its role in *P. aeruginosa* colonisation and infection. Bioinformatics analyses reveal that this effector is a member of a toxin superfamily commonly associated with type VI secretion systems throughout the proteobacterial phylum. Finally, we present the crystal structure of this effector and identify a fold not previously found in T6SS effector proteins.

Pathogens / Pathogenicity - Part III

IDENTIFICATION AND CHARACTERIZATION OF NOVEL ADHESINS FROM A FISH PATHOGEN, YERSINIA RUCKERI.

A. Wróbel[1], *C. Ottoni*[1], *J. Leo*[1], *D. Linke*[1]
[1]*University of Oslo, Department of Biosciences, Oslo, Norway*

Backgrounds

Yersinia ruckeri is a Gram-negative, rod-shaped bacterium belonging to the genus *Yersinia*. It is the causative agent of enteric redmouth disease affecting salmonids globally and causing devastating economic losses in aquaculture industry.

Objectives

The aim of the research is to characterize *Y. ruckeri* inverse autotransporter adhesins for structural and functional studies. However, we encountered problems in using PCR to amplify one of the genes named ilm (invasin-like molecule)

Methods

The *Y. ruckeri* genome of the strain ATCC29473 was re-sequenced in the PacBio platform and annotated with Prokka. The Single-Molecule Real-Time (SMRT) sequencing of the PacBio platform makes is possible to overcome the limitations of other sequencing technologies - based on shorter read data - in defining highly-repeated DNA regions. We identified two inverse autotransporter adhesins that we called invasin (Inv) and (Ilm). We found that Ilm consists of 19 identical repeats with a low GC content region. In addition, the ilm gene is flanked by insertase, suggesting recent acquisition by horizontal gene transfer. Based on the new genome information, additional analyses were performed including biofilm formation assay and gene expression analysis.

Conclusions

Identification and characterization of the adhesins give valuable information on the evolution of the pathogen. Moreover, current next-generation sequencing technologies, such as SMART sequencing is a useful and an ideal approach for the sequencing of such repetitive regions. The knowledge gained through this study could also be used for the development of novel inhibitors and specific detection methods of this pathogen. Understanding the adhesion mechanism will help in characterization of the infection process.

LENTIVIRUS-MEDIATED GALECTIN-3 GENE DELIVERY AMELIORATES INFLUENZA PATHOGENESIS VIA INDUCTION OF M2 MACROPHAGE ACTIVATION

C.L. Wu[1], Y. Mei-Lin[2], C. Nai-Hui[2], S. Ai-Li[2]
[1]National Chen Kung University Medical College, Department of Biochemistry and Molecular Biology, Tainan, Taiwan R.O.C.
[2]National Chen Kung University Medical College, Department of Microbiology and Immunology, Tainan, Taiwan R.O.C.

Backgrounds

Factors which are implicated in high morbidity and mortality from influenza A virus (IAV) infection include robust cytokine production (cytokine storm), excessive inflammatory infiltrates, and virus-induced lung tissue destruction. Galectin-3 belongs to a family of evolutionally conserved glycan-binding proteins with multifunctional properties. It is expressed in a variety of immune cell types during microbial invasion. It can promote migration of monocytes/macrophages and drive alternative macrophage activation. The status of macrophage polarization upon virus infection has been studied, but much remains obscure.

Objectives

We investigated the roles of galectin-3 and M2 macrophage polarization in influenza virus infection.

Methods

We used lentiviral vectors encoding mouse galectin-3 (LV-gal-3) to overexpress galectin-3 in the lung of mice, and investigated its role in influenza infection. M2 macrophage polarization was examined by immunocytochemistry, and cytokines in the BAL fluid were detected by ELISA.

Conclusions

We show that the levels of galectin-3 were increased in the lungs of mice during influenza virus infection. Galectin-3 is mainly produced by macrophages. Mice treated with LV-gal-3 attracted more inflammatory cell infiltration to the lung, especially M2 macrophages. Furthermore, lentivirus-mediated galectin-3 gene delivery protected mice against lethal influenza virus challenge by reducing inflammation and ameliorating lung injury. Furthermore, IL-10 production in the respiratory tract of mice receiving LV-gal-3 was higher than that of mice receiving the control vector LV-null.

Our results demonstrate that galectin-3 can ameliorate influenza pathogenesis by promoting M2 macrophage activation. This study provides a proof of principle for the potential therapeutic application of galectin-3 for influenza.

Pathogens / Pathogenicity - Part III

THE ANTIMICROBIAL PEPTIDES EXERT ANTIFUNGAL ACTIVITY THROUGH IMPAIRMENT OF MITOCHONDRIA FUNCTION

Y. Xue[1], *G. Lin*[1], *C. Lan*[1]
[1]*National Tsing Hua University, Institute of Molecular and Cellular Biology, Hsinchu, Taiwan R.O.C.*

Backgrounds

Candida albicans is an important human fungal pathogen, which can cause life-threatening infections particularly in immunocompromised patients. Moreover, drug resistance in *C*. *albicans* has also emerged as a serious problem due to the widespread use of fungicides. Therefore, developing new anti-fungal drugs and studying their mechanisms of actions are very important.

