Deletion of the genes encoding these enzymes significantly reduced phage replication and the generation of infectious particles. Complementation studies revealed that these enzymes are required both in the donor (after prophage induction) and in the recipient strain (for infection). Moreover, our results also indicated that to perform their function, the SSAPs require the activity of their cognate single strand binding (Ssb) proteins. Mutational studies demonstrated that the Ssb proteins are also required for phage replication, both in the donor and the recipient strain.

Conclusions

In summary, our results expand the functions attributed to the SSAPs, and demonstrate that both SSAPs and SSB proteins are essential for the life cycle of the staphylococcal phages.

GENOMIC CLUSTERING OF MAL GENES IN YEASTS

T. Alamäe[1], *K. Viigand*[1], *K. Põšnograjeva*[1]
[1]*University of Tartu, Institute of Molecular and Cell Biology- Department of Genetics, Tartu, Estonia*

Backgrounds

Genomic clustering of functionally linked genes is rare in eukaryotes. Yet, subtelomeric regions of *Saccharomyces cerevisiae* harbor gene families including yeast MALT (transporter), MALS (maltase or isomaltase) and MALR (regulator) genes. Similar MAL loci have been described also in *Pichia stipitis*. We have described a genomic MAL locus of a phylogenetically 'old' methylotrophic yeast *Ogataea* (*Hansenula*) *polymorpha*. This locus includes MAL1 gene encoding for maltase-isomaltase [1], and MAL2 encoding for alpha-glucoside transporter. Both proteins have extended substrate specificity. The MAL locus of *O. polymorpha* also contains two putative MAL-activator genes.

Objectives

The aim was to analyze clustering of MAL genes in phylogenetically diverse yeasts.

Methods

Gene and protein sequences were withdrawn from GenBank and UniProtKB/Swiss-Prot, the genomes were accessed mostly through Mycocosm website (http://genome.jgi.doe.gov/programs/fungi/index.jsf). Phylogenetic tree of maltase proteins [1] was built at http://phylogeny.lirmm.fr. Genomes of yeasts from different branches of the phylogenetic tree were analysed for genomic neighborhood of maltase/isomaltase/alpha-glucosidase genes. Genes potentially encoding alpha-glucoside transporters and transcriptional activators were searched adjacent to these genes to locate putative genomic loci for the utilization of alpha-glucosidic sugars.

Conclusions

No MAL loci were found in yeasts *Schizosaccharomyces pombe* and *Blastobotrys adeninivorans* which are considered 'ancient' yeasts. One putative MAL locus was found in *Lodderomyces elongisporus* and *Debaryomyces hansenii*. Several putative alpha-glucosidases and MAL loci were detected in *Lipomyces starkeyi*, *Pichia guillermondii* and *Pichia stipitis*.

Acknowledgements: This work was financed by ERC grant GLTMR1050P (PUT1050).

DISSECTION OF A NOVEL METAL RESISTANCE MECHANISM IN CUPRIAVIDUS METALLIDURANS

M.M. Ali[1], K. Mijnendonckx[1], N. Leys[1], P. Monsieurs[1], D. Charlier[2], R. Van Houdt[1]
[1]SCK•CEN, Microbiology, Mol, Belgium
[2]Vrije Universiteit Brussel, Microbiology, Brussels, Belgium

Backgrounds

Cupriavidus metallidurans strains contain many genes involved in the resistance and processing of heavy metals, which are very well studied and characterized. In addition, studies at SCK•CEN underscored the rapid evolution of *C. metallidurans* strains towards significantly increased metal resistance, particularly for silver.

Objectives

Our objective is to understand the molecular mechanisms of this increased resistance to silver.

Methods

C. metallidurans strains including type strain CH34, its plasmidless derivative AE104 and NA4, isolated from a silver-sanitized drinking water system, were grown in toxic levels of silver to obtain silver-resistant mutants. The latter were characterized in detail via re-sequencing, oligonucleotide microarrays, and deletion and complementation analyses.

Conclusions

Our data indicate that *C. metallidurans* is able to adapt rapidly to toxic silver concentrations. Silver-resistant mutants were obtained from different strains, even from strains cured from the main mega-plasmid encoded metal resistance determinants, indicating that the canonical efflux mechanisms are not involved. Whole-genome expression profiling in non-selective growth conditions showed that only a few genes were commonly up-regulated in all obtained silver-resistant mutants. In addition, deletion mutants and plasmid-based complementation confirmed that a two-component regulatory system and a gene coding for a small periplasmic protein play a central role. These results represent a previously uncharacterized molecular mechanism for metal/silver resistance.

CLOSTRIDIUM DIFFICILE GENE ASSOCIATED WITH HAEMOLYTIC ACTIVITY IN ESCHERICHIA COLI CLONES

Z. Alkudmani[1], R. Williams[2], P. Mullany[1], A.P. Roberts[1]
[1]Eastman Dental Institute- University College of London, Microbial Diseases, London, United Kingdom
[2]University College of London, Infection and Immunity, London, United Kingdom

Backgrounds

It was observed that *Clostridium difficile* exhibit a haemolytic phenotype when grown on brain heart infusion (BHI) agar supplemented with 5% horse blood and 2% glucose. This phenotype however is not observed in the absence of glucose.

Objectives

To determine the genetic basis for haemolysin production in *C. difficile.*

Methods

A genomic library from *C. difficile* strain 630 was constructed and screened for haemolysis in *E. coli*. Multiple haemolytic colonies were identified and the most haemolytic was selected for further investigation. The gene responsible for the phenotype in that clone was localised. It was predicted to encode a protein containing an anthrax toxin lethal factor (ATLF) domain and a signal peptide.

Conclusions

E. coli clones carrying a *C. difficile* gene encoding an uncharacterized protein with an ATLF domain are haemolytic.

COMPARATIVE CELL WALL ANALYSIS OF THE VIBRIONACEAE FAMILY

L. Alvarez[1], K. Kumar[1], I. Abreu[2], T. Moritz[2], F. Cava[1]
[1]MIMS- Umeå University, Molecular Biology Department, Umeå, Sweden
[2]Swedish University of Agricultural Sciences- Umeå Plant Science Centre, Department of Forest Genetics and Plant Physiology, Umeå, Sweden

Backgrounds

Most bacteria surround themselves with a protective cell wall to withstand cell turgor pressure and repel environmental insults. These tough cell walls are primarily made of a peptidoglycan (PG) exoskeleton called the murein sacculus. PG structure is not static, but continuously remodeled in response to environmental and physiological cues, which requires the coordinated actions of numerous PG-acting enzymes and regulatory proteins.

Objectives

Investigation of the cell wall biochemistry is imperative for understanding its biology and its role in growth, division, and morphogenesis. Here we explore the mechanisms responsible for this remodeling and its biological meaning.

Methods

For this purpose, we have developed a new method that allows ultrafast and sensitive PG analysis by in-line UPLC-MS/MS coupled to chemometric tools for identifying cell wall subjacent variability.

Conclusions

By these means, we have characterized the cell wall diversity within the Vibrionaceae family and analyzed how the cell wall chemistry fits in relation with established bacterial phylogeny and ecology. Our analysis has permitted the identification of several species-specific cell wall chemical features, which we are now characterizing in detail. The mechanistic and phenotypic study of these properties will provide new insights about the role of PG remodeling in the bacterial lifestyle and environment adaptability. Moreover, this will provide a unique opportunity to uncover new targets against infecting bacteria.

PREVENTION OF TIGHT JUNCTION INJURY CAUSED BY EPEC IN INTESTINAL EPITHELIAL CELLS BY FACTORS RELEASED BY COMMENSAL AND PROBIOTIC ESCHERICHIA COLI STRAINS

C.S. Alvarez[1], M.J. Fabrega[1], M.A. Cañas[1], R. Gimenez[1], L. Baldoma[1], J. Badia[1]
[1]Facultat de Farmàcia i Ciències de l'Alimentació, Biochemistry and phisiology, Barcelona, Spain

Backgrounds

The gastrointestinal epithelial layer forms a physical and biochemical barrier that maintains segregation between host and microbiota and regulates intestinal permeability. The integrity of this barrier is in part supported by the establishment of tight junctions (TJs) between intestinal epithelial cells. Pathogens such as Enteropathogenic *Escherichia coli* (EPEC) disrupt this barrier. However, some gut microbes and probiotic bacteria modulate the barrier integrity by reinforcing TJs. *E. coli* Nissle 1917 (EcN) is a probiotic with a positive effect on the barrier integrity. We have previously shown that both outer membrane vesicles (OMVs) and soluble factors released by EcN and commensal ECOR63 reinforce the epithelial barrier by positive regulation of ZO-1 and claudin-14, and negative regulation of claudin- 2.

Objectives

Here we analyze the ability of OMVs and soluble factors released by EcN and ECOR63 to protect EPEC-induced TJs damage in T-84 and Caco-2 cell monolayers.

Methods

Transepithelial Electrical Resistance (TER) and distribution of TJ proteins were monitored in polarized cells infected with EPEC in the absence or presence of both extracellular fractions collected from EcN and ECOR63. EPEC caused 50% reduction in the TER levels and altered localization of ZO-1, ZO-2 and occludin. However, OMVs and soluble factors secreted by EcN or ECOR63 avoided TER reduction and promoted redistribution of the altered TJs proteins. The effect of these secreted factors was also evaluated measuring expression of miRNAs associated with the epithelial barrier function.

Conclusions

Results indicate the ability of OMVs and factors secreted by EcN and ECOR63 to protect TJs disruption caused by EPEC.

COMPARISON OF SECOND INTERNAL TRANSCRIBED SPACER (ITS II) OF RIBOSOMAL DNA IN IDENTIFICATION AND DIFFERENTIATION OF TRICHOSTRONGYLUS SPECIES OF LIVESTOCK IN MAZANDARAN PROVINCE, IRAN

A. Amouei[1], A. Azadeh Mizani[2], A. Ali Bakooie Katrimi[3], S. Shirzad Gholami[4]
[1]Committee research student - Mazandaran University of Medical Sciences- Sari- Iran, Parasitology And Mycology, Sari, Iran
[2]Toxoplasmosis Research Center- Mazandaran University of Medical Sciences- Sari- Iran, Parasitology and Mycology, Sari, Iran
[3]Mazandaran Provincial Veterinary Department of Medical Sciences- Sari- Iran, Medical Sciences, Sari, Iran
[4]Parasitology and Mycology Department- Faculty of Medicine- Mazandaran University of Medical Scie nces- Sari- Iran, Medical Sciences, Sari, Iran

Backgrounds

Trichostrongylus is an intestinal parasite of wide range of animals and human with a worldwide distribution. Reliable differentiation of *Trichostrongylus* sp. is important for epidemiological researches and effective control strategies of the parasite.

Objectives

The aim of present study was to identify *Trichostrongylus* spp. among ruminants using molecular method, in Mazandaran Province, northern Iran.

Methods

180 adult T*richostrongylus* specimens of gastrointestinal track of sheep and goat were obtained from a slaughterhouse in Mazandaran Province. After extraction, DNA fragments of the rDNA ITS II region of *Trichostrongylus* adult worms were amplified by conventional PCR.

Based on nucleotide differences between T*richostrongylus* sp., for species differentiation, two enzymes *Hinf* I and *Dra* I were selected to perform PCR-RFLP assay.

Conclusions

Results indicated that 98 out of 180 samples were confirmed positive as *Trichostrongylus* genus with conventional PCR and *Trichostrongylus* specific primers successfully amplified a region of approximately 328bp in all Samples. After RFLP assay, the restriction enzyme *Dra* I produced two different patterns based on previous computer software results for *T. axeil T. colubriformis* (215, 110 bp) and *T. vitrines* (185, 145 bp). *Hinf* I has one cutting site for *T. colubriformis*, and has no cutting sites for two other species, producing two fragments approximately 238, 90 bp for *T. colubriformis*.

PCR-RFLP profile is simple, rapid and also reliable tool for differentiation all *Trichostrongylus* species, and can be used for diagnostic, clinical and epidemiological purposes. These method can also be adopted to identify human and animal samples in endemic region of disease.

UNIQUE FEATURES IN THE CYANOBACTERIAL DIVISOME IN ANABAENA SP. PCC7120.

D.M. Andrade Molina[1], M. Silva[1], H. Osorio[1], J. Chichón[2], J.M. Valpuesta[2], M. Vicente[3], L.M. Vásquez[1]
[1]Pontificia Universidad Católica de Chile, Molecular genetic and Microbiology, Santiago, Chile
[2]Centro Nacional de Biotecnología- CSIC, Molecular Structure, Madrid, Spain
[3]Centro Nacional de Biotecnología- CSIC, Microbial biotechnology, Madrid, Spain

Backgrounds

Cyanobacteria are oxygenic photosynthetic microorganism with cell walls properties and cell division proteins combined of both gram-positive and gram-negative bacteria. The research in cyanobacterial division has been revealed that divisome presents differences in composition and regulation compared to classical division models of bacteria. Previous studies carried out in our laboratory, have determined a gene common to all filamentous cyanobacteria (*cyDiv*), which is involved in cell division.

Objectives

To determine how the CyDiv protein contributes to divisome ensemble in filamentous cyanobacteria *Anabaena* sp. PCC7120

Methods

We analyzed phenotypic variations under different transcription levels controlled by copper-inducible promoter and determined the localization protein by immunofluorescence and morphological effect by TEM and SEM. Furthermore, was evaluated association of CyDiv with other protein of divisome by BIFc and determined secondary structure of periplasmic region by circular dichroism.

Conclusions

Integral results from gene expression, cellular localization and protein interaction suggest that CyDiv is essential for cell division in cyanobacteria and perform its role through interaction with elements of divisome. Alteration of CyDiv in *Anabaena* PCC7120 led to effects in the Z-ring positioning and cell wall damage triggering cell lysis. We show that FtsQ hypothetical protein and CyDiv localized depending of time of division from pole to cell center. Subsequently, we determined that CyDiv interact directly with FtsQ, being functionally homologous to FtsB in *E. coli*. Biochemical characterization of CyDiv determined that the periplasmic region is represented by a-Helix, confirming that this protein has similar topology to FtsB. Our results suggest that CyDiv and FtsQ could be involved in the link between the early recruitment proteins and late proteins of Divisome at the periplasm in cyanobacteria. Furthermore, CyDiv is required to septal junction complex to apparently stabilize the filament, since the absence of this leads to fractionation of the filament, defects in cell division and cell death.

PURIFICATION AND CHARACTERIZATION OF THE ENZYME 3-HYDROXY-3-METHYL GLUTARYL COENZYME A REDUCTASE FROM CANDIDA GLABRATA (REC-HMGRCG)

D. Andrade[1], R. Cuevas[1], J. Ortiz[1], J. Tamariz[2], C. Hernández[1], A. Ibarra[1], L. Vills[1]
[1]Instituto Politécnico Nacional, Microbiología, D.F., Mexico
[2]Instituto Politécnico Nacional, Química Orgánica, D.F., Mexico

Backgrounds

The enzyme 3-hydroxy-3- methyl glutaryl coenzyme A reductase (HMGR) is a glycoprotein involved in the route of biosynthesis of cholesterol in humans and of ergosterol in fungi. The catalytic domain of HMGRs is highly conserved in eukaryotic organisms. We used the HMGR enzyme of *Candida glabrata* (HMGRCg) as a model for studying different lipid-lowering compounds with potential use in humans, as well as for developing new antifungal agents against this opportunistic pathogen, which has innate resistance to azoles.

Objectives

To obtain the recombinant version of HMGRCg in the *E. coli* expression system and demonstrate its inhibition with synthetic drugs.

Methods

1. Primers were designed to amplify the sequence encoding the soluble fraction of HMGRCg. 2. The HMGRCg gene was amplified by PCR. 3. The HMGRCg gene was cloned in the expression vector pMAL-c2xa. 4. Rec-HMGRCg was overexpressed and purified. 5. Rec-HMGRCg was characterized.

Conclusions

We could clone, express and purify the HMGR protein from *C. glabrata* in the heterologous system of *E. coli*, and then to demonstrate its activity and inhibition with synthetic drugs. Rec-HMGRCg showed an optimum pH of 8.0 and optimum temperature of 37°C. The k_m and V_{max} for HMG-CoA were 6.5 µM and 2.26 x 10^{-3} µM min^{-1}, respectively. The recombinant enzyme HMGRCg was inhibited by simvastatin and synthetic compounds presenting a similar IC_{50}. These inhibition data were supported by docking studies. The results suggest that rec-HMGRCg can serve as a model for studying the antifungal activity of synthetic compounds.

Physiology / Biochemistry / Molecular Microbiology

STRUCTURE AND FUNCTION OF THE HEME UPTAKE MACHINERY IN CORYNEBACTERIUM GLUTAMICUM

S. Aono[1], *N. Muraki*[1]
[1]*Institute for Molecular Science, Okazaki Institute for Integrative Bioscience, Okazaki, Japan*

Backgrounds

Heme uptake machinery of Corynebacteria including *Corynebacteria glutamicum* and *Corynebacterium diphtheriae* consists of heme binding proteins, HtaA and HtaB, and the ABC-type heme transporter HmuTUV. Sequence analysis identified a conserved region (CR) of approximately 150 amino acids that is duplicated in HtaA and present in a single copy in HtaB. HtaA consists of two homologous CRs in the N- and C-terminal regions.

Objectives

To elucidate the molecular mechanisms of heme uptake in Corynebacteria, we have determined the crystal structures of HtaA, HtaB, and HmuT.

Methods

Crystallization was carried out in a 96-well crystallization plate at 20 ºC by hanging drop vapor diffusion method. Diffraction data were obtained at 100 K on the beamline BL44XU at SPring-8.

Conclusions

We have determined the crystal structures of the N-, and C-terminal CR of HtaA (HtaA-N and HtaA-C, respectively) and HtaB at the resolution of 2.0, 1.3, and 1.7 Å, respectively. HtaA-N consists of 11 β strands and two short α helices and accommodates one heme molecule with Tyr58 located in the first α helix as the heme axial ligand. Tyr58 forms a hydrogen bond with His111.

HtaA-C and HtaB show similar global structures to HtaA-N. The key residues for heme-binding and recognition including the axial ligand of heme and residues involved in the hydrogen bonding interactions with heme are conserved among HtaA-N, HtaA-C, and HtaB.

We also determined the crystal structure of HmuT at the resolution of 1.4 Å. HmuT consists of structurally similar two domains located in the N-terminal and C-terminal regions connected a long a helix. A single heme molecule is bound in the cleft between these domains. Heme iron is ligated by His141 and Tyr240, and Tyr240 forms a hydrogen bond with Arg242. Intriguingly, HmuT binds a heme with two different orientations.

HIGH GENOMIC AND METABOLIC DIVERSITY IN INFANT-DERIVED BIFIDOBACTERIUM LONGUM STRAINS

S. Arboleya[1], F. Bottacini[2], M. O'Connell-Motherway[2], C.A. Ryan[3], R.P. Ross[4], D. van Sinderen[2], C. Stanton[1]
[1]Teagasc Food Research Centre Moorepark, APC Microbiome Institute, Cork, Ireland
[2]APC Microbiome Institute, School of Microbiology, Cork CIty, Ireland
[3]APC Microbiome Institute, Department of Neonatology, Cork CIty, Ireland
[4]APC Microbiome Institute, School of Science- Engineering & Food Science, Cork CIty, Ireland

Backgrounds

Bifidobacterium longum is an abundant species in the human intestinal microbiota and is widely used as a probiotic. This species is highly competitive in the complex intestinal community and is commonly present at high numbers in the gut of infants, adults and the elderly, thus indicative of a close symbiotic host-microbe relationship with humans throughout life.

Objectives

The objective of this study was to assess the genetic and metabolic diversity in *B. longum* strains isolated from healthy infants.

Methods

Twenty infant-derived *B. longum* strains were subjected to whole genome sequencing and their phylogenetic relatedness and pan-genome was analysed *in silico*. To better understand this diversity, a comparative genomic analysis was performed using other publicly available *B. longum* genome sequences. The twenty strains were then assessed for their ability to utilize different carbohydrates in an attempt to distinguish strains based on their metabolic abilities with regards to a wide range of carbohydrates, from monosaccharides to complex sugars and human milk oligosaccharides (HMOs).

Conclusions

The results showed high diversity in terms of genes and predicted glycosyl-hydrolases, as well as the ability to metabolize a large range of sugars. Moreover, we corroborate the capability of *B. longum* spp. *longum* to metabolise HMOs. Ultimately, these observations may provide an explanation for the persistence of this species throughout life.

COLE1 PLASMID COEXISTENCE IS MEDIATED BY COMPENSATORY ADAPTATION

M. Ares-Arroyo[1], C. Bernabé-Balas[1], A. Santos-López[1], A. San Millan[2], A. Hoefer[1], B. Gonzalez Zorn[1]
[1]Faculty of Veternary Medicine and VISAVET- Complutense Univesrity of Madrid, Department of Animal Health, Madrid, Spain
[2]Hospital Universitario Ramón y Cajal and Instituto de Investigación Sanitaria IRYCIS, Servicio de Microbiología, Madrid, Spain

Backgrounds

ColE1-like plasmids are small multicopy plasmids that are highly prevalent in nature. Despite the fitness cost they impose on their host, the coexistence of these replicons is a very common phenomenon. Furthermore, it has been described that this cohabitation can drive antimicrobial multiresistance. As such, understanding the behavior of these coexisting plasmids is of great significance.

Objectives

This study aims to characterize the selection for plasmid cohabitation without antibiotic pressure, despite the high biological cost associated, by evaluating two hypothesis: positive epistasis and compensatory adaptation.

Methods

As a model, we used *Haemophilus influenzae* RdKW20 and three different Cole1-like plasmids: pB1000, pB1005 and pB1006, bearing the genes bla_{ROB-1}, *strA* and *tet*(O), respectively. We performed experimental evolutions where the fitness cost of the replicons was determined by direct competition experiments. We also analyzed the plasmid copy number and the resistance level of the bacteria harboring the plasmid(s).

Conclusions

In our study, pB1000, pB1005 and pB1006 maintained their resistance phenotype, plasmid copy number and fitness cost, whether alone or in combination. Thus, the positive epistasis hypothesis cannot explain the cohabitation phenomenon, as there is no fitness advantage associated with plasmid coexistence. However, by performing experimental evolutions, *H. influenzae* Rd was able to completely compensate for the fitness cost associated with one of these ColE1 plasmids. Once the bacterium had compensated this first replicon, the acquisition of the other ColE1 plasmid(s) did not produce any additional fitness cost. Therefore, compensatory adaptations explains the acquisition and coexistence of multicopy plasmids in nature.

[4]Universidad Autónoma de Guerrero, Unidad Académica de Ciencias Quimico Biológicas, Chilpancingo, Mexico
[5]Instituto Politécnico Nacional, Departamento de Microbiología, Mexico city, Mexico

Backgrounds

Klebsiella pneumoniae is a common opportunistic pathogen causing nosocomial infections. One of the main virulence determinants of *K. pneumoniae* is the type 3 pilus (T3P). T3P is genetically organized in three transcriptional units: the *mrkABCDF* polycistronic operon, the *mrkHI* bicistronic operon and the *mrkJ* gene. MrkH is a regulatory protein encoded in the *mrkHI* operon, which positively regulates the *mrkA* pilin gene and its own expression. In contrast, the H-NS nucleoid protein represses the transcriptional expression of T3P. No reports have been described for the role of MrkH protein in regulating *mrkJ* promoter in *K. pneumoniae.*

Objectives

Determine the role of MrkH and H-NS in transcription of *mrkJ* promoter.

Methods

Transcriptional expression of *mrkI* gene was carried out by qRT-PCR. Using EMSA, promoter region (PCR) of *mrkJ* was incubated with purified MrkH protein and DNA-proteins complexes were observed.

Conclusions

MrkH and H-NS positive and negatively regulated *mrkJ* expression, respectively, by binding to the promoter of *mrkJ*. MrkH acted as an anti-repressor of H-NS. Moreover, our results support that high levels of MrkH represses *mrkJ* expression. Our data provide new insights about the complex regulatory role of the MrkH protein on the transcriptional control of T3P in *K. pneumoniae*.

INTESTINAL MICROBIOTA DYSBIOSIS AND EMERGING INFLAMMATION CAUSED BY A HIGH FAT DIET

A. Nerea[1], P. Miguel Angel[1], A. Laura[2], R. Andoni[3], R. Alfonso[4], G. Ana[5]
[1]Azti tecnalia, Food research, Derio, Spain
[2]Azti tecnalia, marine research, Sukarrieta, Spain
[3]EHU/UPV, Immunology- microbiology and parasitology, Leioa, Spain
[4]Instituto hispalense de pediatría, pediatría, Sevilla, Spain
[5]Instituto hispalense de pediatría, Gastroenterología, Sevilla, Spain

Backgrounds

A number of functions required for host survival are encoded by human core microbiome, being among others digestion, restriction of the growth of potentially harmful bacteria, or development of the immune response. The role that microbes have in energy homeostasis has driven to study their association with diseases such as diabetes, obesity or Alzheimer.

As we learn more about microbiome composition and functions in healthy individuals, it will become possible to use the microbiome as a novel target for diagnostic and therapeutic applications. This microbial diversity can be modified by genetic and environmental factors, including dietary habits and physical activity that have been shown to play a decisive role on defining the intestinal microbiota profile.

Recent studies have focused on the microbial environmental factor that pre-disposes humans to obesi. The obesity epidemic is characterized by an excessive accumulation of body fat and a low-grade systemic inflammatory tone. Energy-dense foods and overnutrition represent major starting points altering the lipid metabolism, systemic inflammation and gut microbiota.

Objectives

To elucidate the relationship between the gut microbiota dysbiosis and the emerging metainflammation caused by high fat diet consumption.

Methods

Adult zebrafish individuals were maintained during 6 weeks with either a control diet or a high fat diet. Intestinal microbiota dysbiosis was studied by 16S sequencing and the total number of bacteria by qPCR. Furthermore, intestinal inflammation was studied by gene expression profile and histology.

Conclusions

A HFD causes changes in the intestinal microbiota composition closely related to an emerging inflammation in adult zebrafish.

ZEBRAFISH GUT AS A HOUSE FOR HUMAN INTESTINAL BACTERIA

M.A. pardo[1], N. Arias[1], A. Ramirez[2], A.P. Galera[3], A. Rodriguez[4], L. Alonso[5]
[1]azti tecnalia, food research division, Derio, Spain
[2]EHU/UPV, immunology- microbiology and parasitology, Leioa, Spain
[3]IHP, AE gastroenterología, Sevilla, Spain
[4]IHP, Pediatría, Sevilla, Spain
[5]Azti tecnalia, Marine research divisin, Sukarrieta, Spain

Backgrounds

The human gut houses a vast microbial community that is vital for maintaining host health. The complexity and the high inter-individual variability of the human gut microbiota are inherent problems in the study of host-microbe interactions.

Gnotobiotic animals offer the opportunity to circumvent some problems. For that reason, it would be desirable to have a simple animal model to study the interactions between the gut microbiota and the host. Zebrafish is a vertebrate model that is being widely used to investigate the interactions between a host and its resident microbial communities because it is genetically similar to humans and easier and cheaper to house and care for than rodents.

Objectives

To know which species directly obtained from the human gut microbiota are able to colonize the zebrafish gut.

Methods

We have colonized the intestine of 5 days post fertilization (dpf) zebrafish larvae with human intestinal microbiota. A thorough protocol is followed to obtain axenic zebrafish larvae that are infected with the microbiota during 48 hours. The colonization is monitorized by 16S sequencing.

Conclusions

Certain interenting strains included in the human intestinal microbiota are able to colonize the zebrafish gut almost during 48 hours post infection (hpi). As a matter of fact, we resolved that different bacteria commonly found in the human intestine, including obligate anaerobes, are able to colonize and compete into the zebrafish intestine.

These data suggest that the developing zebrafish could be a suitable model for studying few species of the human gut microbiota, the interactions with the host, and the related diseases, as a result, diabetes, obesity, IBD.

TRANSCRIPTIONAL AND TRANSLATIONAL REGULATION OF RIBOSOMAL PROTEIN OPERONS IN ESCHERICHIA COLI

L. Aseev[1], L. Koledinskaya[1], I. Boni[1]
[1]M.M. Shemyakin and Yu.A. Ovchinnikov Institute of bioorganic chemistry, Department of Genetics and Postgenomic Technologies, Moscow, Russia

Backgrounds

Ribosome biogenesis in bacteria requires the coordinated synthesis of three rRNAs (16S, 23S and 5S) and more than 50 ribosomal proteins. While regulation of rRNA and about a half of r-protein operons in *E. coli* has been already well defined, a number of r-protein operons remain largely unexplored. It is important to obtain a deeper understanding of the regulatory mechanisms responsible for balanced synthesis of all ribosomal components.

Objectives

Our main goal was to characterize the mechanisms regulating expression of three previously unexplored r-protein operons, *rplM-rpsI, rplU-rpmA*, and *rpmB-rpmG* which encode r-proteins L13-S9, L21-L27, and L28-L33, respectively.

Methods

To study transcriptional control, we evaluated the changes in amounts of the transcripts in total RNA isolated before and after induction of serine starvation by treatment with L-serine hydroxamate of wild-type cells as well as ppGpp-null and *dksA* mutants. For this purpose, RT-qPCR with an external RNA standard was used. Translation regulation has been examined by measuring expression of the operon-specific chromosomal *lacZ* fusions under normal versus augmented synthesis of operon products.

Conclusions

Under amino acid starvation, transcription of all three operons is subject to ppGpp/DksA–dependent negative stringent control, in parallel with the rRNA operons. At the translational level, only one of these operons, *rplM-rpsI*, is regulated by the mechanism of autogenous repression, indicating that translational feedback control is not a general rule for modulating r-protein expression. L13, a primary protein in 50S subunit assembly, serves as an autogenous repressor of the *rplM-rpsI* mRNA by recognizing the complex structure of the *rplM* 5'-UTR.

DOMAIN OF UNKNOWN FUNCTION IS INVOLVED IN THE CONVERSION OF 2-THIOURACIL INTO URACIL

A. Aučynaitė[1], R. Rutkienė[1], R. Meškys[1], J. Urbonavičius[1,2]
[1]Vilnius university Institute of Biochemistry, Department of Molecular Microbiology and Biotechnology, Vilnius, Lithuania
[2]Vilnius Gediminas Technical University, Department of Chemistry and Bioengineering, Vilnius, Lithuania

Backgrounds

Modified nucleotides are present in many RNA species in all Domains of Life. The biosynthetic pathways of such nucleotides are well studied. However, much less is known about the degradation of RNAs and the salvage of modified nucleotides, their respective nucleosides or heterocyclic bases to the metabolism.

Objectives

To screen the metagenomic libraries for genes, which would allow the conversion of 2-thiouracil to uracil in *E. coli* cells.

Methods

Using an *E. coli* uracil auxotrophic strain, we screened the metagenomic libraries for genes, which would allow the conversion of 2-thiouracil to uracil and thereby lead to the growth on a defined synthetic medium. We show that a novel gene encoding previously uncharacterized Domain of Unknown Function (DUF) is responsible for such phenotype. We have purified this recombinant protein and demonstrated that it contains a Fe-S cluster. The substitution of cysteines, which have been predicted to bind such clusters, with alanines abolished the growth phenotype.

Conclusions

We conclude that previously uncharacterized Domain of Unknown Function is required for conversion of 2-thiouracil into uracil *in vivo*.

ROEMERINE: A NEW MULTIDRUG RESISTANCE PUMP INHIBITOR?

F.G. Avci[1], M. Guillerminet[2], C. Orelle[2], J.M. Jault[2], B. Sariyar-Akbulut[1]
[1]Marmara University - Faculty of Engineering, Department of Bioengineering, Istanbul, Turkey
[2]University Lyon- CNRS, UMR5086-Molecular Microbiology and Structural Biochemistry, Lyon, France

Backgrounds

Increasing resistance against current antimicrobials leads to loss in drug efficacy.Bacteria reduce the effects of drugs using various resistance mechanisms that include efflux through multidrug resistance (MDR) pumps. Combinatorial therapies of antimicrobials with pump inhibitors are a promising strategy to recover sensitivity to current antimicrobials.

Objectives

(-)-Roemerine is an aporphine type alkaloid with significant antibacterial and antifungal activities. It has been reported to increase the cytotoxicity of vinblastine in multidrug-resistant KB-V1 cells by interacting with the eukaryotic MDR pump, P-glycoprotein. In the light of this information our study investigates the possible modulation of the activity of P-glycoprotein homologue BmrA in *Bacillus subtilis* 168 by aporphine type alkaloids, (-)-roemerine, boldine, and bulbocapnine.

Methods

Growth curves were obtained for *Bacillus subtilis* 168 cells in the presence of berberine and the inhibitors. Berberine was used as the model antimicrobial agent and its concentration was kept at 75 µg/mL. The inhibitor concentrations were kept at 25 µg/mL. Furthermore inverted membrane vesicles were constructed with wild-type BmrA to test inhibition of the ABC transporter of *B. subtilis* 168.

Conclusions

75 µg/mL berberine had no significant effect on microbial growth of *B. subtilis* 168 cells. The combination of 75 µg/mL berberine with 25 µg/mL (-)-roemerine retarded cell growth. No effect was observed in berberine combinations with boldine or bulbocapnine. When the effects of berberine, boldine, and (-)-roemerine were tested for their inhibition of wild-type BmrA overexpressed in *E. coli* inverted membrane vesicles, the results showed that (-)-roemerine selectively bound and blocked the function of BmrA.

STRUCTURAL AND BIOPHYSICAL CHARACTERIZATION OF A NOVEL LYSOZYME INHIBITOR FROM NEISSERIA MENINGITIDIS

A. Awanye[1], V. Humbert[2], L.Y. Lian[3], M. Christodoulides[2], J. Derrick[1]
[1]University of Manchester, Faculty of Biology- Medicine and Health, Manchester, United Kingdom
[2]University of Southampton, Faculty of Medicine, Southampton, United Kingdom
[3]University of Liverpool, Institute of Integrative Biology, Liverpool, United Kingdom

Backgrounds

Neisseria meningitidis is a Gram negative bacterium which can cause septicaemia and meningitis. One mechanism which may promote its survival in the nasopharynx is inhibition of endogenous lysozyme activity. The Adhesin Complex Protein (ACP) is a surface exposed and highly conserved outer membrane protein with the ability to confer protection against meningococcal infections (Hung et al, mBio 4(2):e00041-13).

Objectives

We report the structural and biophysical characterization of ACP and demonstrate that it is a potent inhibitor of human lysozyme.

Methods

Recombinant ACP was expressed in *E. coli* and purified by Ni-IDA affinity, cation exchange and size exclusion chromatography (SEC). Binding between ACP and lysozyme was demonstrated by SEC and verified using microscale thermophoresis; the equilibrium binding constant (K_D) was 11 μM. The lysozyme inhibitory activity of ACP was assessed using a fluorimetric method; it was observed that ACP is a stronger inhibitor of human lysozyme (92% inhibition), compared to hen egg white lysozyme (82% inhibition). Crystals of ACP were obtained by the sitting drop method and native data collected to 1.35Å resolution. The crystal structure was solved using anomalous diffraction phasing from iodide ions, and gave a single molecule in the asymmetric unit. The structure of ACP revealed an 8-stranded β–barrel structure, with several loop regions.

Conclusions

ACP is structurally similar to *Pseudomonas* MliC, *Brucella* and *Salmonella* PliC although it does not share significant primary sequence similarity (less than 25%) or described sequence motifs with either protein. Our results suggest that ACP is the first lysozyme inhibitor to be identified from *Neisseria*.

COMPARATIVE MIRNAOME ANALYSIS IN HIV-1 INFECTED PATIENTS REVEALED ALTERED MIRNA EXPRESSION PROFILES IN ELITE CONTROLLERS AND LONG-TERM NON PROGRESSORS

R. Ayala Suárez[1], E. Calonge[1], H.E. De la Torre Tarazona[1], F. Díez Fuertes[1], J. Alcami Pertejo[1]
[1]Centro Nacional de Microbiología - Instituto de Salud Carlos III, AIDS Immunopathology Unit, Majadahonda- Madrid, Spain

Backgrounds

Long-term non progressors (LTNP) and elite controllers (EC) represent spontaneous models of efficient immune response against HIV-1 due to their capacity to maintain CD4>500 cell/µL for more than 10 years and to control viral replication in the absence of treatment, respectively. Altered expression of some miRNAs has previously been associated with these phenotypes.

Objectives

The main purpose of this work is to characterize the miRNAome of HIV-1 infected patients with extreme phenotypes (EC-LTNP and LTNP) and to identify different miRNA expression profiles.

Methods

Thirty miRNAomes of PBMCs collected from EC-LTNP (n=8), viremic LTNP (n=8) and typical progressors (n=7) before (TP) and after receiving antiretroviral therapy (TP-ART) were sequenced by miRNA-Seq and subsequently analysed to find differential expression profiles. A mean of 13.211.670 reads per patient were aligned to the miRNAome using miRanalyzer, obtaining an average of 472 pre-miRNAs and 355 miRNAs. Differential expression analyses between phenotypes were conducted by DESeq2.

Conclusions

A total of 15 miRNAs were deregulated comparing LTNP with TP, including the downregulation of miR-144/451 cluster in LTNP, which has previously been associated with the inhibition of CCR5 agonists, and the downregulation of miR-18a in LTNP, which regulates Dicer expression and the canonical-maturation of miRNAs. A deregulation of 43 miRNAs was observed when EC-LTNP and viremic-LTNP patients were compared, including the downregulation of miR-29a in EC-LTNP, associated with the inhibition of Nef protein. The downregulation of miR-146a/miR-106 and the upregulation of miR-30a in EC-LTNP were also detected and linked to an enhanced immune response in these individuals.

EXPERIMENTAL AND BIOINFORMATIC ANALYSES OF STRESS TOLERANT AND RESPONSE ON ACETIC ACID BACTERIA

Y. Azuma[1]
[1]*Kindai University, Biology-Oriented Science and Technology, Kinokawa, Japan*

Backgrounds

Acetic acid bacteria (AAB) are obligate aerobic and Gram-negative bacteria, and taxonomically belong to the family *Acetobacteraceae* of alpha-proteobacteria. *Acetobacter pasteurianus* and *Gluconacetobacter* species of AAB are historically and world-widely used for vinegar fermentation, and many kinds of AAB were used in a variety process of food fermentation, including precursors of vitamin C, chocolate, and kombucha.

Objectives

Despite the industrial values, AAB show noticeable physiological instability or high adaptation potential under stress environments in two means, i.e. temporal acclimation and heritable adaptation. To clarify genomic backgrounds and take advantage of the genetic flexibility, comparative omics analyses were performed.

Methods

For temporal acclimation and heritable adaptation analyses, comparative omics analyses were performed using hyper glucose-tolerant AAB, *Tanticharoenia sakaeratensis* and *Asaia bogorensis*, and using an adapted strain of *A. pasteurianus* at unviable high-temperature, respectively.

Conclusions

The two hyper glucose-tolerant AAB, *T. sakaeratensis* and *A. bogorensis* were shown to alter expressions of homologous genes and systems under higher glucose-concentration conditions, especially repression of glycolysis and pentose phosphate pathways and induction of antioxidant enzymes, such as SOD and peroxidases. Interestingly the involvement of antioxidant enzymes in the thermo-tolerant adaptation was observed, and some of the genes were common with ones involved in high glucose-tolerance. Based on the fact that enzymes managing oxidative stresses were also engaged in overcoming different stresses, such as the high glucose stress and thermo-stress, we propose a hypothesis that disruption of cell homeostasis by oxidative stress is a general reason for death or quiescence under a variety of stress conditions.

QNRD IS SOS REGULATED BY SUB-MIC TOBRAMYCIN IN ESCHERICHIA COLI

A. Babosan[1], L. François[2], D.C. Christophe[1], P. Gerald B.[3], S. David[3], G. Thomas[1]
[1]University of Reims Champagen Ardenne, UFR Medecine, Reims, France
[2]Massachussets Eye and Ear Infirmary- Harvard Medical School, Microbiology and Immunology, Boston, USA
[3]Channing Laboratory- Brigham and Women's Hospital- Harvard Medical School, Infectious Diseases, Boston, USA

Backgrounds

Little is known about the regulation of *qnrD*, which confers low-level resistance to fluoroquinolones (FQ), and carried, by a small plasmid in *Proteeae.*

Objectives

We investigated SOS transcriptional regulation of *qnrD,* after treatment with sub-inhibitory concentrations of ciprofloxacin (CIP), mitomycin C (MMC) and tobramycin (TM).