Objectives

In this study, we investigated the mechanisms of several histatin 5-derived antimicrobial peptides (AMPs) involved in eradicating *Candida albicans* cells.

Methods

To study the mechanisms of the histatin 5-derived peptides, a mutant library of *C*. *albicans* was used. The susceptibility of mutants to the AMPs was examined and the results indicated a number of mutants exhibiting resistance to the AMPs testing were defective in mitochondria. These results raise a possibility that the mitochondria may be a target for the AMPs testing. Therefore, the ROS level and the oxygen consumption after peptide treatment were measured. Finally, the ROS scavenger was introduced to verify the role of ROS derived from the AMPs in *C*. *albicans* killing.

Conclusions

The AMPs testing increase the intracellular ROS levels of *C*. *albicans*. The oxygen consumption rate of the cell is also significantly decreased after the treatment with AMPs. These results indicate the peptides exert their fungalcidal activity through attacking the mitochondria.

Pathogens / Pathogenicity - Part III

PROPER CONTROL OF FLAGELLAR ROTATION OF OPPORTUNISTIC PATHOGENS IS REQUIRED TO EVADE INNATE IMMUNITY OF HEALTHY HOSTS

K. Yamazaki[1], T. Kashimoto[1], T. Kado[1], Y. Akeda[2], T. Kodama[3], K. Yoshioka[1], S. Ueno[1]
[1]Kitasato Univ. School of Veterinary Medicine, Veterinary Medicine, Towada, Japan
[2]Univ. Hospital- Osaka Univ., medicine, Suita, Japan
[3]RIMD- Osaka Univ., Bacterial Infections, Suita, Japan

Backgrounds

Opportunistic pathogens can cause fulminant wound infection that potentially progress to necrotizing fasciitis for a short time even in healthy individuals. *Vibrio vulnificus* is one of those pathogens: 80% of the wound-infected people were not having underlying diseases and survived even in being suffered severe local symptoms, whereas 20% of the wound-infected people were having some chronic diseases and died due to fatal sepsis. However, the mechanism by which opportunistic pathogens evade immunity of healthy hosts at the site of wound infection has remained unknown.

Objectives

We explore the essential factors of opportunistic pathogens to cause wound infection, and elucidate the role of the factor in immune evasion at the site of wound infection.

Methods

We identified the proper control of flagellar rotation as an essential function for *V. vulnificus* wound infection by applying signature-tagged transposon mutagenesis to a murine wound infection model. Role of the proper control of flagellar rotation was investigated by in vivo imaging system, measuring bacterial burdens, detection of serum biomarkers of muscular damage, histopathological studies, and comparison of lethality among the routes of s.c., i.m., and i.v. inoculation. Furthermore, we used neutropenic mice to investigate the relationship between opportunistic pathogens and neutrophils.

Conclusions

We demonstrated that the proper control of flagellar rotation contribute to spread of bacteria through subcutaneous tissue and to invade muscular tissue from dermis in wound infection, and the invasion of the muscular tissue is a key process for evasion of neutrophil killing and for proliferation of bacteria in wound infection.

FEMS7-0716
Pathogens / Pathogenicity - Part III

EVALUATION OF THE IMMUNOGENICITY AND VACCINE POTENTIAL OF RECOMBINANT ACINETOBACTER BAUMANNII GLYCOPROTEIN A1S_0556

C.Y. Yang[1], Y.C. Kung[1], S.C. Kuo[2]
[1]National Chung Hsing University, Institute of Molecular Biology, Taichung, Taiwan R.O.C.
[2]National Health Research Institutes, National Institute of Infectious Diseases and Vaccinology, Miaoli, Taiwan R.O.C.

Backgrounds

Acinetobacter baumannii, an opportunistic human pathogen, is a key source of nosocomial infection causing severe clinical diseases in people with compromised immune systems. It poses a great threat for human health because these organisms are resistant to most antibiotics. Vaccine is one plausible approach for prevention of multi-drug resistant bacteria.

Objectives

A general O-linked protein glycosylation system appears to be present in all clinical *A. baumannii* isolates suggesting an important role of glycoproteins in *A. baumannii* virulence. Thus, the *A. baumannii* glycoproteins may be good vaccine candidates. A1S_0556 was previously identified as an O-glycosylated protein in the membrane extracts of *A. bumannii*. In this study, we investigate whether A1S_0556 protein can be used as a vaccine antigen.

Methods

The coding regions of A1S_0556 were PCR amplified from *A. baumannii* ATCC 17978 and expressed in *E. coli*. The recombinant proteins were purified using the Ni^{2+} affinity column and used to immunize mice in the presence or absence of Freund's adjuvants. The expression of A1S_0556 in *A. baumannii* was monitored by Western blotting. The potential use of A1S_0556 as a vaccine candidate was evaluated by *in vivo* active protection assay and *in vitro* serum bactericidal assay.

Conclusions

A1S_0556 protein is ubiquitously expressed in *A. baumannii*. Mice immunized with the *E. coli* expressed non-glycosylated A1S_0556 were protected from *A. buamannii* in a pulmonary challenge model and the antisera raised against the recombinant protein with or without the presence of adjuvant possessed *in vitro* bactericidal activity. Collectively, we conclude that A1S_0556 is an ideal vaccine candidate.

FEMS7-0323
Pathogens / Pathogenicity - Part III

FIMZ OF SALMONELLA ENTERICA SEROVAR TYPHIMURIUM MEDIATES DIFFERENT PHYSIOLOGICAL FUNCTIONS

K.S. Yeh[1], C.H. Chang[1], H.C. Lin[1]
[1]National Taiwan University, Veterinary Medicine, Taipei, Taiwan R.O.C.

Backgrounds

Salmonella enterica serovar Typhimurium produces type 1 fimbriae on the outer membrane and such hair-like appendages are involved in adherence of the bacteria to host cells and tissues. The *fim* gene cluster is responsible for the phenotypic expression of type 1 fimbriae in *S*. Typhimurium. Production of type 1 fimbriae is cooperatively regulated by *fimZ*, *fimY*, *stm0551*, *fimW*, and *fimU* within the *fim* gene cluster. FimZ belongs to the response regulator of the two-component regulatory system in bacteria and has been shown to activate type 1 fimbrial expression.

Objectives

Our objective is to further explore the role that FimZ may participate besides type 1 fimbrial regulation.

Methods

A *fimZ* mutant in LB5010 strain was constructed by allelic exchange and was found to be non-fimbriate. Transcriptomic analysis by microarray revealed that the stress response related gene *cpxP*, *soxS* and type 1 fimbriae related genes *fimA-fimF*, and *fimW* were down-regulated, whereas plasmid-encoded fimbriae, chemotaxis, flagella associated genes and virulence genes like *virK*, *invC* and *mgtC* were up-regulated in the *fimZ* mutant strain. Oxidative stress response assay was performed with disc diffusion method and indicated that the *fimZ* mutant was more sensitive to H_2O_2 and paraquat than its parental strain LB5010. However, a homologue of *fimZ* from *Enterobacter cloacae* cloned in pACYC184 could not complement the *fimZ* mutant in the oxidative stress response.

Conclusions

FimZ protein of *S*. Typhimurium may serve as a multi-functional regulator that interacts with other genes in addition to the *fim* genes. Mechanisms of this crosstalk warrant further investigation.

Pathogens / Pathogenicity - Part III

DETECTION OF MYCOPLASMA GALLISEPTICUM INFECTION FROM CHICKEN BREEDER FLOCKS AND EMBRYONATED EGGS BY REAL-TIME PCR, CULTURE AND SEROLOGY

Ö. Yılmaz[1], S. Kahya[1], K.T. Carlı[1]
[1]Institute of Health Sciences, Microbiology, Bursa, Turkey

Backgrounds

Mycoplasma gallisepticum (MG) infections cause severe economic losses in poultry industry. Because it is transmitted vertically, control of MG has become important. Upper respiratory problems caused by MG is diagnosed by detection of spesicif DNA, isolation of MG or detection of antibodies.

Objectives

This study aimed to identification of MG by using ELISA, culture and real-time PCR (rPCR) from breeder flocks, chicks and embryonated eggs. We compared this rPCR test with serology and culture for the detection of MG.

Methods

Culture and rPCR were applied to 630 egg yolk swab samples and 110 tracheal swab samples (pooled in groups of 5). 900 blood samples from breeder flocks suffering from respiratory disease problems were tested by ELISA. Swabs were serial diluted up to 10^{-4} into Frey's broth and incubated. Dilutions which is turned into orange-red, were immediately cultivated in Mycoplasma agar and incubated. At the end of the incubation 'fried egg' appearance which is occured in plates was observed with stereomicroscope. At the same time egg yolk and tracheal swabs were vortexed with Frey's broth for rPCR. Then swabs were removed and rPCR was applied to the suspensions.

Conclusions

25 (16.8%) of the pooled 148 swab samples came out positive by using MG culture, 65 (43.9%) of the same samples came out positive by rPCR. The ELISA result of 900 blood samples were 460 MG seropositive. In conclusion, rPCR is a highly specific, sensitive method for MG identification. MG infection remains a common respiratory tract infection in breeders and it continues vertically transmission.

Pathogens / Pathogenicity - Part III

DIFFERENT TRANSCRIPTIONAL RESPONSES IN HUMAN MACROPHGE CELLS, THP-1 CELLS, TO BRUCELLA ABORTUS MUTANTS

S. Soo Jin[1], I. Young Bin[1], Y. Han Sang[1]
[1]College of Veterinary Medicine - Seoul National Univer, Department of Infectious Diseases, Seoul, Republic of Korea

Backgrounds

Brucella abortus, a zoonotic agent, causes undulant fever, arthritis, endocarditis in human and abortion and infertility in cattle. *B. abortus* is a facultative intracellular bacterium that can survive and replicate within host macrophages. Recognition of the interaction of the bacterium with host cells is crucial to elucidation of the infectious process. As the first step, *B. abortus* mutants were generated using transposon mutagenesis. Biological properties of the mutants were characterized in the growth rate, internalization and intracellular survival and replication.