Methods

The expression of *qnrD* transcripts was measured using qRT-PCR, in *E. coli* MG1656 (WT) and derivatives, after exposure to CIP, MMC and TM. The fold change in *qnrD* gene expression was calculated using the $2^{-\Delta\Delta CT}$ method. We performed growth with or without antibiotics, allowing reactive oxygen species (ROS) or nitric oxide (NO) detection.

Conclusions

In the WT strain, *qnrD* transcript expression was increased with SOS inducers CIP and MMC. In two strains were the SOS system was blocked, no transcript expression was found. These results indicated that *qnrD* expression is mediated by the SOS response.

Strikingly, *qnrD* transcript expression in the WT was induced by TM, whereas no response was observed in SOS blocked strains, showing that TM induces also the SOS response in *E. coli*.

No ROS was measured for *qnrD* plasmid-carrying bacteria with CIP or TM, whereas NO was detected when TM was added. In *qnrD* plasmid-carrying strains, TM induced a nitrosative stress that damage the DNA, thus SOS response and repair.

Overall, our findings revealed an unexpected antibiotic resistance co-selection with AG that may promote emergence of FQ resistance. This could be a worst-case scenario, enhancing the risk for emergence of high-level resistance to FQ in Qnr-producing *E. coli*.

DNA REPAIR PATHWAYS INVOLVED IN THE RESPONSE TO LOW DOSES OF AMINOGLYCOSIDES IN E. COLI AND V. CHOLERAE

Z. Baharoglu[1]
[1]*Institut Pasteur, Genomes et genetique, paris, France*

Backgrounds

Antibiotic treatments challenge bacteria to develop new survival strategies. Antibiotics at low doses that do not affect bacterial growth were found to induce various stress responses in Gram-negative bacteria. Particularly, low concentrations of aminoglycosides induce the SOS response in *Vibrio cholerae* but not in *Escherichia coli*.

Objectives

Our goal is to study the strategies adopted to respond to such antibiotic stress, through the characterization of molecular responses involved, and the study of subsequent DNA damages.

Methods

In order to determine whether a specific factor present in *E. coli* prevents this induction, we developed a genetic screen where only SOS inducing mutants are viable. We identified the vsr gene coding for the Vsr protein of the very short patch mismatch repair (VSPR) pathway. The effect of mismatch repair (MMR) mutants was also studied. To further understand the mechanisms involved in the response to aminoglycosides in *V. cholerae*, we have also constructed large mutant libraries in order to identify genes that become essential in the presence of such stress.

Conclusions

We propose that lesions formed upon aminoglycoside treatment are preferentially repaired by VSPR without SOS induction in *E. coli* and by MMR when VSPR is impaired. The identification of the molecular mechanisms triggered by the presence of sub-MIC antibiotics will point to physiological processes that are important for the induction of stress responses and bacterial adaptation.

A NEW CLASS OF ICE IN THERMUS THERMOPHILUS

I. Baquedano[1], *A. Blesa*[1], *M. Mencía*[1], *J. Berenguer*[1]
[1]*Centro de Biología Molecular Severo Ochoa UAM-CSIC, Molecular biology, MADRID, Spain*

Backgrounds

Integrative and Conjugative Elements (ICEs) are found in many bacteria. They frequently encode genes required for their insertion and excision and also for their mobilization from an *ori*T sequence and conjugal transfer (Type 4 secretion, T4SS) to a new host. In contrast with well known conjugation models, in some Thermus thermophilus strains a very active cell-to-cell DNA transfer mechanism exists that depends on the combination of a DNA secretion system (Push system) in the donor and a DNA incorporation system (pull system) in the recipient, both playing and active role in a process named transjugation. The pull system is the same used for natural competence, whereas the push system requires a DNA translocase of the FtsK family (CptA) encoded within a region of significantly lower G+C content than the genome.

Objectives

To analyse if the DNA-push system in transjugation is encoded by a mobilizable element integrated into the genome of *Thermus thermophilus*.

Methods

DNA transfer assays with mutants in different genes around the DNA pushing translocase. Integration and excision assays detected by specific PCR and qPCR.

Conclusions

The CptA protein is encoded by a new type of ICE that integrates at and excises from a specific tRNA in the genome. In addition to its own transfer, this new class of ICE promotes the massive transfer of genes from its host to a recipient competent cell by transjugation.

This work has been funded by Spanish national project BIO2016-77031-R. IB is the holder of a fellowship from the MINECO

BREAKING THROUGH THE STRESS BARRIER: THE ROLE OF BOLA IN FLAGELLAR SYNTHESIS AND BIOFILM FORMATION

S. Barahona[1]
[1]*Instituto de Tecnologia Química e Biológica António Xavier, MostMicro, Oeiras, Portugal*

Backgrounds

Bacteria are extremely versatile organisms, which rapidly adjust their gene expression to induce physiological and molecular adaptation to changing environments. When bacterial cells switch from planktonic to biofilm state of growth, flagella formation is turned off, and the production of fimbriae and extracellular polysaccharides is activated. BolA protein is widespread in nature and has been associated with several cellular processes.

Objectives

Unraveling the overall picture of BolA global effects and specific targets.

Methods

High-troughput techniques, such as Microarrays and ChIP-seq, have showed that BolA protein is a new bacterial transcription factor, which regulates the switch between motile and sessile lifestyle.

Conclusions

BolA negatively modulates flagellar biosynthesis and swimming capacity in *Escherichia coli*. Moreover, its overexpression favors biofilm development, involving fimbriae-like adhesins and curli production. Our recent results show that BolA action in these pathways is related with c-di-GMP a relevant intracellular signaling molecule involved in biofilm formation. We demonstrate that BolA contributes to a fine-tuned expression of different diguanylate cyclases and phosphodiesterases and c-di-GMP has a negative influence in the *bolA* mRNA transcription. Herein we propose that BolA is a key player in motile/adhesive transcriptional switch, contributing to a fine-tuned regulation of these important pathways.

INTEGRATIVE CONJUGATIVE ELEMENTS IN MINIMAL BACTERIA: FROM INDIVIDUAL TO COLLECTIVE BEHAVIOR

E. Baranowski[1], E. Dordet-Frisoni[1], E. Sagne[1], M.C. Hygonenq[1], G. Pretre[1], S. Claverol[2], L. Fernandez[1], X. Nouvel[1], C. Citti[1]
[1]INRA/ENVT, UMR1225 IHAP, Toulouse, France
[2]Université de Bordeaux, Pôle Protéomique, Bordeaux, France

Backgrounds

The evolution of the wall-less mycoplasmas was long thought to be only driven by genome reduction, resulting in current mycoplasmas having a minimal genome. Evidences of massive gene flows within and across mycoplasma species provided a new frame to understand the successful adaptation of these minimal bacteria to a broad range of environments. This phenomenon was discovered in *Mycoplasma agalactiae* that contains an Integrative Conjugative Element (ICEA) belonging to a new clade of the Mutator-like superfamily in prokaryotes. Unlike classical ICEs, ICEA has no preferential insertion specificity and multiple copies can be found at different loci of the host chromosome.

Objectives

The overall objective of this study was to address ICEA functions and interactions among co-resident ICEAs to propose a model of conjugative transfer in mycoplasmas.

Methods

This was done by combining classical matting experiments to functional genomics.

Conclusions

The individual behavior of co-resident ICEAs was supported by complementation studies showing that conjugative-deficient ICEAs can only be plasmid-complemented despite the co-occurrence of multiple chromosomal ICEA copies. One exception was CDS14 knock-out ICEAs whose conjugative transfer was conditioned by the occurrence of additional ICEA copies. CDS14 encodes a lipoprotein expressed at the surface of ICEA positive cells and may participate in the early steps of the conjugative process. Remarkably, CDS14 expression in the ICEA-negative mating partner was able to restore the conjugative phenotype of an ICEA-positive partner carrying a single CDS14 knock-out ICEA. The complex behavior of co-resident ICEAs raises questions regarding the dynamics and evolution of these conjugative elements, including vestigial ICEAs.

GENETIC DISSECTION OF PROTEIN SYNTHESIS INITIATION IN MTB REVEALS WHICH GENES ARE ESSENTIAL, SUGGESTING THE UNIVERSAL ESSENTIALITY OF METHIONINE AMINOPEPTIDASE LEYS IN AN UNIDENTIFIED ACTIVITY

D. Barkan[1], *M. Vanunu*[1]
[1]*The Hebrew University of Jerusalem - The Faculty of Agriculture, veterinary medicine, Rehovot, Israel*

Backgrounds

Protein synthesis initiation differs in prokaryotes and eukaryotes. In prokaryotes, the initiating methionine is formylated (by Formyl-methionine transferase, *fmt*), then de-formylated (by Peptide deformylase, *def*). Then, this methionine is removed by methionine peptidases (MAP) – a process essential in al life forms. In Mtb, two genes encode for MAP (*mapA, mapB*), with conflicting evidence as to which of them is essential.

Objectives

To systemically dissect the genetics of this metabolic pathway by targeted deletion of *fmt*, *def, mapA* and *mapB* in *M. smegmatis* and *Mtb*

Methods

For *fmt*, we created merodiploid mutanst in *M. smegamis* and Mtb, performed targeted deletions, then removed the complementing copy – by silencing and cassette-switch. For *mapA* and *mapB*, we created merodiploid strains, deleted the native gene, then exchanged the complementing for either an empty vector, a functional, or several mutated versions. We created double deletion mutants of both genes

Conclusions

fmt was completely dispensable in *M. smegmatis*, but essential in Mtb. *def* is essential in *M. smegmatis*. We unequivocally show that *mapB*, and not *mapA* is the essential one. **Despite complete essentiality, *mapB* could be replaced by at least 2 mutated, enzymatically inactive, versions**.

fmt essentiality differs in M.smegmatis and Mtb. *def* is essential in *M. smegmatis*, but revertant rate limits usefulness as drug target. *mapB*, and not *mapA*, is the essential MAP in Mtb. Most important, we suggest **that in Mtb – and perhaps in all life forms – MAP essentiality may not ley in their characterized activity, but in some other unidentified property or activity**.

INVESTIGATING THE RELATIONSHIP BETWEEN QUORUM SENSING, THE TYPE III SECRETION NEEDLE-TIP PROTEIN LCRV AND AUTO-AGGREGATION IN YERSINIA PSEUDOTUBERCULOSIS

N.A. Barratt[1], A. Wiechmann[2], J. Purves[3], P. Williams[1], S. Atkinson[1]
[1]University of Nottingham, Centre for Biomolecular Sciences, Nottingham, United Kingdom
[2]Current Address Goethe University, Department of Molecular Microbiology and Bioenergetics, Frankfurt am Main, Germany
[3]Current Address University of Leicester, Department of Genetics, Leicester, United Kingdom

Backgrounds

The enteropathogen Y. pseudotuberculosis possesses a 70 kb virulence plasmid (pYV) that encodes a Type 3 Secretion (T3S) system, consisting of a needle-like injectisome that delivers effector proteins into host cells triggering apoptosis.

Y. pseudotuberculosis uses a quorum sensing (QS) system to control gene expression, which requires the density dependent production and transduction of N-acylhomoserine lactone (AHL) signal molecules, which accumulate with increasing cell number. AHLs are synthesised by the LuxI family of synthase proteins and transduced by LuxR response regulators. Y. pseudotuberculosis has two LuxR/I homologues, YtbR/I and YpsR/I, which regulate virulence related phenotypes, including the regulation of components of the T3S system, biofilm production and cellular auto-aggregation (A-Ag).

The T3S system, pYV and QS have been linked to YadA independent A-Ag since an AHL negative, but pYV positive, ytbI/ypsI double mutant shows a considerable increase in A-Ag compared to the parent. However, when the T3S needle protein YscF is mutated or when the double mutant is cured of pYV A-Ag is abolished.**Objectives**

To extend our knowledge of the relationship between QS, the T3S system and A-Ag the T3S needle-tip protein LcrV was mutated and A-Ag assessed in an AHL positive or negative background.

Methods

lcrV single and ytbI/ypsI/lcrV triple mutants were constructed using the suicide plasmid pDM4 and the ability of the newly constructed mutants to A-Ag was assessed using a Coulter-LS230 laser diffraction particle size analyser.

Conclusions

The lcrV mutant was unable to aggregate, whereas ytbI/ypsI/lcrV mutant showed restoration of the aggregation phenotype, suggesting that QS regulates A-Ag in a LcrV dependent manner.

Physiology / Biochemistry / Molecular Microbiology

DECIPHERING THE ROLE OF A NEW STREPTOCOCCUS PNEUMONIAE PLAYER IN RIBOSOME ASSEMBLY AND TRANSLATION

C. Bárria[1]
[1]*Instituto de Tecnologia Química e Biológica António Xavier, MostMicro, Oeiras, Portugal*

Backgrounds

Ribosomes are macromolecular machines that translate mRNA into functional proteins. In bacteria, the 70S ribosome is composed of two subunits, a small 30S subunit and a large 50S subunit. Each subunit is composed of ribosomal RNA and ribosomal proteins. A proper and coordinated assembly of these players is crucial to form an active ribosomal particle.Ribonucleases (RNases) are enzymes that ensure maturation, degradation and quality control of RNA.

Objectives

Escherichia coli RNB family of enzymes is present in all domains of life and includes RNase R, RNase II and the eukaryotic Rrp44/Dis3, Dis3L1 and Dis3L2 proteins. In *Streptococcus pneumoniae* only RNase R was identified. RNase R level is increased in several stress conditions such as heat shock, stationary phase or cold shock, conditions in which most of the proteins translation is blocked.

Here, we investigated the role of RNase R in translation by comparing the wild type strain with an *rnr* mutant strain.**Methods**

We compared the ribosomal profile between the two strains using sucrose gradient separation and Western blots. We have also performed Northern blots analysis of transcripts involved in translation and ribosome assembly.

Conclusions

In this study we show that RNase R interacts with ribosomes mostly with the 50S subunit. Moreover, in the absence of this enzyme we have observed a decrease in the amount of the 70S ribosomal subunit, concomitantly with the increase of 50S subunit. RNase R seems also to be involved in the regulation of other RNases responsible for the processing of ribosomal RNA.

Physiology / Biochemistry / Molecular Microbiology

GENOME-WIDE ANALYSIS OF PARB BINDING SITES IN PSEUDOMONAS AERUGINOSA

A.A. Bartosik[1], *K. Glabski*[1], *A. Kawalek*[1], *G. Jagura-Burdzy*[1]
[1]*Institute of Biochemistry and Biophysics- Polish Academy of Sciences, Department of Microbial Biochemistry, Warsaw, Poland*

Backgrounds

ParA and ParB homologs are involved in chromosome segregation in bacteria. ParBs participate in proper folding and initial separation of ori domains by binding to specific *parS* sites (centromere-like sequences), mainly localized in the close proximity to origin of replication *oriC*. In *P. aeruginosa* PAO1161 neither lack of *parB* gene nor modification of ten *parS*s is lethal. However, such mutants show not only defects in chromosome segregation but also growth retardation and motility dysfunctions. Moreover, in $parB_{null}$ strain expression of thousand of genes is affected.

Objectives

The aim of this study was to find all ParB binding sites in the *P. aeruginosa* genome to elucidate the role of ParB in chromosome segregation and regulation of gene expression.

Methods

DNA immunoprecipitation with anti-ParB antibodies followed by deep sequencing (ChIP-seq) analysis was performed for WT and ParB-overproducing strains of *P. aeruginosa* PAO1161. qPCR, DNA pull-down assays supported by mass spectroscopy analysis and EMSA tests were used to verify the ChIP-seq results for selected ParB binding sites.

Conclusions

ChIP-seq analysis demonstrated a specific genome-wide distribution of ParB in *P. aeruginosa.* All previously postulated *parS* sites with exception of *parS5* interacted with ParB *in vivo.* The hierarchy of *parS* sites was confirmed. Additional ParB binding sites with no or partial similarity to *parS* site consensus sequence were identified. We speculate that in *P. aeruginosa* ParB through interactions with DNA influences genome topology and modulates gene expression.

This work was supported by the National Science Centre in Poland (grant 2013/11/B/NZ2/02555).

Physiology / Biochemistry / Molecular Microbiology

PARTITIONING PROTEIN PARB CONTROLS EXPRESSION OF GENES ADJACENT TO ITS HIGH AFFINITY BINDING SITES PARS3 AND PARS4 IN PSEUDOMONAS AERUGINOSA

A. Kawalek[1], K. Glabski[1], A.A. Bartosik[1], A. Fogtman[2], G. Jagura-Burdzy[1]
[1]Institute of Biochemistry and Biophysics- Polish Academy of Sciences, Department of Microbial Biochemistry, Warsaw, Poland
[2]Institute of Biochemistry and Biophysics- Polish Academy of Sciences, Laboratory of Microarray Analysis, Warsaw, Poland

Backgrounds

In *Pseudomonas aeruginosa* the ParABS system comprising an NTPase (ParA), a DNA-binding protein (ParB) and *parS* sequences recognized by ParB, is involved in segregation of the newly replicated chromosomes. Lack of *parB* manifests in pleiotropic phenotypic effects and leads to global changes in the transcriptome of *P. aeruginosa* cells, indicating that, directly or indirectly, ParB could play a role in regulation of gene expression.

Objectives

Here we focused on the changes in the transcriptome of *P. aeruginosa* strain exposed to a slight increase in ParB production to define the primary targets of ParB action in the cells.

Methods

Microarray-based transcriptomic analysis was performed on WT strain, its transformants with empty vector and strain carrying arabinose-inducible *araBAD*p-*parB* transcriptional fusion on a medium-copy-number plasmid. Results were verified by RT-qPCR. Chosen promoter regions were linked to *lacZ* and their activities were monitored in strains producing various amounts of ParB.

Conclusions

Increase in ParB level significantly alters the expression of 211 loci. Most notably, the mRNA level of genes adjacent to high-affinity ParB binding sites *parS1-4* close to *oriC* is reduced. Whereas *parS1* and *parS2* are intragenic to *recF* in *dnaA-dnaN-recF-gyrB* operon, *parS3* and *parS4* are located in promoter regions of operons involved in stress adaptation. In cells lacking either *parB* or functional *parS* sequences the orfs adjacent to *parS3* and *parS4* are upregulated, indicating that direct ParB interactions with *parS3* and *parS4* may repress transcription of these operons.

This work was supported by the National Science Centre in Poland (grant 2013/11/B/NZ2/02555).

STUDY OF THE METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS COLONIZATION AND INFECTION IN AN ORGANOTYPIC KERATINOCYTE-FIBROBLAST CO-CULTURE MODEL

N. Barua[1], *M. Luo*[1], *M. Ip*[1]
[1]*The Chinese University Of Hong Kong, Microbiology, Hong Kong, Hong Kong S.A.R.*

Backgrounds

The difference in the array of virulence factors make some MRSA strains more virulent and capable of causing disease globally. Skin is the major site of *Staphylococcus aureus* infection and the pathogen invades across the keratinocyte barrier by modulating necrosis, pyroptosis or autophagy. An organotypic keratinocyte-fibroblast model, provides a platform to study the interactions that closely resemble the human epidermis.

Objectives

To study the adherence, internalization and the modulation of cell death by the prevalent clonal types of MRSA in a 3-D organotypic skin model.

Methods

The organotypic culture were exposed to prevalent clonal types ST239, ST45 and ST22 of healthcare-associated MRSA and ST8 (USA300), ST30 and ST59 of community-associated MRSA at log-phase containing $3.3x10^5$ CFU/ml. In addition, knockout strains of *sortase A* and *sortase B* genes of USA300 were included. Histological sections and enumeration of bacterial counts were obtained at 2hr, 16hr, 24hr and 48hr to study the adherence and internalization of the bacteria. The cell death was analyzed quantitatively by TUNEL assay and DAPI staining

Conclusions

Our study illustrates the variation in adherence, invasion and the cell death modulation among the multiple strains studied longitudinally. The MRSA clonal type ST59 showed the maximum colonization and cell death. The knockout strains of *sortase A* and *sortase B* genes of USA300 did not exhibit invasion of the organotypic skin model. The study provides an insight in the interactions between the different MRSA strains and the human skin during the establishment of the infection.

AN ANTISENSE RNA CONNECTS SOS-RESPONSE WITH CELLULAR STRESS

L. Bastet[1], C. Caballero[1], M. Villanueva[1], I. Lasa[2], A. Toledo[1]
[1]Instituto de Agrobiotecnología, Laboratory of Bacterial Gene Regulation, Mutilva Baja, Spain
[2]Navarrabiomed-Universidad Pùblica de Navarra, IdiSNA, Pamplona, Spain

Backgrounds

Latest advancements in RNA-sequencing have disclosed an unexpected variety of antisense-RNAs (asRNAs) in bacteria. These non-coding RNAs are typically transcribed from the DNA strand opposite to a gene and thus present a perfect base-complementarity to the cognate mRNA. Emerging evidences indicate that asRNAs can interfere with the transcription, translation or stability of the associated mRNA. Beyond this preliminary knowledge, the physiological relevance and the regulatory mechanism of asRNAs remain elusive.

Objectives

In a previous work, we showed that several asRNAs of *Staphylococcus aureus* affect the expression level of their related gene. Among the targets, we identified the *lexA* gene, which encodes for the master regulator of the bacterial SOS-response. Herein, we aimed to further decipher the function of the *lexA* asRNA in controlling gene expression.

Methods

First, we characterized the *lexA* asRNA using Northern blot experiments and fluorescent transcriptional fusions analyzed by flow cytometry. Second, we assessed the effect of the asRNA on *lexA* expression employing time-lapse fluorescence microscopy associated to microfluidic systems. This technic allowed following the expression of fluorescent transcriptional fusions in single cells over the bacterial growth.

Conclusions

We demonstrated that the *lexA* asRNA is originated from the transcriptional read-through of the terminator of a SigmaB-controlled gene. Consequently, the expression of the asRNA is activated during the cellular stress. Microfluidic experiments suggested that the expression of *lexA* is modulated by the asRNA. Altogether, these results showed that a long complex transcript links the cellular stress with the SOS-response in *S. aureus*.

CLONAL DIVERSITY OF NOSOCOMIAL MDR AND XDR ACINETOBACTER BAUMANNII ISOLATES AND PREVALENCE OF OXA GENES

T. Kula Atik[1], M. Ozyurt[1], B. Atik[2], B. Bektore[1], M.B. Selek[1], E. Yenilmez[3], O. Baylan[1]
[1]Health Sciences University- Sultan Abdulhamid Han Training and Research Hospital, Department of Medical Microbiology, Istanbul, Turkey
[2]Health Sciences University- Sultan Abdulhamid Han Training and Research Hospital, Department of Anesthesiology and Reanimation, Istanbul, Turkey
[3]Health Sciences University- Sultan Abdulhamid Han Training and Research Hospital, Department of Infectious Diseases, Istanbul, Turkey

Backgrounds

Acinetobacter baumannii is an opportunistic pathogen, which can stay alive especially in intensive care units (ICUs) for prolonged periods. Development of drug resistance, including carbapenems, causes serious problems in treatment of infections with this pathogen. Carbapenem resistance is generally caused by OXA-type carbapenemases. Pulsed field gel electrophoresis (PFGE) method, used in determination of clonal relation, is accepted as the gold standard method.

Objectives

We aimed to screen OXA-type β-lactamases and determine clonal relation in 100 distinct *A. baumannii* isolates.

Methods

All isolates are isolated from inpatients in Anesthesiology and Reanimation ICU (ARICU) and Internal Medicine ICU (IMICU) between 2012 to 2014 in our hospital. We investigated OXA-type β-lactamases via multiplex polymerase chain reaction method and clonal relation via PFGE method.

Conclusions

31 of the samples were isolated from ARICU while remaining 69 samples were from IMICU. 57% of the samples were from respiratory system. Colistin was the most effective antibiotic with 100% susceptibility rate. All isolates possessed OXA-51 gene while 92% had OXA-23 gene. During PFGE genotyping analyses, similarity coefficient was set as 80% and 19 different clusters were determined for 100 samples. The intense positivity of OXA-51 and OXA-23 genes and the proved presence of clonal relationship in *A. baumannii* isolates showed the evolution of the agent in ICU environment. While defining the hospital infection control programs to prevent the dissemination of this agent, every center should identify their OXA-type resistance profiles and common clones. We want to emphasize the importance of molecular epidemiology and related studies once more with this study.

THE INFLUENCE OF DEPOSITED DIAMOND NANOPARTICLES ON LATERAL GROWTH OF BACTERIAL COLONIES

J. Beranová[1], P. Matyska Lišková[1], E. Ukraintsev[2], R. Fišer[3], O. Kofroňová[4], O. Benada[4], A. Kromka[2], I. Konopásek[1]
[1]Charles University - Faculty of Science, Department of Genetics and Microbiology, Prague 2, Czech Republic
[2]Institute of Physics of the Czech Academy of Sciences, Department of Optical Materials, Praha 6, Czech Republic
[3]Charles University - Faculty of Science, Department of Genetics and Microbiology, Prague 2, Czech Republic
[4]Institute of Microbiology of the Czech Academy of Sciences, Laboratory of Molecular Structure Characterization, Praha 4, Czech Republic

Backgrounds

Diamond nanoparticles were shown to possess bactericidal potential if applied to bacteria in suspension. However, in our previous work we also observed the influence of diamond nanoparticles (DNPs) on bacterial colony size and shape if they were applied on solid medium surface. *B. subtilis* colonies grown on DNP layer were of reduced diameter and changed shape. This effect differed for Gram-positive and Gram-negative bacterium. In this work we focused on this phenomenon in more detail.

Objectives

Colony count and colony forming ability assay is a method widely employed in testing of antibacterial potential of various materials. However, materials of nanoparticle character (such as DNPs) are deposited with bacteria on the agar plate surface during plating. We show that the nanoparticle layer can bring additional effects on bacterial colony growth in lateral direction. We observed the concentration dependent influence of DNPs on the colony area and biomass of model bacteria colonies.

Methods

Escherichia coli and *Bacillus subtilis* were chosen as representatives of Gram-negative and Gram-positive bacteria, respectively, and *Proteus mirabilis* as a model of bacterium exhibiting intensive swarming motility. We analysed the count, area and weight of bacterial colonies grown on agar surface covered with DNPs and also tested the physical characteristics of DNP-covered agar surface.

Conclusions

We conclude that DNPs function like mechanical obstacle reducing bacterial motility on the surface. This effect results in colony lateral growth suppression. We suppose that also increased hydrophobicity and roughness contributes to this motility-preventing effect of DNP layer.

THE ACQUISITION OF INSERTION SEQUENCES DRIVES THE ADAPTATION OF MULTICOPY PLASMIDS TO NOVEL BACTERIAL HOSTS

C. Bernabe-Balas[1], M. Ares-Arroyo[1], A. Santos-Lopez[1], A. Hoefer[1], L. Carrilero[1], C. M. Ovejero[1], D. Thomas-Lopez[1], G. Moyano[1], J.F. Delgado-Blas[1], B. R. Matamoros[1], N. Montero[1], B. Gonzalez-Zorn[1]
[1]Faculty of Veterinary Medicine and VISAVET- Complutense University of Madrid, Animal Health, Madrid, Spain

Backgrounds

Plasmid dissemination via horizontal transfer facilitates the spread of antibiotic resistance, a critical problem worldwide. When plasmids are acquired by new bacterial hosts they need to be maintained to continue propagating their resistance genes, both horizontally and vertically. However, the mechanisms involved in plasmid adaptation are not completely understood.

Objectives

To investigate the adaptive capacity of plasmids to novel hosts.

Methods

pB1000, a multicopy plasmid from *Pasteurellaceae*, was propagated in *Escherichia coli*, where it has never been described and is rapidly lost, to explore the adaptive changes of the plasmid throughout evolution assays under antibiotic pressure. The evolved plasmids were then transformed into non-evolved *E. coli* to investigate the effects of the pB1000's adaptive modifications on its stability. The plasmid's sequence and copy number (PCN), the MIC and growth profile of the host bacteria were also analyzed, as well as the transformation efficiency both in *E. coli* and the original host.

Conclusions

Over the experimental evolutions pB1000 acquired two different insertion sequences (ISs) from the *E. coli* chromosome, both inserted into the same region of different pB1000s. Additionally, various SNPs appeared in the putative *oriV* of pB1000. Both the ISs and the SNPs triggered an increase in the stability of pB1000 in *E. coli*. While the SNP increased both the PCN and MIC, the insertion sequences reduced the biological burden of pB1000 by disrupting a specific region of the plasmid. Interestingly, both modifications impeded the retro-transformation of the original plasmid host, suggesting a non-return adaptation of pB1000 from *Pasteurellaceae* to *Enterobacteriaceae*.

TERMINOMICS REVEALS EXTENSIVE PROTEOLYSIS OF CELL SURFACE PROTEINS IN A GENOME-REDUCED BACTERIAL PATHOGEN

I.J. Berry[1], V.M. Jarocki[1], J.L. Tacchi[1], B.B.A. Raymond[1], M. Widjaja[1], M.P. Padula[1], S.P. Djordjevic[1]
[1]University of Technology Sydney UTS, Faculty of Science, Ultimo, Australia

Backgrounds

Proteolytic processing profoundly affects protein function but few studies have used a systems approach to understand its role in prokaryotes. The genome-reduced pathogen, *Mycoplasma hyopneumoniae* processes members of the P97 and P102 adhesin families. It was used here as a model to study protein processing on a global scale.

Objectives

Our aim is to characterise the extent of protein processing, including methionine excision, in a genome-reduced, host-adapted pathogen. *M. hyopneumoniae* proteins that are retained on agarose resin coupled separately with different host proteins were characterised as a means to independently recover processed fragments and to determine how they differ in their binding capabilities compared with the parent. We also determined the composition of the surfaceome of *M. hyopneumoniae* and the proportion of proteins that are processed on the cell surface.

Methods

We took an untargeted, high-throughput approach to identify proteolytic events using protein mass spectrometry. Cell surface shaving and biotinylation approaches were used to confirm the surface localisation of these proteoforms and affinity chromatography bait-prey studies were used to investigate putative bait-prey interactions.

Conclusions

We identified 669 unique N-terminal peptide sequences from 164 predicted ORFs. Multiple processing events were mapped to each of 141 proteins downstream of the initiating methionine. Cleavage occurred most often with arginine in P1 and serine/threonine in P1', a pattern consistent with trypsin-like activity but other cleavage motifs were characterised. Surfaceome studies identified 159 proteins and 75 (47%) were processed extensively. Protein processing represents a mechanism to expand the function of proteins that reside on the cell surface.

[2]University of Oxford, Chemistry, Oxford, United Kingdom
[3]National University of Singapore, Duke-NUS Medical School, Singapore, Singapore
[4]Aalborg University, Chemistry and Bioscience, Aalborg, Denmark
[5]Aarhus University, Molecular Biology and Genetics, Aarhus, Denmark

Backgrounds

Construction of a bacterial biofilm matrix often requires amyloid fibrils to be exported to the extracellular milieu via specialised biogenesis machineries. Amyloid production requires a dedicated multi-component secretion system through which unfolded amyloid substrates are translocated and assembled, with the most documented example being the *Escherichia coli '*Curli' system. More recently, it has come to light that *Pseudomonas* utilises a novel system for similar purposes, encoded in the single operon *fapABCDEF*, which is genetically distinct to the Curli system of *E. coli.*

Objectives

We set out to obtain structural insight into the system, starting with the outer-membrane transporter FapF. Also, we test the functional determinants of the FapC amyloid *in vivo*, and investigate the roles of other Fap components.

Methods

We use X-ray crystallography, native mass spectrometry and single channel conductance measurements to reveal the first high-resolution structural insight into the amyloid transporter FapF. We also employ mutagenesis and secretion assays to shed light on the mechanism of FapC secretion.

Conclusions

FapF forms a trimer of gated β-barrel channels, in which activation is regulated by a helical plug connected to an intriguing extended coiled-coil platform spanning the bacterial periplasm. Although FapF represents a unique type of secretion system, it shares mechanistic features with a diverse range of peptide translocation systems. Our findings highlight alternative strategies for handling and export of amyloid protein sequences, and contribute to a growing understanding of how bacteria can safely handle amyloidogenic polypeptides. The *Pseudomonas* Fap system also provides inspiration for new approaches in the control of bacterial biofilms.

ADDITIONAL PROMOTERS IN THE DPS REGULATORY REGION: ACTIVATING TRANSCRIPTION AND SENSING METABOLIC CHANGES

T. Bessonova[1,2], U. Shvyreva[1], D. Gagarinskaya[1], M. Tutukina[1], O. Ozoline[1]
[1]Institute of Cell Biophysics RAS, Functional genomics and cellular stress, Pushchino, Russia
[2]Ural Federal University, Biology, Ekaterinburg, Russia

Backgrounds

Dps is a nucleoid protein well known for its protective role. Regulatory region of the *dps* gene in *E. coli* is longer than average and includes additional promoters P1, P1', P2 and P3 that stimulate transcription from Pdps. At these distal promoters, possible binding sites for proteins controlling metabolic switches, such as CRP, ExuR, GntR and SdiA, were found. This is not typical for a gene coding for nucleoid protein.

Objectives

The major aim was to study the role of metabolic regulators in mediation of *dps* expression.

Methods

Alignments were done with TCoffee and BLAST. DNA sampling results were analyzed with LC/MS-spectrometry. Mutants were prepared by "gene doctoring". Expression was measured by qRT-PCR and RNA-seq.

Conclusions

Global metabolic regulator cAMP-CRP activated *dps* in all growth conditions, while GntR acted as a repressor. Two other proteins bound to the *dps* regulatory region, ExuR and SdiA were sugar-dependent and phase-dependent dual regulators. Thus, metabolic regulators, indeed, contribute to *dps* expression. Multiple alignment showed that all *Escherichiae* and related species have Pdps and P1 promoters, but not P1', P2 and P3. As the same combination of additional *dps* promoters was found in *Dickeya dadantii*, a bacterial plant pathogen, we made a guess that these promoters were horizontally transferred to the *E. coli* genome together with their own regulation mode. At the first stage of infection, *Dickeya* starts using oligosaccharides as the main carbon source and *dps* expression becomes elevated. Additional promoters in the *dps* regulatory region may thus contribute to adaptive switch of carbon metabolism.

A SENSOR MONITORING PHOSPHORYLATION OF THE CELL CYCLE RESPONSE REGULATOR CTRA IN CAULOBACTER CRESCENTUS

A. Fioravanti[1], A.A. Galizzi[1], E. Biondi[1]
[1]IMM, LCB, Marseille, France

Backgrounds

Caulobacter crescentus cells divide producing distinct cells types. The development of different cellular types is caused by the asymmetrical localization of factors before cell division. The phosphorylated response regulator CtrA represses the origin of chromosome replication and activates the expression of tens of genes that are crucial for cell cycle progression and cellular asymmetry. After the G1-S transition, in which CtrA is proteolyzed, its transcription is reactivated by GcrA in early S-phase. CtrA is then phosphorylated by the CckA/ChpT phosphorelay at the new pole of the predivisional cell. This spatial organization of CckA suggests that in predivisional cells CtrA-P levels should be higher at the swarmer new pole.

Objectives

Here we describe the development of a biosensor able to detect the phosphorylation level of CtrA in vivo by exploiting the ability of response regulators to dimerize upon phosphorylation.

Methods

The receiver domain of CtrA (CtrA-REC) was individually fused with CFP and YFP, purified and phosphorylated in vitro; the phosphorylation-dependent dimerization of the sensor was demonstrated by FRET measurements. Next we confirmed the functionality of this sensor also in vivo by expressing together both fusions in *Caulobacter* cells and measuring the FRET signals in different conditions. Finally we explore the subcellular localization of the CtrA-P levels, revealing that phosphorylation levels of CtrA in predivisional cells are higher in the proximity of the new pole.

Conclusions

The development of this biosensor indeed shows that bacterial cells are able to asymmetrically distribute phosphorylation of response regulators controlling cell cycle and the development of specific cell types.

GENOME-WIDE ANALYSIS OF THE FLEQ DIRECT REGULON IN THE BIOCONTROL STRAIN PSEUDOMONAS FLUORESCENS F113

E. Blanco-Romero[1], *D. Garrido-Sanz*[1], *F. Martínez-Granero*[1], *C. Muriel*[1], *D. Durán*[1], *R. Rivilla*[1], *M. Redondo-Nieto*[1], *M. Martín*[1]
[1]*Universidad Autónoma de Madrid, Departamento de Biología- Facultad de Ciencias, Madrid, Spain*

Backgrounds

Bacterial motility plays a crucial role in competitiveness and colonization in the rhizosphere environment. Moreover, this trait is highly important in the biotechnological application and improvement of microbial inoculants employed in sustainable agriculture. FleQ appears to be the master regulator of flagella and exopolysaccharide biosynthesis in pseudomonads. Specifically, in *Pseudomonas fluorescens* F113, an interesting biocontrol and plant growth promoting bacteria, FleQ participates in the regulation of motility and biofilm formation.

Objectives

The aim of this work was to identify the genes and operons regulated by FleQ and to analyze the overlap between the FleQ and AmrZ regulons in *P. fluorescens* F113.

Methods

By using the ChIP-seq method we expected to find the DNA regions where FleQ binds to regulate gene expression. Regulation was subsequently confirmed with RT-qPCR assays in wild-type and *fleQ* mutant backgrounds.

Conclusions

ChIP-seq analysis has shown that FleQ is a global regulator in *P. fluorescens* F113 and 106 FleQ putative binding sites have been identified. Genes presumably regulated by FleQ included, as expected, flagellar and motility-related genes and others involved in adhesion and exopolysaccharide production. Surprisingly, the ChIP-seq analysis also identified iron uptake-related genes. Regulation of these genes by FleQ was verified by RT-qPCR. The results also showed that FleQ shares an important part of its direct regulon with AmrZ, a global regulator implicated in environmental adaption. Although AmrZ also regulates motility and iron uptake, the overlap occurred only with the iron-related genes, since both regulators control a different set of motility-related genes.

PHYSIOLOGICAL AND MOLECULAR CHARACTERIZATION OF ARTHROSPIRA SP. PCC 9108 IN ORDER TO DEVELOP GENETIC ENGINEERING TOOLS

A. Blanco-Rivero[1], *M.C. Aparicio*[1], *P. Suárez-Rodríguez*[1], *F.G. Guevara*[1], *J.M. Navarro-Llorens*[1], *J. Perera*[1]
[1]*Universidad Complutense de Madrid,*
Departamento de Bioquímica y Biología Molecular- I. - Facultad de Ciencias Biológicas., Madrid, Spain

Backgrounds

The filamentous cyanobacterium known as "spirulina" or *Arthrospira platensis* is one of the most commercially important species of microalgae. Due to its high nutritional value and pharmacological and industrial applications it is extensively cultivated on a large commercial scale.

Despite its widespread use, no precise genetic manipulation tools have yet been developed to carry out important improvements in its industrial production. This is probably due to cyanobacterial defense mechanisms against foreign DNA transfer. Previous analysis performed in our laboratory show that *A. platensis* PCC9108 has 13 transcriptionally active R-M systems, which could act preventing the entry of exogenous DNA to the cell, and thus avoiding its genetic transformation**Objectives**

Before designing strategies for *Arthrospira´*s succesful transformation, two studies were aimed: studying the functionality of some of the 13 R-M systems and characterizing the growing ability of this strain under certain stressful conditions that could increase the production of certain compounds of interest.

Methods

For this work, several methods were followed: growth studies of *A. platensis* PCC9108 strain at different external pH values and different NaCl concentrations; studies of sensitivity to antibiotics; and *in vitro* endonuclease activity assays.

Conclusions

The ranges of pH values and salt concentration have been defined for the growth of *A. platensis*. Similarly, the sensibility of this cyanobacterium to several antibiotics has been evaluated. Finally, *in vitro* assays of *A. platensis* endonuclease activities have been carried out.

ESCHERICHIA COLI FOF1-ATPASE ACTIVITY AND ITS COOPERATION WITH HYDROGENASE 4 (HYF) DEPEND ON GLUCOSE CONCENTRATION

S. Blbulyan[1], A. Trchounian[1]
[1]Yerevan State University, Biochemistry- Microbiology and Biotechnology, Yerevan, Armenia

Backgrounds

Escherichia coli produces dihydrogen (H_2) by hydrogenase (Hyd) enzymes during glucose fermentation. It was shown that Hyd-4 (*hyf*) operates at pH 7.5 and sensitive to the F_OF_1-ATPase's inhibitor *N,N'*-dicyclohexylcarbodiimide (DCCD).This ATPase is required for Hyd activity, and some relationships between these enzymes are suggested.

Objectives

The overall and DCCD-inhibited ATPase activity of *E. coli* BW25113 wild type (WT) and JRG3621 (*hyfB-R*) mutant membrane vesicles were studied.