Objectives

To demonstrate roles of the *B. abortus* genes, THP-1 cells were infected with *B. abortus* wild type and mutant strains C1, C10, C27, and C32, and then different transcriptional responses of the cells were determined using microarray.

Methods

After infection of THP-1 cells with *B. abortus* wildtype and mutant strains, altered gene expression was categorized by molecular function and biological process. Amount of cytokines was measured in the cell culture supernatans by ELISA.

Conclusions

Mutants C27 and C32 up-regulated the gene expression in the cells while gene expression was suppressed with mutants C1 and C10. Also, gene showed higher fold changes were listed. In the analysis of KEGG pathway, genes related with cytokine-cytokine receptor interaction, chemokine signaling pathway, and Toll-like receptor signaling pathway were down-regulated in the THP-1 cells with mutants C1 and C10. But, those genes were up-regulated with mutants C27 and C32. The alterations were coincided with the amounts of cytokines in the supernatant of the cells. This research was supported by KHIDI, the Ministry of Health & Welfare, (HI16C2130) and BK21, ROK.

ATYPICAL PROTEINS EXPOSED ON THE SURFACE OF CANDIDA GLABRATA BIND TO HUMAN ENDOTHELIAL CELLS

D. Zając[1], O. Bochenska[1], A. Kozik[1]
[1]Jagiellonian University,
UJ Faculty of Biochemistry- Biophysics and Biotechnology- Department of Analytical Biochemistry, Krakow, Poland

Backgrounds

Candida glabrata is the second most common cause of fungal infections in humans after *C. albicans*. The knowledge on proteinaceous components of *C. glabrata* cell wall is still unsatisfactory, possibly suggesting that this fungus has evolved different mechanisms for the interaction with the host cells, in comparison to *C. albicans*.

Objectives

To identify proteins exposed on the surface of *C. glabrata* and involved in the interaction with human umbilical vein endothelial cells (HUVECs).

Methods

A mixture of *C. glabrata* cell wall-associated proteins was released with beta-1,6-glucanase. Using the chemical cross-linking and liquid chromatography-coupled tandem mass spectrometry methods, we identified several cell wall proteins involved in the interaction with HUVECs. The “cell surface shaving”, based on a short treatment of fungal cells with trypsin, was used to analyze the changes in *C. glabrata* cell wall proteome after co-culture with HUVECs.

Conclusions

In the present study we identified several fungal proteins that are capable of interacting with human endothelial cells. Among them, after using both cross-linking and “cell surface shaving” methods, we found "atypical" cell wall proteins that originate from the cytoplasm, such as glyceraldehyde-3-phosphate dehydrogenase 3 (Tdh3). Interestingly, alcohol dehydrogenase 1 (Adh1) and phosphoglucose isomerase (Pgi) were found to be exposed on the surface of *C. glabrata* only after the contact with endothelial cells. Our data indicate that *C. glabrata* cell wall proteins can be taken into consideration in attempts to develop new antifungal therapies.

This work was financially supported by the FBBB funds for young scientists (KNOW BMN grant no. 15/2016 awarded to D.Z.).

THE ROLE OF SALMONELLA PATHOGENICITY ISLAND (SPI)1 EFFECTOR MOLECULES FOR ENTEROCYTE INVASION, INTRACELLULAR PROLIFERATION AND TRANSCRIPTIONAL ACTIVATION IN VIVO

K. Zhang[1], A. Riba[1], N. Torow[1], U. Repnik[2], G. Griffiths[2], M. Hensel[3], M. Hornef[1]
[1]Uniklinik RWTH Aachen, Institute of Medical Microbiology, Aachen, Germany
[2]University of Oslo, Department of Biosciences, Oslo, Norway
[3]University of Osnabrück, Division of Microbiology, Osnabrück, Germany

Backgrounds

Due to the lack of a suitable animal model, the molecular mechanisms of *Salmonella enterica* in epithelial cells invasion and mucosal barrier penetration have been studied using immortalized cell culture models. Recently we have established a neonatal murine infection model that allows the analysis of the contribution of both *Salmonella* and host factors during the host-microbial interplay *in vivo*.Using this model, we demonstrate spontaneous intestinal colonization, formation of intraepithelial microcolonies, mucosal translocation and spread to systemic organs following oral administration of *Salmonella*. In contrast to the situation in adult animals, mucosal translocation in the neonate intestine in the absence of M cells depends on pathogenicity island (SPI)1-mediated enterocyte invasion. Innate immune stimulation via Toll-like receptor 4 and 9 occurs in an invasion-dependent manner and induces a strong transcriptional epithelial response.

Objectives

The role of Salmonella SPI1 effector molecules for enterocyte invasion, intracellular proliferation and transcriptional activation will be studied in the established neonatal murine infection model.

Methods

In order to study single SPI1 effector molecule *in vivo*, the quadruple, triple and single mutant bacteria in combination with complementation of individual SPI1effectors are orally fed to new born mice.

Conclusions

We identify the dominant role of SipA and SopE/E_2 in enterocyte invasion, innate immune stimulation and mucosal translocation. Intraepithelial *Salmonella* microcolony formation requires fully SPI1. Together, our new mouse infection model illustrates the critical role of enterocyte invasion for mucosal translocation, innate immune stimulation and characterizes the contribution of individual SPI1 effector molecules during early infection *in vivo*.

THE INTRODUCTION OF AN ACTIVE CARBONIC ANHYDRASE ALLOWS CO2-DEPENDENT BRUCELLA STRAINS TO GROW UNDER ATMOSPHERIC CO2 CONCENTRATION

L. Pérez-Etayo[1], M.J. De Miguel[2], R. Conde-Álvarez[1], P.M. Muñoz[2], I. Moriyón[1], M. Iriarte[1], A. Zúñiga-Ripa[1]
[1]Instituto de Salud Tropical. Universidad de Navarra, Microbiología y Parasitología, Pamplona, Spain
[2]Centro de Investigación y Tecnología Agroalimentaria, Unidad de Sanidad Animal, Zaragoza, Spain

Backgrounds

Brucellosis is an important zoonosis caused by bacteria of the genus *Brucella*. Animal vaccination is the main way to prevent this disease but there is no vaccine against *B. ovis* and protection is achieved using *B. melitensis* Rev1. Stopping vaccination with Rev1 when *B. melitensis* is eradicated leads to an increase in the number of infections caused by *B. ovis* and thus, research on specific vaccines is essential. Nevertheless, one of the main difficulties to develop a *B. ovis*-vaccine is the requirement of a high-CO_2 atmosphere to grow.

Objectives

To analyze the mechanisms underlying CO_2 dependence in *Brucella* and to obtain a CO_2-independent *B. ovis* strain.

Methods

We first sequenced and analyzed the genes encoding carbonic anhydrases (CAs) I and II from *B. ovis* and two *B. abortus* strains (292 and 544). Then, we inserted the genes encoding CAI and/or CAII into the genome of the three strains using the mini-Tn7 system. We studied their growth under atmospheric conditions and their infection kinetics in mice.

Conclusions

In the case of *B. ovis*, both genes encoding CAI and CAII are disrupted. In contrast, although CAI is conserved in the two *B. abortus* strains, the lack of a functional CAII seems to be responsible for the requirement of a high-CO_2 atmosphere. Consequently, the introduction of an active CAII allows *Brucella* growth under atmospheric conditions, while the role of CAI remains to be unveiled. Interestingly, the introduction of a functional CAII into *B. ovis* does not affect the virulence of this strain, and therefore, it is an excellent background for the development of specific vaccines.

INFECTION RATES OF WOLBACHIA SP., BARTONELLA SP. AND RICKETTSIA SP. IN DIFFERENT POPULATIONS OF FLEAS

A. ZURITA CARRASCO[1], *R. CALLEJÓN FERNÁNDEZ*[1], *M. DE ROJAS ÁLVAREZ*[1], *C. CUTILLAS BARRIOS*[1]
[1]*University of Sevilla, Department of Microbiology and Parasitology- Faculty of Pharmacy, Sevilla, Spain*

Backgrounds

Flea-borne organisms are widely distributed throughout the world in endemic disease foci, where components of the enzootic cycle are present. However, flea-borne human pathogens have emerged recently (e.g., *Bartonella henselae*, *Rickettsia felis*), suggesting that much remains to be learned about the potential role of fleas as disease vectors. Thus flea-borne diseases could re-emerge in epidemic form because of changes in the vector–host ecology due to environmental and human behaviour modifications. On the other hand, *Wolbachia* strains are globally distributed, and currently these bacteria are considered the most abundant endosymbionts found in invertebrates.

Objectives

In the present study, we carried out a molecular detection of *Bartonella* sp. *Rickettsia* sp. and *Wolbachia* sp. in different populations of fleas isolated from different hosts from different geographical areas of Europe.

Methods

Molecular studies were performed by Polymerase Chain Reaction (PCR) of ribosomal DNA (16S, 16S-23 intergenic spacer region and 23S–5S intergenic spacer region) of *Wolbachia* sp., *Bartonella* sp. and *Rickettsia* sp., respectively.

Conclusions

In the present work, we detected the presence of *Bartonella* sp., *Rickettsia* sp. and *Wolbachia* sp. in different flea species. Some species such as *Nosopsyllus barbarus* were tested for these pathogens for the first time. Our results strongly support the role of *W. pipientis* as a common endosymbiont of fleas as well as the idea that several flea species might play an important role as vectors in human *Bartonella* sp. and *Rickettsia* sp infections in different geographical areas.

[3]National University of Tucuman, INSIBIO UNT-CONICET, San Miguel de Tucumán, Argentina
[4]International Science and Technology Centre, International Science and Technology Centre, Moscow, Russia

Backgrounds

The nasal administration of *Corynebacterium pseudodiphtheriticum* strain 090104 increases the elimination of *Staphylococcus aureus* from the nasal cavity in volunteers. The ability of the 090104 strain to improve respiratory immunity or its capacity to increase resistance against respiratory virus were not investigated before.