Methods

Bacteria were grown anaerobically with glucose supplementation, pH 7.5. ATPase activity was determined by liberation of P_{inorg} during ATPase reaction.

Conclusions

ATPase activity of WT was 1.5-fold higher ($p \leq 0.025$) compared to mutant under 0.2% glucose fermentation. It was 1.8-fold higher compared to that of mutant upon 100 mM K^+ supplementation. Furthermore, K^+ stimulated (1.4-fold) ($p \leq 0.025$) ATPase activity in WT and 1.2-fold ($p \leq 0.02$) in the mutant. DCCD inhibited ATPase activity of both WT and mutant was 5-fold and 7-fold ($p \leq 0.02$), respectively. 0.8% glucose fermented WT showed higher ATPase activity upon K^+ free and 100mM K^+ conditions compared to 0.2% glucose fermented cells. The ATPase activity of 0.8% glucose fermented mutant was the same in dependently of K^+; DCCD inhibited markedly (~8-fold, $p \leq 0.05$) ATPase activities of investigated strains.

The F_OF_1-ATPase activity and its relationship with Hyd-4 depend on growth medium glucose concentration, which is more evident at low concentration of glucose (0.2%) and in the presence K^+. This confirms the finding that Hyd-4 is active at 0.2% glucose.

FEMS7-0704
Physiology / Biochemistry / Molecular Microbiology

BACTERIAL DRUG EFFLUX PUMP MACAB AS A NEW TARGET FOR DRUG DEVELOPMENT

L. Matrosova[1], I. Khilyas[1], T. Shirshikova[1], L. Kamaletdinova[1], Y. Danilova[1], L. Bogomolnaya[1,2]
[1]Kazan Federal Volga-Region University, Fundamental Medicine and Biology, Kazan, Russia
[2]Texas A&M University Health Science Center, Microbial Pathogenesis and Immunology, Bryan, USA

Backgrounds

Bacterial drug efflux pumps are protein membrane complexes that function to actively expulse antimicrobials from the cells. Recent data indicate that the role of drug efflux pumps is not limited to just antibiotic resistance. Macrolide-specific ABC-type drug efflux pump MacAB first identified in *E. coli* has been linked to virulence of *Salmonella enterica* serotype Typhimurium in mice. We have recently showed that MacAB efflux pump is required for protection of *Salmonella* Typhimurium against oxidative stress both *in vitro* and *in vivo*.

Objectives

Here we sought to investigate if the function of MacAB in protection against an oxidative stress is conserved across other members of *Enerobacteriaceae* family.

Methods

Here we show that MacAB is essential for survival of *Serratia marcescens* in the presence of hydrogen peroxide. We further show that *S. marcescens* Δ*macAB* mutant cells could be protected against peroxide-mediated killing by low molecular weight metabolites present in the media used to grow wild type bacteria but not in the media conditioned by growth of Δ*macAB* mutant strain. Protective effect of these metabolites was abolished by heat- or proteinase K treatment. These data indicate that the identified molecules are proteins or peptides. We are currently working on identification of MacAB substrates with anti-H_2O_2 properties.

Conclusions

Combined, our data strongly suggest that the drug efflux pump MacAB present in many Gram-negative bacteria represents an attractive target for development of new antimicrobials.

Physiology / Biochemistry / Molecular Microbiology

DETECTION, IDENTIFICATION AND CHARACTERIZATION OF FUNGAL SPECIES IN HUMAN BREAST MILK, AND THEIR RELATIONSHIP WITH MACRONUTRIENTS AND HUMAN SOMATIC CELLS

A. Boix-Amorós[1]
[1]*Instituto de Agroquímica y Tecnología de Alimentos IATA-CSIC, Biotechnology, Paterna, Spain*

Backgrounds

Human breast milk (HBM) is considered the optimal food source for infants, providing nutrients and functional compounds unmatched by formula. Emerging evidence demonstrates the presence of bacteria in breast milk, some of which are being considered as potential probiotics to promote infant health. However, little is known about the presence of other microorganisms as yeasts and fungi, although both have been detected in gut microbiome's from infants.

Objectives

Our aim was to characterize the fungal organisms present in breast milk, their composition and load, and their relationships with macronutrients and human cells in samples from healthy lactating mothers.

Methods

Milk fungal composition was analyzed by 28S-pyrosequencing and culturing in three different media; fungal loads were estimated by qPCR calibrated by flow cytometry; and fat, protein, lactose and dry extract of milk as well as the number of human somatic cells were analyzed by spectrophotometry and cytometry.

Conclusions

Based on morphological and biochemical analysis, 21 viable fungi were isolated and identified by Sanger sequencing, most of them belonging to the species *Rhodotorula mucilaginosa* and *Candida parasilopsis*. Fungal presence was detected by specific qPCR in 89% of the samples, showing that the median fungal load was 10E5 cells/ml, 10-fold lower than previously estimated for bacteria. Pyrosequencing of 28S rDNA showed that the most common genera were *Malassezia*, *Saccharomyces* and *Candida*. There was no correlation between fungal load and somatic cells numbers, suggesting that milk fungi are not sensed as an infection by the immune system, although their origin and beneficial role should be elucidated.

DEVELOPMENT OF UNIVERSAL FLUORESCENCE EXPRESSION TOOLS TO STUDY HOST-MYCOPLASMA INTERACTIONS

T. Bonnefois[1], *V. Rodrigues*[1], *P. Totté*[1], *F. Thiaucourt*[1], *L. Manso-Silvan*[1]
[1]*CIRAD, BIOS, Montferrier-sur-Lez, France*

Backgrounds

The genus *Mycoplasma* consists of Gram-positive bacteria that lack a cell wall, many of which can cause disease in humans and animals. There are no fluorescence expression systems available to monitor the dynamics of mycoplasma infections *in vivo* or *in vitro.*

Objectives

The aim of this work was to develop fluorescence expression tools for stable whole mycoplasma cell labelling and to validate their use for the study of host-mycoplasma interactions.

Methods

For this purpose, a Tn4001-derivative mini-transposon affording unmarked, stable mutagenesis in mycoplasmas was modified to allow the constitutive, high-level expression of mCherry, mKO2 and mNeonGreen. These tools were used to introduce the respective fluorescent proteins as chromosomal tags in the phylogenetically distant species *Mycoplasma mycoi*des subsp. *mycoides* and *Mycoplasma bovis*.

Conclusions

The production and characterisation of fluorescent clones were straightforward and resulted in the unprecedented observation of fluorescent colonies in the two species, with no apparent cytotoxicity. Equivalent fluorescence expression levels were quantified by flow cytometry in both species, suggesting that these tools can be broadly applied in mycoplasmas. A macrophage infection assay was performed to assess the usefulness of mNeonGreen-expressing strains for monitoring mycoplasma infections and cell invasion. The presence of fluorescent mycoplasmas inside live cells was detected and quantified by flow cytometry and corroborated by confocal microscopy, which allowed the identification of individual mycoplasmas in the cytoplasm of infected cells. The fluorescence expression tools developed in this study are suitable for host-pathogen interaction studies and offer perspectives for the functional analysis of mycoplasmas both *in vitro* and *in vivo*.

EMERGENCE OF A CLONAL LINEAGE OF STREPTOCOCCUS AGALACTIAE WITH RESISTANCE TO FLUOROQUINOLONES AMONG INVASIVE ISOLATES FROM ARGENTINA RECOVERED DURING 2014-2015

B. Arias[1], V. Kovacec[1], L. Müller[1], L. Vigliarolo[2], M. Suárez[2], C. Tersigni[2], H. Lopardo[2], L. Bonofiglio[3], M. Mollerach[3]
[1]Universidad de Buenos Aires- Facultad de Farmacia y Bioquímica, Departamento de Microbiología- Inmunología y Biotecnología- Cátedra de Microbiología, Buenos Aires, Argentina
[2]Universidad Nacional de La Plata, Facultad de Ciencias Exactas, La Plata, Argentina
[3]Universidad de Buenos Aires- Facultad de Farmacia y Bioquímica- CONICET, Departamento de Microbiología- Inmunología y Biotecnología- Cátedra de Microbiología, Buenos Aires, Argentina

Backgrounds

Resistance to fluoroquinolones (FQ) in *Streptococcus agalactiae* (GBS) was firstly described in 2003. Currently, it has become a worldwide growing problem.

Objectives

To determine the prevalence of FQ resistance, the clonal relationship among these isolates and to analyze their epidemiological characteristics.

Methods

In the frame of a "national prospective multicenter study of *S. agalactiae* invasive infections in Argentina", 162 isolates were recovered between July 1, 2014 –June 30, 2015. A five-disc scheme of levofloxacin, ciprofloxacin, norfloxacin, ofloxacin and pefloxacin was designed to detect FQ resistant isolates. MIC of levofloxacin was performed by agar dilution. Quinolone resistance determining regions were sequenced to detect mutations. Capsular typing was done using the Strep-B Kit. Pulsed-field gel electrophoresis (PFGE) was performed to investigate the genetic relationship of GBS-FQ-resistant isolates.

Conclusions

Results: The prevalence of FQ resistance was 15.4% (25/162). All of the FQ resistant strains showed point mutations in *gyrA* and/or *parC* genes. One PFGE group (PFGE-A) accounted for 88% of the isolates (23/25) and included 13/23 isolates with identical pattern. PFGE-A clustered isolates from 9 Argentinean cities and were assigned to serotypes: Ib (14/23) and III (8/23).

Conclusions: The resistance rate (15.4 %) is higher than that found previously in our country and even in other countries of Latin America. FQ-resistant GBS isolates were recovered from different cities of Argentina and a major clone was detected.

[3]Universidad de Buenos Aires- Facultad de Farmacia y Bioquímica- CONICET, Departamento de Microbiología- Inmunología y Biotecnología- Cátedra de Microbiología, Buenos Aires, Argentina
[4]Universidad de Buenos Aires, División Neumonología- Hospital de Clínicas José de San Martín, Buenos Aires, Argentina

Backgrounds

S. pneumoniae (Spn) is a major cause of morbi-mortality worldwide. Data regarding serotype distribution and its association with antibiotic resistance is scarce.

Objectives

The aim was to determine the serotype and antimicrobial susceptibility of Spn isolated from adult-patients that were attendant at Hospital de Clínicas, University of Buenos Aires and to evaluate the theorical coverage (TC) of PCV-13 and PPSV-23 vaccines.

Methods

Spn isolates were collected from patients >18 y.o. in two periods 2010-2012 (1P) and 2013-2014 (2P). Serotyping was performed by PCR (CDC). MIC determination was done by the BD-Phoenix-™-System.

Conclusions

Results: 86 Spn isolates were recovered, 46 belonged to 1P and 40 to 2P. All isolates except two were recovered from non-meningeal sites. 26 serotypes were identified: main 1P serotypes were S14(26%), S6(13%), S17F(13%), S19F(11%), S19A(8.7%) and S22(6.5%); from 2P were S17F(12.5%), S7F(10%), S6(7.5%) and 22F(7.5%).The TC for PCV13/PPSV23 was 59/84.6% respectively. There was a significant decrease in the TC between both periods for both vaccines (p= 0.01).

Overall, 35%(1P) and 45%(2P) of isolates were penicillin non-susceptible, most were serotypes 19A, 14, 6 and 17F. The resistance for 1P and 2P was: erythromycin (30 and 33%), clindamycin(13 and 13%), tetracycline(28 and 20%) and TMS(35 and 20%). All strains were susceptible to amoxicillin, ceftriaxone, meropenem, levofloxacin, linezolid and vancomycin.

Conclusions: A continuous surveillance program of serotypes and resistance in our Hospital is mandatory to predict treatment and monitor change in vaccine coverage since our results are different to those reported in our country.

2-AMINOACRYLATE STRESS REVEALS DIVERGENCE OF SALMONELLA ENTERICA AND ESCHERICHIA COLI METABOLIC NETWORKS

A. Borchert[1], *D. Downs*[1]
[1]*University of Georgia, Microbiology, Athens, USA*

Backgrounds

The metabolic network of an organism includes the sum total of the biochemical reactions present. Roughly 80% of protein-encoding components and regulatory machinery of *Escherichia coli* K12 are shared by *Salmonella enterica* LT2. Based on this, and supported by numerous studies, it is often assumed these organisms share metabolic network structure. Multiple recent phenotypic studies suggest a need to readdress this assumption. In *S. enterica*, the enamine intermediate, 2-aminoacrylate (2AA) inactivates a number of pyridoxal 5'-phosphate(PLP)-dependent enzymes *in vivo*. The phenotypic consequence of these perturbations is determined by the metabolic network.

Objectives In this study, metabolism of 2AA and the consequences of its accumulation are investigated in *E. coli*. The results will define metabolic network differences between *S. enterica* and *E. coli*. A secondary objective is to characterize structural features of PLP-enzymes that generate, or are targeted by, 2AA.

Methods A primarily biochemical-genetic approach is used to characterize cellular components defining the 2AA stress system in both *E. coli* and *S. enterica*. Manipulation of the active site of PLP-dependent enzymes and in vitro characterization will identify residues affecting the impact of 2AA on the respective enzyme.

Conclusions

Despite conservation of relevant enzymes, *S. enterica* and *E. coli* differ in both the generation and consequence of 2AA. The findings suggest distinct structures for the metabolic network surrounding the generation and response to endogenous 2AA stress. Mechanistic investigation of traits governing 2AA generation and damage will help to refine our ability to predict the influence of 2AA in other organisms.

BENZOATE DEGRADATION BY PSEUDOMONAS STUTZERI AN10

R. Bosch[1], *I. Brunet-Galmes*[2], *J.A. Christie-Oleza*[3], *J. Lalucat*[1], *J. Armengaud*[4], *B. Nogales*[1]
[1]*University of Balearic Islands UIB & IMEDEA CSIC-UIB, Microbiology, Palma de Mallorca, Spain*
[2]*University of Balearic Islands UIB, Microbiology, Palma de Mallorca, Spain*
[3]*University of Warwick, School of Life Sciences, Coventry, United Kingdom*
[4]*CEA-Marcoule, DSV/DIR/IBEB/SBTN/LBSP, Bagnols-sur-Cèze, France*

Backgrounds

Pseudomonas stutzeri AN10 (CCUG 29243) is a naphthalene degrading bacterium isolated from polluted marine sediments. Biochemical and physiological analyses demonstrated that strain AN10 was unable to use benzoate as carbon and energy source. However, its complete genome sequence revealed the presence of benzoate degradation genes (*ben*).

Objectives

In this study we have tried to clarify this discrepancy using genomic, proteomic and genetic engineering approaches.

Methods

First, we performed an in-depth genetic analysis of the AN10 *ben* genes and we observed two mutations that could be responsible for the observed phenotype: a stop codon disruption of *benR* (the transcriptional regulator) and a frameshift mutation in *catA* (catechol 1, 2-dioxygenase encoding gene). Using selective pressure we isolated strain BZ4D, an AN10-derivative able to use benzoate as carbon and energy source. Genetic analysis of BZ4D *ben* genes suggested that recovery of benzoate-degradation capability was probably due to the reversion of the two above mentioned mutations. Shotgun proteomic analysis of BZ4D grown on benzoate revealed the expression of all *ben*-encoded proteins. Finally, in order to demonstrate that both *benR* and *catA* mutations were responsible for the lack of benzoate degradation ability of strain AN10, we complemented AN10 *in trans* with both, *benR* and *catA* genes of BZ4D. As result, the recombinant AN10-derivative was able to grow on benzoate.

Conclusions

We have demonstrated that strain AN10 contained mutated forms of *benR* and *catA* genes that explained its lack of growth on benzoate, and that reversion of these mutations can be obtained by applying selective pressure.

BIOCHEMICAL DIVERSITY OF CHITOSANASES BELONGING TO FAMILY GH46 OF GLYCOSIDE HYDROLASES IN THE SOIL ACTINOMYCETE KITASATOSPORA SETAE

R. Brzezinski[1], P. Viens[1], M. Zitouni[1], M. Ghinet[1]
[1]Universite de Sherbrooke, Biologie, Sherbrooke- QC, Canada

Backgrounds

Chitosan is a polysaccharide: a partly deacetylated derivative of chitin composed mainly of D-glucosamine units with β-1,4 links. Chitosan is hydrolyzed by chitosanases, belonging to several families of glycoside hydrolases (GH8, 46, 75 and 80). Many actinomycetes and bacilli produce chitosanases. However, most studies were dedicated to only one enzyme per bacterial species. The genus Kitasatospora is closely related to Streptomyces. Genome mining showed that K. setae has three GH46 chitosanase genes (csn1, csn2, csn3).

Objectives

Our aim is to characterize the biochemical diversity of the GH46 chitosanases in Kitasatospora setae.

Methods

Chitosanases were expressed in Streptomyces lividans. Chitosanase Csn2 was found in two forms: a longer polypeptide (Csn2BH) composed of a carbohydrate-binding module and a catalytic module, and a shorter form (Csn2H) composed only of the catalytic module. The activity of all four enzymes was measured against chitosans of various degrees of acetylation or chitosan complexed with natural acidic compounds: polyphosphoric acid or humic acid. Activity was compared at low temperatures. The kinetic parameters were also determined.

Conclusions

Csn1 and Csn2H were relatively similar in most tests. Csn2H had a pronounced preference for highly deacetylated chitosan and was more performant on chitosan complexed with polyphosphoric acid. Csn3 was apart from the others in all the tests: had preference for moderately acetylated chitosan, lost more activity at low temperatures, and had lower activity on complexed chitosan forms. Its specific activity was also much higher. Using 3D models for Csn1 and Csn3, we discuss how differences in structure can explain the observed biochemical diversity.

STRUCTURE OF A MYCOBACTERIAL TYPE VII SECRETION SYSTEM MEMBRANE COMPLEX

C. Bunduc[1], K. Beckham[2], L. Ciccarelli[3], A. Parret[2], M. Wilmmans[2], T. Marlovits[3], W. Bitter[4], E. Houben[1]
[1]Vrije Universiteit, Molecular Microbiology, Amsterdam, The Netherlands
[2]European Molecular Biology Laboratory, EMBL, Hamburg, Germany
[3]Research Institute of Molecular Pathology, Molecular and Cellular Biology, Vienna, Austria
[4]Vrije Universiteit Medical Center, Medical Microbiology and Infection Control, Amsterdam, The Netherlands

Backgrounds

Type VII secretion (T7S) systems are used by mycobacteria to translocate a wide range of proteins across their distinct cell envelope. Pathogenic mycobacteria, including *Mycobacterium tuberculosis*, have up to five T7S systems termed ESX-1 to ESX-5, each having its own crucial role in viability and/or virulence. T7S does not resemble other known specialized secretion systems and the actual mechanism of transport is unknown. As a first step in this analysis, we have previously isolated the ESX-5 membrane complex and determined its size to be ~1.5 MDa, consisting of four membrane components, i.e. EccBCDE (ref).

Objectives

The aim of this study is to elucidate the structure and further characterize the T7S membrane complex.

Methods

We have reconstituted, isolated and analysed the ESX-5 membrane complex by negative stain single particle electron microscopy and a suite of biochemical and biophysical techniques.

Conclusions

To more easily analyse T7S systems, we reconstituted the ESX-5 system in the avirulent and fast-growing mycobacterial species *Mycobacterium smegmatis* that lacks ESX-5. The reconstituted system proved to be active and was efficiently secreting specific substrates. We subsequently purified the ESX-5 membrane complexes and analysed them through negative stain electron microscopy, resulting in the first structural images of a T7S membrane channel at 13 Å resolution. The ESX-5 complex has a six-fold symmetry and displays a marked different architecture to other bacterial secretion systems. The cytosolic domain, consisting of multiple copies of the ATPase EccC, is highly flexible. The T7S channel is not large enough to span both membranes, indicating that this core complex is located solely in the inner membrane. Finally, several lines of evidence show that EccE is a peripheral component of the transport system.

ENVIRONMENTAL REGULATION OF PIA/PNAG SYNTHESIS IN STAPHYLOCOCCUS AUREUS

S. Burgui[1], *J. Valle*[1], *I. Lasa*[1]
[1]*Centro de Investigación Biomédica Navarrabiomed/ UPNA, Laboratory of Microbial Pathogenesis, Pamplona, Spain*

Backgrounds

Staphylococcus aureus is one of the leading bacteria causing nosocomial infections associated with medical devices. The difficulty of treating these infections is mainly related with the ability to form biofilms. Biofilm production protects the bacteria from both the host immune system and antibiotics. One of the main components of the *S. aureus* biofilm matrix is the intercellular exopolysaccharide adhesin PIA/PNAG, whose synthesis depends on the expression of *icaADBC*-encoded enzymes and is repressed by the *icaR* gene product. Because PIA/PNAG synthesis is expensive for bacteria, its expression needs to be tightly regulated in response to environmental conditions.

Objectives

Understand the environmental regulation of PIA/PNAG synthesis.

Methods

A collection of mutants containing a single two component (TCS) systems and different environmental conditions have been used to identify TCS responsible to connect PIA/PNAG production with environmental conditions.

Conclusions

The results revealed that synthesis of PIA/PNAG depends on ArlRS and temperature. ArlRS regulates PIA/PNAG synthesis through IcaR repressor. An ArlRS deficient strain shows higher transcriptional levels of *icaR* and consequently lower PIA/PNAG synthesis. Temperature stimulates *icaADBC* gene transcription at 28ºC and inhibits at 37ºC in an IcaR independent manner. Temperature-dependent regulation of icaADBC operon transcription occurs when *ica* operon is expressed in *S. carnosus*, a bacteria that is naturally deficient in *icaADBC* operon. These results suggested that temperature-mediated regulation of icaADBC operon depends on a regulator present both in *S. aureus* and *S. carnosus*. Alternatively, it is also possible that temperature mediated regulation depends on intrinsic structural properties of the icaADBC promoter.

HYDROCARBONS DEGRADATION BY CITREICELLA AESTUARII: GENOMIC AND PHYSIOLOGICAL APPROACH

A. Busquets Bisbal[1], R. Bosch Zaragoza[2], M. Mas Llado[1], B. Nogales Fernandez[2]
[1]Universitat de les Illes Balears UIB, Microbiology, Palma de Mallorca, Spain
[2]University of the Balearic Islands UIB and IMEDEA UIB-CSIC, Microbiology, Palma de Mallorca, Spain

Backgrounds

During the course of a diversity survey in sand samples polluted after the Prestige oil tanker accident in Spain we obtained three isolates of the Roseobacter lineage in marine agar that later were shown to grow with naphthalene. Their closest relative by 16S rDNA sequence analysis was *Citreicella aestuarii* AD8^T, isolated from a tidal flat, and for which there were no reports of hydrocarbon degradation.

Objectives

The aim of the study was to determine the genomic characteristics that differentiate these four strains of *C. aestuarii*, particularly in reference to hydrocarbon catabolism.

Methods

Draft genome sequences of the strains 328, 329 and AD8T were obtained, and they were compared with the sequence of strain 357. Genomic comparison by Tetra, ANIb/ANIm and GGDC confirmed that all of them belonged to the same species. Genomes were similar in size (4.51-4.74 Mb) and mol% G+C content (64.2%-64.4%). Putative extrachromosomal elements were observed in all strains, although in variable number: 5 in strain 329, 6 in 328 and AD8T, and 8 in 357.

Conclusions

Hydrocarbon degradation genes were found in two putative plasmids present in all strains: a 183 kb-scaffold with genes for naphthalene and gentisate degradation, and a 106 kb-scaffold with homogentisate degradation genes. Growth kinetics experiments show that all strains grow with naphthalene as the sole source of carbon and energy, confirming the genomic data.The results of this study show that the ability to degrade the polyaromatic hydrocarbon naphthalene seems to be plasmid-encoded and characteristic of *C. aestuarii* strains, independently of their isolation origin

CARRIAGE OF TYPE II TOXIN-ANTITOXIN SYSTEMS BY THE GROWING GROUP OF INCX PLASMIDS. A NOVEL SYSTEM REVEALED

P. Bustamante[1], *J. Iredell*[1]
[1]*Westmead Institute for Medical Research- The University of Sydney, Centre for Infectious Diseases and Microbiology, Sydney, Australia*

Backgrounds

The stable maintenance of certain plasmids in bacterial populations has contributed significantly to the current worldwide antibiotic resistance (AbR) emergency. IncX plasmids have achieved recent notoriety for their roles in transmission of resistance to carbapenem and colistin, the last-line antibiotics for Gram-negative infections. Toxin-antitoxin (TA) systems contribute to stable maintenance of many AbR plasmids, and only a few TA systems have been previously described in the IncX plasmids.

Objectives

Our main aim was to elucidate the diversity of type II TA systems carried by the IncX plasmids group and specifically to describe and characterize a novel system, TsxTA, encoded by IncX4 plasmids.

Methods

Web-tools PlasmidFinder, TAfinder and RASTA-Bacteria were used to search for IncX plasmids and TA systems, respectively. The effect of TsxTA expression on bacterial growth/physiology were analyzed by growth curves, microscopy and protein/mRNA expression measures. The contribution of TsxTA to plasmid maintenance, stress tolerance and persister cell formation, were also analysed.

Conclusions

RelE-like toxins are abundant within IncX1 and IncX4 subgroups. By contrast, the HicBA and the novel TsxTA systems are almost exclusively encoded by IncX4 plasmids. PIN, GNAT and CcdB/MazF toxins were also identified. TsxT expression causes high culture density, low cell viability, cell elongation and decrease of FtsZ cellular levels; some key cell division genes were upregulated under these conditions. TsxT increases the frequency of persister cell formation and its deletion destabilizes the plasmid.

Our results show that AbR plasmids could contain an underappreciated diversity of TA systems, some of them with novel characteristics, as the system TsxTA described here.

Physiology / Biochemistry / Molecular Microbiology

MOLECULAR CHARACTERIZATION OF SPOT PARTNERS IN CAULOBACTER CRESCENTUS

J. Caballero-Montes[1], *K. Van Neerom*[1]
[1]*Free University of Brussels ULB, Structural Biology and Biophysics, Gosselies, Belgium*

Backgrounds

The (p)ppGpp alarmone is used by bacteria to quickly respond to environmental stress. This alarmone induces various biological modulations allowing cells to survive during the wait for a more favorable context. The a-proteobacteria *Caulobacter crescentus* exhibits an asymmetric division leading to two phenotypically different daughter cells: a sessile stalked cell and a chemotactically active motile swarmer cell that differentiates later in the sessile form. Upon nitrogen starvation, *C. crescentus* triggers (p)ppGpp accumulation, which in turn controls the cell cycle by extending the G1 swarmer phase.

Recently, a new molecular mechanism involving PTS^{Ntr} (nitrogen-related phosphotransferase system) has shown to stimulate (p)ppGpp production. PTS^{Ntr} system acts as metabolic sensor translating glutamine deprivation signal into (p)ppGpp accumulation. Once phosphorylated, the PTS^{Ntr} component $EIIA^{Ntr}$~P directly reduces the (p)ppGpp hydrolase activity of SpoT, the only RelA/SpoT homologue in *C. crescentus* responsible of the synthesis and degradation of the alarmone. The cellular (p)ppGpp level seems therefore to be increased by direct inhibitory interaction of the phosphorylated form of $EIIA^{Ntr}$ with SpoT.

Objectives

This project aims at understanding the molecular basis of bacterial stress survival mechanisms by unravelling and characterizing the interactions between the nitrogen-related phosphotransferase protein $EIIA^{Ntr}$ and the hydrolase/synthetase SpoT.

Methods

The production of high purity samples of wild-type and mutated SpoT and $EIIA^{Ntr}$ proteins will provide quantitative informations about their interactions, by Isothermal Titration Calorimetry, among others. Diffracting crystals will provide the tridimensional structure of $EIIA^{Ntr}$-SpoT complex using the power of X-Ray crystallography that will lead to new knowledges regarding $EIIA^{Ntr}$ mode of action on SpoT.

Conclusions

ADAPTIVE CHANGES IN D-ALANINE-POLY(PHOSPHORIBITOL) LIGASE GENE EXPRESSION LEVEL IN LACTOBACILLUS SAKEI UNDER DIFFERENT STRESS CONDITIONS

L. Calabrone[1], *M.G. Bonomo*[1], *K. Di Tomaso*[1,2], *G. Salzano*[1]
[1]*Università degli Studi della Basilicata, Sciences, Potenza, Italy*
[2]*Università degli Studi della Basilicata, Ph.D school in Applied Biology and Environmental Safeguard, Potenza, Italy*

Backgrounds

Lactobacillus (*L.*) *sakei* is widely used as starter in the production process of fermented sausages and its growth and survival are affected by various factors such as temperature, pH and salt concentration.

Objectives

The effect of different acid, osmotic and heat stress treatments on expression level of D-alanine-poly(phosphoribitol) ligase gene was investigated by qPCR for a better knowledge of its function and role in *L. sakei* metabolism.

Methods

L. sakei cells were treated at pH 2.5 and 3.0 and 9% (w/v) NaCl for 30 min at 30°C, and at 50, 55 and 60°C. Identification and evaluation of a panel of seven reference genes for qPCR normalization was performed. The control genes were ranked according to their stability (M) values and coefficient of variation (V) using geNorm software. Once stable internal control genes were identified, the expression level of the target gene was analyzed by using the geometric mean of copy numbers as normalization factor.

Conclusions

The quantitative expression gene analysis showed that various changes in the transcription level of the gene appeared in response to different stress conditions. Particularly, a significant increase of the expression level in the samples stressed at pH 3.0 and with decreasing temperature was occurred, while a significant decrease in the presence of 9% NaCl if compared to the control was observed.

Physiology / Biochemistry / Molecular Microbiology

EXPLORING THE TOLERANCE OF PSEUDOMONAS PUTIDA TO NON-CONVENTIONAL SALINE STRESSES

P. Calero Valdayo[1], *P.I. Nikel*[1]
[1]*Technical University of Denmark, DTU Biosustain, Kgs. Lyngby, Denmark*

Backgrounds

The soil bacterium *Pseudomonas putida* has received considerable attention in the last few years as a cell factory due, among other reasons, to its high tolerance towards stressful conditions and a wide range of compounds such as organic solvents and metal ions. However, the impact of saline stress has not been studied in depth in this bacterium. The Fluoride ion (F^-) is ubiquitous in the environment and it is known to exert antimicrobial effects (e.g. in *Escherichia coli* or *Streptococcus mutans*), which has been proposed to contribute to its anticavities activity.

Objectives

In this work, we describe the physiological effects of sodium fluoride (NaF) on the laboratory strain *P. putida* KT2440 and its reduced-genome derivatives (e.g. EM42), which have been demonstrated to display improved growth and a higher tolerance to certain stresses.

Methods

To assess the effects on *P. putida,* we compared the minimal inhibitory concentration (MIC) of F^- and Na^+ in *P. putida* KT2440 and *P. putida* EM42 to the MIC in *E. coli*, as well as toxicity curves in order to test the growth of each strain in the presence and absence of these ions. Further experimentation will provide insights into the saline stress tolerance of *P. putida* to improve the performance of this bacterium as a cell factory.

Conclusions

New tools for the assessment of intracellular F^- are currently being developed to unravel detoxification mechanisms and to highlight possible differences due to the presence of F^-.

CLONAL DIVERSITY AND METHICILLIN RESISTANCE IN STAPHYLOCOCCUS EPIDERMIDIS ISOLATES FROM RUMINANTS WITH SUBCLINICAL MASTITIS

I. Camacho[1], A. Vela[2], M. Pérez-Sancho[1], L. Zamora[1], E. San Martin[1], I. Cerdá[1], J. Fernández-Garayzabal[2], L. Domínguez[1]
[1]VISAVET HEALTH SURVEILLANCE CENTRE, Identificación y Caracterización Molecular ICM, MADRID, Spain
[2]Universidad Complutense de Madrid, Sanidad Animal- Facultad de Veterinaria, Madrid, Spain

Backgrounds

Subclinical mastitis is one of the most common infectious disease found in dairy herds around the world. *Staphylococcus epidermidis* is one of the main species associated with this clinical process; however, its genetic epidemiology is poorly understood. On the other hand, resistance of this bacterium to oxacillin (methicillin) has been a matter of concern due to the possibility of transfer of resistance determinants to other bacteria.

Objectives

To improve the knowledge concerning the strain genetic diversity and prevalence of methicillin resistance of *S. epidermidis* isolates from subclinical mammary gland infections in ruminants from different farms located around Spain.

Methods

We analyzed 74 isolates from goats, sheep and cows by MLST (http://pubmlst.org/sepidermidis/). Oxacillin was used for detecting methicillin-resistant *S. epidermidis* by disk diffusion test. All isolates were additionally tested by PCR for the *mec*A and *mec*C genes (Frey et al., 2013. J Dairy Sci 96 2247–57).

Conclusions

Twenty-eight sequence types (STs) were identified. Genetic diversity 0.64, 0.35 and 0.52 among goat, sheep and cow isolates, respectively. Four STs (ST5, ST100, ST293 and ST575) represented the 51% of isolates. These STs included isolates from two (ST5 and ST575) or three animal species (ST100 and ST293). The 14.9% of isolates were resistant to methicillin. All methicillin resistant isolates harbored the *mecA* gene and were from cows. None isolate carried the *mecC* gene.

IDENTIFICATION OF DESULFOVIBRIO FAIRFIELDENSIS RECOVERED FROM SWINE BY MALDI TOF MASS SPECTROMETRY

I. Camacho[1], M. Pérez-Sancho[1], M. Calderón[2], A. Casamayor[1], J. Fernández-Garayzabal[3], L. Domínguez[1], A. Vela[3], S. Vadillo[2]
[1]VISAVET HEALTH SURVEILLANCE CENTRE, Identificación y Caracterización Molecular ICM, MADRID, Spain
[2]Universidad de Extremadura, Departamento de Sanidad Animal, Badajoz, Spain
[3]Universidad Complutense de Madrid, Sanidad Animal- Facultad de Veterinaria, Madrid, Spain

Backgrounds

Desulfovibrio are sulfate-reducing anaerobic bacteria frequently isolated from the environment. However, some *Desulfovibrio* species, e.g. *D. fairfieldensis*, could be opportunistic pathogens for humans and animals. The traditional identification of *D. fairfieldensis* based on phenotypical/biochemical methods may present limitations leading to possible underdiagnoses of this bacterium.

Objectives

Evaluate the suitability of MALDI-TOF MS for the identification of *D. fairfaldensis.*

Methods

The spectra of the reference strains of *D. desulfuricans*, *D. intestinalis*, *D. vulgaris* and *D. fairfieldensis* were added to BDAL Bruker Data Base, which does not contain *Desulfovibrio* entries. Afterwards, 31 *D. fairfieldensis* isolates from mucohaemorrhagic faeces and previously identified by PCR (Loubinoux *et al*., 2002. Int J Syst Evol Microbiol 52: 1305-8) were used to assess the ability of MALDI-TOF for its identification**.** A protein extraction protocol based on ethanol-formic acid-acetonitrile was used. Spectra were acquired using a Bruker Daltonics UltrafleXtrem MALDI TOF/TOF device.

Conclusions

The MALDI ions profiles of field isolates were quite homogeneous with the presence of common ions, but with a high number of differences (m/z 3512, 4325, 4416, 4754, 5211 and 7550) with the reference strain (m/z 3641, 4263, 4407, 4776, 5392, 5643, 7282 and 8527). This result suggests a relative diversity in the protein profiles of members of this species. The inclusion of the spectra profile of one additional field isolate allowed the accurate identification of the remaining 30 *D. fairfieldensis* field isolates with a mean score value of 2.567 (2.318–2.702), suggesting good performance of MALDI TOF MS approach for identifying this species.

GENETIC ANALYSIS OF PERSISTER CELL FORMATION IN PSEUDOMONAS AERUGINOSA

D. Cameron[1], *B. Mojsoska*[2], *Y. Shan*[1], *S. Molin*[2], *K. Lewis*[1]
[1]*Northeastern University, Department of Biology, Boston, USA*
[2]*Technical University of Denmark, DTU Biosustain, Kongens Lyngby, Denmark*

Backgrounds

Chronic pulmonary infection is the leading cause of mortality in patients with Cystic Fibrosis (CF). *Pseudomonas aeruginosa* is a bacterial pathogen frequently isolated from the airways of chronically infected CF patients. Multidrug tolerant persister cells contribute to the recalcitrance of infection in these cases, however the mechanisms underlying the generation of these cells in *P. aeruginosa* is poorly understood.

Objectives

In the current study, we aimed to determine the genetic determinants of persister formation in *P. aeruginosa.*

Methods

We utilized two complimentary screening approaches. First, we exposed a highly saturated transposon library of *P. aeruginosa* PAO1 to the fluoroquinolone antibiotic ofloxacin and compared the frequency of each mutant before and after treatment using transposon sequencing (Tn-seq). Secondly, we performed a high throughput screen of a collection of longitudinal genome-sequenced clinical isolates for the 'high persister' phenotype.

Conclusions

In total, 100 genes were associated with decreased ofloxacin tolerance as determined by Tn-Seq. The highest hit, *carB,* codes for the large subunit of carbamoylphosphate synthase. When challenged with antibiotics from three distinct classes, a *carB* mutant produced 5-500 fold less persister cells compared to the wild-type strain. Within longitudinal clinical *P. aeruginosa* series, up to 18 genes were correlated with the in vivo evolution of the high persister phenotype.
We have identified novel genetic pathways that affect antibiotic tolerance in *P. aeruginosa*. Understanding the precise mechanism by which these genes control the generation of drug-tolerant persisters is ongoing.

Physiology / Biochemistry / Molecular Microbiology

THE TRANSIENT MULTIDRUG RESISTANCE PHENOTYPE OF SALMONELLA ENTERICA SWARMING CELLS IS ABOLISHED BY SOS RESPONSE ACTIVATION THROUGH CHEW TITRATION

O. Irazoki[1], S. Campoy[1], J. Barbe[1]
[1]Universitat Autònoma de Barcelona, Departament de Genètica i de Microbiologia, Cerdanyola del Vallès, Spain

Backgrounds

RecA protein, through its interaction with CheW, is involved in swarming motility, a rapid and coordinated multicellular migration of bacteria across a moist surface. Besides its association with virulence, during swarming, cells exhibit high-level resistance to multiple antibiotics, a phenomenon described as adaptive resistance.

Objectives

To further understand how SOS response modulates swarming, the RecA and CheW location within SOS response-activated swarming cells, the regions involved in RecA-CheW interaction and its relationship with swarming motility were studied. Further, the possible inhibitory effect of antibiotics on swarming motility and on the transient acquisition of multidrug resistance were also analyzed.

Methods

The intracellular location of these proteins within cells was analyzed by using 3D-STED microscopy. *In silico* docking studies were performed to identify the specific RecA and CheW regions associated with their interaction, that were confirmed by site-directed mutagenesis and immunoprecipitation techniques. Further, swarming ability, chemoreceptor array assembly, cell flagellation and increased antibiotic resistance phenotype in the presence of sub-lethal concentrations of several antimicrobials differing in their mechanisms of action were also analyzed.

Conclusions

Our results pointed out that the titration effect on CheW protein mediated by RecA modulates the CheW distribution within the cell when SOS response is activated, thus modulating the swarming ability. Further, and in the presence of sub-lethal concentrations of some antibiotics, this effect not only abolished swarming ability but also affects the transient multidrug-resistance phenotype acquired by swarming cells, thus revealing the potential of targeting swarming inhibition in the development of strategies to enhance the therapeutic effectiveness of antimicrobial agents.

IDENTIFICATION AND CHARACTERIZATION OF RNA-BINDING PROTEINS IN STAPHYLOCOCCUS AUREUS

A. Catalán-Moreno[1], *C. Caballero*[1], *A. Toledo-Arana*[1]
[1]*Instituto de Agrobiotecnología, Laboratory of Bacterial Gene Regulation, Mutilva, Spain*

Backgrounds

In bacteria, post-transcriptional regulatory elements, such as small RNAs (sRNAs), riboswitches and RNA-binding proteins (RBP) control RNA decay, transcription elongation and translation efficiency in response to environmental changes. Although sRNAs-mediated regulation has been extensively studied, post-transcriptional regulatory mechanisms involving RBPs remain to be deciphered. RBPs are present in all kingdoms of life and can be divided in different groups depending on their protein domains: ribosomal proteins, ribonucleases or RNA chaperones.

Objectives

In order to have a better understanding of RBPs-mediated regulation, we aimed to identify and characterize the RNA chaperones and their targets using as a bacterial model *Staphylococcus aureus*, one of the most important human pathogens.

Methods

First, we performed an *in silico* analysis to identify the potential RNA chaperones present in the staphylococcal genome. Subsequently, relevant RBPs were chromosomally flagged with a 3xFLAG tag and their expression patterns analyzed by Western Blot. Finally, to identify the RNA targets recognized by RBPs *in vivo*, we performed Cross-Linking Immuno-Precipitation assays (CLIP).

Conclusions

The expression analyses revealed that the RNA chaperones, CspA, CspB, CspC, CvfB and SA_00892 are highly expressed in all the analyzed points of the growth curve of *S. aureus*. In contrast, we could not detect Hfq expression in these conditions. CLIP experiments demonstrated that the selected RBPs bind RNA *in vivo*. Preliminary results on the targets recognized by these RNA chaperones will be discussed at the meeting.

MOBILIZATION MECHANISM OF PATHOGENICITY ISLANDS BY ENDOGENOUS PHAGES IN STAPHYLOCOCCUS AUREUS

M. Cervera Alamar[1], *K. Guzmán*[1], *M. Žiemytė*[1], *M.Á. Tormo Mas*[1]
[1]*Hospital Universitario la Fe, Infección Grave, Valencia, Spain*

Backgrounds

Staphylococcus aureus is a pathogen that is able to cause a variety of community and hospital acquired diseases. The broad ranges of infections caused by *S.aureus* are related to a number of virulence factors. Most of these virulence factors are encoded in mobile genetic elements (MGE). We concentrate in *S. aureus* pathogenicity islands (SaPIs) which are controlled by the master repressor (Stl). This repressor is activated by helper phages, which encode specific inductor proteins. Binding of Stl and the inductor induces the SaPI excision, replication and packaging cycle. These events allow transference of SaPIs spreading virulence factors among bacteria.

Objectives

To detect strains with endogenous phages capable to mobilize its own SaPIs and to identify the specific inductor protein

Methods

.

Conclusions

We tested SaPIs mobilization of 15 sequenced clinical *S. aureus* strains. Five strains were induced and mobilized by its endogenous phages. We focused in the regulation module of two strains whose SaPIs present the same Stl. We identified the endogenous phage responsible of SaPI induction and its specific inductor protein. This protein corresponds to a hypothetical protein with a conserved domain. Mutant of this protein was not able to induce and mobilize the SaPI. We also demonstrated the binding Stl-inductor and the existence of allelic variants of this protein codified in other phages with different affinities for Stl. This confirms that this mechanism is general for others strains. In the future we would like to characterize the protein structure, the binding motif to Stl and to determine the function in the phage.

EPSTEIN-BARR VIRUS-ENCODED MIR-BART5-5P UPREGULATES PD-L1 THROUGH PIAS3/PSTAT3 MODULATION IN GASTRIC CARCINOMA CELLS

D.H. Kim[1], C.J. Yoon[1], J.S. Kim[1], S. Park[2], E. Choi[2], J.H. Woo[1], M.S. Chang[2]
[1]Asan Institute for Life Sciences- University of Ulsan College of Medicine, infectious diseases, Seoul, Republic of Korea
[2]Seoul National University College of Medicine- Boramae Hospital, Pathology, Seoul, Republic of Korea

Backgrounds

Epstein-Barr virus (EBV) infection is detected in a subset of gastric carcinomas, about 5~10% of the total gastric carcinoma cases. MicroRNAs (miRs) are 22±2 nucleotide non-coding RNAs, and regulate various functions in cells. The function of EBV-encoded microRNA-BART5 (miR-BART5) has been elucidating.

Objectives

The aim of the present study was to investigate target proteins for miR-BART5 and alteration of cellular proteins and biologic properties by miR-BART5 in gastric carcinoma cells.

Methods

The miR-BART5-5p mimicker or miR-BART5-5p-stable transfectants in EBV-negative gastric carcinoma cells was constructed. Apoptosis was quantified with the annexin V-fluorescein isothiocyanate (FITC) apoptosis kit on a FACScan flow cytometer. For cell proliferation assay, ‘cell counting kit-8’ (CCK-8) was used. The miR and protein levels were measured using Taqman RT-PCR and western blot, respectively. To search a direct target of miR-BART5-5p, bioinformatics analysis and 3'UTR luciferase activity assay were performed. As a result, there were no significant differences in proliferation or apoptosis between miR-BART5-5p-expressing gastric carcinoma cells and miR-control-transfected cells. PIAS3 protein expression was significantly lower in two cell lines of naturally EBV-infected gastric carcinoma than in three cell lines of EBV-negative gastric carcinomas**.** PIAS3 protein expression was reduced in miR-BART5-5p-transfected EBV-negative gastric carcinoma cells. Additionally, PIAS3 3′UTR reporter activity was suppressed in miR-BART5-5p-expressing gastric carcinoma cells. As a downstream of PIAS3, ‘phospho-signal transducer and activator of transcription 3’ (pSTAT3) was considered. The pSTAT3 increased in miR-BART5-5p expressing gastric carcinoma cells, which was dependent upon PIAS3, Interestingly, ‘programmed cell death ligand 1’ (PD-L1), one of proteins associated with immune regulation, increased in miR-BART5-5p expressing gastric carcinoma cells in a pSTAT3-dependent manner.

Conclusions

PIAS3 is a direct target of miR-BART5-5p in gastric carcinoma cells. PIAS3 decrease leads to pSTAT3 increase, and PD-L1 was upregulated in pSTAT3-dependent manner. These findings may provide a clue of the immunologic modulation mechanism in EBV-infected gastric carcinoma.

STRUCTURAL BASIS OF MEMBRANE PORE-FORMATION MECHANISM OF BACTERIAL PORE-FORMING TOXINS

N. Kundu[1], R. Kathuria[1], K. Chattopadhyay[1]
[1]Indian Institute of Science Education and Research Mohali, Department of Biological Sciences, Mohali, India

Backgrounds

Pore-forming toxins (PFTs) represent a unique class of protein toxins that are ubiquitously found in wide array of organisms ranging from bacteria to human. PFTs act by punching holes in the membranes of their target cells, thereby leading to killing of the target cells. PFTs act as the major virulence factors of many pathogenic bacteria. Indeed, one third of the bacterial protein toxins belong to the PFT family. In their generalized mode of action, PFTs are secreted by the pathogenic bacteria, which in contact with their target eukaryotic cells generate the transmembrane pores, thus leading to membrane-permeabilization, and killing of the target host cells.

Objectives

In spite of sharing an overall general mode of action, individual members of the bacterial PFT family differ from each other in the intricate details of their mechanism of action. Therefore, characterization of the structure-function mechanism of each of the individual bacterial PFTs is essential in terms of elucidating their mode of action.

Methods

In our study, we have explored the multiple facets of the structural mechanisms associated with some of the archetypical bacterial PFTs, and examined their functional implications. Specifically, we have explored the functional implications of specific structural motifs/domains present in the PFTs. We have explored the mechanisms of membrane pore-formation employed by the PFTs, and examined the implications of specific membrane components in regulating such processes.

Conclusions

Results obtained from our study have provided novel insights regarding the structural basis associated with the mode of action of some of the prominent bacterial PFTs.

IDENTIFICATION AND PRELIMINARY CHARACTERIZATION OF A XYLANASE GENE FROM A NOVEL SPECIES OF ANTARCTIC FUNGUS

R. Chavez[1], C. Gil-Duran[1], C. Ravanal[2], I. Vaca[3]
[1]Universidad de Santiago de Chile, Departamento de Biologia, Santiago, Chile
[2]Universidad de Chile, Departamento de Ingenieria Quimica y Biotecnologia, Santiago, Chile
[3]Universidad de Chile, Departamento de Quimica, Santiago, Chile

Backgrounds

Xylan is one of the main hemicellulose polysaccharide in plant cell walls. The biodegradation of xylan requires a set of enzymes called xylanases. To date, most xylanolytic fungi studied have been isolated from mesophilic and thermophilic terrestrial environments. On the contrary, very little is known about xylanolytic activities in Antarctic marine fungi. In our laboratory, we recently isolated a strain of the Antarctic marine fungus *Cladosporium* sp. In previous analyses, this fungus showed high xylanolytic activity at low temperature.

Objectives

In the present work, we advance in the phylogenetic identification of *Cladosporium* sp. In addition, we describe preliminary results about the characterization of a xylanase gene from this fungus, and its expression.

Methods

The phylogenetic position of *Cladosporium* sp. within the currently known species of the genus *Cladosporium* was determined by using three suitable molecular markers. On the other hand, part of a gene (750 base pairs) encoding for an endoxylanase, was isolated by PCR. Finally, the expression of this gene in the presence of xylan as carbon source at 15 °C was assessed by RT-PCR.

Conclusions

Our results indicate that *Cladosporium* sp. is phylogenetically different from all other known species of the genus and likely, it is a new species not described yet. On the other hand, the endoxylanase gene from this fungus has maximal expression at day 2 of culture at 15 °C. In summary, the Antarctic fungus *Cladosporium* sp. contains a gene encoding for a xylanase that is expressed at low temperatures. Work supported by grant INACH RG_03-14 and DICYT-USACH.

ERK AND AMPK SIGNALING PATHWAYS INVOLVE IN APICAL SOLUTION-INDUCED DOWNREGULATION OF ION TRANSPORT IN CULTURED PIG TRACHEAL EPITHELIA

W. Xu[1,2], W.N.F. Li[1,2], J.H. Chen[1,2]
[1]University of Hong Kong, School of Biomedical Sciences, Hong Kong, Hong Kong S.A.R.
[2]HKU Shenzhen Institute of Research and Innovation, ., Shenzhen, China

Backgrounds

Respiratory epithelium controls transepithelial ion and fluid transport for maintaining homeostasis of airway surface.

Objectives

Whether the epithelia could sense and respond to surface fluid changes is vastly unknown.

Methods

To test this hypothesis, we gently washed and then covered the apical surface of cultured pig tracheal epithelia with a thin layer of the Krebs solution, followed by examining alterations in the transepithelial short-circuit currents (Isc) at 1 to 24 hr after the treatment.

Conclusions

Our data demonstrate that either Isc at basal condition (Isc_{-Basal}) or reduction of Isc by adding the epithelial Na^+ channel (ENaC) inhibitor amiloride (ΔIsc_{-Amil}) was largely decreased at 4, 7 and 10 hr after apical application of the Krebs solution, compared to that of the control epithelia with no treatment. Similarly, the study on stimulation of the cystic fibrosis transmembrane conductance regulator (CFTR) activity by forskolin and IBMX found that drug-induced increase in Isc ($\Delta Isc_{-F\&I}$) were also moderately reduced at 7 hr after the treatment. These data indicate that the apical Krebs solution caused transient reductions in ENaC- and CFTR-mediated ion transport of tracheal epithelia. In addition, epithelia basolaterally pretreated with the ERK inhibitor U0126 or the AMPK inhibitor compound C all largely attenuated the inhibition on Isc_{-Basal} and ΔIsc_{-Amil} by the apical Krebs solution. These data suggest that fluid challenge on the luminal surface of the tracheal epithelia may reduce the ENaC activity in the apical membrane, partly due to activation of the ERK and AMPK signaling pathways.

EMRR, A MARR-REGULATOR FOR ALCOHOL METABOLISM AND ORGANIC PEROXIDE-SENSING IN ACINETOBACTOR BAUMANNII.

S.J. Chen[1], *G.H. Lin*[1]
[1]*Tzu Chi University, Master Program in Microbiology and Immunology, Hualien, Taiwan R.O.C.*

Backgrounds

Acinetobacter baumannii, an aerobic gram-negative bacterium, is one of the most important nosocomial pathogen. Previous study showed that low-level ethanol-exposure induces the expression of MarR(Multiple Antibiotic Resistant Regulator) regulator in *A. baumannii*. This MarR regulator was named as Ethanol-related MarR regulator (EmrR) here. *In silico* analysis, OhrR(Organic hydroperoxide resistance), the MarR protein that can regulated oxidative stress in *Xanthomonas campestris*, is 56.3% identity to EmrR. OhrR regulated *ohr* which encode a thiol-dependent peroxidase directly catalyze the reduction of organic peroxidases to less toxic organic alcohol in *Xanthomonas campestris*.

Objectives

Investigate the function of EmrR(Ethanol-related MarR regulator) for alcohol metabolism and organic peroxide-sensing in *Acinetobactor baumannii.*

Methods

In order to prove whether *emrR* was related to ethanol metabolism in *A. baumannii*. *emrR* mutant its growth condition is compared to wild type with cultivation in difference concentration of alcohol as the sole carbon source. Promoter activity of *adh* (alcohol dehydrogenase) in ethanol condition was determined by GFP assay. The EMSA(Electrophoretic Mobility Shift Assay) was performed to know which promoters were bound by EmrR directly. Disk assay was determined to know *emrR* mutant its growth condition is compared to wild type with cultivation in difference concentration of organic peroxide.

Conclusions

Results indicated ADH4 expression was repressed by EmrR in *A. baumannii*. An *emrR* mutant is more sensitive to *tert*-butyl hydroperoxide than wild type, indicating that EmrR mediates the defensive system against organic peroxide.

BISMUTH-BASED DRUGS INHIBIT- PORPHYROMONAS GINGIVALIS: PROTEOMIC/TRANSCRIPTOMIC PROFILING AND MOLECULAR MECHANISMS

T. Cheng[1], Y.T. Lai[2], Y. Yang[2], H. Sun[2], L. Jin[1]
[1]The University of Hong Kong, Faculty of Dentistry, Hong Kong, Hong Kong S.A.R.
[2]The University of Hong Kong, Department of Chemistry, Hong Kong, Hong Kong S.A.R.

Backgrounds

Porphyromonas gingivalis is a 'keystone' pathogen for the highly common periodontal disease worldwide.

Objectives

This study aimed to investigate the protein targets and effects of bismuth-based drugs on the gene expression of *P. gingivalis*, through metal-based proteomics and RNA seq & Real-time PCR.

Methods

The minimal inhibition concentration of ranitidine bismuth citrate (RBC) for *P. gingivalis* was determined after 48-hour incubation with series-diluted RBC and other antimicrobials. Fluorescence-labeling-based 2D-PAGE was performed on *P. gingivalis* cell lysates with a fluorescence probe of Bi^{3+}-TRACER. The identified proteins were selected and cloned, and subsequently recombinant proteins were overexpressed and purified for activity determination. The effects of bismuth on mRNA expression profile of *P. gingivalis* were analyzed by RNA seq, and selected genes were further evaluated by Real-time PCR.

Conclusions

It was shown that bismuth could inhibit *P. gingivalis* growth, and enhance the bacterial sensitivity to antimicrobials (e.g. metronidazole and *chlorhexidine*). Multiple protein spots on the 2D-PAGE of *P. gingivalis* lysates were lit up by Bi^{3+}-TRACER after UV-radiation, and dozens of potential bismuth-associating proteins were identified by peptide mass fingerprinting on these lit-up spots. Notably, bismuth could partially or even completely inactivate these selected proteins. Whole-genome RNA seq revealed that the expression of substantial amounts of genes with various functions was markedly affected during the first hour of bismuth treatment which was selectively verified by Real-time PCR. This pioneering study indicates that *P. gingivalis* undergoes extensive influences by bismuth which leads to bacterial inhibition.

DETECTION AND QUANTIFICATION OF DIFFERENTIALLY CULTURABLE TUBERCLE BACTERIA IN SPUTUM FROM PATIENTS WITH TUBERCULOSIS

M. Chengalroyen[1], G. Beukes[1], B. Gordhan[1], E. Streicher[2], G. Churchyard[3], R. Hafner[4], N. Martinson[5], K. Otwombe[5], B. Kana[6]
[1]Centre of Excellence for Biomedical TB Research, Pathology, Johannesburg, South Africa
[2]MRC Centre for Tuberculosis Research, Division of Molecular Biology and Human Genetics, Cape Town, South Africa
[3]The Aurum Institute, Aurum, Johannesburg, South Africa
[4]Tuberculosis Clinical Research Team, Department of Health and Human Services-, Bethesda, USA
[5]Perinatal HIV Research Unit, Health Science, Johannesburg, South Africa
[6]Center of Excellence for Biomedical TB Research, Pathology, Johannesburg, South Africa

Backgrounds

Recent studies suggest that baseline tuberculous sputum comprises a mixture of routinely culturable and differentially culturable tubercle bacteria (DCTB). The latter seems to be drug tolerant and dependent on resuscitation-promoting factors (Rpfs) for growth.

Objectives

To further explore this, we assessed sputum from patients with tuberculosis for DCTB and studied the impact of exogenous Rpf-containing or deficient culture filtrate (CF) supplementation *ex vivo*.

Methods

Sputum samples from adults with tuberculosis and either HIV-1 or no HIV-1 were used for most probable number (MPN) assays supplemented with CF and Rpf-deficient CF, to detect CF-dependent and Rpf-independent DCTB, respectively.

Conclusions

In 110 individuals, 19.1% harbored CF-dependent DCTB. Furthermore, 11.8% yielded Rpf-independent DCTB. In addition, 53.6% displayed both CF-dependent and Rpf-independent DCTB, 1.8% carried CF-independent DCTB, and 13.6% had no DCTB. Sputum from individuals without HIV-1 yielded higher CF-supplemented MPN counts compared with their counterparts. Furthermore, individuals with HIV-1 with CD4 counts greater than 200 cells/mm3 displayed higher CF-supplemented MPN counts compared with participants with HIV-1 with CD4 counts less than 200 cells/mm3. Notably, CF supplementation allowed for detection of mycobacteria in 34 patients with no culturable bacteria on solid media. Additionally, the use of CF enhanced detection of sputum smear–negative individuals.These observations demonstrate a novel Rpf-independent DCTB population in sputum and reveal that reduced host immunity is associated with lower prevalence of CF-responsive bacteria. Quantification of DCTB in standard TB diagnosis would be beneficial because these organisms provide a putative biomarker to monitor treatment response and risk of disease recurrence.

BIOCONVERSION OF ALGAL BIOMASS: METABOLIC POTENTIAL OF ZOBELLIA AMURSKYENSIS

N. Chernysheva[1], A. Stenkova[1], O. Nedashkovskaya[2], M. Isaeva[1]
[1]G.B. Elyakov Pacific Institute of Bioorganic Chemistry, Laboratory of marine biochemistry, Vladivostok, Russia
[2]G.B. Elyakov Pacific Institute of Bioorganic Chemistry, Laboratory of microbiology, Vladivostok, Russia

Backgrounds

The algal sulfated and carboxylated polysaccharides have been extensively studied for their variable biological activities (antitumor, anticoagulant, and antiviral). Marine polysaccharides are complex decorated, therefore they are less bioavailable and their study tightly associates with the polysaccharide degrading/modifying enzymes. For algal biomass converting the investigation of alga-associated bacteria and their enzymes has a great value. Marine flavobacteria possess a remarkable metabolic potential for effective utilization of seaweeds. Very famous of them is *Zobellia galactinovorans*, which harbors an enormous number of carbohydrate active enzymes.

Objectives

The objective was sequencing and genomic analysis of another *Zobellia* species isolated from a seawater sample collected in Amursky Bay, Sea of Japan.

Methods

Draft genome of the *Zobellia amurskyensis* 3526^T was obtained using the Roche/454 pyrosequencing technology on the GS Junior. Assembly, automatic and manual annotations of the genome were performed via Newbler v3.0 software, RAST annotation server and BLAST search on the Protein Database, Swiss-Prot, COG and KEGG databases. Genomic analysis was focused on genes encoding carbohydrate-active enzymes using CAZy database.

Conclusions

We revealed that the genome encodes a great number of carbohydrate-active enzymes covering many of known enzyme classes according to CAZy nomenclature. Additionally, the genome is enriched with sulfatase genes. Many of the detected genes are arranged in Polysaccharide Utilization Loci. The enzymatic repertoire enables *Z. amurskyensis* to decompose green, red and brown algal biomass, and participates in marine organic carbon cycling.

This work was supported by the Program for Basic Research FEB RAS “Far East”, project №15-I-5-014.

ELUCIDATION OF NOVEL ROLE OF ESCHERICHIA COLI BIPA EXPRESSED AT LOW TEMPERATURE

E. Choi[1], *M. Lim*[1], *H. Jihwan*[1]
[1]*Pusan National University, Microbiology, Busan, Republic of Korea*

Backgrounds

BipA is a conserved ribosome-associated GTPase and shares structural similarity with other translational GTPases such as IF-2, EF-Tu, and EF-G. Its binding site on the ribosome appears to overlap with that of those translational GTPases. Mutation in *bipA* causes a variety of phenotypes, including cold sensitivity, antibiotics sensitivity, and decreased pathogenicity, implying that BipA may participate in diverse cellular processes by regulation of translation. According to the recent studies, *bipA*-deletion strains show ribosome assembly defect at low temperature, suggesting that BipA may be involved in ribosome assembly. Despite such extensive research on BipA, the exact function of BipA is still unknown.

Objectives

Our ultimate objectives are to find the reason why growth and ribosome assembly defects were observed only at low temperature and to elucidate precise role of BipA at low temperature in *Escherichia coli*.

Methods

We analyzed ribosomal protein composition of pre-50S particles accumulated in *bipA*-deletion strain at 20°C by sucrose gradient sedimentation and SDS-PAGE. Then, we carried out qRT-PCR to examine the expression pattern of *bipA* at various temperatures, and did mutational analysis of the BipA protein. Lastly, we tested chaperone activity of BipA by using denatured green fluorescence protein (GFP).

Conclusions

Our results showed that BipA is expressed under low temperature condition and deletion of *bipA* causes accumulation of pre-50S particles lacking L6 at 20°C. In addition, BipA possesses chaperone activity.. These results demonstrate that BipA is a novel ribosome-associated translational GTPase which is induced at low temperature and facilitates the folding of ribosomal protein and ribosomal subunit.

Physiology / Biochemistry / Molecular Microbiology

PURIFICATION AND BIOCHEMICAL CHARACTERIZATION OF A LACCASE FROM COPRINUS COMATUS

H. Choi[1], *E. Park*[2]
[1]*Kangwon National University, Biochemistry, Chuncheon-Si- Gangwon-Do, Republic of Korea*
[2]*Kangwon National University, Biochemistry, Chunchon, Republic of Korea*

Backgrounds

Laccases (benzenediole: oxygen oxidoreductase, EC 1.10.3.2) are multicopper blue oxidases, and there have been many reports that fungal laccases are involved in fungal development, pigment generation and pathogenicity of plant/animal infecting fungi. We have worked many laccase isozymes from several mushroom-forming fungi, and their biochemical characteristics were determined. We have also analyzed the enzyme applications for the degradation of recalcitrant chemicals such as dyes, endocrine-disrupting compounds and explosives.

Objectives

Coprinus comatus, an inky cap, synthesizes and secretes laccase in YEPD (yeast extract 10 g, peptone 20 g, dextrose 20 g, 1 L d-H_2O) liquid medium at neutral pH. The culture broth turned black after day 3, and laccase synthesizes this black melanin. We have purified a laccase from a liquid culture of this fungus, and its biochemical characteristic and its dye-decolorization activity were examined.

Methods

Coprinus comatus were grown in YEPD liquid medium (250 ml in 1 L flask) for 3 days in a shaking incubator, and the culture supernatants were collected for the enzyme source. A laccase was purified through DEAE-Sapharose ion-exchange chromatography and polyacrylamide preparative gel electrophoresis.

Conclusions

The biochemical parameters were as follows: optimum temperature was 25ºC and optimum pH was 4.3 when *o*-tolidine was used as a substrate, and its estimated molecular weight was 52 KDa. We have used this enzyme for the degradation of PolyR-478 and Remazol Brilliant Blue R dyes at 25ºC, and the enzyme treatment resulted in decolorization of both dyes. This enzyme can be used for the industrial dye removal

CONTRIBUTION OF LON AND CLPP PROTEASES OF PANTOEA ANANATIS TO VIRULENCE

O. Choi[1], B. Kang[2], J. Park[2], Y. Lee[2], J. Kim[3]
[1]Gyeongsang National University, Institue of Agriculture & Life Science, Jinju, Republic of Korea
[2]Gyeongsang National University, Division of Applied Life Science BK21 Plus, Jinju, Republic of Korea
[3]Gyeongsang National University, Institue of Agriculture & Life Science- Division of Applied Life Science BK21 Plus, Jinju, Republic of Korea

Backgrounds

The ATP-dependent proteases Lon and ClpP (Clp proteolytic subunit) are responsible for the turnover of misfolded proteins and the degradation of regulatory proteins in bacterial cells. γ-proteobacterium *Pantoea ananatis* PA13, our model bacterium, causes bacterial rice sheath rot and onion center rot diseases.

Objectives

The objective of this study was to assess the contribution of Lon and ClpP proteases of *P. ananatis* to virulence.

Methods

Using *Mariner* transposon mutant screening, we isolated *lon* and *clpP* mutants, exhibiting the deficiency in swimming motility and virulence in rice. We constructed mutants in the *lon* and *clpP* genes of *P. ananatis* PA13 by SacB-dependent manner and found that both mutants were impaired in growth at 28°C, swimming motility, and virulence.

Conclusions

The *lon* mutant of *P. ananatis* displayed a severe defect in colony morphology. The growth of the *clpP* mutant of *P. ananatis* was impaired at high temperature, a condition known to increase the level of misfolded protein. Further characterization of the *lon* mutant revealed enhanced autoagglutination. All phenotype deficiencies of both mutants were recovered by genetic complementation with intact *lon* and *clpP* (pOR84; pBBR1MCS-5::*lon* and pOR78; pBBR1MCS-5::*clpP*, respectively). These data suggested that the proteases may contribute to the virulence of *P. ananatis*.

MOLECULAR CHARACTERISTICS OF HLYU, A TRANSCRIPTIONAL REGULATOR OF VIBRIO VULNIFICUS VIRULENCE GENES

S.H. Choi[1], Z.W. Lee[1], Y.J. Bang[2], K.K. Jang[1]
[1]Seoul National University, Department of Agricultural Biotechnology, Seoul, Republic of Korea
[2]The University of Texas Southwestern Medical Center, Department of Immunology, Dallas, USA

Backgrounds

An opportunistic pathogen *Vibrio vulnificus* produces a large pore-forming toxin, RtxA, which triggers necrotic and apoptotic cell death. Previous studies reported that HlyU upregulates *rtxA* expression by direct binding to the promoter region of the *rtxHCA* operon.

Objectives

As a transcriptional regulator, HlyU was further characterized, and the mechanism of HlyU in *rtxA* regulation was elucidated.

Methods

The *hlyU* mutant was constructed, and the transcriptomic profiles of the wild type and the *hlyU* mutant were analyzed by RNA-sequencing. In addition to *rtxA*, genes encoding virulence factors such as hemolysin and phospholipase were down-regulated in the *hlyU* mutant, implying that HlyU contributes to the *V. vulnificus* pathogenesis by regulating various virulence genes. Furthermore, the levels of *rtxA* and *hlyU* transcripts in *V. vulnificus* cells grown in different conditions were determined. Induction of the *rtxA* expression occurred in the wild-type cells either exposed to the INT-407 human epithelial cells or grown under anaerobic conditions, but not in the *hlyU* mutant, indicating that HlyU mediated the induction. Since the levels of *hlyU* transcript in the wild-type cells were not significantly changed in those conditions, the *rtxA* activation might be attributed to altered activity rather than amounts of HlyU. To better understand this activity alteration of HlyU, C30, C96, and M87, which were predicted as essential amino acids from structural analysis, were mutated by site-directed mutagenesis. Among the mutants, *V. vulnificus* expressing HlyU-C30S showed a decreased *rtxA* level and cytotoxicity toward the HT-29 MTX cells than the wild type, suggesting that C30 is a critical residue of HlyU for *rtxA* activation.

Conclusions

Taken together, HlyU might act as a global regulator for the various virulence genes and induce *rtxA* under host environment by altering its activity.
This research was supported by a grant (14162MFDS172) from Ministry of Food and Drug Safety in 2017.

EVALUATION OF REFERENCE GENES FOR GENE EXPRESSION ANALYSIS USING QUANTITATIVE RT-PCR IN MICROSPORUM CANIS

A. Ciesielska[1], *P. Staczek*[1]
[1]*University of Lodz, Department of Microbial Genetics, Lodz, Poland*

Backgrounds

The selection of reference genes used for data normalization to quantify gene expression by qRT-PCR is a crucial step of this technique. Moreover, little information regarding such genes is available for gene expression analyses in dermatophytes.

Objectives

We investigated the suitability of nine candidate reference genes in isolates of *Microsporum canis* subjected to different environmental stimuli typical for the stage of host infection such as different carbon sources, pH shifts, growth phase transition.

Methods

The stability of these genes was determined by NormFinder, geNorm and BestKeeper software.

Conclusions

To the best of our knowledge this is the first report on selection of reference genes for qRT-PCR data normalization in *Microsporum canis* and the results of these studies should permit further analysis of *Microsporum canis* gene expression under several conditions.

Physiology / Biochemistry / Molecular Microbiology

CHARACTERIZATION OF THE LIPOPROTEIN FROM THE CPR RESISTANCE MACHINERY OF CLOSTRIDIUM DIFFICILE

R. Clemens[1], *S.H.J. Smits*[1]
[1]*Heinrich-Heine-University- Duesseldorf, Institute of Biochemistry, Duesseldorf, Germany*

Backgrounds

The Gram-positive bacterium *Clostridium difficile* is a human pathogen that causes chronic intestinal disease. This spore forming anaerobe bacterium is resistant against antibiotics. Therefore a special need is to obtain new antibiotics to cure the diseases associated with *C. difficile*. Here, lantibiotics which are small antimicrobial peptides due to their high antmicrobial activities interesting candidates. .

However, within the *C. difficile* genome a protein machinery generating a lantibiotic resistance is encoded, the so called Cpr system (McBride and Sonenshein 2011). Upstream of this system a lipoprotein is localized encoding *Cd*Lipo, similar to other lantibiotic resistance systems (Khosa et al. (2016)). *Cd*Lipo however, is uncharacterized till date. The understanding of the molecular mechanism of this *Cd*Lipo protein would allow to synthesise an effective compound circumventing the occurring lantibiotic resistance.

Objectives

The goal of this study is to characterize the *Cd*Lipo.

Methods

To characterize *Cd*Lipo, we express in *Escherichia coli* and purify the lipoprotein with affinity and size exclusion chromatography. To get some information about its function we do co-elution studies with the purified *Cd*Lipo and several potential interaction partners for example the model lantibiotic nisin. In addition we do structural studies to obtain the first glimpse of this protein using a combination of SAXS, NMR and crystallography measurements.

Conclusions

Here we present our initial structural as well as functional results of the *Cd*Lipo protein using these *in vivo* and *in vitro* results and clarify its role in lantibiotic resistance.

NEW INSIGHTS INTO THE ASSEMBLY OF ESCHERICHIA COLI OUTER MEMBRANE LIPOPROTEINS

S.H. Cho[1], A. Asmar[1], J.F. Collet[1]
[1]Université catholique de Louvain, de Duve Institute, Brussels, Belgium

Backgrounds

Bacterial lipoproteins are a very diverse group of proteins characterized by the presence of an N-terminal lipid moiety that serves as a membrane anchor. Lipoproteins have a wide variety of crucial functions, ranging from envelope biogenesis to stress response. In Gram-negative bacteria, lipoproteins can be targeted to various destinations in the cell, including the periplasmic side of the cytoplasmic or outer membrane, the cell surface or the external milieu.

Objectives

One of the objectives of our lab is to understand how lipoproteins can reach the cell surface of Escherichia coli and other Gram-negative bacteria.

Methods

By focusing on the lipoprotein stress sensor RcsF, we dissected the molecular mechanism allowing this protein to become surface-exposed.

Conclusions

This allowed us to discover and specify the role played by beta-barrel proteins in this process.

JANTHINOBACTERIUM SP. ROICE36 AS A PROMISING SOURCE OF NOVEL ANTIMICROBIAL COMPOUNDS

A. Baricz[1], C. Chiriac[1], E. Szekeres[1], C. Coman[1]
[1]Institute of Biological Research Cluj-Napoca- branch of NIRDBS Bucharest, Taxonomy and Ecology, Cluj-Napoca, Romania

Backgrounds

Since their discovery, antibiotics have changed the face of medicine, saving millions of lives from deadly infections. But, due to improper use of antibiotics, the phenomenon of antimicrobial resistance has been growing constantly. Natural products are an important source of novel antibiotics in modern medicine, and have made an unquestionable impact on global health so far. The *Janthinobacterium* sp. ROICE36 strain, isolated during the ROICE Romanian expeditions to Antarctica, is a promising candidate in the research for possible novel antimicrobials.

Objectives

To perform a biochemical characterization, to test several growth conditions and to sequence the genome in order to obtain an improved yield of bacterial biomass and to characterize the antimicrobial biosynthetic pathways.

Methods

Determine the carbohydrate utilization capability and the semiquantitation of enzymatic activities of the *Janthinobacterium* sp. ROICE36 strain. Characterize the strain's growth parameters on solid and in liquid media. Whole genome sequencing and description of the genome features.
Obtain the bacterial extract and test its antibacterial activity against multidrug resistant pathogens.

Conclusions

Species of the genus *Janthinobacterium* synthesize secondary metabolites that exhibit exceptional antibacterial, antifungal, antiviral and antiprotozoal activity. As the levels of resistance to some antibiotics in several important pathogens are growing worldwide, it is important to identify promising sources of novel antimicrobials with potential usefulness in biotechnological applications.

A STRESS-INDUCED REGULON REQUIRED FOR STAPHYLOCOCCAL INFECTION

M.D.M. Cordero Alba[1], *D. Lopez*[1]
[1]*Centro Nacional de Biotecnología CNB-CSIC, Biotecnología Microbiana, Madrid, Spain*

Backgrounds

A large number of bacterial infections are caused by opportunistic pathogens, like *Staphylococcus aureus,* which represents the most common source of infections in clinical setting due to the fact that it colonizes human skin and causes device contamination during surgical practice. *S. aureus* possesses different systems that can control cell-density that could be involved in infection, like the quorum-sensing (QS) system.

Objectives

In this report, we investigate the functionality of a new genetic regulon that is necessary for virulence in *Staphylococcus aureus* cells and is triggered by diverse types of cellular stresses.

Methods

We carry out a comprehensive number of omics approaches in combination to classical biochemical methods and *in vivo* animal experimentation.

Conclusions

We identify a new regulon that is triggered in specific conditions and is necessary for the progression of an infection. This regulon is not active during non-infective conditions. We will show the genes that constitute the regulon and will provide details about the genetic pathway that leads to the activation of the cascade *in vitro* and also *in vivo* using a murine infection model.

SPATIAL TARGETING OF HETEROLOGOUS CLASS I PI3K IN SACCHAROMYCES CEREVISIAE AND DEVELOPMENT OF TOOLS FOR PHOSPHOINOSITIDE IN VIVO MONITORING

J.M. Coronas-Serna[1], T. Fernádez-Acero[1], V.J. Cid[1], M. Molina[1]
[1]Complutense University of Madrid - School of Pharmacy, Department of Microbiology II, Madrid, Spain

Backgrounds

Phosphoinositides play a key role in various signaling pathways. In mammals, *in situ* generation of PtdIns(3,4,5)P_3 by PI3K in plasma membrane (PM) regulates growth factor response through the Akt pathway. Heterologous expression of mammalian class I PI3K catalytic subunit p110α in the model organism *S. cerevisiae* leads to growth inhibition due to the conversion of essential PM PtdIns(4,5)P_2 into PtdIns(3,4,5)P_3, naturally absent in yeast.

Objectives

Our aim was to target PtdIns(4,5)P_2 removal to discrete PM domains by fusing p110α to either the Cdc10 septin or the eisosome component Pil1, as well as to develop a fluorescence double marker-based tool to study the localization of PI3K activity *in vivo* by simultaneous monitoring of PtdIns(4,5)P_2 and PtdIns(3,4,5)P_3.

Methods

Functional analyses on cells expressing chimaeras of p110α and distinctly localized yeast proteins. Construction of GFP/mCherry-based phosphoinositide-specific markers for fluorescence microscopy.

Conclusions

Expression of either Cdc10-p110α or Pil1-p110α fusions led to growth inhibition of yeast cells similar to that induced by N-myristoylated p110α, which is not targeted to specific PM domains. Both fusion proteins caused a delay in endosomal trafficking. Cdc10-p110α exclusively localized to the bud neck. A fusion of p110α to a Cdc10 mutant version, which failed to localize properly, did not inhibit growth, demonstrating that anchoring to the septin ring was required for toxicity. Single-cell monitoring of PM phosphoinositide species by the double marker plasmid developed revealed that, despite the spatially restricted activity of p110α, PtdIns(4,5)P_2 conversion to PtdIns(3,4,5)P_3 was observed along the whole PM.

FEMS7-3238

AS AFFECT THE ABSENCE OF NITROGEN OR CARBON PEP4, LAP4, PRC AND APE3 GENES OF CANDIDA GLABRATA

J.L. Cortez Sánchez[1], *J.A. Ibarra García*[2], *C.H. Hernández Rodríguez*[2], *M.D.L. Villa Tanaca*[1]
[1]*Instituto Politécnico Nacional, Microbiologia, Mexico, Mexico*
[2]*Instituto Politécnico Nacional, Microbiología, Mexico, Mexico*

Backgrounds

C. glabrata is an opportunistic pathogen, resistant to conventional antifungals such as azoles, is currently considered the second cause of disseminated candidiasis and mucosal candidiasis in humans. A great variety of virulence factors have been studied, but many are still to be described and control of *C. glabrata* infections. In other microorganisms it has been observed that the proteolytic system vacuolar is very important for its adaptation and survival. On the other hand, despite the relevance that *C. glabrata* has acquired, to date the *C. glabrata* vacuolar proteolytic system has not been studied in detail.

Objectives

This work seeks to understand the role of *PEP4*, *APE1, APE3, PRC* in absence of nitrogen, carbon or both and determine the conditions where induced expression of these genes and at the same time evaluate the specific activity of the proteins encoded by these genes.

Methods

A bioinformatic analysis was performed using the *S. cerevisiae* protein sequences to search for *C. glabrata*, the promoter sequences were analyzed using the genomatix server, the genes were analyzed by RT-qPCR and the specific activity of each of the proteins was determined.

Conclusions

Taken together our results showed that PrA, Ape1, Ape3 and CpY have varying activities and expression depending on whether nitrogen or carbon is added to the media and that these vacuolar proteases might have a role in the autophagy process.

FEMS7-1393
Physiology / Biochemistry / Molecular Microbiology

REGULATION OF THE SYNTHESIS AND SUBCELLULAR LOCALIZATION OF THE ESCHERICHIA COLI ZIPA DIVISION PROTEIN

L. Cueto[1], *A. Sanchez Gorostiaga*[1], *M. Vicente*[1]
[1]*Centro Nacional De Biotecnologia, Biotecnologia Microbiana, Madrid, Spain*

Backgrounds

The ZipA protein is essential for *Escherichia coli* division. It is a transmembrane protein solely present in gammaproteobacteria. Together with FtsA and FtsZ, they form the proto-ring, a protein complex required to initiate the assembly of the divisome. Transcription of the *ftsZ* and *ftsA* genes, located in the *E. coli dcw* (division and cell wall) cluster, is driven by a combination of gearbox (RpoS-dependent) and housekeeper (RpoD-dependent) promoters. However, *zipA* maps outside the *dcw* cluster and the signals controlling its expression need to be identified.

Objectives

Characterization of the *zipA* expression pattern in *E. coli* depending to the growth rate. Identification of the signals that regulate *zipA* expression. Determine if ZipA is specifically associated to particular membrane microdomains.

Methods

Use of reporter GFP-fusions to locate, sequences able to act as potential promoters and regulatory binding sequences in the 96 bp upstream region. Deletions in the *zipA* promoter regions to determine their effect on cell division. Measurements of the ZipA amount relative to cell mass in the *E. coli* MG1655 wild-type strain and an isogenic Δ*rpoS* strain at different growth rates and during different phases of population growth. The presence of ZipA in specific membrane microdomains was analyzed by Western blot using suitable membrane fractions.

Conclusions

In contrast to the growth rate-independency of the amounts of FtsA and FtsZ found per cell, the levels of ZipA in *E. coli* cells increase, as it occurs with other membrane proteins, accordingly to their growth rate. Finally, we could localize ZipA associated to specific cytoplasmic membrane microdomains.