Objectives

Therefore, this work examined the effect of viable (Cb) or heat-killed (HkCb) *C. pseudodiphtheriticum* 090104 on the innate respiratory antiviral immune response and the resistance against influenza infection in mice.

Methods

Adult Balb/c mice were treated with 10^8 cells of Cb or HkCb by the nasal route during two consecutive days. Treated and untreated control mice were then nasally challenged with influenza virus. Lung tissue damage and respiratory and systemic immune responses were studied at several time points after viral challenge.

Conclusions

Cb treatment protected mice by reducing pulmonary injury and lung viral loads. This effect was associated to a differential regulation of the production of antiviral factors since respiratory levels of IFNs were enhanced ($p<0.01$) in Cb-mice. In addition, Cb down-regulated the expression of inflammatory cytokines while increased the regulatory cytokine IL-10 ($p<0.05$). Cb treatment also improved activation of lung antigen presenting cells and the numbers of IFN-γ and IL-10 producing $CD4^+$ lymphocytes. HkCb did not induce significant effects in the immune response to influenza infection, indicating that the viability of the respiratory commensal is a key factor to achieve the protective effect. These results strongly suggest that administration of Cb may represent an interesting alternative to modulate respiratory immune response and reduce respiratory virus-associated pulmonary damage.

EFFECT OF IMMUNOBIOTIC BIFIDOBACTERIA ON THE INNATE ANTIVIRAL IMMUNE RESPONSE IN BOVINE INTESTINAL EPITHELIAL CELLS: IMMUNOTRANSCRIPTOMIC ANALYSIS

L. Albarracín[1], A.K.M.H. Kober[2], H. Kobayashi[2], N. Sato[2], K. Paulraj[2], W. Ikeda-Ohtsubo[2], T. Nochi[2], H. Aso[2], N. Iwabuchi[3], J.Z. Xiao[3], T. Saito[2], J. Villena[1], H. Kitazawa[2]
[1]CENTRO DE REFERENCIA PARA LACTOBACILOS CERELA-CONICET, Laboratory of Immunobiotechnology, San Miguel de Tucumán, Argentina
[2]Tohoku University, Graduate School of Agricultural Science, Sendai, Japan
[3]Morinaga Milk Industry Co.- Ltd., Food Science and Technology Institute, Kanagawa, Japan

Backgrounds

Previous studies showed that *Bifidobacterium infantis* strain or *B. breve* strain significantly reduced rotavirus titers in infected bovine intestinal epithelial (BIE) cells.

Objectives

In this work, transcriptomic studies in BIE cells were performed to advance in the understanding the mechanisms involved in the antiviral activity of bifidobacteria.

Methods

BIE cells were stimulated with *B. infantis* or *B. breve* (5 x 10^8 cells/ml) and then challenged with the TLR3 agonist poly(I:C). BIE cells with no bifidobacteria treatment were used as controls. The transcriptomic response was evaluated 12 h after poly(I:C) challenge using the Bovine (G3) Gene Expression Microarray (Agilent). Variations in transcript abundance with a t-test $p<0.05$, and a cutoff in abundance of at least 2-fold were considered statistically different. Selected genes were further evaluated by RT-PCR.

Conclusions

TLR3 activation in BIE cells significantly increased the expression of type I interferons, interferon-induced factors and pro-inflammatory cytokines and chemokines. Both bifidobacteria improved the expression of *IFN-α* and *IFN-β* as well as the antiviral factors *RNASEL*, *MX1,* and *MX2* when compared to controls. In addition, bifidobacteria increased the expression of *IL-1β*, *IL-20*, *IL-6, CXCL2, CXCL3, CXCL6, CCL20*, and *CCL4*. Increased expression of *IL-1α* and *NLRP3* genes was also observed in *B. breve*-treated BIE cells. These results indicate that both immunobiotic bifidobacteria are able to improve the antiviral state of BIE cells that correlate with their capacity to reduce rotavirus replication. In addition, the transcriptomic analysis showed that both immunobiotic bacteria would be able to improve the recruitment and activation of immune cells to the site of viral infection.

MECHANISTIC AND PHENOTYPIC CHARACTERISATION OF RGG/SHP QUORUM SENSING SYSTEM IN STREPTOCOCCUS PNEUMONIAE

I. Abdullah[1], R. Wallis[2], P. Andrew[1], H. Yesilkaya[2]
[1]University of Leicester, Infection- Immunity and Inflammation, Leicester, United Kingdom
[2]University of Leicester, Infection-Immunity and Inflammation, Leicester, United Kingdom

Backgrounds

The Rgg (Regulator Gene of Glucosyltransferase) regulators with their short signaling peptides called SHP (short hydrophobic peptides) form part of a quorum sensing system in Gram positive bacteria. They play an important role in stress response, sugar metabolism, and virulence, but their function and mechanism of action remain unclear in the important human pathogen *Streptococcus pneumoniae.* The pneumococcal type 2 D39 strain has five homologues of Rggs, and two of them (SPD_0144 and SPD_0939) are predicted to be associated with putative *shp* genes encoding for SHP peptides, which regulate their own expression, and are predicted to be required for Rgg activation