Physiology / Biochemistry / Molecular Microbiology

PHYSICAL INTERACTION BETWEEN THE MAPK SLT2 OF THE PKC1-MAPK PATHWAY AND GRX3/GRX4 GLUTAREDOXINS IS REQUIRED FOR THE OXIDATIVE STRESS RESPONSE IN BUDDING YEAST

M.A. de la Torre-Ruiz[1], N. Pujol-Carrion[1], A. Barbero Farran[1], M.A. Mechoud[1]
[1]Institute for Biomedical Research IRB LLEIDA, Basic Medical Sciences, Lleida, Spain

Backgrounds

Slt2 is the MAPK of the CWI pathway in budding yeast whereas Grx3/Grx4 are two redundant monothiol glutaredoxins with a role in iron homeostasis. Slt2/Grx3/Grx4 are functionally related in the oxidative response.

Objectives

To analyse at the molecular and biochemical level the physical interaction between the MAPK Slt2 and Grx3/Grx4 monothiol proteins.

To elucidate the biological function of Slt2/Grx3/Grx4 complex in the oxidative response.

Methods

See: Free Radic Biol Med. 2017. 103:107-120.

Conclusions

This study demonstrates that both monothiol glutaredoxins Grx3 and Grx4 physically interact with the MAPK Slt2 forming a complex involved in the cellular response to oxidative stress. The simultaneous absence of Grx3 and Grx4 provokes a serious impairment in cell viability, Slt2 activation and Rlm1 transcription in response to oxidative stress. Our results suggest that Slt2 form iron/sulphur bridged clusters with Grx3 and Grx4. For the assembly of this complex, cysteines of the active site of each Grx3/4 glutaredoxins, glutathione and specific cysteine residues from Slt2 provide the ligands. One of the ligands of Slt2 is required for its dimerisation upon oxidative treatment and iron repletion. These interactions are relevant for the oxidative response, given that mutants in the cysteine ligands identified in the complex show a severe impairment of both cell viability and Slt2 phosphorylation upon oxidative stress. Grx4 is the relevant glutaredoxin that regulates Slt2 phosphorylation under oxidative conditions precluding cell survival. Our studies contribute to extend the functions of both monothiol glutaredoxins to the regulation of a MAPK in the context of the oxidative stress response.

Physiology / Biochemistry / Molecular Microbiology

IDENTIFICATION OF RCTB MUTATIONS THAT PROMOTE V. CHOLERAE ORI2 OVER-INITIATION

F. de Lemos Martins[1], *M.E. Val*[1], *D. Mazel*[1]
[1]*Institut Pasteur, Genomes and Genetics, Paris, France*

Backgrounds

Vibrio cholerae has two chromosomes, Chr1 (3 Mbp) and Chr2 (1 Mpb). Replication initiation of the two chromosomes is not synchronous but their termination is. Indeed, initiation of Chr2 replication is triggered when 2/3rd of Chr1 has been replicated. On Chr1, a binding site for the initiator of Chr2 (RctB) called *crtS* (Chr2 replication triggering Site) is crucial for the activation of Chr2 replication. We showed that the replication of *crtS* triggers Chr2 replication. This revealed a novel check-point control mechanism in bacteria in which one chromosome communicates with another chromosome to coordinate their replication. However the molecular basis behind this process is largely unknown.

Objectives

In this work we aimed to unravel potential factors involved in *V. cholerae* Chr2 replication regulation.

Methods

We performed an experimental evolution of *ΔcrtS* mutants. After growth for 200 generations these mutants acquired point mutations affecting exclusively *rctB*. By testing these mutations on a synthetic mini-chromosome based on *V. cholerae ori2* (mini-Chr2) we observed that they were able to stabilize it in *E. coli*, when it is normally lost without selection. By qPCR we found that all *rctB* mutated mini-Chr2 have a higher copy number suggesting that they over-initiate their replication.

Conclusions

Overall, our results show that the *rctB*-associated mutations are able to partially restore the defects caused by *crtS* deletion by altering Chr2 initiation regulation. This might suggest a direct interplay between *crtS* and RctB to coordinate chromosome replication in *V. cholerae*.

AWAKENING DORMANT SECONDARY METABOLITE GENE CLUSTERS IN STREPTOMYCES

A. de Pedro[1], E.G. Barreales[1], Á. Rumbero[2], C.M. Vicente[1,3], T.D. Payero[1], J.F. Aparicio[1]
[1]Universidad de León, Biología Molecular, León, Spain
[2]Universidad Autónoma de Madrid, Química Orgánica, Madrid, Spain
[3]Present address: Université de Lorraine, Dynamique des Génomes et Adaptation Microbienne, Vandoeuvre-lès-Nancy, France

Backgrounds

Sequencing of *Streptomyces* genomes has unveiled that the secondary metabolite biosynthetic potential of these bacteria has been greatly underestimated. Most secondary metabolite gene clusters in these bacteria are silent (they are not expressed or they do little), and through their activation we can achieve the production of new molecules. Heterologous expression of the regulator PimM (an archetype of PAS-LuxR regulator) has been successfully used to trigger the production of several polyene antifungal macrolides in different producing strains, but also to boost the production of other compounds.

Objectives

Activation of silent secondary metabolite gene clusters for the discovery of new drugs.

Methods

A deregulated *pimM* gene where its original promoter has been replaced by a strong constitutive promoter was introduced in different *Streptomyces* strains, and the antibiotic and/or antifungal activity of the exconjugants was determined by bioassay. Subsequently, the novel activities identified were characterized by HPLC, and the responsible compounds purified and characterized by MS, and NMR structural studies.

Conclusions

Overexpression of *pimM* in different *Streptomyces* strains results in increased production of secondary metabolites of diverse nature such as polyketides: amphotericin in *S. nodosus*, filipin in *S. avermitilis* and *S. filipinensis,* or depsipeptide antimycins: in *S. albus* and *S. ambofaciens.* This makes PAS-LuxR regulators an excellent tool for the activation of silent gene clusters for secondary metabolites, and therefore for the discovery of new drugs.

MULTIPLE GENE CLUSTER CONTROL BY A SINGLE PAS-LUXR TRANSCRIPTIONAL REGULATOR

C.M. Vicente[1,2], A. de Pedro[2], E.G. Barreales[2], T.D. Payero[2], J.F. Aparicio[2]
[1]Present address: Université de Lorraine, Dynamique des Génomes et Adaptation Microbienne, Vandoeuvre-lès-Nancy, France
[2]Universidad de León, Biología Molecular, León, Spain

Backgrounds

PAS-LuxR regulators are highly conserved proteins involved in the control of antifungal production by binding to operators located in given promoters of polyene biosynthetic genes. These regulators have been found to be encoded in all know biosynthetic gene clusters of polyene polyketides, and hence they have been considered pathway-specific modulators. PteF is the PAS-LuxR transcriptional activator of filipin biosynthesis in *Streptomyces avermitilis*.

Objectives

Identification of gene targets of regulatory control.

Methods

We have used the canonical operator of PimM, archetype of this class of regulators, to search for putative targets of orthologous protein PteF in the genome of *S. avermitilis*. Multiple DNA-binding sites for PimM (and therefore for PteF) were found in the genome. Several of these operators were selected and their binding to PimM DNA-binding domain was assessed by electrophoretic mobility shift assays. Additionally we carried out comparative transcriptome analyses in parental and mutant strains by microarrays. Transcriptomic results were validated by quantitative reverse transcription polymerase chain reaction, and by metabolite production studies.

Conclusions

Contrary to the established opinion, PAS-LuxR regulators control a plethora of different processes previously unforeseen, such as genetic information processing; DNA, energy, carbohydrate, and lipid metabolism; morphological differentiation; and transcriptional regulation; among others, but particularly secondary metabolite biosynthesis. Notably, fourteen secondary metabolite gene clusters out of 38 encoded by *S. avermitilis* genome, many of them encoding cryptic compounds, showed to be controlled by the regulator, suggesting a regulatory role for PteF wider than expected. This opens new possibilities for enhancement and awakening of metabolite production in *Streptomyces*.

FUNCTIONAL ANALYSIS OF THE MYCOBACTERIUM SMEGMATIS MSMEG_3765 GENE, CODING A TETR-LIKE PROTEIN

F. Perrone[1], B. De Siena[1], L. Muscariello[1], S. Kendall[2], S. Waddell[3], M. Sacco[1]
[1]Università degli Studi della Campania Luigi Vanvitelli, Di.S.T.A.Bi.F., Caserta, Italy
[2]The Royal Veterinary College, Pathology and Pathogen Biology, London, United Kingdom
[3]University of Sussex, Medical School, Brighton, United Kingdom

Backgrounds

Mycobacterium tuberculosis has the ability to survive in the macrophage under acid- nitrosative stress. The expression profile of *M. tuberculosis* and *M. smegmatis* exposed to acid-nitrosative stress shows up-regulation of *M. smegmatis MSMEG_3765* and of its ortholog, *M. tuberculosis Rv1685c* (Cossu *et al.*, Microb. Pathog. 65:89, 2013). Both genes are annotated as TetR transcriptional regulators. This family of proteins regulates a wide range of cellular activities, including multidrug resistance, efflux pumps, virulence and pathogenicity. In the Mycobacteria genus they are the most abundant transcriptional regulator and the majority of them remains uncharacterized.

Objectives

The aim of this study was to identify the genes regulated by *MSMEG_3765* in order to further understand the role of this regulator in the stress response.

Methods

A deletion was made in *MSMEG_3765* by homologous recombination and changes in genome-wide expression levels as a result of the deletion were measured using microarray analysis. Local gene expression levels were also quantified by RTq-PCR and by measuring promoter activity using GFP reporters. The TetR regulator (MSMEG_3765) was expressed and purified and used to identify promoters bound.

Conclusions

MSMEG_3765 was found to regulate the adjacent operon (*MSMEG_3762-63-65).* The purified regulator was found to bind to the promoter region upstream of *MSMEG_3762-63-65*, but no TetR motif was predicted in this region. These results show that MSMEG_3765 regulates an efflux pump with an, as yet, undefined role in the stress response.

Physiology / Biochemistry / Molecular Microbiology

BREAKING THE BOND BETWEEN HELICOBACTER PYLORI AND ITS HOST

A. Debraekeleer[1], F. Coppens[1], G. Castaldo[1], K. Moonens[1], H. Remaut[1]
[1]Vrije Universiteit Brussel, Structural and Molecular Microbiology, Brussel, Belgium

Backgrounds

Helicobacter pylori is a human stomach pathogen infecting over half the world's population. The infection is generally associated with asymptotic gastritis, but can progress to peptic ulcers and stomach cancers. To sustain infection, the bacteria maintain an intimate interaction with the stomach epithelial cells and overlaying mucus by using a set of structurally conserved autotransporter-like adhesins called Hops.

Objectives

A highly conserved C-terminal domain is believed to represent the Hop transmembrane domain, but lacks typical features seen in classical autotransporters. We here set out to investigate the Hop architecture and transport route to the outer membrane.

Methods

We use X-ray crystallography, directed mutagenesis and localization studies to delineate the Hop passenger and transmembrane domain. Recombinant expression in *E. coli* is used to determine the minimal Hop fragment that is targeted to the outer membrane as a stable b-barrel.

Conclusions

We found that Hops represent a novel family of autotransporter-like adhesins with a conserved discontinuous β-barrel, interrupted by the α-helical passenger domain in extracellular loop 1. The Hop architecture is incompatible with prevailing models for autotransporter insertion into and passenger transport across the outer membrane, leading us to further investigate the route and mechanism of Hop biogenesis as a means of targeting this family of primary *Helicobacter pylori* virulence factors.

TUBERCULOUS LYMPHADENITIS IN ETHIOPIA PREDOMINANTLY CAUSED BY STRAINS BELONGING TO THE DELHI/CAS LINEAGE AND NEWLY IDENTIFIED ETHIOPIAN CLADES OF THE MYCOBACTERIUM TUBERCULOSIS COMPLEX

F.B. Degeneh[1]
[1]*Bahir Dar University, Medical Microbiology - immunology and parasitology, Bahir Dar, Ethiopia*

Backgrounds

Recently, newly defined clades of *Mycobacterium tuberculosis* complex (MTBC) strains, namely Ethiopia 1-3 and Ethiopia H37Rv-like strains, and other clades associated with pulmonary TB (PTB) were identified in Ethiopia.

Objectives

We investigated whether these new strain types exhibit an increased ability to cause TB lymphadenitis (TBLN) and raised the question, if particular MTBC strains derived from TBLN patients in northern Ethiopia are genetically adapted to their local hosts and/or to the TBLN.The study was conducted to extend our understanding of the diversity; phylogeny, and transmission dynamics of MTBC strains isolated from TBLN patients in Ethiopia

Methods

Genotyping of 196 MTBC strains was performed by spoligotyping and 24-loci mycobacterial interspersed repetitive unit-variable number of tandem repeats (MIRU-VNTR) typing. A statistical analysis was carried out to see possible associations between patient characteristics and phylogenetic MTBC strain classification.

Conclusions

In the studied area, strains obtained from lymph node samples are mainly belonging to the MTBC Dehli/CAS lineage. The lower cluster rate in this study as compared to previous studies on PTB patients might reflect the dead end characteristics of the disseminated form of the disease or may be associated to a higher rate of TBLN patients among TB reactivation events. We found no indication that strains of particular genotypes are specifically associated with TBLN. Nevertheless the identification and treatment of TB bacteria in TBLN patients is of great importance.

FEMS7-1572
Physiology / Biochemistry / Molecular Microbiology

REGULATION OF VIBRIO CHOLERAE COLONY MORPHOLOGY BY TEMPERATURE

T. del Peso-Santos[1], *J. Blake*[2], *V. Benes*[2], *F. Cava*[1]
[1]*Umeå University, Department of Molecular Biology, Umeå, Sweden*
[2]*European Molecular Biology Laboratory, Genomics Core Facility, Heidelberg, Germany*

Backgrounds

A common strategy for bacterial growth and survival is the formation of biofilms - bacterial communities found in surfaces and interfaces held together by an extracellular matrix composed by exopolysaccharides, proteins and extracellular DNA. The biofilm life style provides protection from the external environment, i.e. predators and physical and chemical stresses such as antibiotics, controls nutrient adsorption and enhances bacterial persistence.

Vibrio cholerae - an aquatic bacterium that is the causative agent of Cholera disease - forms biofilms during both the acquatic and intestinal phases of its life cycle. Among all the diverse environmental signals that regulate biofilm in *V. cholerae*, temperature is of major importance upon infection of a host and subsequent transmission, since this bacterium undergoes a temperature shift in its transition between the human host (37ºC) and the aquatic environment (lower temperatures).

Objectives

This work aims to unravel the molecular mechanism(s) behind temperature-dependent regulation of *V. cholerae*'s biofilm.

Methods

We have performed: (1) a global transcriptome analysis of *V. cholerae* at different temperatures that result in different colony morphology (rugose colonies = biofilm; smooth colonies= less or biofilm) by means of RNA seq; and (2) a massive transposon mutagenesis, in order to find crucial activities important for this temperature-dependent regulation.

Conclusions

The identified activities that are involved in temperature-mediated regulation of *V. cholerae*'s biofilm are presented here.

Physiology / Biochemistry / Molecular Microbiology

OBGE* CAUSES CELL DEATH BY INTERFERING WITH CELL DIVISION

L. Dewachter[1], *N. Verstraeten*[1], *M. Fauvart*[1,2], *J. Michiels*[1]
[1]*KU Leuven, Centre of Microbial and Plant Genetics, Leuven, Belgium*
[2]*imec, Smart Systems and Emerging Technologies Unit, Leuven, Belgium*

Backgrounds

Although intensely studied, cell division remains a universal core process that is incompletely understood. Even in well-studied organisms, such as *Escherichia coli*, many factors involved in cell division remain to be identified or are not fully characterized.

Objectives

We here demonstrate a role for the widely conserved GTPase, ObgE, in the regulation of cell division in *E. coli*. We do so by showing that a mutant form of this protein, ObgE*, interferes with division. Insights gleaned from characterizing the effect of ObgE* can reveal more about the role of wild-type ObgE in cell division.

Methods

Morphological changes upon ObgE* expression indicate that ObgE* can inhibit the separation of newly-formed daughter cells and cause the formation of cell chains. Lysis then occurs through rupture of membrane blebs that form at division sites. Additionally, in the absence of lysis, ObgE* can block cell division before constriction has started.

Conclusions

Cell death caused by ObgE* occurs either through an irreversible block in cell division or through inhibition of cell separation. Since a defect in division underlies both pathways, these results strongly implicate ObgE in the regulation of cell division in *E. coli*. Because Obg proteins are widely conserved and essential for bacterial viability, our findings might be applicable to other organisms as well.

NADPH REGENERATION AND REDOX BALANCE SYSTEMS IN OENOCOCCUS OENI ETHANOL-STRESSED CELLS

K. Di Tomaso[1,2], M.G. Bonomo[1], L. Calabrone[1], G. Salzano[1]
[1]Università degli Studi della Basilicata, Sciences, Potenza, Italy
[2]Università degli Studi della Basilicata, Ph.D school in Applied Biology and Environmental Safeguard, Potenza, Italy

Backgrounds

Various physical/chemical factors, such as ethanol, pH and temperature, are known to affect the growth and bacterial survival of *Oenococcus (O.) oeni* that faces the hostile environment of wine by activation of several mechanisms.Ethanol tolerance appeared to be a crucial feature for the activity of *O. oeni* cells in wine because ethanol acts as disordering agent of the *O. oeni* cell membrane and negatively affects metabolic activity.

Objectives

A transcriptomic analysis of *O. oeni* ethanol stressed cells by NGS approach allows to investigate variations in transcripts involved in energy metabolism pathways and changes in *O. oeni* metabolic profile induced by ethanol stress.

Methods

In this study RNA-seq was used to assemble *O. oeni* S12 transcriptome and detect genes differentially expressed in ethanol stress conditions.
Results showed changes in pentose phosphate and ethanol forming pathway, i.e. the overexpression of 6-phosphogluconate dehydrogenase and short chain alcohol dehydrogenase genes, due to the competition for NAD(P)H, in stressed cells. Two systems for cofactor regeneration were revealed: NADPH oxidoreductase activity, overexpressed in stressed cells, and an alternative use of pyruvate, shifted in diacetyl, acetoin and 2,3-butanediol, confirmed by the upregulation of acetoin reductase transcript.

Conclusions

NGS approach revealed ethanol stress triggers deep changes in *O. oeni* transcriptome to ensure cell viability, resulting a valid tool for studying stress responsive mechanisms and to improve knowledge on *O. oeni* adaptive response to ethanol stress.

[7]Instituto de Biocomputación y Física de Sistemas complejos,
Instituto de Biocomputación y Física de Sistemas complejos, Zaragoza, Spain

Backgrounds

MTBVAC is a live attenuated *M. tuberculosis* vaccine based on two independent stable deletion mutations without antibiotic resistance markers in the virulence genes *phoP* and *fadD26*. MTBVAC is being tested in clinical trials. At present there are no studies to characterize metabolic expression in the attenuated strain

Objectives

Find the differences in expression of metabolites between strains and the involvement of the *phoP* gene in the differences in metabolite expression, and characterize the associated changes in pathogenicity and activation of the immune system.

Methods

Five replicas of *Mycobacterium tuberculosis* and five replicas of MTBVAC were cultivated and their supernatants were analyzed by liquid chromatography coupled to high resolution mass spectrometry with four different conditions. Reverse-phase and HILIC chromatographic modes were applied to deal with highly polar as well as hydrophobic metabolites required for untargeted metabolomics and positive and negative ionization

Conclusions

Using a metabolomics approach, we identified specific metabolites that may be used to characterize the genomic differences. We found about 200 differential metabolites significantly in the four analyses. Within the molecules that have been identified, there are different components involved in the formation of membranes, lipids, mainly phosphatidylinositol and molecules directly involved in the metabolism, such as nucleotide, glutamine or glutamate. Through the tentatively identified metabolites, a relationship can be established that helps elucidate mechanistic pathways for a better understanding about pathogenicity and potentiation of the immune system.

FUNCTIONAL STUDY OF THE ROLE OF BACTERIAL CYCLOPHILIN PPIB IN CELL DIVISION

A. Skagia[1], C. Zografou[1], A. Venieraki[1], C. Fasseas[1], P. Katinakis[1], M. Dimou[1]
[1]Agricultural University of Athens, Faculty of Crop Science, Athens, Greece

Backgrounds

E. coli PpiB belongs to the superfamily of peptidyl prolyl *cis*/*trans* isomerases (PPIase, EC: 5.2.1.8), which are conserved among organisms and are implicated in many biological processes in addition to protein folding. Here we show that the Δ*ppiB* deletion strain and the PpiB overexpression wild type strain are both characterized by defects in cell division involving milder or severe cell filamentation, respectively.

Objectives

We aim to identify whether PpiB interfering with cell division occurs via one or more components of the divisome machinery and/or via additional protein interactions not directly involved in the division process. Furthermore, we aim to identify the essential PpiB structural features for the inhibitory effect of PpiB overexpression in cell division.

Methods

We express various divisome components or putative PpiB prey proteins in Δ*ppiB* cells and check for phenotype restoration. We examine the protein interaction of PpiB with FtsZ under native or denaturing conditions and we further assess their association using enzymatic and localization studies. We express various PpiB mutants in wild type cells and observe the effect on cell morphology.

Conclusions

PpiB is involved in bacterial cell division in a way that employs its prolyl isomerase activity along with structural features apart from the catalytic site as well as its association with FtsZ. However, PpiB seems to also modulate the function of additional proteins not previously related to cell division.

SCREENING FOR COMPOUNDS WHICH SPECIFICALLY INHIBIT THE YEAST MULTIDRUG TRANSPORTER PDR5

K. Döhl[1], S.H.J. Smits[1], L. Schmitt[1]
[1]Heinrich-Heine-University- Duesseldorf, Institute of Biochemistry, Duesseldorf, Germany

Backgrounds

The ABC transporter Pdr5 is part of the pleiotropic drug resistance (PDR) network of the yeast *Saccharomyces cerevisiae* and plays a major role in drug resistance against a large number of structurally unrelated compounds. Pdr5 is a functional homologue of Cdr1 from the clinical relevant fungi *Candida albicans*.

Objectives

Consequently, the development of new inhibitors against these multidrug exporter proteins plays an important role in our fight against resistance fungi.

Methods

With a two-fold *in vitro* and *in vivo* strategy, we determined the inhibitory effect of unknown compounds to the yeast protein Pdr5. We were able to identify several substances, which inhibit the ABC transporter *in vitro*. To analyze the inhibitory effect *in vitro* we isolated highly enriched plasma membranes of a Pdr5 overexpressing yeast strain. We performed a high throughput assay monitoring the transport process of Pdr5 in real time. Several substances were identified to inhibit Pdr5 specifically. The oligomycin-sensitive Pdr5 ATPase was used as a second measurement to confirm and further characterize the inhibitory effect of these substances.
In vivo, a liquid drug assay was used to demonstrate that these substances are able to inhibit the transport as well. Therefore, we incubated Pdr5 wild type and an ATPase deficient mutant with different concentrations of the previously identified substances.

Conclusions

So far, none of the compounds that were identified *in vitro* inhibit Pdr5 *in vivo*. A reason could be that the substances are not able to cross the membrane efficiently or that much higher concentrations of the compounds are necessary.

MYCOPLASMA CHROMOSOMAL TRANSFER: A NEW GATEWAY FOR EVOLUTION AND INNOVATION IN MINIMAL BACTERIA

E. Dordet-Frisoni[1], E. Sagne[2], E. Baranowski[1], X. Nouvel[2], C. Citti[1]
[1]INRA, IHAP- Université de Toulouse- INRA- ENVT- Toulouse- France, Toulouse, France
[2]ENVT, IHAP- Université de Toulouse- INRA- ENVT- Toulouse- France, Toulouse, France

Backgrounds

Horizontal gene transfer (HGT) is a major driving force of bacterial evolution and innovation. In mycoplasmas, this phenomenon was long thought to be marginal because of these bacteria having very few recombination systems and genetic mobile element. Mycoplasmas represent the simplest, self-replicating bacteria due to a minute-size genome whose evolution is driven by genetic losses. Our data recently challenged this dogma by showing the occurrence of significant HGT between ruminant mycoplasmas and, in some strains, of putative integrative conjugative elements (ICE). We demonstrated that mycoplasma chromosomal transfers (MCT) occur via conjugation using a new mechanism that does not conform to classic oriT-based conjugation models. While MTC and classical ICE transfer take place in the same population, MCT is independent from ICE movement.

Objectives

The purpose of this study is to understand the mechanisms underlying MCT

Methods

NGS sequence data from entire mating progenies and from several, individual transconjugants were compared.

Conclusions

Results showed that a single Mycoplasma recipient chromosome can acquire several segments of donor DNA. Transferred segments range from ~1,500 bp to ~80,000 bp in length and are exchanged with their recipient orthologs all around the genome. Transconjugant genomes contained up to 10% of donor-derived chromosome, distributed over 7 segments. MCT involves a recombination process, with micro-homologous regions as short as 12 nt flacking the transferred segment.
The discovery of MCT radically change our current views concerning the evolution of mycoplasmas, with particularly far-reaching implications given that over 100 species are human or animal pathogens.

PROTEOMIC ANALYSES OF STREPTOCOCCUS SUIS DURING EXPOSURE TO HUMAN MACROPHAGES

K. Duangsonk[1], P. Prangsuwan[1], H. Thananchai[1], S. Roytrakul[2]
[1]Faculty of Medicine- Chiang Mai University, Department of Microbiology, Maung Chiang Mai, Thailand
[2]National Center for Genetic Engineering and Biotechnology, Proteomics Research Laboratory, Pathum Thani, Thailand

Backgrounds

Streptococcus suis is a zoonotic bacterium that can cause septicemia, meningitis and permanent hearing loss in human. Previous studies have shown that *S. suis* is able to resist phagocytosis, however, a small number of *S. suis* can enter and survive inside phagocytes. In an effort to understand the molecular mechanisms underlying *S. suis* adaptation, we investigated *S. suis* proteomes during exposure to intracellular condition of cultured human macrophages.

Objectives

This study was aimed to investigate the proteomic profiles of *S. suis* serotype 2 and 14 strains during exposure to intracellular condition cultured human macrophages U 937.

Methods

Cultured human macrophage U937 cells were infected with *S. suis* serotype 2 and 14 strains isolated from healthy pigs and human patients in northern Thailand. The protein patterns of the intracellular bacteria were analyzed by the one-dimensional electrophoresis combined with identification of proteins by the liquid chromatography mass spectrometry (LC-MS/MS).

Conclusions

The results indicated that all *S. suis* strains differentially expressed 118 proteins during exposure to intracellular condition of cultured human macrophages U937. Most of them were translation-associated proteins such as translation initiation factor IF-2, 30S ribosomal protein S7, 50S ribosomal protein L33 and Elongation factor G. These results indicated that all *S. suis* strains differentially adapted themselves to stress-conditions in human macrophages. These findings may lead to better understanding about the adaptation of this bacterium inside the harsh environment of host cells and the pathogenesis of *S. suis*.

A PUTATIVE ADP-RIBOSYLTRANSFERASE TOXIN ASSOCIATED WITH AN RHS SYSTEM INHIBITS CELL DIVISION IN E. COLI

B. Dumont[1]
[1]*Free University of Brussels ULB, Laboratory of Bacterial Genetics and Physiology, Gosselies, Belgium*

Backgrounds

Contact-dependent growth inhibition (CDI) systems and rearrangement hotspots (*rhs*) are coding for long conserved proteins containing extremely variable C-terminal toxin domains (CdiA-CT/Rhs-CT). In addition, they also encode small cognate immunity proteins that antagonize the toxic domain activity (CdiI/RhsI). These systems were recently shown to play an important role in inter-bacterial competition as well as biofilm formation and are likely to possess still unknown functions.

Objectives

We investigated an Rhs-CT toxic domain from *X. bovienii* predicted to be an ADP-ribosyltransferase and analyzed its effect and mechanism of action in *E. coli*.

Methods

Validation of the toxic domain and its cognate immunity protein was performed by expression of the proteins in *E. coli*. Fluorescence microscopy technics were used to monitor morphological effects after toxin induction using DAPI staining and an FtsZ-GFP fusion. Inactive toxin mutants were constructed. We are currently setting up *in vitro* experiments to purify toxin-target complexes to identify the target.

Conclusions

We experimentally validated the functionality of the Rhs-CT/RhsI toxin-immunity pair in *E. coli*. Upon overexpression, the Rhs-CT toxin induces a strong filamentation phenotype while DNA replication and nucleoid segregation appear to be unaffected. Furthermore, filamentation appears to be independent of the SOS system. Using an FtsZ-GFP fusion, we observed that the Z-ring is destabilized upon toxin overexpression. Altogether, these data indicate that the Rhs-CT toxin directly inhibits cell division. The direct target is under investigation.

THE ROLE OF DIVALENT METAL ION IN THE SELF-ASSEMBLY OF TET-AMINOPEPTIDASES

R. Dutoit[1], N. Brandt[2], V. Durisotti[2], C. Bauvois[2], D. Van Elder[3], L. Droogmans[3]
[1]Université Libre de Bruxelles - IRMW, Molecular biology Dept, Brussels, Belgium
[2]IRMW, NA, Brussels, Belgium
[3]Université Libre de Bruxelles, Molecular Biology Dept, Charleroi, Belgium

Backgrounds

The TET-aminopeptidases are dinuclear metallopeptidases requiring two divalent metal ions. These enzymes are able to self-assemble into a tetrahedron-shaped structure with 12 subunits. Their quaternary structure consists in the association of six dimers to form the functionally active dodecamer. In *Pyrococcus horikoshii*, both dimers and dodecamers co-exist *in vivo*, suggesting the self-assembly is regulated. However, their physiological function is unknown and the self-assembly is ill described due to the lack of structure of dimers. The divalent metal ions could also play an important role in the self-assembly.

Objectives

To unravel the role of the metal ions in the self-assembly, we have studied TmPep1050, a TET-aminopeptidase from *Thermotoga maritima*. This enzyme could be a model to understand the balance between dimers and dodecamers.

Methods

TmPep1050 was studied through a biochemical and structural approach. Its structure was solved by X-ray crystallography and its substrate specificity was determined with chromogenic substrates. To understand the role of metal ions in the oligomerization, several residues of the catalytic sites were mutated.

Conclusions

TmPep1050 self-assembles into a tetrahedron-shaped structure. This enzyme is cobalt-activated with broad substrate specificity and is highly thermostable at 75°C. The loss of cobalt ions led to a dramatic decrease of thermostability and the disassembly of dodecamers into dimers. The structure of the dimer showed the catalytic site is strongly impaired with a collateral impact on the dodecamerization interface. This phenomenon was observed in mutants unable to self-assemble. The self-assembly seems to depend on a correctly folded active site triggered by the presence of metal ions.

ORAL MICROBIOTA DEVELOPMENT DURING CHILDHOOD IN RELATION TO DELIVERY MODE, BREASTFEEDING PRACTICES AND CARIES AT 9 YEARS OF AGE

M. Dzidic[1], M. Stensson[2], M.C. Collado[3], A. Artacho[1], T. Abrahamsson[4], M. Jenmalm[5], A. Mira[1]
[1]FISABIO Public Health, Genomics and Healthy, Valencia, Spain
[2]Jönköping University, Centre for Oral Health- School of Health and Welfare, Jönköping, Sweden
[3]Institute of Agrochemistry and Food Technology- Spanish National Research Council IATA-CSIC, Department of Biotechnology- Unit of Lactic Acid Bacteria and Probiotics, Valencia, Spain
[4]Linköping University, Department of Clinical and Experimental Medicine- Division of Paediatrics, Linköping, Sweden
[5]Linköping University,
Department of Clinical and Experimental Medicine- Unit of Autoimmunity and Immune Regulation, Linköping, Sweden

Backgrounds

The development of the infant microbiome is instrumental for human health. Although much is known about gut microbial colonization, information about early microbiome development in the oral cavity is scarce.

Objectives

We aimed to determine the acquisition and maturation of oral microbiota in saliva samples collected at 3,6,12, 24 months and 7 years of age in 90 children.

Methods

This was performed by using 16S-rRDNA high-throughput *Illumina* sequencing and other molecular techniques.

Conclusions

Bacterial diversity and richness increased steadily throughout childhood. Bacterial composition patterns changed through time and started with colonizers associated with the initial breastfeeding period, including *Lactobacillus* and *Veillonella,* while bacterial genera such as *Neisseria* and *Gemella* settled after two years of age. Infants born by C-section had initially skewed bacterial composition, compared to vaginally-delivered babies, although this recovered with age. Presence of caries at 9 years of age was associated with differences in colonization patterns at 7 years of age, with similar tendencies observed already at 2 years. No specific bacterial genera could be associated with increased risk of developing tooth decay, however. Partial breastfeeding until 12 months of age was associated with a different bacterial composition and the altered colonization patterns was enlarged with age.

This is the first longitudinal study where the salivary microbial colonization has been analysed by high-throughput sequencing. The data suggest that an altered colonization pattern during the first years of life may have long-term consequences for oral microbiome development, and the potential impact for the child's oral and systemic health should be further studied.

REWINDING THE TAPE OF EVOLUTIONARY INNOVATION OF INTEGRON INTEGRASES

J.A. Escudero[1], A. Nivina[2], H. Kemble[3], A. Babic[2], C. Loot[2], O. Tenaillon[3], D. Mazel[2]
[1]Universidad Complutense de Madrid, Sanidad Animal, Madrid, Spain
[2]Institut Pasteur, Genomes and Genetics, Paris, France
[3]Universités Paris Diderot et Paris Nord Sorbonne Paris Cité-,
Infection- Antimicrobiens- Modélisation- Evolution IAMEpar, Paris, France

Backgrounds

Integrons are genetic platforms that allow bacteria to evolve rapidly through the acquisition of new genes encoded in cassettes and their differential expression. They are key players in the rise of multidrug resistance. Recombination in integrons is governed by integrases, remarkable proteins from an evolutionary perspective, as they represent molecular examples of evolutionary innovation. Modern integrases innovated to recombine single stranded (ss-)DNA, while retaining low levels of their ancestral activity, the recombination of exclusively double stranded (ds-)DNA molecules.

Objectives

We sought to obtain integrases that are hyperactive on ds-DNA, resembling ancestral integrases at the moment of evolutionary divergence.

Methods

We have carried directed evolution experiments using the *intI1* gene and two synonymous sequences to explore a broader protein sequence space. Among the three alleles, we found 8 independent mutations that enhanced integrase activity. Together they increased recombination rates 100-fold. All mutations were inserted into the three alleles and were re-evolved, yielding five new beneficial mutations. Negative epistasis was a burden in the process. We designed an epistasis purification system building a library of all possible combinations of the 13 mutations and subjecting it to our selective cycles. We now have alleles showing a 10.000 fold increase in activity with only 8 mutations.

Mutations revealed the structural constraints for ds-DNA recombination. They confirmed the pivotal role of integrase-specific I2 domain in innovation towards ss-DNA recognition. Hyperactivity on ds-DNA came with an asymmetric trade-off on ss-DNA.

Conclusions

We have successfully rewound the tape of evolutionary innovation in integrases by exploring a broader evolutionary landscape.

THERAPEUTIC EFFECT OF RESVERATROL ON RESPIRATORY INFECTION BY NONTYPABLE HAEMOPHILUS INFLUENZAE

B. Euba[1,2], N. López-López[1], I. Rodríguez-Arce[1], A. Fernández-Calvet[1], N. Caturla[3], R. Díez-Martínez[4], J. Garmendia[1,2]
[1]Instituto de Agrobiotecnología- CSIC-Universidad Pública Navarra-Gobierno Navarra, Sanidad Animal, Mutilva, Spain
[2]Centro de Investigación Biomédica en Red de Enfermedades Respiratorias, CIBERES, Madrid, Spain
[3]Monteloeder- Elche Parque Empresarial- Elche, Monteloeder, Alicante, Spain
[4]The Zebrafish Lab- Centro Europeo de Empresas e Innovación de Navarra, The Zebrafish Lab, Noáin, Spain

Backgrounds

Therapies that are safe, effective and not vulnerable to developing resistance are highly desirable to counteract bacterial infections. The respiratory pathogen nontypeable *Haemophilus influenzae* (NTHi) is an important cause of acute exacerbation of chronic obstructive pulmonary disease (COPD) that requires novel efficient treatments. A previous screening for host cell genes differentially expressed upon NTHi infection identified a repertoire of candidates to be targeted by host-directed therapeutics (1), including *sirtuin 1*, which encodes a NAD-dependent deacetylase, protective against emphysema by acting as a negative regulator of matrix metalloproteinase-9 (MMP9). COPD relates to an inappropriate MMP9 elevation, and SIRT1 activation may be a useful therapeutic approach. SIRT1 is activated by the plant polyphenol immunomodulator resveratrol.

Objectives

Evaluation of resveratrol therapeutic potential against respiratory infection by NTHi.

Methods

Resveratrol antimicrobial effect was determined for a collection of NTHi COPD clinical isolates by susceptibility assay. Resveratrol modulatory effect on the NTHi-host cell interplay was analyzed in terms of bacterial location upon infection, anti-inflammatory and anti-oxidative effects, by using cultured human airway epithelial cells. Resveratrol therapeutic potential was tested *in vivo*, by using both zebrafish septicemia and mouse respiratory NTHi infection model systems.

Conclusions

Resveratrol decreases NTHi viability in a dose-dependent manner through a bacteriostatic effect, and reduces airway epithelial inflammatory response upon NTHi infection. Resveratrol shows a significant bacterial clearing effect *in vivo*, without signs of host toxicity. These results highlight the antimicrobial potential of resveratrol against NTHi respiratory infection.

OUTER MEMBRANE VESICLES OF THE PROBIOTIC ESCHERICHIA COLI NISSLE 1917 ACTIVATE THE NOD-1 SIGNALLING PATHWAY IN INTESTINAL EPITHELIAL CELLS

M.A. Canas Pacheco[1], M.J. Fabrega[1], C.S. Alvarez[1], R. Gimenez[1], J. Badia[1], L. Baldoma[1]
[1]University of Barcelona, Biochemistry and Animal Physiology, Barcelona, Spain

Backgrounds

To distinguish between pathogen and commensal bacteria intestinal epithelial cells are equipped with a range of pattern recognition receptors (PPRs), which specifically detect bacterial molecules and trigger the innate immune response. Among PPRs, the intracellular receptors NOD-1 and NOD-2 recognize intracellular peptidoglycan (PG) delivered by internalized pathogens or outer membrane vesicles (OMVs).

Objectives

The main objective of this work is to study whether OMVs released by the probiotic *Escherichia coli* Nissle 1917 (EcN) activate NOD1 and/or NOD-2 signalling pathways.

Methods

By using confocal fluorescence microscopy we have shown that EcN OMVs are internalized in Caco-2 cells and interact with both NOD1 and the endosomal protein EEA-1. To assess OMV-specific immune responses through NOD-1 activation we analysed expression of IL-6 and IL-8 in Caco-2 cells transfected with siRNA to knockdown NOD-1 levels (NOD1-KD). RT-PCR analysis revealed that NOD1-KD cells stimulated with EcN OMVs showed reduced significantly mRNA expression of IL-6 and IL-8, compared with control cells. Consistently, secreted levels of both cytokines measured by ELISA were lower in NOD1-KD cells, although values were only statistically significant for IL-6. No differences between control and NOD2-KD Caco-2 cells were observed. The study was completed by measuring degradation of the inhibitor IKB-alpha by Western blot to evaluate activation of NF-KB.

Conclusions

Overall, this study showed for the first time interaction of EcN OMVs with NOD1 and the activation of the innate immunity that results in a pro-inflammatory response.

DISSECTING THE ROLE OF THE SMALL RNA ERSA IN PSEUDOMONAS AERUGINOSA MOTILITY AND BIOFILM REGULATION

M. Falcone[1], S. Ferrara[1], E. Rossi[2], H.K. Johansen[2], S. Molin[3], G. Bertoni[1]
[1]University of Milan, Biosciences, Milan, Italy
[2]Rigshospitalet, Clinical Microbiology, Copenhagen, Denmark
[3]Technical University of Denmark, Novo Nordisk Foundation Center for Biosustainability, Kgs. Lyngby, Denmark

Backgrounds

ErsA is a novel *Pseudomonas aeruginosa* small RNA responsive to infection-relevant host stimuli. Its transcription is under the control of the alternative sigma factor σ^{22} (AlgT/U), implicated in bacterial virulence.
In strain PAO1, ErsA exerts a direct negative post-transcriptional regulation in an incoherent feed-forward loop with σ^{22} on the bi-functional enzyme AlgC, which is involved in the biosynthesis of sugar precursors for alginate and polysaccharide exoproducts.

Objectives

We aim at the characterization of novel target genes regulated by ErsA to expand the knowledge about the ErsA-based regulatory network.

Methods

We employed different approaches: i) bioinformatics analysis, ii) *in vitro* electrophoretic mobility shift assays, iii) *in vivo* translational fusions based on the *gfp* reporter gene, iv) RNA-seq, and v) biofilm and motility assays on mutant strains.

Conclusions

Our results comprise:

i) *In silico* analyses identified new putative target genes mainly involved in biofilm formation and exopolysaccharides production.

ii) Among these targets, we specifically validated the interaction between ErsA and *amrZ* mRNA, both *in vitro* and *in vivo*

iii) The RNA-seq analysis showed that some of the genes whose expression is positively controlled by ErsA are important for biofilm development (i.e. genes belonging to the *pel* operon, *algD*).

iv) In line with the other results, the ErsA deletion mutant shows a hyper-motile phenotype compared to the wildtype and develops a thin and flat biofilm.

Overall, our results suggest that the small RNA ErsA might represent a relevant post-transcriptional regulator in biofilm development at different levels, likely interacting with different mRNA targets.

Physiology / Biochemistry / Molecular Microbiology

ENGINEERING OF NOVEL RECOMBINANT ESCHERICHIA COLI STRAIN – A SOURCE OF BETA-GALACTOSIDASE

U. Falkouskaya[1], *A. Kastsianevich*[1], *L. Sapunova*[2]
[1]*Institute of Microbiology- National Academy of Sciences- Belarus, Laboratory of protein, Minsk, Belarus*
[2]*Institute of Microbiology- National Academy of Sciences- Belarus, Laboratory of enzymes, Minsk, Belarus*

Backgrounds

Beta-galactosidase is glycosidase which hydrolyzes beta-glycosidic bond formed between beta-D-galactosides, including disaccharide lactose, with glucose and galactose as the end products of the reaction. This enzyme is important for organisms as a key provider in the production of energy and a source of carbon released through break down of lactose to galactose and glucose. It is also vital for lactose intolerant community as it is responsible for making lactose-free milk and other dairy products.

Objectives

The study was aimed at engineering of novel recombinant *E. coli* strain– a source of beta-galactosidase.

Methods

PCR, POE-PCR, screening, electrophoretic analysis, chromatography.

Conclusions

A novel recombinant *E. coli* strain producing beta-galactosidase of *Arthrobacter sulfonivorans* was constructed by genetic engineering methods.

The specific primers for the gene *B-gal* were designed. This gene was amplified by PCR technique. The vector pET42a(+) was linearized with primers in such a way that a sequence of nucleotides that provides for presence of an additional octa-histidine oligopeptide at the target protein C-terminus was added into target gene 3'-terminus. The method of prolonged overlap extension PCR was applied for cloning gene encoding beta-galactosidase. The cells of strain *E. coli* BL21 were transformed by POE-PCR products. Six plasmid–containing colonies were selected by PCR-screening. After induction with 0.1 mM IPTG the target protein was purified by metal affinity chromatography. Biochemical properties of purified beta-galactosidase will be estimated at the next stage of research.

MOLECULAR BASIS OF MEMBRANE POTENTIAL-GENERATING SYSTEM IN STAPHYLOCCOUS AUREUS

S.H. Fan[1], S. Reichert[1], F. Goetz[1]
[1]Interfaculty Institute for Microbiology and Infection Medicine Tübingen IMIT, Microbial Genetics, Tuebingen, Germany

Backgrounds

In many aerobic or facultative microorganisms, the major electron donor is $NADH+H^+$ produced during glycolysis and TCA cycle. In *Escherichia coli,* this is accomplished by NADH:quinone oxidoreductase (Ndh1). *Staphylococcus aureus* does not possess such complex, but a non-electrogenic type 2 (Ndh2) protein that oxidizes $NADH+H^+$. In addition, a protein called MpsA (*mps* for membrane potential-generating system) was identified in *S. aureus* showing sequence similarity to the proton-translocating subunit NuoL of complex 1 in *E. coli*. *mpsA* is the first part of an operon comprising three genes: *mpsA, mpsB and mpsC*. MpsB and MpsC show no significant sequence homologies to proteins with known function. However, MpsB carries a conserved metal binding motif similar to a domain that is found in carbonic anhydrases (CA).

Objectives

CA catalyzes the interconversion of $CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$. MpsB in *S. aureus* might play a role in CO_2 transport and respiration. Therefore, this study aims to investigate the involvement of MpsB in respiration, especially in CO_2 metabolism.

Methods

Deletion mutant of the *mpsB* and its complementation vector were constructed. Preliminary experiments were performed to characterize its growth on solid and liquid medium in aerobic and high (5%) CO_2.

Conclusions

Under normal conditions the growth of Δ*mpsB* was severely affected; however, in the presence CO_2 it was almost like the wild type. The pH profile of the mutant was also altered compared to the wild type. With regard to these observations, MpsB in *S. aureus* is postulated to be an integral part in CO_2 metabolism and energy conservation.

HORIZONTAL CHROMOSOMAL TRANSFER: AN ACCELERATOR FOR THE EMERGENCE OF ANTIBIOTIC RESISTANCE IN MYCOPLASMAS ?

M. Faucher[1], L.X. Nouvel[1], E. Dordet-Frisoni[1], M. Marenda[2], F. Tardy[3], C. Citti[1]
[1]ENVT- INRA, UMR IHAP, TOULOUSE, France
[2]University of Melbourne, Faculty of veterinary and agricultural sciences, Victoria, Australia
[3]ANSES, UMR Mycoplasmose of ruminants, Lyon, France

Backgrounds

In recent years, antibiotic-resistance (AbR) has been increasingly observed in mycoplasmas, a large group of wall-less bacteria that comprises several important ruminant pathogens. In bacteria, two mechanisms are responsible for AbR emergence: acquisition of chromosomal mutations and/or horizontal gene transfer (HGT).

Objectives

The discovery of massive conjugative gene transfers in the ruminant pathogen *Mycoplasma agalactiae* radically changed how we viewed these minimal bacteria. This prompted us to address the impact of this phenomenon in mycoplasma AbR acquisition using *M. agalactiae* and enrofloxacin (Enro) as model.

Methods

We first isolated spontaneous *M. agalactiae* $Enro^R$ mutants by serial *in vitro* passages, in increasing Enro concentration. Mating experiments were then conducted using a mutant having the highest $Enro^R$ level as donor and an $Enro^S$ strain as a recipient.

Conclusions

A sequential accumulation of mutations was observed in 4 genes distributed in 3 genomic loci: *gyrA* and *gyrB*, encoding the DNA gyrase and *parC* and *parE*, encoding the topoisomerase IV for spontaneous mutation experiments. Mating experiments resulted in $Enro^R$ transconjugants and revealed the simultaneous transfer, in a single chromosome, of distant loci carrying the mutated target genes.
Since most mycoplasmas are deprived of plasmids, this study comforts the importance of chromosomally mediated AbR in mycoplasmas, with cumulative and sequential mutations correlating with the level of AbR. More importantly, our data point towards HGT as a major contributor and an accelerator of AbR acquisition in mycoplasmas by allowing the concomitant transfer of multiple dispersed mutations in one single event.

PHENOTYPIC SWITCHING IN PSEUDOMONAS FLUORESCENS SBW25

G. Ferguson[1], P. Remigi[2], J. Gallie[3], P. Rainey[4]
[1]Massey University Auckland, Institute of Natural and Mathematical Sciences, Auckland, New Zealand
[2]Massey University Auckland, Institute for Advanced Study, Auckland, New Zealand
[3]Max Planck, Institute for Evolutionary Biology, 24306 Plön, Germany
[4]École Supérieure de Physique et de Chimie Industrielles de la Ville de Paris ESPCI ParisTech, Laboratoire de Génétique de l'Evolution, Paris, France

Backgrounds

When challenged with repeated selective cycles through two contrasting environments, the bacterium *Pseudomonas fluorescens* SBW25 evolved, *de novo*, the ability to switch repeatedly between two bistable states – one where cells secrete an extracellular colanic acid-like capsule (Cap+), and an ancestral, uncapsulated state (Cap-). Subsequent characterisation showed the switch to be epigenetic, though underpinned by mutation at the start of the pyrimidine biosynthesis pathway.

Objectives

Taking a genetic approach, we sought to identify the ultimate cause of bistability.

Methods

Exploration of the genotype-phenotype map through a combination of transposon mutagenesis screens, reevolution and genome resequencing, transcriptome analysis, and gene deletion revealed a complex network of 'players' whose activities modulate Cap-/Cap+ switching.

Conclusions

Among these are the Gac/Rsm signalling pathway and the stringent response, specifically, RpoD and the nucleotide alarmone ppGpp, recently shown to underpin another bistable phenotype – that of antibiotic 'persisters'. Moreover, several lines of evidence indicate that expression of ribosome proteins is up-regulated in the switchers (Cap+) compared to wild-type cells. We present evidence in support of aberrant regulation of ribosome production as the underlying cause of Cap+/Cap- bistability in SBW25 'switcher' mutants.

MAMMALIAN AKT PROTEIN KINASE OVERRUNS SLM1/2-YPK1/2-TORC2 SIGNALING IN SACCHAROMYCES CEREVISIAE

T. Fernandez-acero Bascones[1], *I. Rodriguez-escudero*[1], *V. Jimenez Cid*[1], *M. Molina Martin*[1]
[1]*Facultad De Farmacia- Universidad Complutense De Madrid, Microbiologia II, Madrid, Spain*

Backgrounds

Akt is a mammalian protein kinase involved in the regulation of key cellular processes and its up-regulation is commonly related to tumorigenesis. It is recruited to the plasma membrane (PM) by PIP_3, a lipid second messenger generated in response to extracellular stimuli by phosphoinositide 3-kinase (PI3K), and further activated through phosphorylation by the PDK1 and TORC2 kinases. An analogous mechanism has been reported for its essential *S. cerevisiae* counterparts Ypk1/2, which are recruited to the PM by the PIP_2-interacting proteins Slm1/2 and activated by yeast orthologues Pkh1/2 and Tor2. We have previously reported that *GAL1*-driven co-expression in yeast of PI3K and Akt leads to growth inhibition. Akt activation in yeast depends on both PM recruitment by ectopic PI3K-generated PIP_3 and phosphorylation by Pkh1/2, and that toxicity relies on severe PM overgrowth.

Objectives

We aimed to characterize the subcellular effects and signaling events occurring in yeast upon Akt stimulation.

Methods

We have used fluorescence and electronic microscopy to characterize membrane structures, transcriptomics to analyze the response to Akt activation and phosphorylation assays to identify Akt substrates in yeast.

Conclusions

We have found that Akt-derived membrane structures are enriched in actin patches, phosphatidylserine, PIP_2 and cell wall deposits in yeast cells. Overexpression of Akt leads to an oxidative stress transcriptional response and is able to complement the lack of Ypk1/2, causing the hyperphosphorylation of the PIP_2-effector, Slm1, thus indicating that activation of mammalian Akt in yeast is short-circuiting the normal function of the Slm1-Ypk1/2-TORC2 pathway in the maintenance of PM homeostasis.

Backgrounds

Nontypable *Haemophilus influenzae* (NTHi) is an opportunistic pathogen associated to exacerbations of chronic obstructive pulmonary disease (COPD), a progressive irreversible airflow limitation accompanied by emphysema, fibrosis, inflammation and mucus hypersecretion. Fatty acid metabolites are key molecular mediators of COPD. Thus, NTHi may encounter free fatty acids in its colonizing niche. NTHi contains the *fadL* gene, encoding a fatty acid outer membrane (OM) transporter, but lacks a complete b-oxidation pathway, and a bactericidal effect of polyunsaturated fatty acids has been described for this pathogen. Conversely, NTHi contains all fatty acids and phospholipids (PL) biosynthetic genes, and *vacJ*/*mlaA*-*mlaBCDEF*, an intermembrane PL trafficking system serving to prevent PL accumulation in the OM, being VacJ/MlaA an OM lipoprotein. Mla mutant suppression by phospholipases (Pld) may result in production of free fatty acids that, in turn, could be taken by FadL, therefore functionally relating VacJ and FadL. In NTHi, Plds distribution is unknown, fatty acids uptake has not been shown, and VacJ contributes to virulence. We hypothesize that fatty acids uptake may not be fruitful to NTHi; also, VacJ and FadL may modulate bacterial fatty acid composition and/or interaction dynamics with exogenous hydrophobic molecules.

Objectives

Analysis of FadL and VacJ contribution to NTHi-host interplay.

Methods

NTHi *vacJ* and *fadL* mutant strains were generated and characterized in terms of growth, lipidic composition, lipid A structure, resistance to hydrophobic antimicrobials, airway infection *in vitro* and *in vivo*.

Conclusions

The results obtained highlight the importance of maintaining the bacterial surface integrity as a whole during NTHi airway infection.

DNA-BINDING ACTIVITY OF CLOSTRIDIUM DIFFICILE FUR DEPENDS ON ITS CYSTEINES REDOX STATE

A. Fernández-Otal[1], M.L. Peleato[1], M.F. Fillat[1], Á. Lanas[2], M.T. Bes[1]
[1]Faculty of Sciences and Biocomputation and Complex Systems Physics Institute BIFI- University of Z aragoza,
Department of Biochemistry and Molecular and Cell Biology- Biochemical- Biophysical and Computati onal Biology Group - CSIC Joint Unit, Zaragoza, Spain
[2]Aragón Health Research Intitute- IIS, Department of Medicine- University of Zaragoza, Zaragoza, Spain

Backgrounds

Clostridium difficile, a gram-positive, anaerobic bacterium is regarded as the major cause of antibiotic associated colitis. In recent years, *C. difficile* antibiotic-resistance strains have appeared and different studies link such resistance with altering both the expression of redox proteins and iron metabolism. Iron homeostasis in bacteria is highly controlled by the metal-dependent transcriptional regulator Fur (Ferric uptake regulator). Apart from its well-known role in iron homeostasis, it has also been described as a redox sensitive protein in some microorganisms.

Objectives

The aim of this work was to study the redox characteristics of *C. difficile* Fur (*Cd*Fur) and their implication in the mechanism of action of this protein.

Methods

We overexpressed in *Escherichia coli* and purified by Immobilized Metal ion Affinity Chromatography the *Cd*Fur repressor and several cysteine mutants. We also analyzed the biochemical features of the native protein and its seven single cysteine mutants. Gel retardation assays with selected promoter genes (EMSA) were used to verify the biological activity of the recombinant proteins under different conditions *in vitro*. Furthermore, a modified FURTA (Fur titration assay) analysis was set up to determine Fur activity *in vivo.*

Conclusions

The *Cd*Fur protein showed two forms, a reduced one showing DNA-binding activity to its own promoter and an oxidized inactive form. Conversion between them was dependent on the formation of a disulphide bridge. Moreover, a single cysteine residue was essential for the binding of the protein to the corepressor metal.

HIGH-THROUGHPUT SCREENING FOR MODULATORS OF CLOSTRIDIUM DIFFICILE FUR ACTIVITY

A. Fernández-Otal[1], M.L. Peleato[1], M.F. Fillat[1], J. Sancho[1], Á. Lanas[2], M.T. Bes[1]
[1]Faculty of Sciences and Biocomputation and Complex Systems Physics Institute BIFI- University of Z aragoza,
Department of Biochemistry and Molecular and Cell Biology- Biochemical- Biophysical and Computati onal Biology Group - CSIC Joint Unit, Zaragoza, Spain
[2]Aragón Health Research Institute IIS Aragón, Department of Medicine- University of Zaragoza, Zaragoza, Spain

Backgrounds

Clostridium difficile is a Gram-positive, spore-forming, anaerobic, intestinal bacterium and a common cause of antibiotic-associated colitis. The development of antimicrobials is critical in this time of increasing emergence of hypervirulent strains that display resistance to antibiotics. Several studies relate resistance to some antibiotics with altering iron metabolism in this pathogenic bacterium. The canonical bacterial repressor responsible for iron-dependent regulation is the ferric uptake regulator (Fur). *C. difficile* has a functional Fur (*Cd*Fur) implicated in the regulation of a subset of genes including virulence genes. Therefore *Cd*Fur constitutes an attractive target for the development of new antimicrobial compounds against this pathogen.

Objectives

Identification of bioactive compounds that may specifically modulate Fur activity in *Clostridium difficile*.

Methods

A high-throughput screening methodology based on thermal denaturation of the purified protein was used to identify small molecules of a chemical library that modulate *Cd*Fur activity. The effect of these compounds on the DNA-binding activity of *Cd*Fur *in vitro* was tested using gel retardation assays.

Conclusions

Several compounds from the chemical library were able to bind to *Cd*Fur homolog increasing protein stability. Some of them enhanced *Cd*Fur affinity for its own promoter and other gene promoters involved in iron acquisition by this pathogen.

CHANGES IN LIPID A HYDROXYLATION AND LPXO EXPRESSION ARE REGULATED BY THE GLOBAL REGULATOR FNR IN SALMONELLA ENTERITIDIS

P. Fernández[1], F. Velásquez[1], J. Ortega[1], C.A. Silva[2], H. Garcias-Papayani[1], F. Amaya[1], C.A. Santiviago[1], S.A. Álvarez[1]
[1]Universidad de Chile, Facultad de Ciencias Químicas y Farmacéuticas, Santiago, Chile
[2]Tufts University, Department of Molecular Biology and Microbiology, Boston- MA, USA

Backgrounds

Lipid A is the bioactive component of lipopolysaccharide and presents a dynamic structure that undergoes modifications in response to environmental changes. Lipid A hydroxylation, catalyzed by LpxO, is important for *Salmonella* virulence and is dependent on oxygen as substrate. Noteworthy, a regulatory role for oxygen availabity on *lpxO* expression has not been established. The adaptation of *Salmonella* to anaerobiosis involves changes in the expression of numerous genes, and the transcription factor FNR is a major regulator of this process.

Objectives

The aim of this work was to determine if *lpxO* expression and lipid A hydroxylation are regulated by the oxygen availability in *S.* Enteritidis, and the participation of FNR in this process.

Methods

We determined by mass spectrometry that lipid A hydroxylation is reduced when wild-type *S.* Enteridis is grown anaerobically, while this change is not observed in the case of a Δ*fnr* mutant, indicating that FNR regulates this process. Also, we demonstrated by qRT-PCR and the analysis of a *lacZ* transcriptional fusion that *lpxO* expression is higher when wild-type bacteria are grown aerobically than anaerobically. This differential expression pattern is not observed in the Δ*fnr* mutant strain. Finally, electrophoretic mobility shift assay revealed that FNR directly interacts with *lpxO* promoter region.

Conclusions

FNR binds to *lpxO* promoter and this would account for the oxygen-dependent changes observed in lipid A hydroxylation and in the expression of this gene in *S.* Enteritidis.

THE TOPOLOGICAL ORGANIZATION OF THE CHROMOSOME OF STREPTOCOCCUS PNEUMONIAE REVEALED BY TRANSCRIPTOMIC ANALYSIS

M.J. Ferrandiz[1], *A.J. Martín-Galiano*[1], *A.G. de la Campa*[1]
[1]*National Centre for Microbiology- ISCIII, Unidad de Genética Bacteriana, Majadahonda- Madrid, Spain*

Backgrounds

DNA-supercoiling and the association of nucleoid-binding proteins compact bacterial chromosome in a way optimal for DNA transactions. The supercoiling level is maintained homeostatically by the opposing activities of relaxing DNA topoisomerases (topoisomerases I and IV) and by gyrase, which introduces negative supercoils. Changes in DNA-supercoiling orchestrated a transcriptomic response of the genome of *Streptococcus pneumonia, which* reveals topological reacting domains. Relaxation of DNA with the gyrase inhibitor novobiocin affects 36% of the genome, 68% of the differentially-expressed genes (DEGs) forming 15 domains (Ferrándiz, Nucleic Acids Res, 2010). Hyper-supercoiling achieved with seconeolitsine (a topoisomerase I inhibitor) affects 10% of the genome, 25% of the DEGs forming 12 domains (Ferrándiz, Nucleic Acids Res, 2016)**.** Domains detected under these opposing situations essentially overlapped

Objectives

To study the topological organization of the chromosome of *Streptococcus pneumoniae* under conditions of no global supercoiling alterations

Methods

RNA-seq, Chromatin Immunoprecipitation (ChIP), Bioinformatic analysis

Conclusions

The analysis of the transcriptomic response to subinhibitory concentrations of seconeolitsine plus novobiocin did reveal a response. DEGs accounted for 41% of the genome, 70% of them being located into 18 topological domains. These domains were larger, although overlapping those detected under supercoiling alterations caused by a single drug. In addition, a higher order organization, including the whole genome, with 9 domains containing an average of 227 genes was detected. These results will be correlated with those obtained by topoisomerase I and gyrase ChIP. These transcriptomic results support that the chromosome is organized into topological domains with fixed location

ROLE OF THE CSRA POST-TRANSCRIPTIONAL REGULATORS IN PSEUDOMONAS SYRINGAE PV. TOMATO DC3000

M.D. Ferreiro García[1], J. Nogales[2], G.A. Farias[1], A. Olmedilla[3], M.T. Gallegos[1]
[1]Estación Experimental del Zaidín-Consejo Superior de Investigaciones Científicas, Department of Soil Microbiology and Simbiotic Systems, Granada, Spain
[2]The Samuel Roberts Noble Foundation, Plant Biology Division, Ardmore- Oklahoma, USA
[3]Estación Experimental del Zaidín-Consejo Superior de Investigaciones Científicas, Department of Biochemistry- Cell and Molecular Biology of Plants, Granada, Spain

Backgrounds

RsmA/CsrA proteins are post-transcriptional regulators widely distributed among gamma-proteobacteria. They alter translation, mRNA turnover, and/or transcript elongation by binding to the 5′ untranslated region (5'-UTR) and/or early coding regions of mRNAs. CsrA proteins are released from their target mRNAs upon being sequestered by the small regulatory RNAs rsmX, rsmY or rsmZ, whose expressions depend on the GacS/GacA two-component system. *Pseudomonas syringae* pv. tomato DC3000 (Pto DC3000) is a model pathogenic bacteria used to study plant-phytopathogen interactions. So far, the Gac-rsm regulatory pathway has been shown to control virulence, motility, production of secondary metabolites, carbon metabolism and quorum sensing in Pto DC3000. This strain encodes in its genome seven rsm regulatory RNAs: rsmX1-5, rsmY and rsmZ and five CsrA paralogs, three of which are well conserved among *Pseudomonas* species, *csrA1*, *csrA2* and *csrA3*.

Objectives

Although the possible components of the Gac-rsm pathway in Pto DC3000 are known, their physiological roles have not yet been established. Therefore the aim of this work is to elucidate the role of CsrA1, CsrA2 and CsrA3 in Pto DC3000 biology, paying particular attention to virulence-related phenotypes.

Methods

We have constructed deletion mutants and carried out their phenotypic characterization in different laboratory conditions (swimming, swarming, flagella production, syringafactin and alginate synthesis) and *in planta.*

Conclusions

CsrA1, CsrA2 and CsrA3 have non-redundant functions repressing alginate production, swimming and swarming motility, flagella and syringafactin synthesis and virulence in tomato plants. Gac-rsm regulation of those processes is exerted mainly through CsrA3, CsrA2 has a minor role, and CsrA1 does not intervene at all.

COMPLEX REGULATORY NETWORK CONTROLS CHROMOSOME SEGREGATION IN STREPTOMYCETES

Ž. Filić[1], T. Paradžik[1], D. Jakimowicz[2], D. Vujaklija[1]
[1]Institut Ruđer Bošković, Division of Molecular Biology, Zagreb, Croatia
[2]Faculty of Biotechnology- University of Wrocław, Department of Molecular Microbiology, Wrocław, Poland

Backgrounds

Streptomyces species are multicellular filamentous Actinobacteria, producers of numerous secondary metabolites used in biotechnology and medicine. Streptomycetes undergo complex cellular differentiation including formation of vegetative mycelium followed by aerial mycelium and then spores. The spores are produced at the tip of aerial filaments and help these multicellular bacteria to disperse in the environment. These processes require a complex gene regulatory network of proteins ensuring the proper chromosome organization and partitioning of DNA into pre-spore compartments before septa closure. Various proteins are known to be involved in chromosomal segregation during sporulation and some of them were used in this study.

Objectives

Our goal was (I) to construct double and triple mutants of ssbB, parB and smc, (II) to examine how these mutations affect chromosome segregation during sporulation in order to elucidate whether these genes participate in the same or various regulatory cascades.

Methods

PCR targeting system and conjugation were used to construct various strains mutated in selected genes. These strains were examined for growth and sporulation defects. Fluorescence microscopy was used to determine the efficiency of DNA distribution in spores compartments, spore size as well as the number of spores in areal hyphae.

Conclusions

The results revealed a severe chromosome segregation defect in SsbB depleted *S. coelicolor* mutant, indicating the importance of SsbB protein for the reproductive stage of growth. In double and triple mutants more pronounced defects in chromosome segregation during sporulation occured than previously reported for any of the parental strains indicating that analysed genes participate in different regulatory network.

[2]Aula Dei Experimental Station EEAD-CSIC and Complex Systems Physics Institute BIFI,
Biochemical- Biophysical and Computational Biology Group - CSIC Joint Unit, Zaragoza, Spain
[3]Complex Systems Physics Institute BIFI and Fundación ARAID- University of Zaragoza,
Biochemical- Biophysical and Computational Biology Group - CSIC Joint Unit, Zaragoza, Spain

Backgrounds

FurB (Zur) is the FUR (ferric uptake regulator) paralog present in *Anabaena* sp. PCC 7120 that controls zinc homeostasis by binding to DNA in a zinc-dependent manner. Most Zur proteins contain a structural zinc atom that is tretracoordinated by four highly-conserved cysteine residues also present in FurB from *Anabaena* sp. PCC 7120. Apart from the structural atom, most Zur proteins are able to bind one to two additional zinc atoms, involved in DNA binding and protein dimerization.

Objectives

To elucidate the relationship among the zinc-binding ability of *Anabaena* sp. PCC 7120 FurB, the redox environment and the activity of this protein.

Methods

Zinc content in recombinant FurB was determined by Inductively Coupled Plasma spectrometry (ICP). Homology modelling was driven with Modeller using the structures of *H. pylori* Fur, *M. tuberculosis* FurB/Zur and *S. coelicolor* Zur as templates and analysed with PyMol 1.4.1. Interaction of FurB with zinc was studied by isothermal titration calorimetry (ITC). Contribution of cysteine residues to FurB activity was determined by site-directed mutagenesis and FurB activity was assessed by electrophoretic mobility shift assays (EMSA).

Conclusions

Recombinant FurB was able to bind three zinc atoms under reducing conditions. The redox state of cysteine C93 influences the binding of the second regulatory zinc atom and in turn modulates the affinity for a specific DNA target.

IDENTIFICATION OF STRESS-RESPONSIVE MICRORNAS IN PLANT-MICROBE INTERACTIONS

M.M. Finetti Sialer[1], D. De Paola[1], K. Ogata Gutierrez[2], D. Zúñiga-Dávila[2], C. Chumpitaz-Segovia[2]
[1]Institute of Biosciences and Bioresources IBBR-CNR, DISBA, Bari, Italy
[2]Laboratorio de Ecología Microbiana y Biotecnología- Universidad Nacional Agraria La Molina, Dpto. de Biología, Lima, Peru

Backgrounds

Non-coding small RNAs (sRNAs) regulate gene expression in plant development and stress response. Different sRNA, in particular microRNAs (miRNAs) are principal mediators of the plant immune system. Roots endophytic bacteria and fungi affect crops performance acting as key soil factors underpinning ecosystem functioning and determining the properties of associated biota.

Objectives

We aimed at identifying plant miRNAs involved in the tri-trophic interaction of a beneficial bacterium (*Pseudomonas* sp.) and *Solanum lycopersicum* challenged with the pathogenic fungus *Alternaria alternata*, through comparative analyses carried out in different plant-microorganism associations.

Methods

sRNA profiling was performed on 3-week-old plants of *S. lycopersicum* plants treated with *Pseudomonas* sp. (Ps155) or challenged with the pathogen, alone or in combination, or non-treated as control. RNA extraction and library construction was carried out in two biological replicates per treatment and sequenced by Illumina technology. The sRNA libraries were aligned to the tomato genome (release 2.40). Reads (100% matching) were mapped onto the miRBase release 21.0 to identify known miRNAs. Differential miRNA expression (DE) analysis was based on DESeq2.

Conclusions

334 known tomato miRNAs were identified in the sRNA libraries, of which near 50% were shared across libraries. The four treatments were evaluated in pairwise comparisons to gain evidence for their DE among treatments. Statistical analyses highlighted 27 differential regulated miRNAs. These DE targeted different tomato genes including transcription and growth-regulating factors based on computational target prediction. Data provide a comparative analysis of changes in the small RNA profiles and the putative gene targets they control.

STRIPPING BACILLUS ANTHRACIS' PROTECTIVE COAT

A. Fioravanti[1], W. Jonckheere[1], E. Pardon[1], J. Steyaert[1], H. De Greve[1], H. Remaut[1]
[1]VIB/Vrije Universiteit Brussel, Structural Biology Research Center, Brussels, Belgium

Backgrounds

The Gram-positive spore forming bacterium *Bacillus anthracis* is the aetiological agent of anthrax. *B. anthracis* spores' enter the body via skin lesions, lungs or a gastrointestinal route and germinate within the host, giving rise to the vegetative form of the bacillus. The surface of the vegetative bacterium is covered by a two-dimensional protein array known as "S-layer". Two mutually exclusive S-layers sequentially appear at the cell surface in a growth phase-dependent manner (Sap-layer: exponential growth; EA1-layer: stationary phase).

Objectives

Previous studies showed that in laboratory condition, deletion of Sap led to cell division defects causing a chain length phenotype, suggesting that Sap is a promising candidate for the development of new strategies to fight anthrax disease.

Methods

The self-assembling characteristic of S-layer proteins hampers their ease of handling under non-denaturing conditions and has hitherto proven prohibitive for structural and biophysical characterisation.In order to address the self-polymerisation issue, we optimised the expression and purification of native monomeric Sap to allow immunisation of llamas with the aim of obtaining Nanobodies (Nbs) specific for the monomeric form of the protein.

Conclusions

A systematic search identified a set of Nbs that stabilise Sap and allowed its crystallisation and structure determination, showing an extended structure composed of 6 immunoglobulin-like domains. In addition, we identify Nbs able to inhibit Sap *in vitro* polymerisation. These inhibitory Nbs will be candidates for *in vivo* inhibition assays and evaluation for their infection attenuating ability.

COMPLETE GENOME SEQUENCE AND METHYLOME ANALYSIS OF BEGGIATOA LEPTOMITOFORMIS STRAINS D401 AND D402

A. Fomenkov[1], Z. Sun[2], T. Vincze[3], M. Orlova[4], B. Anton[1], M. Grabovich[4], R. Roberts[1]
[1]New England Biolabs, Genome biology, Ipswich, USA
[2]New England Biolabs, Bioinformatic, Ipswich, USA
[3]New England Biolabs, IT, Ipswich, USA
[4]Voronezh State University, Biology, Voronezh, Russia

Backgrounds

The taxonomy of *Beggiatoa* genus is still a work in progress. Despite many morphotypes of the *Beggiatoa* genus having been described in the literature, only one species, *B. alba* has been validated until now. We described a second species, *B. leptomitoformis.* Two strains of *B. leptomitoformis* D401 and D402 have been isolated from different regions of Russia. They differ in their morphology and physiology especially their ability to growth lithotrophically in the presence of thiosulfate. While *B. leptomitoformis* D402 is able to accumulate elemental sulfur, strain D401 cannot.

Objectives

We performed genomic sequencing of these two strains using the PacBio SMRT platform and assembled the reads into two complete circular genomes.

Methods

The advantage of the PacBio sequencing platform is its ability not only assemble complete closed genome, but to detect the epigenetic state of the sequenced DNA, which allows for the identification of modified nucleotides and the corresponding motifs in which they occur.

Conclusions

Both genome sequences have been deposited in GenBank with accession numbers CP018889 and CP012373 respectively. Surprisingly these two genomes showed almost 90% homology. The preliminary analysis of several thiosulfate oxidation and autotrophic assimilation of CO_2 metabolic operones in both stains did not revel any noticeable differences.
Thirteen DNA methyltransferase recognition motifs were found. They include one m4C and nine m6A modifications that were detected by direct SMRT sequencing and an additional three m5C motifs were detected in Tet2 treated DNA. The motifs were then matched with methyltransferase genes in the genome, and the results have been deposited in REBASE .

Physiology / Biochemistry / Molecular Microbiology

CSRA, UCPA AND PFKA : MORE ALLOSTERIC REGULATION ?

N. Fraikin[1]
[1]*Free University of Brussels ULB, Génétique et Physiologie Bacterienne, Gosselies, Belgium*

Backgrounds

CsrA is a global regulator that modulates carbon distribution between different genetic programs in bacteria. It primarily regulates social behaviors, motility and metabolism. CsrA regulates the expression of several genes at the post-transcriptional level, by binding their transcripts and modulating their stability. It has been known for more than 20 years that glycolysis is impaired in a csrA mutant. However, subsequent works failed to demonstrate direct regulation of glycolytic enzymes by CsrA, suggesting that CsrA regulates glycolysis indirectly. Our lab has been lately interested in UcpA, a protein of unknown function showed to be an excellent candidate gene to be negatively regulated by CsrA. Subsequent data suggest that UcpA could be a regulator of glycolytic activity.

Objectives

We are studying the role of UcpA in the CsrA-mediated regulation of glycolysis, to show whether UcpA regulates glycolysis and how this regulation happens.

Methods

We showed that UcpA and PfkA (Phosphofructiokinase A, a glycolytic enzyme regulated by many allosteric effectors) form a complex in vivo and in vitro. Deleting ucpA in a csrA mutant partially suppresses some phenotypes caused by the deletion of csrA on glycolytic carbon sources (growth defect, hexose phosphate accumulation).

Conclusions

Our results suggest a inhibitory function of UcpA over PfkA. Since UcpA might be negatively regulated by CsrA, this might explain how a csrA mutant is defective for glycolytic activity.

[2]Hospital Universitario de La Ribera, Servicio de Microbiología, Alzira- Valencia, Spain
[3]Hospital Vall d'Hebron, Servicio de Microbiología, Barcelona, Spain
[4]CIBER en Epidemiología y Salud Pública, CIBERESP, Valencia, Spain

Backgrounds

Gonorrhea is the second most common bacterial sexually transmitted disease and its incidence increases every year worldwide. This, together with the growing number of antimicrobial resistance (AMR) isolates, have made *Neisseria gonorrhoeae* (NG) a threat to public health.

Objectives

The aim of the study was to perform an analysis of genomic variation in two sets of clinical samples of NG from two Spanish regions, Comunidad Valenciana (CV) and Catalonia, to compare their genetic structure and pattern of antibiotic resistance.

Methods

We analyzed 220 strains of NG, 127 from CV and 93 from Catalonia. These samples were sequenced using Illumina NextSeq technology. Sequences types (STs) were obtained using SRST2. Complete genome sequences were assembled *de novo* and annotated in order to compare the genetic features of each strain. These data were used for phylogenetic inference by maximum likelihood methods and to compare the diversity of NG isolates of these two regions.

Conclusions

We found 39 different STs, of which 13 were present in both regions and 13 were exclusive to each. 2 unidentified STs were also found in each of the study regions. The most prevalent types were ST1901, ST7363, and ST9363 (>57% in CV, >46% in Catalonia). Most strains were resistant to quinolones and penicillin in both regions. However, sensitivity to cephalosporins was high and no resistance was found to spectinomycin. Some resistance determinants, such *penA* (n=54), TEM-1D (n=30), and *tetM* (n=27), were detected. Further studies are necessary to determine all the possible causes of AMR acquisition in NG.

ROLE OF THE GLUTAMINE-DEPENDENT ACID RESISTANCE SYSTEM OF BRUCELLA SPP. IN RESPONSE TO EXTREME ACID STRESS

L. Freddi[1], M.A. Damiano[1], E. Pennachietti[2], S. Köhler[1], D. De Biase[2], A. Occhialini[1]
[1]IRIM, CNRS, Montpellier, France
[2]Dipartimento di Scienze e Biotecnologie Medico-Chirurgiche, Sapienza Università di Roma, Latina, Italy

Backgrounds

The glutamate-dependent decarboxylase (GAD) system is the most potent acid resistance system (AR2) described in *Escherichia coli.* It consists of a glutamate decarboxylase enzyme and a glutamate/GABA antiporter. Our group showed that the GAD system is also operative in newly described and atypical *Brucella* species, among which *Brucella microti*. Recently, an AR2-Q system, based on deamination of glutamine to glutamate by the glutaminase YbaS, was also described in *E. coli*. In the genome of *Brucella*, a *glsA* gene homologous to *ybaS* is located just upstream and in same orientation as the *gadB* and *gadC* genes encoding the GAD system.

Objectives

Using a panel of genus-representative strains, our aim was to demonstrate the existence of a functional AR2-Q system in *Brucella* spp and its contribution to survival at an extreme acid stress.

Methods

In contrast to the classical *Brucella* species studied, only the new and atypical strains were found AR in the presence of glutamine and glutamate. By RT-PCR experiments, the genes of the *gadBC-glsA* locus were found expressed as an operon. Functional complementation of a *glsA* mutant of *B. microti* with the *ybaS* gene of *E. coli* demonstrated strong homologies between the 2 enzymes. Acid resistance phenotypes of mutant strains of *B. microti* confirmed the role of the AR2-Q system in extreme glutamine-dependent AR at pH 2.5.

Conclusions

The GAD and AR2-Q systems are functional in new and atypical species of *Brucella*. This study provides insight into the adaptation of these strains to extremely acidic environments.

Physiology / Biochemistry / Molecular Microbiology

DETECTION AND IDENTIFICATION OF MYCOBACTERIUM SPECIES BY TWO DIFFERENT MOLECULAR METHODS COMPARING WITH CULTURE

A. gaber[1], E. elsawy[1], H. hamed[1]
[1]urology & nephrology center, microbiology, mansoura, Egypt

Backgrounds

Tuberculosis still remains a worldwide public health problem. Its causative agent is *Mycobacterium tuberculosis* which causes death in developing countries. Nontuberculous mycobacteria (NTM) are responsible for the majority of mycobacterial infections in resource-rich countries, where tuberculosis is not endemic.

Objectives

With the recent global issue of mycobacterial infections, it is necessarily to find rapid, sensitive, and specific diagnostic methods for the detection and identification of *M. tuberculosis* and NTM in clinics The traditional diagnosis of mycobacterial infection are culture-based identification method. Direct examination with microscope.

Methods

140 urine samples, Ziehl-Neelsen Acid Fast staining,culture by VersaTREK were performed. DNA was extracted using High Pure Template Purification Kit .The purified chromosomal DNA was used for PCR and microarray analysis. For PCR, the primers were designed depending on the DNA sequence alignments of the mycobacterial 16S rRNA conservative regions. The amplified DNA is 1350 bp. For microarray analysis, The LCD array kit (Myco ^{Direct} 1.7) was manufactured by Chipron GmbH, (Germany) and designed for identification of *Mycobacterium tuberculosis* complex and other Nontuberculous mycobacteria (NTM). It is based on a PCR amplification of rRNA gene region with 225-265 bp , and a 126 bp fragment from the IS*6110* element.
80 individuals gave positive mycobacterial culture test. 54 individuals were positive results by Ziehl-Neelsen staining. Out of the 80 culture positive samples, only 77 exhibited PCR true positive results. The LCD array analysis showed that the 80 positive cultures from urine specimens contains 10 *Mycobacterium tuberculosis,*30 *Mycobacterium kansasii* , 17 *Mycobacterium celatum*, 9 *Mycobacterium gordonae*,8 *Mycobacterium chelonae*, and 6 *Mycobacterium phlei*.

Conclusions

The simple one step exhibited high sensitivity and specificity would give an encouragement for MTB and NTM rapid diagnosis. Also, it is recommended to use the LCD-microarray for the mycobacterial species identification as a rapid and highly sensitive diagnosis rather than classical methods.

EMM TYPE DISTRIBUTION OF MACROLIDE RESISTANT GROUP A STREPTOCOCCI ISOLATED FROM PATIENTS WITH ACUTE PHARYNGITIS IN SERBIA (2008-2014)

I. Gajic[1], V. Mijac[1], L. Ranin[1], D. Kekic[1], S. Popovic[1], A. Smitran[2], N. Opavski[1]
[1]Medical Faculty, Institute of microbiology and immunology, Belgrade, Serbia
[2]Medical Faculty, Microbiology, Banja Luka, Bosnia - Herzegovina

Backgrounds

The prevalence of erythromycin resistance of pharyngeal group A streptococci (GAS) in Serbia increased significantly from 2.41% in 1990s to 12.5% in 2008.