Objectives

This study was designed to identify the optimum length of SHP144 to stimulate Rgg144-mediated transcription, and quantify the functional importance of each selected SHP144 residue for Rgg144 activation and binding, and establish their importance in Rgg144's phenotypic manifestation

Methods

Several synthetic SHP144 peptides representing the C-terminal end of SHP144 were synthesised to identify active SHP144 using reporter strains P*shp144*::*lacZ*-wt and P*shp144*::*lacZ*-Δ*shp144* ('P'-promoter). Site directed mutagenesis was used for substitution of selected residues of SHP144 with alanine, and the effect of each amino acid replacement was studied using a transcriptional reporter assay. The phenotypic impacts of mutations were determined by H_2O_2 resistance, and by growth assays in chemically defined medium supplemented with different sugars

Conclusions

The SHP144 peptide regulates its own expression and the12 and 13 amino acid long synthetic peptides representing the C-terminal end of SHP144 (C12 and C13, respectively)are sufficient to stimulate P*shp144*::*lacZ* both in wild type and mutant *shp144* background. Furthermore, most of alanine replaced residues abolish P*shp144* driven *lacZ* activity, indicating the importance of selected residues in transcriptional activation.
Finally, we found that mutations of selected SHP144 residues decrease pneumococcal resistance to H_2O_2, and diminish its growth in CDM supplemented with mannose

IN SILICO ANALYSIS OF SAFETY ASPECTS OF A POTENTIALLY PROBIOTIC LACTOBACILLUS PENTOSUS MP-10 ISOLATED FROM BRINES OF NATURALLY FERMENTED ALORENA GREEN TABLE OLIVES

H. Abriouel[1], B. Pérez Montoro[1], M.D.C. Casado Muñoz[1], C.W. Knapp[2], A. Gálvez[1], N. Benomar[1]
[1]University of Jaen, Health Sciences, Jaen, Spain
[2]University of Strathclyde, Department of Civil and Environmental Engineering, Glasgow, United Kingdom

Backgrounds

The genome sequence of a potential probiotic *L. pentosus* MP-10 is considered the largest genome among lactobacilli up to date highlighting its ecological flexibility and adaptability.

Objectives

Our objective was to determine the safety aspects of this bacterium since this is of great importance with regards to the future application of *L. pentosus* MP-10 as probiotic.

Methods

In this study, the genome sequence of *L. pentosus* MP-10 was annotated and analyzed *in silico* for the presence of antibiotic resistance determinants and mobile genetic elements.

Conclusions

The results obtained by means of bioinformatic tools showed the presence of different genes encoding for antibiotic resistance being highly represented by efflux pump genes. Furthermore, analysis of *L. pentosus* MP-10 genome sequence by means of ResFinder (acquired antimicrobial Resistance gene Finder) software revealed the absence of acquired antibiotic resistance genes by horizontal gene transfer. On the other hand, screening for mobile genetic elements that play a key role in the spread of antibiotic resistance determined that *L. pentosus* MP-10 genome possessed 5 prophages (two are intact, the other two are incomplete and the last one is questionable) and several transposases similar to other lactobacilli, however transposons were absent. In conclusion, *L. pentosus* MP-10 could be considered as safe since no acquired antibiotic resistance genes were found and that most of the resistance genes corresponded to efflux pump genes. Furthermore, the mobile genetic elements detected may play a role in genome diversification and evolution of this strain, and thus increase its adaptation potential.

REGULATION OF SPORULATION-INHIBITED SECRETION IN ASPERGILLUS NIGER

D. Aerts[1], R.A. Ohm[1], S.G. van den Bergh[1], M. Arentshorst[2], W.R. Teertstra[1], C. Phippen[3], K.F. Nielsen[3], A.F.J. Ram[2], J.C. Frisvad[3], H.A.B. Wösten[1]
[1]Utrecht University, Biologie, Utrecht, The Netherlands
[2]Leiden University, Molecular Microbiology and Biotechnology, Leiden, The Netherlands
[3]Technical University of Denmark, Systems Biology, Lyngby, Denmark

Backgrounds

Sporulation inhibits enzyme secretion in the industrial cell factory *Aspergillus niger*. By inactivating gene *flbA*, sporulation is abolished while secretion takes place throughout the colony, including the zones of the mycelium that otherwise would sporulate. Deletion of *flbA* also impacts other processes such as cell wall thickness and cell lysis.

Objectives

The aim of this project is to identify transcription factors downstream of FlbA that control secretion.

Methods

FlbA controls (in)directly 38 transcription factor genes. So far, 4 of these genes have been analyzed. Two of them do not function in secretion but are involved in stress resistance and fumonisin biosynthesis, respectively. Two transcription factors do play a role in secretion. Inactivation of one of these genes resulted in a different secretion pattern, while in the other case less protein was secreted.

Conclusions

Together, this implies that we have identified one potential modulator and one activator linking sporulation and protein secretion. Currently, we are studying the impact of these transcription factors on gene expression and the secretome. These findings are interesting leads for improving A. niger as a cell factory.