Objectives

The aims of this study were to determine the prevalence of macrolide-resistant GAS (MRGAS) during 2011-2014 and to describe changes in distribution and dynamics of resistant *emm* types over time.

Methods

A total of 2180 GAS isolated from patients with acute pharyngitis from 2011 to 2014 were included in this study. Susceptibility to erythromycin was determined by disk diffusion test. The sequence-typing was used for MRGAS *emm* assignment. Obtained data were compared with 3891 previously characterized GAS recovered in 2008/2009.

Conclusions

A steady decline in macrolide resistance was recognized from 2008 to 2014 in Serbia (2008/2009-12.5%; 2011/2012-9.6%; 2013/2014-9.4%). A total of 13 *emm* types of MRGAS were detected in the study period. The most frequent *emm* types in 2008/2009 (*emm*75, *emm*77, *emm*12) and 2011/2012 (*emm*75, *emm*12, *emm*1) accounted for 94.7% and 83.7%, respectively. In 2013/2014 *emm*12, *emm*89 and *emm*75 comprised 70.4% of all MRGAS. The genotype *emm*77, the third common in 2008/2009 (14.6%), was not detected in 2011/2012 while in 2013/2014 accounted for just 3.7% of all MRGAS. Genotype *emm*89 was identified for the first time in Serbia in 2011/2012, and its prevalence increased significantly more than 3-fold in 2013/2014, being the second most common type.
The decrease of macrolide resistance during 7-year period might be related to a slight change in the distribution of *emm* types in the community.

IN VIVO INTERACTIONS OF THE TWO COMPONENT SYSTEM EUPK/EUPR IN THE HALOPHILIC BACTERIA CHROMOHALOBACTER SALEXIGENS: A CROSS-REGULATED SYSTEM

R.M. García-Valero[1], M. Argandoña[1], D. Wolf[2], J.J. Nieto[1], T. Masher[2], C. Vargas[1]
[1]Universidad de Sevilla, Microbiología y Parasitología, Sevilla, Spain
[2]Technische Universität TU Dresden, Institute of Microbiology, Dresden, Germany

Backgrounds

Chromohalobacter salexigens is a halophilic bacterium able to grow in a wide range of salinities (0.5 to 3 M NaCl in minimal medium). Its main osmoadaptation strategy is the cytoplasmic accumulation of the biostabilizers ectoines, two compounds with great industrial interest. To coordinate these processes, the cells are equipped with different systems and mechanisms for osmosensing and signal transduction, that induce the cellular response necessary to adapt them to these conditions. These signal transduction pathways have not yet been described in depth in halophilic bacteria. Previously, we phenotypically characterized a two-component system, EupK/EupR, involved in the osmoadaptation and metabolism of this halophile, through the control of the synthesis, degradation and uptake of ectoines. This was also cross-linked with the regulation of its glucose catabolism.

Objectives

Analysis of *in vivo* protein-protein interaction between the histidine kinase EupK and its response regulator EupR in different conditions of salinity and carbon sources.

Methods

Construction of a tagged-protein expression vector based on the pMP92 plasmid. Expression under different salinity and carbon sources conditions of the tagged proteins. Purification and analysis of putative protein-protein interactions performed by a membrane-SPINE assay and co-inmuno precipitation in *C.salexigens*.

Conclusions

Preliminary results demonstrate the interaction between the response regulator and the histidine kinase and reveal the presence of other proteins that interact with this regulation system. From these data it can be suggested that EupK/EupR probably forms part of a more complex transcriptional regulatory network via a cross-regulated system.

FLUOROQUINOLONE RESISTANCE, DNA-CLEAVAGE, REACTIVE OXYGEN SPECIES PRODUCTION, AND PHAGE INDUCTION AFFECTS THE POST-ANTIBIOTIC EFFECT OF LEVOFLOXACIN IN STREPTOCOCCUS PNEUMONIAE

M.V. Valenzuela[1], M.J. Ferrándiz[2], A.G. de la Campa[2], M.T. García-Esteban[1]
[1]Universidad Complutense de Madrid, Microbiología III, Madrid, Spain
[2]Centro Nacional de Microbiología. Instituto de Salud Carlos III, Unidad de Genética Bacteriana, Majadahonda Madrid, Spain

Backgrounds

The fluoroquinolone levofloxacin (LVX) is currently used for treatment of pneumococcal infections. The post-antibiotic effect (PAE) has a clinical impact on antibacterial dosing regimens. LVX acts via the formation of DNA-LVX-topoisomerase complexes, with the subsequent generation of detrimental double-stranded DNA breaks. Its lethality is enhanced by the production of reactive oxygen species (ROS), via the up-regulation of genes that stimulate the Fenton reaction. In addition, LVX causes bacterial lysis by phage induction

Objectives

To study the factors get involved in the PAE of LVX

Methods

Susceptible and resistant pneumococcal strains were analyzed during the postantibiotic phase. Growth curves, level of chromosome fragmentation, and ROS production were determined. In addition, isogenic isolates with prophages inducible or non inducible by LVX were studied

Conclusions

Treatment of 1 h with LVX at 2.5× MIC induced EPAs between 0.22±0.05 and 1.41±0.21 h. Treatment with 10× MIC induced longer EPAs (between 0.56±0.11 and 2.06±0.35 h). EPA values were lower in LVX-resistant strains. In pneumococcal cultures treated with LVX (2.5× MIC, 1 h), after 4 hours of removing the antibiotic, bacteria viability increased by 10-fold, while ROS level decreased by 10-fold, and DNA breakage decreased by 7-fold. EPA induced in an isolate carrying an inducible prophage was 3-fold longer than in a non-inducible isolate. LVX induces significant EPAs in *S. pneumoniae*, which were related with the resistance of the strain, ROS production, DNA cleavage and presence of LVX-inducible prophages

MEMBRANE MICRODOMAINS DISASSEMBLY AFFECTS STAPHYLOCOCCUS AUREUS VIRULENCE

E. García-Fernández[1], *D. López*[1]
[1]*Centro Nacional de Biotecnología, Biotecnología Microbiana, Madrid, Spain*

Backgrounds

The pioneering *fluid mosaic model* of the cell membrane has been reviewed in the past two decades due to the evidence that biological membranes contain diverse lipid species, which tend to segregate laterally into membrane microdomains. Eukaryotic cells organize proteins important for the correct functionality of numerous cellular functions into membrane microdomains or *lipid raft*. The integrity of *lipid rafts* is partly mediated by the activity of raft-associated scaffold proteins termed flotillins. Recently, it has been described that bacterial cells also compartmentalize cellular processes in functional membrane microdomains (FMM) that structurally resemble that of eukaryotic lipid rafts.

Objectives

Here we use the human pathogen *Staphylococcus aureus* to determine the composition, assembly and biological function of bacterial FMM.

Methods

Super resolution microscopy approaches have been used to identify structural determinants of FMM and examine the subcellular localization of flotillin. The constituent lipids and proteins associated to FMM were analyzed using UPLC-ESI-qTOF-MS and MS-LFQ respectively. The influence of perturbation of FMM was analyzed by *in vitro* and *in vivo* experiments.

Conclusions

A mutually guided interaction between flotillin and membrane saccharolipids organizes saccharolipid-rich membrane platforms that promote efficient oligomerization of protein interaction partners. We show that alterations in FMM organization lead to a severe and simultaneous perturbation of proteins complexes that are harbored in the FMM. We show how this can be used to inhibit the virulence potential of this pathogen and how it can be developed as a new antimicrobial therapy.

Physiology / Biochemistry / Molecular Microbiology

CONFORMATIONAL LOCKING BY PHOSPHORYLATION AS A REGULATORY SWITCH FOR BACTERIAL TRANSLATION-ELONGATION FACTORS

A. Garcia-Pino[1]
[1]*Free University of Brussels ULB, Department of Molecular Biology, Gosselies, Belgium*

Backgrounds

Bacterial protein synthesis is intricately connected to metabolic pace. It responds to environmental stress through post-translational modifications of transcription and translation factors. Translation elongation factor Tu (EF-Tu) is among the most heavily modified. EF-Tu is methylated and phosphorylated in response to nutrient starvation upon entering stationary phase and its phosphorylation is a crucial step in the pathway towards sporulation.

Objectives

We have discovered that reversible phosphorylation of EF-Tu strongly affects its function as a translation elongation factor and is potentially a very important regulator of translation in general. Our data indicates that phosphorylation decouples the EF-Tu conformational cycle (open/closed states) from the control of nucleotides and P-EF-Tu remains trapped in an open conformation that precludes aa-tRNA binding. Our X-ray structures show that the bases of the inactivation are intricately related with the function of the switch I and II regions. In addition we use phosphomimetic mutations on other conserved phosphorylation sites to show that the mechanism of inactivation is likely general.

Methods

We performed in-depth studies on the behavior of pEF-Tu in relation to its multiple partners with a variety of structural and biophysical techniques (including thermodynamics, stopped-flow kinetics, SAXS and X-ray crystallography and smFRET). Only from the integration of all these data that combine structure and dynamics, it becomes apparent that the real effects of phosphorylation lay on the EF-Tu dynamics.

Conclusions

Overall these results could have potential implications to the way EF-Tu is further modified *in vivo* for instance during stationary phase to reduce the pace of translation

REGULATION ON NITRATE RESPIRATION IN THERMUS THERMOPHILUS

L. Álvarez[1], C. Bricio[2], N. García-Quintáns[2], A. Blesa[2], I. Baquedano[2], M. Mecía[2], J. Berenguer[2]
[1]Umeå Centre for Microbial Research,
Laboratory for Molecular Infection Medicine Sweden- Department of Molecular Biology, Umeå, Sweden
[2]Centro de Biología Molecular "Severo Ochoa" CSIC-UAM, Molecular Biology, Madrid, Spain

Backgrounds

Denitrification capability is an unevenly distributed property in the extreme thermophile *Thermus thermophilus*, where strictly aerobic, nitrate respiring, and denitrificant strains exist. The corresponding genes are distributed in two gene clusters, one encoding nitrate respiration (NCE) and the other nitrite respiration (*nic*), located in a poorly conserved region of a megaplasmid and easy transferable both by natural competence and by transjugation, a new class of cell-to-cell DNA transfer mechanism. The denitrification genes are expressed in response to oxygen depletion and presence of the corresponding nitrogen oxide. However, no homologues of common regulators described for denitrification in other bacteria such as FNR, DNR or NarX/NarL two component systems are found in *T. thermophilus.*

Objectives

To identify and analyse the regulators that control the expression of the nitrite and nitric oxide reductases encoded by the *nic* cluster of *T. thermophilus*.

Methods

Mutants defective in putative transcription factors were subjected to expression assays using promoter vectors expressing thermostable beta-galactosidase. Pure native and mutant proteins were also subjected to *in vitro* EMSA assays.

Conclusions

Master regulators encoded by the NCE cluster are required for the expression of the promoters in the *nic* cluster. In addition, a regulator related to the NsrR NO-sensing protein of Gram positive bacteria was also required for nitrite respiration. In contrast to its homologues the *T. thermophilus* protein binds the target promoter in its oxidized form, allowing us to propose a global regulation mode for nitrite respiration in *T. thermophilus.*

INVOLVEMENT OF THE SMALL RNA SUHB ON CARBON CATABOLITE REPRESSION OF TETRALIN DEGRADATION GENES IN SPHINGOPYXIS GRANULI STRAIN TFA

I. García-Romero[1], *E. Santero*[1], *B. Floriano*[1]
[1]*Andalusian Center for Developmental Biology,*
Pablo de Olavide University and Department of Molecular Biology and Biochemistry Engineering, Sevilla, Spain

Backgrounds

Sphingopyxis granuli strain TFA is able to use the organic solvent tetralin as the sole carbon and energy source. Structural *thn* genes are induced in the presence of tetralin by ThnR, a LysR-like transcriptional regulator, and ThnY, a ThnR co-activator. Besides, the expression of *thn* genes is under carbon catabolite repression (CCR) by a preferential carbon source, such as β-hydroxybutyrate (β-HB).

Objectives

The main objective is to stablish the role of a small RNA (sRNA) in *thn* genes expression control under CCR conditions.

Methods

Comparison of the global gene expression in tetralin- and β-HB-grown cells revealed the presence of a sRNA expressed preferentially in β-HB, which was annotated by Infernal software 1.1. Northern Blot and β-galactosidase assays confirmed the differential expression of this sRNA. The effect on CCR over *thn* genes of mutant lacking the sRNA was evaluated. Furthermore, its putative targets were detected by IntaRNA software and the interaction validated by RNA-RNA EMSA.

Conclusions

The sRNA is predicted as belonging to the family RF00519 (SuhB), which is highly conserved in α-proteobacteria. The *thn* genes are partially de-repressed in a mutant lacking SuhB under CCR conditions. Furthermore, the 5' UTR of *thnR* mRNA is identified as a target of SuhB in which would block the ribosomal binding site. Accordingly, ThnR levels are higher in the mutant strain. The available data so far indicate that SuhB is involved in CCR of *thn* genes.

OPTIMIZATION OF A REPORTER ASSAY FOR SMALL-RNA TARGET VALIDATION IN A-PROTEOBACTERIA

N.I. García-Tomsig[1], J.I. Jiménez-Zurdo[1], M. Robledo[1]
[1]Estación Experimental del Zaidín- Consejo Superior de Investigaciones Científicas CSIC, Grupo de Ecología Genética de la Rizosfera, Granada, Spain

Backgrounds

High-throughput transcriptome profiling (RNAseq) has uncovered large and heterogeneous populations of small noncoding RNA species (sRNAs) with potential regulatory roles in bacteria. sRNAs mostly act as post-transcriptional regulators of gene expression to fine-tune cellular processes such as general responses to abiotic stress, quorum sensing, virulence or biofilm formation. The so-called trans-sRNAs regulate target mRNAs by protein-assisted short and discontinuous base-pairing interactions. Noncoding RNomics in rhizobia, the nitrogen-fixing symbionts of legumes, has been capitalized to date in the model alfalfa partner *Sinorhizobium meliloti.* The most informative data about trans-sRNA function is the identity of their target mRNAs. Because of imperfect base-pairing interactions, target identification requires experimental confirmation of *in silico* predictions.

Objectives

Development of a genetic reporter assay for the experimental validation of predicted sRNA-mRNA base-pairing interactions in *S. meliloti*.

Methods

Our assay is based on the co-transformation of bacteria with two compatible plasmids that independently overexpress the selected sRNAs and a translational fusion of the putative target mRNA interaction region to the reporter GFP. Here, we compared efficiency of sRNA constitutive and IPTG-inducible overexpression systems using known target mRNAs of the homologous AbcR1 and AbcR2 sRNAs, encoding ABC transporters.

Conclusions

Interestingly, we observed that sRNA inducible overexpression is more efficient than constitutive overexpression to verify sRNA-mRNA interactions. Using this method, we verified two new AbcR1 and AbcR2 targets, encoding periplasmic components of ABC transporters. One of them is also a new target of a yet uncharacterized sRNA influencing nodule formation efficiency (NfeR1).

NONTYPABLE HAEMOPHILUS INFLUENZAE GENOMIC PATHO-ADAPTATION IN THE AIRWAYS OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE PATIENTS WITH LONG-TERM MICROBIAL PERSISTENCE

J. Moleres[1], J.C. Mell[2], R. Ehrlich[2], F.C. Ariadna[1], S. Martí[3,4], S. Cuesta[1], L. Caballero[1], I. Rodriguez-Arce[1], G. Ehlrich[2], J. Liñares[3,4], J. Garmendia[1,4]
[1]Instituto de Agrobiotecnología, Animal Healthcare, Mutilva, Spain
[2]Drexel University, Microbiology & Immunology, Philadelphia, USA
[3]Hospital Universitario Bellvitge, Departamento de Microbiología, Barcelona, Spain
[4]Centro Investigación Biomédica en Red, Centro Investigación Biomédica en Red, Madrid, Spain

Backgrounds

The respiratory pathogen nontypeable *Haemophilus influenzae* (NTHi) is encountered in a significant proportion in the lower airways of Chronic Obstructive Pulmonary Disease (COPD) patients. The COPD lung is likely to be a unique niche favouring its adaptation to persistent infection.

Objectives

To unravel NTHi evolutionary dynamics in the lung of the COPD patient over time, and to identify microbial patho-adaptive features.

Methods

Ninety-two NTHi isolates from sputum samples of 13 COPD patients at exacerbation, recovered in a prospective longitudinal study (2000-2014), were genome sequenced: (a) Pacific Biosciences long-read sequencing was used to generate complete assemblies for one representative of each clonal type; (b) Illumina short-read sequencing was applied to all isolates. Genome assembly used a customized pipeline and raw reads were also aligned to the PacBio reference genomes to generate variant tables for each set of clonal type isolates. Functional characterization of parallel evolution-related allelic variation was analyzed for selected genes.

Conclusions

Ninety-two NTHi COPD isolates have been (i) phylogenomically analyzed in the context of all publicly available NTHi genome sequences, (ii) organized in 33 clonal types, (iii) used to establish variation in NTHi genome architecture, (iv) used to identify traits of parallel evolution by fixing at least one single nucleotide variant in more than one clonal type. Detailed analysis of the *fadL-ompP1* gene parallel evolution and allelic variation will be discussed, in terms of its role as an exogenous long-chain fatty acids transporter, as a ligand of the human receptor CEACAM-1 and as a source of antigenic variation.

PHENOTYPIC AND GENOTYPIC CHARACTERIZATION OF NEISSERIA GONORRHOEAE RESISTANT ISOLATES IN BUCHAREST, ROMANIA

V.C. Cristea[1], I. Gheorghe[2], A.I. Cotar[2], M. Popa[2], G. Gradisteanu[2], V. Burloiu[2], G.R. Pricop[1], V. Lazar[2], M.C. Chifiriuc[2]
[1]Central Reference Laboratory Synevo- Bucharest- Romania, Microbiology, Bucharest, Romania
[2]Faculty of Biology- University of Bucharest- Research Institute of the University of Bucharest, Microbiology, Bucharest, Romania

Backgrounds

Although gonporrhoea is among the top public health problems in Romania, leading to a series of complications, however, there is a lack of data regarding the antibiotic resistance of local *Neisseria gonorrhoeae* strains, while molecular typing methods have not yet been introduced for their molecular characterisation.

Objectives

The purpose was to characterize the *N. gonorrhoeae* recent isolates exhibiting antibiotic resistance to penicillin, tetracycline and fluoroquinolones using phenotypic methods, PCR and Antigen Sequence Typing (NG-MAST).

Methods

This study was conducted on 20 strains isolated from *January – June 2016* from men urethral secretions sent to Synevo Laboratory in Bucharest. Isolates were identified by mass spectrometry and antibiotic susceptibility was determined in accordance with the CLSI, 2016. PCR were performed on genomic DNA, in order to identify the penicillin resistance genes [TEM like β-lactamase; PenA and PonA (penicillin binding protein); mutation of the *mtrR* gene, outer membrane porin *PorB1b* and also the mutations in the *pilQ* gene], tetracycline resistance genes (*tetM* and mutation in the *rpsJ* gene) and fluoroquinolone resistance (mutations in *gyrA* and *parC*). The molecular study revealed the presence of the followed resistance genes: ciprofloxacin (*gyrA* – 45% and *parC* – 40%); tetracycline (*rpsJ* - 100% and tetM - 10%); penicillins (*PilQ* - 95%; *mtr* - 90%; *PonA* - 35%; *PenA* - 15*%; bla*$_{\text{TEMlike}}$ - 15% and *PorB* - 5%).

Conclusions

The molecular typing of resistant isolates may provide the capacity to identify possible associations between ST and AMR (antimicrobial resistance) phenotype and patient characteristics, having as the final purpose to guide treatment algorithms.

Physiology / Biochemistry / Molecular Microbiology

THE SPREADING OF CTX-M-15 IN KLEBSIELLA PNEUMONIAE IS LINKED WITH MULTIDRUG RESISTANT PHENOTYPE

I. Czobor[1], I. Gheorghe[2], I. Avram[3], S. Petrut[3], V. Lazar[2], M.C. Chifiriuc[2], Z. Zhiyong[4]
[1]Faculty of Biology- University of Bucharest- Research Institute of the University of Bucharest, Genetics, Bucharest, Romania
[2]Faculty of Biology- University of Bucharest- Research Institute of the University of Bucharest, Microbiology, Bucharest, Romania
[3]Faculty of Biology- University of Bucharest, Genetics, Bucharest, Romania
[4]Centre of Infectious Diseases- West China Hospital- Sichuan University, Microbiology, Chengdu, China

Backgrounds

Acquired infections caused by multidrug-resistant CTX-M-15-producing *Klebsiella pneumoniae* have dramatically increased in recent years however, the extent of distribution in the country or the genetic support for their emergence and spread are unknown.

Objectives

The aim of this study was to analyze the population structure and genetic elements responsible for the dissemination of extended-spectrum β-lactamase (ESBL)-producing *K. pneumoniae* identified in one main hospital in Bucharest, south of Romania.

Methods

Thirty-four *K. pneumoniae* isolates from different clinical specimens were selected (May 2016) according to multidrug resistant phenotype (MDR). Bacterial identification and antibiotic susceptibility testing were performed by standard methods. The presence of β–lactamases was investigated by PCR and sequencing and the population structure were investigated by Pulsed-field gel electrophoresis (PFGE) analysis. All *K. pneumoniae* strains were MDR, most frequently involving resistance to β-lactam antibiotics, aminoglycosides, quinolones and colistin. bla_{NDM-1} gene was detected only in one strain of *K. pneumoniae* whereas OXA-48 was identified in 25% of the analysed strains. One *K. pneumoniae* isolate produced both NDM and CTX-M, and 82% of the isolates produced CTX-M-15. 6% of isolates produced both CTX-M-15 and OXA-48 and another 6% co-produced TEM and OXA-48. Among ten PFGE-types identified, one of them was more frequently identified (n=15/34); none of the pulsotype could be linked to any specific resistance pattern.

Conclusions

CTX-M-15 is the most prevalent β-lactamase detected amongst the MDR *K. pneumoniae*. As there were observed a lot of pulsotypes, we can conclude that antibiotic resistance is not linked with a specific clone and it`s spreading in Romanian hospitals.

STUDY INHIBITORY EFFECT OF PEPTIDE NUCLEIC ACIDS AGAINST FUSOBACTERIUM NUCLEATUM GROWTH BY TARGETED TO NECESSARY GENES

P. Gholizadeh[1], M. Aghazadeh[2], H. Samadi Kafil[3]
[1]Student Research Committee, Tabriz University of Medical Sciences, Tabriz, Iran
[2]Tabriz University Of Medical Sciences, Medical Microbiology, Tabriz, Iran
[3]Drug Applied Research Center, Tabriz University Of Medical Sciences,Tabriz, Iran

Backgrounds

Fusobacterium nucleatum is an anaerobe, gram negative, fusiform or spindle shaped rods. It is associated with periodontal disease, gut disease (ulcerative colitis (UC), inflammatory bowel disease (IBD) and Crohn's disease) and it has an increased risk of oral cavity, pancreatic and colorectal cancers. Peptide nucleic acids (PNAs) are one of the DNA mimic, synthetic components that can bound to single strand and double strand DNA or RNA. Binding the peptide-PNA to PNA targeting DNA or RNA inhibit expression or translation of PNA targeting genes.

Objectives

We are developing PNA targeted to *16srRNA*, *rpoD* (encoded RNA polymerase subunit sigma) and *gyrA* (encoded DNA gyrase subunit A) genes in *F. nucleatum* isolates.

Methods

Peptide-PNAs targeted to conserve sequence of *16srRNA*, *rpoD* and *gyrA* genes in *F. nucleatum* isolated from biopsy samples of colorectal cancer patients in vitro.

Conclusions

The initiate results indicated that PPNAs could inhibit expression of *16srRNA*, *rpoD* and *gyrA* and it seems to be successful effect on inhibition of *F. nucleatum* isolates growth. However, based on other results that evaluated PPNA targeting necessary genes effects on *Escherichia coli*, *Klebsiella pneumonia* and *Staphylococcus aureus*, it may demonstrate that conserve sequence of *16srRNA*, *rpoD* and *gyrA* are possible targets for *F. nucleatum*. Finally, PPNAs provide novel sequence designed and ultra-spectrum antibiotics based on DNA antisense and antigene strategies.

CRSIPR/CAS SYSTEM EFFECTS ON ACQUIRED DRUG RESISTANCE AND VIRULENCE FACTORS OF STAPHYLOCOCCUS AUREUS

P. Gholizadeh[1], M. Aghazadeh[2], H. Samadi Kafil[3]
[1]Student Research Committee, Tabriz University of Medical Sciences, Tabriz, Iran(2)Tabriz university of medical sciences, Department of medical microbiology, Tabriz, Iran
[3]Drug Applied Research Center, Tabriz University Of Medical Sciences,Tabriz, Iran

Backgrounds

CRSIPR/Cas systems are adaptive immune system of eubacteria and archaebacteria that called clustered regularity interspaced short palindromic repeats coupled with CRISPR-associated (Cas) proteins. These systems provide adaptive immunity against potentiality dangerous foreign DNA for example bacteriophages DNA, plasmids and transposable elements. *Staphylococcus aureus* is common multi-drug resistant that causes community and hospital acquired infections. Many of the antibiotic resistant phenotypes of these organisms have been carried by R-plasmids that CRISPR/Cas system may control these plasmids.

Objectives

Recent studies demonstrated that CRISPR/Cas system can control and manage VRSA and MRSA plasmids in *S. aureus*.

Methods

We tend to searched CRISPR/Cas system, *S. aureus*, and antibiotic resistance and relevance of full texts on papers were studied in the roles of CRISPR/Cas in VRSA and MRSA plasmids.

Conclusions

The *nickase* gene is homologous with spacer 1 (*spc1*) locus in CRISPR loci and presented in conjugation plasmids of vancomycin resistant and methicillin resistant *S. aureus* strains. The results showed its efficacy on self-splicing intron insertion into MRSA and VRSA plasmids and it interferes with target plasmid directly. If CRISPR/Cas system can be manipulated in clinical treat, these system would provide limitation and also inhibition of spread of antibiotic resistance plasmid genes such as VRSA and MRSA. Development these system may resolve the acquisition of antibiotic resistance and virulence factor problems in potentiality pathogens and open novel vision for development therapeutic strategies.

SUBSTITUTION OF ALANINE AT POSITION 184 IN Ω -LIKE LOOP WITH GLUTAMIC ACID INTRODUCES BETA-LACTAMASE ACTIVITY IN ESCHERICHIA COLI PBP5

A. Ghosh[1], *D. Kar*[1], *S.D. Pandey*[1], *S. Mallick*[1], *M. Dutta*[1]
[1]*Indian Institute of Technology Kharagpur, Biotechnology, Kharagpur, India*

Backgrounds

E. coli PBP5 is a DD-carboxypeptidase that helps in maintaining cell shape and intrinsic beta-lactam resistance. Though, PBP5 does not have beta-lactamase activity under physiological pH, structurally it shares a common but a shorter Ω-like loop, resembling class A beta-lactamases. However, the key glutamic acid residue present in the Ω-loop of beta-lactamase is absent in the Ω-like loop of PBP5. It is assumed that beta-lactamases and DD-carboxypeptidases may undergo divergent evolution leading to distinct functional enzymes with different substrate specificities indicating the versatility of Ω-loops, though supporting experimental evidence is insufficient.

Objectives

To investigate the physiological and biochemical effects of introducing glutamic acid in PBP5 Ω-like loop.

Methods

We substituted A184 to E to create PBP5_A184E. Ectopic expression of PBP5_A184E in *E. coli* ΔPBP5 mutant markedly elevates the beta-lactam resistance, especially towards cephalosporin. However, like PBP5, PBP5_A184E retains the ability to complement the aberrantly shaped *E. coli* septuple PBP mutant indicating unaltered *in vivo* DD-carboxypeptidase activity. Enzyme kinetics of the purified soluble PBP5 and PBP5_A184E, and bioinformatics analyses have substantiated the dual enzyme nature of A184E mutated protein possessing both DD-carboxypeptidase and beta-lactamase activities. Apart from to introducing favorable conditions for beta-lactam hydrolysis, the groove volume of active-site has also been increased by ~20%, which is similar to the enhanced groove volume observed in the dual enzyme of *M. smegmatis*.

Conclusions

Therefore, substitution of A184 to E at Ω-like loop alone can introduce a beta-lactamase activity in *E. coli* PBP5 without hampering its DD-carboxypeptidase activity supporting the possibility of single amino acid polymorphism.

BIOCHEMICAL CHARACTERIZATION OF A VARIANT OF ESCHERICHIA COLI GLUTAMATE DECARBOXYLASE WITH IMPROVED GABA PRODUCTION AT ALKALINE PH

F. Giovannercole[1], E. Pennacchietti[1], D. De Biase[1]
[1]Sapienza University of Rome, Department of Medical-Surgical Sciences and Biotechnologies- Laboratory affiliated to Istituto Pasteur Italia – Fondazione Cenci Bolognetti, Latina, Italy

Backgrounds

Glutamate decarboxylase (Gad), a structural component of the major acid resistance system in many orally-acquired, neutralophilic bacteria, yields CO_2 and γ-aminobutyric acid (GABA), while consuming one proton/catalytic cycle [1]. *Escherichia coli* GadB (*Ec*GadB) has a pH optimum in the pH range 4-5 and displays no activity at pH ≥ 6.5. Intracellularly, the enzyme activity is therefore pH-controlled. Based on the available crystal structures of *Ec*GadB, residues Asp86 and His465, highly conserved in bacterial Gads, were suggested to be major players in the control of *Ec*GadB activity [1].

Objectives

Bacterial Gad is regarded as an interesting tool for “green chemistry” applications because it can be employed to synthesize GABA, a non-proteinaceous amino acid, highly desirable in functional food and precursor of 2-pyrrolidone (an industrial solvent) for the synthesis of nylon 4 [2]. We engineered *Ec*GadB at the level of residues Asp86 and His465 to generate a variant less sensitive to pH increase.

Methods

*Ec*GadB_Asp86Asn-His465Ala was overexpressed and purified. UV-visible and fluorescence spectrophotometry, circular dichroism, pH-dependent enzymatic activity assays and solvent kinetic isotope effect were employed to characterize this variant.

Conclusions

*Ec*GadB_Asp86Asn-His465Ala, while retaining substrate specificity, acts as a robust catalyst in the pH range 7-8 and displays an altered solvent isotope effect. Because pH is no longer a limiting reaction parameter for the mutant enzyme, we suggest that this variant can be a better tool than wild type *Ec*GadB for the industrial synthesis of GABA.

PIVOTAL ROLE OF MRNA STABILITY REGULATION IN E. COLI ADAPTATION

M. Cocaign-bousquet[1], S. Nouaille[2], S. Laguerre[3], B. Enjalbert[1], L. Girbal[1]
[1]LISBP, CNRS INRA INSA, toulouse, France
[2]LISBP, INRA CNRS INSA, Toulouse, France
[3]LISBP, INSA INRA CNRS, Toulouse, France

Backgrounds

Understanding bacterial adaptation is essential to master bacterial proliferation and capacities and is a prerequisite for its efficient use in biotechnology. Bacteria constantly adapt their growth and metabolism to changing environments through complex and partially understood regulatory networks.

Objectives

A vast reorganisation at the transcriptional level coordinated by global and/or specific regulations is known to occur. However how this transcriptional reorganization progress through other intracellular levels remains unclear and the importance of post-transcriptional regulation is undetermined. We have investigated here how the post-transcriptional regulations of mRNA stability impact adaptation of the model bacterium *E. coli*.

Methods

We have measured stabilome (individual mRNA half-life for all bacterial transcripts) in various environments (Esquerre et al., NAR 2014) to evaluate if mRNA stability regulations influence mRNA dynamics. From these Omics data we have computed regulation coefficients and analysed the coordination of mRNA stability control with transcription regulation. Systemic analysis was performed to identify the major determinants of mRNA stability (Esquerre et al. BMC genomics 2015) and to investigate particular regulations. The post-transcriptional CSR system was demonstrated to control thousands of mRNA stabilities impacting significantly the central carbon metabolism and bacterial physiology (Esquerre et al. Sci Rep. 2016, Morin et al. Mol Microbiol 2016). Lastly, we have demonstrated by *in vivo* kinetics approaches that global regulations of mRNA stability do exist in bacteria and superimposed to specific regulations.

Conclusions

mRNA stability is a sensitive process influencing significantly the mRNA dynamics with important consequences in bacterial physiology. This work demonstrates the pivotal role of post-transcriptional regulations.

ANALYSIS OF INTRACELLULAR NADPH ACCUMULATION KINETICS IN C. GLUTAMICUM USING THE GENETICALLY ENCODED SENSOR-PROBE MBFP_CG

O. Goldbeck[1], *G. Seibold*[1]
[1]*Institute of Microbiology and Biotechnology, AG Eikmanns, Ulm, Germany*

Backgrounds

The Gram-positive *Corynebacterium glutamicum* is used in biotechnological applications which come along with high demands for intracellular NADPH. So far, these demands were mainly covered by genetic engineering of the pentose phosphate pathway. However, strains that excessively use the PPP often suffer from negative side-effects. The redirection of the carbon-flux toward the PPP by using a phosphoglucoisomerase-negative strain led to an improvement of *C. glutamicum,* but was accompanied by negative effects on growth and sugar uptake.

Objectives

Inhibition of sugar uptake occurred in *C. glutamicum* Δ*pgi* within seconds, which might be triggered by high intracellular NADPH concentrations. However, kinetics of NADPH accumulation have not been investigated in bacteria so far, due to the lake of tools for fast online-analysis. The sensor probe mBFP_Cg was created to solve this problem.

Methods

The protein mBFP was used for *in vitro* and *in vivo* assays. The protein was biochemically characterized and optimized using genesynthesis for its application in *C. glutamicum*, resulting in the protein mBFP_Cg. The plasmid pMBFP_Cg was used as a genetically encoded sensor to analyze kinetics of NADPH accumulation in *C. glutamicum* strains with altered NADPH metabolism.

Conclusions

Fast accumulation was observed in *C. glutamicum* Δ*pgi*. Strains expressing genes for transhydrogenases were checked upon their NADPH accumulation behavior. A method was established to determine the kinetic background of sugar uptake inhibition in *C. glutamicum* Δ*pgi*. The addition of glucose leads to an accumulation of NADPH resulting in the inhibition of the Glucose-6-phosphate-dehydrogenase. Following this event, Glucose-6-Phosphate accumulates and leads to the inhibition of sugar-transporters.

DIFFERENTIAL REGULATION OF ACTIVATION AND STABILIZATION OF PKC ORTHOLOGS IN FISSION YEAST

E. Gómez Gil[1], B. Vázquez-Marín[1], T. Soto[1], A. Franco[1], J. Vicente-Soler[1], M. Gacto[1], P. Pérez[2], J. Cansado[1], M. Madrid[1]
[1]University of Murcia, Genetics and Microbiology, Murcia, Spain
[2]Instituo de Biología Funcional y Genómica IBFG- Consejo Superior de Investigaciones Científicas, Morphogenesis and cell polarity, Salamanca, Spain

Backgrounds

The two Protein kinase C orthologs Pck1 and Pck2 operate in a redundant fashion in the fission yeast *Schizosaccharomyces pombe* to control essential functions including morphogenesis, cell wall biosynthesis, and the activity of the cell integrity pathway (CIP) and is core element MAP kinase Pmk1.

Objectives

To identify the mechanisms responsible for maturation, catalytic activation, and stabilization of Pck1 and Pck2.

Methods

We show that despite their strong structural similarity and functional redundancy, the mechanisms regulating their maturation, activation, and stabilization have a remarkably distinct biological impact on both kinases. Contrary to Pck2, putative *in vivo* phosphorylation of Pck1 within conserved activation loop, turn and hydrophobic motifs is essential for protein stability and biological functions. Constitutive activation promoted dephosphorylation and destabilization of Pck2, while it enhanced Pck1 stability to interfere with proper downstream signaling to the CIP triggered by Pck2. Importantly, whereas catalytic activity is essential for Pck1 functions, Pck2 remains partially functional in absence of kinase activity.

Conclusions

Our findings suggest that early duplication from a single ancestor involved important changes in the mechanisms regulating catalytic activation and stability of PKC family members to allow for a flexible and dynamic control of downstream functions, including MAPK signaling.

THE CHROMOSOME ARCHITECTURE OF STREPTOCOCCUS PNEUMONIAE IS OPTIMIZED FOR PHYSIOLOGY AND PATHOGENICITY

A. González de la Campa[1], *A.J. Martín-Galiano*[1], *F. Maria José*[1]
[1]*Centro Nacional de Microbiología. Instituto de Salud Carlos III, Unidad de Genética Bacteriana, Majadahonda, Spain*

Backgrounds

The transcriptome of *Streptococcus pneumoniae* is affected by changes in DNA-supercoiling. Relaxation of DNA with the gyrase inhibitor novobiocin reveals than 36% of the genome is differentially-expressed, these genes forming 15 topology-reacting domains. These domains are categorized as up-regulated (UP), down-regulated (DOWN), non-regulated (NR), and AT-rich.

Objectives

To study the characteristics of the diverse domains and the functionalities of their genes

Methods

Location Dispersion Index, Codon adaptation index, Protein-protein interactions

Conclusions

Genes of NR domains were subcategorized into position-conserved non-regulated (pcNR, 17% of the genome) and position-variable non-regulated (pvNR, 36% of the genome) domains. On average, pcNR domains showed high transcription rates, optimized codon usage, and were found to contain a small number of RUP/BOX/SPLICE repeats. These domains were enriched in leading strand genes, essential genes and those that code for proteins involved in primary metabolism but poor in exogenous genes. In contrast, pvNR genes coding for cell wall proteins, paralogs, virulence factors and immunogenic candidates for protein-based vaccines were found to be overrepresented. DOWN domains were enriched in genes essential for infection. Many UP and DOWN domain genes were activated during different stages of competence, whereas pcNR genes tended to be repressed until the competence was switched off. Pneumococcal genes appear to be subject to a topology-driven selection pressure that defines the chromosomal location of genes involved in metabolism, virulence and competence. The pcNR domains are interleaved between UP and DOWN domains according to a pattern that suggests the existence of macrodomain entities of around 200 Kb.

ROLE OF TMRNA IN ANTIBIOTIC SUSCEPTIBILITY IN STREPTOCOCCUS PNEUMONIAE

A. González de la Campa[1], L. Brito[2], J. Wilton[2], M.J. Ferrándiz[1], A. Gómez-Sanz[2], M. Amblar[2]
[1]Centro Nacional de Microbiología. Instituto de Salud Carlos III, Unidad de Genética Bacteriana, Majadahonda, Spain
[2]Centro Nacional de Microbiología. Instituto de Salud Carlos III,
Unidad de Patología Molecular del Neumococo, Majadahonda, Spain

Backgrounds

The tmRNA, encoded by the *ssrA* gene, is a small non-coding RNA involved in *trans*-translation that contributes to the recycling of ribosomes stalled on aberrant mRNAs. In most bacteria, its inactivation has been related with a decreased ability to respond to and recover from a variety of stress conditions.

Objectives

To investigate the role of tmRNA and trans-translation under several stresses, including antibiotic stress, in the human pathogen *Streptococcus pneumoniae*

Methods

Survival rates, construction of genetically-modified strains, efflux, reactive oxygen species (ROS) detection, chromosome fragmentation

Conclusions

A D*ssrA* strain grew slower than the wild type, indicating that is not essential in the pneumococcus. This strain was more sensitive to UV irradiation, exogenous H_2O_2, and antibiotics inhibiting translation and transcription. Remarkably, D*ssrA* was more resistant to fluoroquinolones, showing higher MIC values and survival rates. However, the D*ssrA* strain showed higher accumulation of ethidium bromide and levofloxacin than the wild type. Production of ROS and chromosome fragmentation associated to moxifloxacin and levofloxacin were reduced. Moreover, such protective effect relay mainly on inhibition of protein synthesis, since similar protection against levofloxacin was observed under previous treatment with antibiotics inhibiting translation. Therefore tmRNA has a protective effect under several types of stresses. However, upon FQ treatment, tmRNA is paradoxically harmful. These findings should be taking in consideration in the development of new antibiotics inhibiting trans-translation. In addition, although not currently used in clinical practice, our results suggest that the combined use of FQs and antibiotics inhibiting protein synthesis might not be recommended.