Physiology / Biochemistry / Molecular Microbiology

EXPRESSION AND REGULATION OF THE VIRULENCE GENE SRFJ OF SALMONELLA ENTERICA

J. Aguilera Herce[1], *A. Schikora*[2], *F. Ramos-Morales*[1]
[1]*Universidad de Sevilla, Departamento de Genética, Sevilla, Spain*
[2]*Julius Kühn Institute, Institute for Epidemiology and Pathogen Diagnostics, Braunschweig, Germany*

Backgrounds

Salmonella is a Gram-negative facultative intracellular pathogen, which belongs to the family Enterobacteriaceae. Its pathogenic properties are partially a consequence of virulence genes that encode effector proteins. SrfJ is one of the effectors secreted by the type III secretion system (T3SS) encoded by *Salmonella* pathogenicity island 2 (SPI2) when *Salmonella* is inside the host cell. *srfJ* expression depends on the two-component system regulator SsrA-SsrB, the main regulator of SPI2, and therefore it is coordinated with the expression of the SPI2 T3SS. Interestingly, the expression of *srfJ* is induced by *myo*-inositol. This is due to the location of this gene in the *myo*-inositol utilization island, controlled by the repressor IolR.

Objectives

To understand this dual regulation system and its expression *in vitro* and *in vivo* during mammalian cell infection and plant colonization.

Methods

Fusions with *luxCDABE* operon of *Photorhabdus luminescens*. Expression measurements during animal cell infection and plant colonization.

Conclusions

The expression of *srfJ* is under the control of two promoters that are induced in different conditions. The first one is the promoter of the gene *iolE*, located upstream of *srfJ* and whose expression is regulated by IolR. The second is *srfJ* own proximal promoter region, whose main regulator is SsrB. The regulation has been studied in detail using strains with mutated regulators that affect the expression of different chromosomal virulence regions. *srfJ* is expressed from the proximal promoter during mammalian cell infection and from the *iolE* promoter during growth in plant media and during plant colonization.

COMPLETE GENOME SEQUENCE AND COMPARATIVE GENOME ANALYSIS OF BACILLUS SUBTILIS SUBSP. SUBTILIS KCTC 3135(T)

S. Ahn[1,2,3], *S. Kim*[2,3]
[1]*Seoul National University, Biomedical Sciences, Seoul, Republic of Korea*
[2]*Korea Research Institute of Chemical Technology, Convergent Research Center for Emerging Virus Infection, Daejeon, Republic of Korea*
[3]*Korea Research Institute of Standards and Science, Center for Bioanalysis, Daejeon, Republic of Korea*

Backgrounds

Bacillus subtilis is one of the most ubiquitous and diverse Gram-positive bacteria, which is broadly adapted to grow in many environments especially in the soil and water sources. Previously, only draft genome sequence was available for the *B. subtilis* subsp. *subtilis* type strain.

Objectives

Here, we deeply sequenced and annotated complete genome of *B. subtilis* subsp. *subtilis* KCTC 3135^T, replacing previous draft genome.

Methods

The genomic DNA was extracted from broth culture of the strain and sequenced by Illumina sequencer. The size of the genome is approximately 4 megabase pairs with G+C ratio of 43.51%. Gene prediction was carried out using Prodigal then gene annotation was performed with various tools including NCBI prokaryotic genome annotation pipeline. The genome of *B. subtilis* KCTC 3135^T contains 4,315 CDSs, 10 rRNA operons and 86 tRNA genes. Comparative genomic analysis of *B. subtilis* subsp. *subtilis* KCTC 3135^T with 15 other *B. subtilis* subsp. *subtilis* strains and 2 *B. subtilis* subsp. *spizizenii* strains (including type strain; TU-B-10^T) was carried out using several tools. Phylogenetic trees of polC, rpoB, gyrA and ANI (Average Nucleotide Identity) distinguished *B. subtilis* subsp. *subtilis* strains from *B. subtilis* subsp. *spizizenii* strains. The *tar* genes and *tag* genes which are involved in cell wall phenotype were investigated whether various *B. subtilis* subspecies strains can be grouped based on the cell wall related genes.

Conclusions

In conclusion, the genome of *B. subtilis* KCTC 3135^T was completely sequenced and closely related *B. subtilis* subspecies can be clearly distinguished based on the genotypic comparison.

FEMS7-2403
Physiology / Biochemistry / Molecular Microbiology

RECOMBINASES ARE ESSENTIAL FOR BACTERIOPHAGE REPLICATION

M.M. Neamah[1], *J.R. Penades*[1]
[1]*University of Glasgow, Biomedical Research Centre, Glasgow, United Kingdom*

Backgrounds

DNA-single strand annealing proteins (SSAPs) are a type of recombinases frequently encoded in the genome of many bacteriophages. Since these proteins can promote homologous recombination among DNA substrates with an important degree of divergence, it has been assumed that the main role for these enzymes is to generate mosaicisms, driving phage evolution.

Objectives

Here, analysing Sak and Sak4 as representatives of two different families of SSAPs present in phages infecting the clinically relevant bacterium *Staphylococcus aureus*, we demonstrate for the first time that these enzymes are absolutely required for phage reproduction.

Methods