PTC1, A SERIN/THREONIN PHOSPHATASE REGULATING MAPKS PATHWAYS AND MORPHOGENETIC PROCESSES IN SACCHAROMYCES CEREVISIAE THROUGH ITS ADAPTOR PROTEIN NBP2

G. González-Rubio[1], A. Sacristán-Reviriego[1], L. Palacios[1], H. Martín[1], M. Molina[1]
[1]Complutense University of Madrid. School of Pharmacy, Department of Microbiology II, Madrid, Spain

Backgrounds

The type 2C protein phosphatase Ptc1 is the closest yeast homolog of human Wip1, which has been reported to be involved in the regulation of oncogenic processes. It has been shown that Ptc1, together with its protein adaptor Nbp2, has an essential role in the negative regulation of both the Hog1-mediated High Osmolarity (HOG) and the Slt2-mediated cell wall integrity (CWI) MAPK pathways. Loss of Ptc1 leads to numerous phenotypic defects including cell wall stress sensitivity and the delay of organelles inheritance in *S. cerevisiae* cells. Moreover, *ptc1* mutants displayed a multibudded phenotype when grown at 37ºC, Nevertheless, many of the mechanisms underlying these phenotypic defects remain unknown.

Objectives

The goal of this study was to gain insight into the morphogenetic defects that have been observed in Ptc1-deficient cells as well as to know if the absence of its protein adaptor, Nbp2, leads to the same effects.

Methods

In this work we characterized different mutants of *S. cerevisiae* employing the next techniques: gene expression studies, Western blotting analyses and fluorescence and Differential Interference Contrast (DIC) Microscopy.

Conclusions

Lack of Ptc1 protein adaptor Nbp2 results in the hyperactivation of HOG and CWI pathways, and the same multibudding phenotype at 37ºC as the *ptc1*Δ mutant. In both mutants, every bud contains a nucleus, but a still assembled septin ring, in contrast to that observed in the mother cell side. This phenomenon provides an excellent experimental setting to gain insight into the molecular mechanism connecting cell separation and septin disassembly.

MOLECULAR TIPYNG OF CLOSTRIDIUM DIFFICILE ISOLATES FROM PATIENTS IN THREE HOSPITALS OF HIGH COMPLEXITY OF MEDELLIN, COLOMBIA

C.L. Salazar[1], C. Reyes[1], S. Atehortua[2], P. Sierra[3], M. Correa[1], W.N. Fawley[4], A. Gonzalez[1]
[1]Universidad de Antioquia, Microbiology School, Medellin, Colombia
[2]Hospital Universitario San Vicente Fundación, Microbiology, Medellin, Colombia
[3]Clínica León XIII, IPS UNiversitaria, Medellin, Colombia
[4]Leeds Teaching Hospitals NHS Trust, Departament of Microbiology, Leeds, United Kingdom

Backgrounds

Hypervirulent genotypes of *Clostridium difficile* have frequently been associated to hospital outbreaks of diarrhea in Europe and North America during the last two decades. However, in Colombia, genotypes of this bacterium have not yet been described.

Objectives

To molecularly characterize clinical isolates of *C. difficile* obtained from patients with suspicion of *C. difficile* associated disease (CDAD).

Methods

Stool samples were analyzed to determine the presence of A/B toxins using EIA. *C. difficile* was isolated by culture. DNA was extracted and PCR applied to detect *tcdA*, *tcdB* and binary toxin (CDTa/CDTb) genes. PCR-ribotyping was performed using a sequencer based on capillary electrophoresis (ABI-3100).

Conclusions

A total of 913 stool samples collected during 2013-2014 were evaluated. A total of 143 isolates of *C. difficile* were recovered from culture. The frequency of toxins A/B was 9.3% (85/913).After amplification, 100 (70%) isolates were *tcdA*+/*tcdB*+, 11 (7.8%) *tcdA*-/*tcdB*+ and 32 (22.4%) *tcdA*-/*tcdB*-. The most frequent ribotype was 591 (20%), followed by 106 (9%) and 002 (7.9%); only one isolate corresponded to ribotype 027 (considered hypervirulent); four ribotype 078 isolates and four new ribotypes (794,795, 804,805) were identified.

A low frequency of CDAD was detected in comparison to other countries. The *tcdA*+/*tcdB*+-CDTa/CDTb+ gene profile was correlated with epidemic ribotypes. There was a low frequency of ribotype 027 which is common in other countries. Interestingly, a high frequency of ribotype 591,of low circulation in Europe, was observed, followed by ribotypes 106 and 002, all of them considered epidemic in Europe dufingn the past decade.

QUORUM SENSING BASED ON INTERSPECIES COMMUNICATION AMONG E. COLI SE15 AND OTHER STRAINS OF BIOFLM IN THE PATIENTS INDWELLING URINARY CATHETERS: GENOME EDITING OF CRISPR-CAS9

S.R. Kang[1], J. Kim[2], J.K. Hur[3], S.S. Lee[1]
[1]Kyonggi University, Department of Bio-engineering, Suwon, Republic of Korea
[2]Kyonggi University, Department of Life Science, Suwon, Republic of Korea
[3]Korea University, Biomedical Research Center- Anam Hospital, Seoul, Republic of Korea

Backgrounds

The predominant strains *E. coli*, *P. aeruginosa* and *S. aureus* are the most common pathogens in catheter associated urinary tract infections (CA UTIs). The CA UTIs were mainly occurred from biofilm formation by Quorum Sensing (QS) system of predominant strains. Moreover, AI-2, one of QS signal molecules, plays an important role in enabling interspecies communication. Although many bacteria species have been studied to use the AI-2 for interspecies communication to regulate various behaviors, such as biofilm formation, the molecular mechanisms of AI-2 internalization and signal transduction remain poorly understood.

Objectives

This study is to elucidate interaction between *E. coli* SE15 and other dominant strains, which frequently form biofilm on the catheter surface, via co-culture.

Methods

We then manipulated the Δ*rbsB* and Δ*luxS* in *E. coli* SE15 by using clustered regularly interspaced short palindromic repeats (CRISPR)-Cas9 system. And we observed biofilm formation assay in Δ*rbsB* and Δ*luxS* mutants of *E. coli* SE15. Moreover, Δ*rbsB* and Δ*luxS* mutants of *E. coli* SE15 were co-cultured with predominant strains *P. aeruginosa* and *S. aureus* in response to the wild type *E. coli* and analyzed AI-related genes expression by qRT-PCR.

Conclusions

Autoinducer synthesis gene *luxS* gene of *E. coli* SE15 has been affected by other dominant strains because the gene expression was more increased and rapidly initiated in co-culture than single culture. Based on these data, we concluded that *luxS* and *rbsB* affected on interaction of other predominant bacteria. Such interactions among predominant bacteria were helpful to understand their symbiosis or competition.

Physiology / Biochemistry / Molecular Microbiology

METAGENOMIC CHARACTERIZATION OF THE SOS TRANSCRIPTIONAL RESPONSE IN THE PATESCIBACTERIA SUPERPHYLUM

M. Sánchez-Osuna[1], *J. Barbé*[1], *I. Erill*[2]
[1]*Universitat Autònoma de Barcelona, Departament de Genètica i de Microbiologia, Bellaterra, Spain*
[2]*University of Maryland- Baltimore County, Department of Biological Sciences, Baltimore, USA*

Backgrounds

Metagenomics and single-cell genomics provide unprecedented insights into the genetic composition of microbial communities inhabiting natural environments. Recent surveys have uncovered a major radiation of candidate phyla in the Bacteria domain, represented predominantly by the proposed Patescibacteria superphylum. Patescibacteria have small genomes (<1Mbp) and a limited genetic repertoire that suggest a symbiotic or parasitic lifestyle.

Objectives

In order to shed light on the lifestyle and evolution of these uncultivated organisms we combine *in silico* and *in vitro* approaches to define LexA-binding motif of the Patescibacteria, and we leverage metagenomics data to characterize the SOS regulatory network in this superphylum.

Methods

Orthologs for Patescibacteria LexA were identified through reciprocal BLASTP and their upstream sequences were submitted to MEME to perform motif discovery. Having identified the LexA-binding motif, we searched for instances of it in Patescibacteria whole genome shotgun assemblies and comparative genomics analyses were performed in order to reconstruct the putative SOS regulon. EMSA assays validated and defined the computationally predicted LexA-binding sites.

Conclusions

Our work shows that the Patescibacteria LexA controls a small core set of SOS genes by binding to a novel LexA-binding motif with an unusual direct-repeat structure, complemented by varying degrees of LexA regulation of other SOS functions. These results suggest that the presence of a functional SOS response hints an intermediate step in the process of bacterial genomic reduction resulting from intimate association with a host species or a structured community, and may thus provide insights into the lifestyle of uncultivated bacteria.

THE MOLECULAR BASIS OF THE PLANT GROWTH PROMOTING CAPACITY OF STREPTOMYCES SP.

S. Goormachtig[1], S. Langendries[2], A. Lampens[2], T. Viaene[2]
[1]Ghent University - VIB, Plant Systems Biology, Ghent, Belgium
[2]Ghent University - VIB- Plant Systems Biology- Ghent- Belgium., Plant Systems Biology, Ghent, Belgium

Backgrounds

Streptomyces are described as powerful plant growth promoting rhizobacteria which contribute significantly to the composition of the root microbiome in the model plant *A. thaliana* as well as important crops such as rice and maize. Although Streptomyces strains have been shown to produce siderophores, volatile organic compounds and plant hormones like auxin and cytokinin and elicit induced systemic resistance, more investigations are required to understand the mechanisms by which these PGPR strains are perceived by the plants and evoke growth promotion and/or plant protection.

Objectives

We have identified several Streptomyces strains that promote growth of Arabidopsis as well as important crops such as wheat and maize. We aim at understanding the plant signaling networks on which the bacteria impinge to provoke the growth promoting traits.

Methods

We have analyzed the phenotypic effects provoked by different streptomyces sp., through the analysis of Arabidopsis mutants and marker lines.

Conclusions

Our study revealed two different mechanisms by which Streptomyces strains promote growth in Arabidopsis, one by impinging on the jasmonate response while a second one impinging on the cytokinin response.

Physiology / Biochemistry / Molecular Microbiology - Part II

A NEW MODEL FOR BACTERIAL PERSISTENCE TO OFLOXACIN

F. Goormaghtigh[1], *L. Van Melderen*[1]
[1]*Free University of Brussels ULB, Département de Biologie Moléculaire, Gosselies, Belgium*

Backgrounds

Together with the current antibiotic resistance crisis, bacterial persistence appears to play an increasingly important role in the frequent failure of antibiotic treatments. Persister cells are rare bacteria that transiently become drug tolerant, allowing them to survive lethal concentrations of antibiotics. The specific physiology of persisters has been shown to rely on several global molecular mechanisms, such as the SOS response, the stringent response and/or dormancy. As a result, development of efficient anti-persister treatments remains elusive.

Objectives

We aim at a better understanding of the specific molecular mechanisms leading to persistence to ofloxacin in *E. coli* and allowing persisters to elude the lethal effect of ofloxacin, a question which has mostly been overlooked previously.

Methods

A mathematical model of the ofloxacin killing curve was developed and metabolic parameters were measured in the culture. Persisters were analysed at the single-cell level, in a microfluidic device. Finally, populational and single-cell analyses were combined to develop a working model for persistence to ofloxacin.

Conclusions

We showed that on the contrary to most antibiotics, ofloxacin treatment does not yield a biphasic killing curve, but a complex killing curve composed of four different phases. We confirmed the major role of the SOS response both at the population and at the single-cell level. Interestingly, using a microfluidic device, we observed that the SOS response only allows cells to recover more efficiently after ofloxacin removal. Finally, we showed that addition of a chemical inhibitor of the SOS response appears to be a promising strategy to eradicate ofloxacin persisters.

FEMS7-1630
Physiology / Biochemistry / Molecular Microbiology - Part II

METABOLIC PARAMETERS INFLUENCING PERSISTENCE

F. Goormaghtigh[1], *L. Van Melderen*[1]
[1]*Free University of Brussels ULB, Département de Biologie Moléculaire, Gosselies, Belgium*

Backgrounds

Together with the current antibiotic resistance crisis, bacterial persistence appears to play an increasingly important role in the frequent failure of antibiotic treatments. Persister cells are rare bacteria that transiently become drug tolerant, allowing them to survive lethal concentrations of antibiotics. Although interest in the persistence phenomenon seriously increased in the past decade, persister cells physiology remains elusive up to now.

Objectives

We aim at characterizing persister cells metabolism and establishing quantitative relationships between persistence and metabolic activities such as DNA replication, growth rate, induction of efflux pumps and induction of stress responses.

Methods

A mathematical model was used to describe persisters time-kill curves. A combination of genetic, chemical and microscopic analyses was performed to characterize the physiological nature of *E. coli* persisters to ampicillin and ofloxacin.

Conclusions

We first showed that while ampicillin treatment yields a typical biphasic killing curve, ofloxacin treatment results in a very complex killing curve composed of four different phases. One of these phases is a regrowth phase, which is likely to rely on an increased plating efficiency rather than bacterial divisions in the presence of the antibiotic. We then confirmed the direct link between persistence and the growth rate using chemostat experiments. Further analyses revealed this link to be correlated with the ppGpp production observed at early treatment times and independent of DNA synthesis rate.

Physiology / Biochemistry / Molecular Microbiology - Part II

OVEREXPRESSION OF THE PLEIOTROPIC REGULATOR CODY DECREASES SPORULATION, ATTACHMENT AND PELLICLE FORMATION IN BACILLUS ANTHRACIS

M. Gopalani[1], *R. Bhatnagar*[1]
[1]*Jawaharlal Nehru University, School of Biotechnology, New Delhi, India*

Backgrounds

CodY is a pleiotropic transcriptional regulator conserved in many low G+C gram-positive bacteria, where it actuates adaptation in response to the nutritional and energetic status of the cell. CodY senses the intracellular GTP and Branched-chain amino acids (BCAAs) levels and brings about appropriate changes in the transcriptome of the cell. In *Bacillus anthracis,* the top rated bioterrorism agent, CodY regulates around 500 genes and is required for the attainment of full virulence by the pathogen. However, its implication in the physiology of the pathogen like sporulation, biofilm formation etc is yet unexplored.

Objectives

Our study focuses on the regulation of CodY itself in different growth phases and nutrient deprived conditions in *B. anthracis*. We also determined its connotation in the physiology of *B. anthracis.*

Methods

qRT-PCR, immunoblotting, electroporation, titer estimation.

Conclusions

The cellular levels of CodY during the exponential to stationary phase transition and under different nutrient limiting conditions remained constant in *B. anthracis*. Immunoblotting studies revealed the presence of CodY in the whole spore lysate and secretome of *B. anthracis*. Further, CodY was overexpressed in *B. anthracis* Sterne strain by electroporation which led to a 100-fold decrease in the sporulation titer and a 2.5-fold decrease in the *in vitro* attachment ability of the bacteria. The pellicle formation by overexpressed strain was substantially low as compared to wild type bacilli. The overexpressed strain exhibited chaining phenotype during growth in liquid media and pellicle. Thus, this study provides insights into the role of this regulator in sporulation, pellicle and biofilm formation of *B. anthracis.*

[4]*Institute of Biochemistry and Physiology of Plants and Microorganisms - RAS, Immunochemistry, Saratov, Russia*
[5]*Zelinsky Institute of Organic Chemistry - RAS, Structural Research, Moscow, Russia*
[6]*Kazan Federal University, Botany and Plant Physiology, Kazan, Russia*

Backgrounds

Bacterial exopolysaccharides (EPS) are structurally and functionally diverse polymers that perform many biological functions and confer multiple properties to microbial population, in particular providing the formation of biofilms. *Pectobacterium atrosepticum* (*Pba*) – a causative agent of plant rots all over the world, was demonstrated to form biofilm-like structures – bacterial emboli *in planta* that is necessary for effective systemic plant colonization. Herewith, neither the role of *Pba* EPS was demonstrated in the formation of bacterial emboli nor these polymers were yet described for pectobacteria.

Objectives

In the present study, we attempted to identify and characterize the molecular structure of *Pba* EPS and to assess their role in plant colonization and formation of bacterial emboli in particular.

Methods

Pba EPS were characterized by various methods of chromatography, NMR spectroscopy and dynamic light scattering. For immunodetection of *Pba* EPS, specific antibodies were obtained. Various models were applied to analyze contribution of *Pba* EPS to plant colonization.

Conclusions

Pba was shown to synthesize polydisperse EPS (MW 100-800 kDa) with a backbone consisted of [→3)-α-D-Gal*p*-(1→2)-α-D-Man*p*-(1→4)-α-L-Rha*p*-(1→] and the side chains of β-D-erwiniose-(1→3)-α-D-Gal*p*-(1→ attached to mannopyranosyl residue at O-3 position. The synthesis of EPS was increased during stress conditions and especially during host plant colonization. Immunolabeling showed that *Pba* EPS were included in the extracellular matrix of bacterial emboli. Characterization of rheological and phytoimmune properties of these polymers pointed to their significant role in plant-pectobacteria interactions. This study was supported by RSF (15-14-10022) and a grant MK-2191.2017.4.

HORIZONTAL TRANSMISSION FACTORS SPREADING ANTIBIOTIC RESISTANCE

F. Graf[1,2,3], H. Alalam[1,2,3], M. Zackrisson[1], P. Sunnerhagen[1,2], J. Warringer[1,2], A. Farewell[1,2]
[1]University of Gothenburg, Department of Chemistry and Molecular Biology, Gothenburg, Sweden
[2]University of Gothenburg, Centre for Antibiotic Resistance Research CARe, Gothenburg, Sweden
[3´], coauthor, contributed equally, Sweden

Backgrounds

Horizontal gene transfer accelerates the spread of antibiotic resistance genes among bacteria within and between infected hosts, and likely also in the environment. Conjugation of plasmids is thought to be the predominant form of spreading (multi-)drug resistance through horizontal gene transfer. The chromosomal factors controlling the rate of antibiotics resistance transmission by conjugation, however, remain largely unknown.

Objectives

We aim to identify those genetic host factors with the ultimate aim to develop drugs that inhibit conjugation and thereby the spread of antibiotic resistance genes to use in combination therapy with antibiotics.

Methods

We developed a massively parallelized system to accurately monitor conjugation of resistance plasmids in real time in *E. coli*. We screened the complete collection of *E. coli* deletion strains using the single gene knock-out strains as donors of a F'-plasmid carrying a tetracycline resistance gene and measured its transfer rate into recipient cells. We identify as many as 90 chromosomal genes required for fast transmission of antibiotics resistance by conjugation.

Conclusions

These chromosomal factors are prime targets for novel drug development initiatives aiming to delay conjugation and the spread of antibiotic resistance genes in combination therapy. We are currently repeating the screen with clinical and environmental resistance plasmids of different incompatibility groups to find common potential targets for therapeutic exploitation.

MODULATION AND ANALYSIS OF THE ACTIVITY OF RECOMBINANT STAPHYLOCOCCUS SAPROPHYTICUS GTC1 LIPOLYTIC ENZYMES

A. Gricajeva[1], *L. Kalėdienė*[1]
[1]*Vilnius University, Life Sciences Center- Institute of Biosciences, Vilnius, Lithuania*

Backgrounds

Lipases of *Staphylococcus saprophyticus* are implicated as possible virulence determinants in pathogenesis during infections and, nevertheless, they can also be considered as potential industrial biocatalysts. Only fragmented information is known about *S. saprophyticus* as a biotechnological tool. In the present work we found that *S. saprophyticus* GTC1 exhibits high lipolytic activity and depending on environmental *in vitro* conditions secretes up to six lipolytic enzymes (Lip).

Objectives

- *In silico* analysis of *S. saprophyticus* GTC1 *Lip* genes and achievement of their recombinant forms;
- Increase of activity of the Lip enzymes;
- Determination of biochemical properties of achieved derivatives comparing with free forms.

Methods

Lip genes were cloned and expressed in *E. coli* DH5α / BL21 (DE3), respectively, using pET26(+)b. Positive targets were purified by immobilized metal affinity chromatography. Modulation of the recombinant Lip enzymes activity was achieved by non-conventional hydrophobic adsorption on octyl-Sepharose beads, chemical modulation and bioimprinting with surfactants techniques. Biochemical properties of the derivatives as well as V_{max}, K_M, k_{cat} and k_{cat}/K_M were determined using spectrophotometric assay with *p*-NP substrates. Regioselectivity (with 1,3-dipalmitoyl-2-oleoylglycerol substrate), hydrolysis and transesterification of natural fats were determined using thin layer chromatography.

Conclusions

Immobilization and bioimprinting of lipolytic enzymes resulted in the hyperactivation of the target proteins due to maintenance of their open lid forms. Activity of such enzymes became no longer dependent on the medium conditions. Modulation experiments resulted not only in hyperactivation but also change of enzymes selectivity. Such enzymes can be proposed as highly valuable catalysts with rationally designed properties. Their utilization can greatly boost many biotechnology-based industries.

Unité d'Immunologie- Microbiologie Environnementale et Cancérogenèse, Bizerte, Tunisia
[3]MICALIS- UMR 1319- INRA AgroParisTech,
Equipe Bioadhésion- Biofilm et Hygiène des Matériaux B2HM, Massy, France

Backgrounds

Due to their very low water solubility, hydrocarbons and lipids are weakly bioavailable. Despite this obstacle, many microbes are able to assimilate them by means of specialized strategies such as biofilm formation at the hydrocarbon/lipid-water interface so called oleolytic biofilms.

Objectives

In order to determine whether the extracellular polymeric substances (EPS) constituting the oleolytic biofilm matrix are involved in hydrocarbons/lipids assimilation, we undertook a characterization of the EPS of a biofilm of *Marinobacter hydrocarbonoclasticus* developing at the alkane water interface.

Methods

Matrix proteins were identified by proteomic analysis and their participation in oleolytic biofilm determined by proteolysis. The role of secreted proteins was assessed with a type-2 secretion system (T2SS) mutant.

Conclusions

The extracted matrix was largely composed of proteins typically cytoplasmic such as translation factors and chaperones, and a lesser amount of proteins of unknown function that are predicted extra-cytoplasmic. Matrix proteins were found mandatory for the development of biofilms on alkanes, lipids and polystyrene. Exo-proteins secreted through the T2SS were shown to be essential for the formation of oleolytic biofilms on both alkanes and triglycerides. The T2SS effector involved in biofilm formation on *n*-hexadecane is likely involved in the mass transfer, capture or transport of alkanes. We propose that *M. hydrocarbonoclasticus* uses cytoplasmic proteins possibly released by a regulated auto-lysis mechanism to form a proteinaceous matrix and dedicated proteins secreted through the T2SS to act specifically in the assimilation pathways of hydrophobic substrates.

PHYSIOLOGICAL PORTRAIT OF PECTOBACTERIUM ATROSEPTICUM UNDER IN PLANTA CONDITIONS IN TERMS OF TRANSCRIPTOME PROFILING

R. Gubaev[1], V. Gorshkov[1,2], C. Nuriakhmetova[3], S. Tatarkin[1], N. Gogoleva[1], Y. Gogolev[1,2]
[1]Kazan Institute of Biochemistry and Biophysics - RAS, Molecular Biology, Kazan, Russia
[2]Kazan Federal University, Biochemistry and Biotechnology, Kazan, Russia
[3]Kazan Federal University, Genetics, Kazan, Russia

Backgrounds

Necrotrophic pectobacteria cause severe parenchymatous rots in plants. Expression of symptoms is preceded by latent infection when pathogen predominantly inhabits xylem vessels, prepares host for further colonization, and behaves as biotroph. Herewith, the pathogen reprograms its physiology from “outside” to “inside the host” status. However, general picture of such “switch” remains to be developed.

Objectives

We aimed to get better insight into physiological portrait of pectobacteria during the initial and advanced stages of plant colonization.

Methods

We took advantage of RNA-Seq approach, high efficient for a global view on cell physiology, but to out knowledge not previously applied for any of plant pathogenic bacteria under *in planta* conditions. Transcriptomes of pectobacteria *in planta* at initial and advanced stages of plant colonization were compared with those of different model cultures *in vitro*. In order to create demonstrative picture of cell physiology from the lists of the revealed differentially expressed genes (DEGs), original multiple functional classification of DEGs was performed using KEGG and BioCyc sources as well as various specialized databases (e.g. CAZy, REBASE, TAD, etc.).

Conclusions

Under *in planta* vs. *in vitro* conditions several alterations in general metabolism (e.g. switching from aerobic metabolism to fermentation, amino acid and carbon metabolism, etc.) were revealed. Many pathways related to virulence and adaptation were up-regulated *in planta*. Differential features of pectobacteria during different stages of infection (e.g. phytotoxin coronatine metabolism and type III secretion system, etc.) were detected. Further details on pectobacteria physiology *in planta* will be discussed during presentation. This study was supported by RSF (15-14-10022).

A NEW COLISTIN RESISTANCE GENE HOMOLOGOUS FOUND IN WASTEWATER METAGENOME

A. Gundogdu[1,2], *M.G. Onal*[2,3], *A. Ulu-Kilic*[4], *U. Nalbantoglu*[2,5]
[1]*Erciyes University, Microbiology and Clinical Microbiology, Kayseri, Turkey*
[2]*Erciyes University, Genome and Stem Cell Center GENKOK, Kayseri, Turkey*
[3]*Erciyes University, Medical Genetics, Kayseri, Turkey*
[4]*Erciyes University, Clinical Microbiology and Infectious Diseases, Kayseri, Turkey*
[5]*Erciyes University, Computer Engineering, Kayseri, Turkey*

Backgrounds

Colistin, a drug of last resort, has been used in order to cope with multi-drug resistant pathogens. A recently defined plasmid mediated colistin resistance gene (*mcr-1*) raised attention, since the mobilty of this gene means rapid dissemination of colistin resistance. Despite the increasing colistin resistance, *mcr-1* or recently discovered variants have not been detected in Turkey. This brings the hypothesis that another mcr-variant might be present in the geography.

Objectives

This study aimed to search for a mcr-like gene in the wastewater microbiome, which is considered to be the hot-spots of antibiotic resistance genes, using next-generation sequencing technologies.

Methods

Three weekly samples from wastewaters (STP and hospital) were collected. Total DNA isolation was performed using commercial kits, and the sequencing was done using Illumina-NextSeq500 technology. Sequencing reads similar to *mcr-1* and *mcr-2* genes were searched within the metagenome using Blastx. The detected reads were subject to fragment assembly using Cap3-assembler to obtain longer fragments. Primer sets were designed on the assembled contigs to employ genome walk for further sequencing of the uncovered gene regions. Amplified regions were sequenced using Sanger sequencing and scaffolded with the previous assembly.

Conclusions

A new mcr-homologous gene was sequenced from wastewater samples. Since no mcr genes responsible for colistin resistance in Turkey was detected before, this newly discovered gene is an interesting candidate for the dissemination agent of the colistin resistance in the region. Although this gene resembles its recently defined homologs, functional validation should be conducted to reveal if this variant is actually responsible for colistin resistance.

TAIL-ANCHORED INNER MEMBRANE PROTEIN ELAB INCREASES STRESS RESISTANCE WHILE REDUCING PERSISTENCE IN ESCHERICHIA COLI

Y. Guo[1], X. Liu[1], B. Li[1], J. Yao[1], T.K. Wood[2], X. Wang[1]
[1]Chinese Academy of Sciences- South China Sea Institute of Oceanology, LMB, Guangzhou-, China
[2]Pennsylvania State University, Department of Chemical Engineering, University Park, USA

Backgrounds

Host-associated bacteria, such as *Escherichia coli*, often encounter various host-related stresses such as nutritional deprivation, oxidative stress and temperature shifts. There is growing interest in searching for small endogenous proteins that mediate stress responses.Here, we characterized a small C-tail anchored inner membrane protein ElaB in *E. coli*. ElaB belongs to a class of tail-anchored inner membrane proteins with a C-terminal transmembrane domain but lacking an N-terminal signal sequence for membrane targeting. Proteins from this family have been shown to play vital roles such as membrane traffic and apoptosis in eukaryotes.

Objectives

To uncover the roles of this family protein in prokaryotes.

Methods

We found that transcription of *elaB* is induced in the stationary phase, and sigma factor RpoS regulates *elaB* transcription by binding to the promoter of *elaB*. Moreover, ElaB protects cells against oxidative stress and heat shock stress. However, unlike membrane peptide toxins TisB and GhoT, ElaB does not lead to cell death, and deletion of *elaB* greatly increases persister cell formation. We also demonstrate that ElaB protects the integrity of membrane and inhibits the flux of H_2O_2 into cells. The *elaB* mutant strain had wrinkled thinner membrane and more susceptible to oxidative stress. Using granulocytopenic mouse model, survival was decreased in the Δ*elaB* strain, suggesting that ElaB might participate in pathogen-host interaction.

Conclusions

We demonstrate that targeting C-tail anchored inner membrane proteins for treating bacterial infections might be problematic, since, although disruption of membrane proteins can reduce stress resistance, it can also lead to deleterious effects such as increased persistence.

Physiology / Biochemistry / Molecular Microbiology - Part II

FUNCTIONAL CHARACTERIZATION OF BAS2108-2109 TWO COMPONENT SYSTEM OF B. ANTHRACIS INVOLVED IN REGULATION OF PROTEASES

V. Gupta[1], P. Gulati[2], R.B. Bhatnagar[1]
[1]jawaharlal nehru university, Biotechnology, New Delhi, India
[2]Maharshi Dayanand University, Microbiology, Rohtak- Haryana, India

Backgrounds

Bacillus anthracis is the causative agent of anthrax, a bioweapon. This bacteria have a complex secretome which includes secreted proteases along with other virulence factors. Although protease sevretion varies under different conditions, there are no reports about regulatory mechanisms governing protease expression. Pathogens commonly use two component system (TCS) for environment sensing and regulation of virulence factors. The genome of B. anthracis encodes 41 such TCS pairs, however, the role of any TCS pair in regulation of its proteases is not known.

Objectives

In silico screening for a putative TCS regulating protease expression in *B. anthracis.* Biochemical characterization of TCS and to study its role in virulence.

Methods

TCS screening was performed using homology search. The identified TCS was biochemically characterized. Their expression was analyzed using qRT-PCR. DNA-protein interaction was analyzed by electrophoretic mobility shift assay. Multiple sequence alignment was done to predict conserved residues and validated by mutational studies.

Conclusions

The present study have identified BAS2108-2109 as a putative homolog of protease regulator, DegUS of *B. subtilis*. It is a functionally active TCS, where BAS2108, a histidine kinase, autophosphorylates and transfers phosphate group to BAS2109, the response regulator. The expression of *BAS2109* was increased under simulation of host milieu. BAS2109 was established as the transcriptional regulator for different genes of *B. anthracis*, particularly proteases. Lys167, Thr179 and Thr182 residues were significant for the DNA binding activity of BAS2109. Therefore, this report establishes BAS2108-2109 as a canonical TCS pair which is involved in the regulation of expression of proteases in *B. anthracis.*

ROLE OF CSRA GLOBAL REGULATOR IN UROPATHOGENIC E. COLI BIOFILMS STRUCTURE

T. Hallaert[1], E. Seyll[1], S. Zedek[1], D. Monteyne[1], P.M. David[1], L. Van Melderen[1]
[1]Université Libre de Bruxelles - IRMW, Faculté des Sciences, Brussels, Belgium

Backgrounds

The CsrA protein is a global post-transcriptional regulator controlling carbon fluxes and social behaviors in bacteria. Independent studies have shown that CsrA regulates different processes involved in biofilm formation such as flagella synthesis, exopolysaccharides production or c-di-GMP homeostasis.

Objectives

Internal organization of K-12 *Escherichia coli* biofilms had recently been described at cellular resolution using macrocolony model and scanning electron microscopy (SEM) by the group of R. Hengge. Our objective is to decipher the role of CsrA into biofilm organization by characterizing biofilms formed by a mutant deleted for *csrA* in *E. coli* CFT073.

Methods

Using genetics and biochemical approaches and scanning electron microscopy, we analyzed at macro- and microscopic level a collection of mutants deleted for *csrA* and other genes encoding proteins involved in production of extracellular structures such as curli, N-acetylglucosamine (PGA), flagella or participating to c-di-GMP homeostasis.

Conclusions

SEM observations of wild-type macrocolonies revealed very organized structures such as vertical pillars and differentiated horizontal layers. In a mutant deleted for *csrA*, macrocolony organization is lost. We also showed that deletion of *csrA* abolishes negative regulation of the YcdT c-di-GMP cyclase, leading to an increase of intracellular c-di-GMP concentration. In turn, both cellulose and PGA are highly overproduced. We propose that this abundant extracellular matrix is produced anarchically thereby hindering macrocolony internal organization.

METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS ISOLATED IN THE COMMUNITY, CARRIERS OF THE MECC GENE.

A. Hamdan-Partida[1], B. Sánchez-Mier[1], S. González- García[1], J. Bustos-Martínez[1]
[1]Universidad Autónoma Metropolitana Xochimilco, Atención a la Salud, Mexico City, Mexico

Backgrounds

Staphylococcus aureus is a Gram-positive bacterium that has the ability to express a wide variety of virulence factors, through which it produces various diseases. In particular, methicillin-resistant *S. aureus* (MRSA) strains, which present the *mecA* gene responsible for resistance to methicillin, since it encode a penicillin binding protein 2a (PBP2a), that has low affinity by β-lactam antibiotics. Recently, a new gene for resistance to methicillin, *mecC*, was discovered, which has not been reported in strains isolated in Mexico.

Objectives

The objective of this work was to know if MRSA strains isolated in the population of Mexico City, carry the *mecC* gene .

Methods

In the present study, pharyngeal and nasal exudates of 1800 people, aged 1 to 80 years old, were performed in day care centers, schools, nursing homes and factories in Mexico City. Isolation and identification of staphylococci were performed by established microbiological methods. Sensitivity to methicillin was performed using the MIC-oxacillin test. Identification of *mecA* and *mecC* genes were performed by the PCR technique.

Conclusions

1135 *S. aureus* strains were isolated, and only 135 strains were MRSA. Most of the MRSA strains were carries of the *mecA* gene and only 7 srains MRSA were carriers of the *mecC* gene.

This is of great importance since it is the first report in Mexico of MRSA strains carrying the gene *mecC*.

ANTIMICROBIAL EFFECT OF SILVER NANOPARTICLES AGAINST VIBRIO FLUVIALS

A. Hamdan-Partida[1], J. Meneses-Márquez[1], J. Bustos-Martínez[1], C. Monroy-Dosta[2]
[1]Universidad Autónoma Metropolitana Xochimilco, Atención a la Salud, Mexico City, Mexico
[2]Universidad Autónoma Metropolitana Xochimilco, El Hombre y su Ambiente, Mexico City, Mexico

Backgrounds

Nanotechnology is a field of research in nanoparticles due to their properties, some of these nanoparticles have an antimicrobial effect, in particular silver nanoparticles. The use of silver as an antimicrobial has been since ancient times. In aquaculture, ornamental fishes have expressed bacterial diseases, some of these bacteria have resistance to different types of antibiotics. The aquaculture industry are looking for new alternatives for the control of these bacteria.

Objectives

The aim of this work was determine the antimicrobial effect of silver nanoparticles (AgNPs) against *Vibrio fluvialis*. Characterize the nanoparticles, and determine the minimum inhibitory concentration (MIC).

Methods

The AgNPs were synthesized at different concentrations (10, 100, 250, and 500 ppm) using sodium citrate as a reducing agent. To determine the minimum inhibitory concentration (MIC), the bacteria *V. fluvialis* were grown in Muller Hilton broth for 24 h to obtain a concentration of 0.5 McFarland, and were mixed with serial dilutions of different concentrations of AgNPs.

Conclusions

The result showed that the MIC of the AgNPs to *V. fluvialis* was between 7.81 and 15.62 ppm. We concluded that our AgNPs showed antimicrobial activity against *V. fluvialis*. We recommended continue studying the effect of AgNPs in other pathogenic microorganisms which affect the health of the ornamental fishes.

DETECTION OF B -LACTAMASE ENZYMES USING CONVENTIONAL AND MOLECULAR METHODS

H. HAMED[1], E. el sawy[1], A. gaber[1]
[1]urology and nephrology center, microbiology, mansoura, Egypt

Backgrounds

Resistance to antimicrobials is a serious clinical problem, with more than 70% of the bacteria that cause hospital-acquired infections resistant to at least one of the drugs that are currently used for treatment of infections, β-Lactam antibiotics remain the most commonly used antibacterial agents.

Objectives

Detection methods for β-lactamases are nitrocefin test, Phenol red method, Iodometric method, and Double-Disc Test and PCR.

Methods

97 beta-lactam resistant bacterial strains 50 *E.coli* and 47 as *Klebsiella pneumoniae* were studied. The Combined disc method, Etest ESBL strips, Phenol red method, Iodometric method, and nitrocefin tests were performed. DNA extraction of the resistant strains was performed, followed by polymerase chain reaction test(PCR) for detection of TEM and SHV β-lactamase genes.

80 strains gave positive results for Etest ESBL strips, combined disc method, Phenol red test, Iodometric test, and nitrocefin tests, while 17 strains gave negative results. 8 strains(4 *E.coli* & 4 *Klebsiella pneumoniae*) were positive for TEM gene and SHV gene; 27 strains(14 *E.coli* & 13 *Klebsiella pneumoniae*) were positive for TEM gene only; 28(15 *E.coli* & 13 *Klebsiella pneumoniae*) strains were positive for SHV gene only; while 34 strains(17 *E.coli* & 17 *Klebsiella pneumoniae*) were negative for the two genes.

Conclusions

The development and spread of extended-spectrum β-lactamases(ESBLs) have most likely been caused by the overuse of expanded spectrum cephalosporins in the hospital setting. Numerous methods have been proposed for the detection of ESBLs in clinical isolates. Regardless of the method used for detection, none of the methods that rely on phenotypic expression of the β-lactamase will detect every ESBL-producing isolate. Nevertheless, increased awareness of the ESBL problem among clinical microbiology laboratory and infection control personnel will help in the interpretation of these tests. Strains expressing ESBLs will present a host of challenges for clinical microbiologists and clinicians alike as we head into the 21st century.

Physiology / Biochemistry / Molecular Microbiology - Part II

DETERMINATION OF TRANSFER ORIGIN OF INCA/C PLASMIDS

A. Hegyi[1], M. Szabó[1], F. Olasz[1], J. Kiss[1]
[1]NARIC Agricultural Biotechnology Institute, Genetics, Gödöllő, Hungary

Backgrounds

The plasmids of incompatibility group A/C are often responsible for multi-drug resistance (MDR) of enteric bacteria. IncA/C plasmids spread efficiently due to their broad host-range and effective conjugative transfer system, thus they are major factors in dissemination of MDR phenotype in pathogenic bacteria. Although more than 140 family members have been identified, the biology of their spread received more attention only recently.

Objectives

Our goal was to identify and analyse the origin of transfer of three IncA/C plasmids – R55, R16a and IP40a.

Methods

R55 plasmid library was created. The minimal length of the presumed oriTs required for fully active transfer of a non-conjugative cloning vector have been determined and analysed by directed deletions and conjugation tests.

Conclusions

We detected two mobilizable regions – named as $oriT_1$ and $oriT_2$ – whose locations on the plasmid are quite different. We found that deletion of $oriT_2$ completely abolished the conjugation of the IncA/C plasmids confirming that it is a functional transfer origin. The $oriT_2$ locates between divergent genes, and one of them, ORF001, is also required for the transfer of IncA/C plasmids. Unlike $oriT_2$, deletion of $oriT_1$ had no significant effect on the conjugation. Furthermore, high transfer frequency observed with a non-mobile plasmid carrying the cloned $oriT_1$ region was due to the frequent cointegration of IncA/C and $oriT_1$-plasmid via a short sequence in $oriT_1$. Thus, the sequence named as $oriT_1$ rather seems to be a recombination hotspot than a real transfer origin.

FEMS7-1450
Physiology / Biochemistry / Molecular Microbiology - Part II

STUDY OF A VIBRIO CHOLERAE DETERMINANT OF PROPER MORPHOLOGY

S.B. Hernández[1], M.K. Waldor[2], F. Cava[1]
[1]MIMS- Umeå University, Molecular Microbiology, Umeå, Sweden
[2]Harvard Medical School, Department of Microbiology and Immunobiology, Boston- Massachusetts, USA

Backgrounds

The bacterial cell wall is a net-like structure composed mainly of peptidoglycan (PG). PG is essential for maintenance of cell shape and survival, therefore inhibition of PG synthesis and certain cell wall damages usually lead to cell death.
During a morphological screening, we found a locus of *Vibrio cholerae* whose mutation results in the formation of round, osmotically sensitive cells in stationary phase. Stationary phase-specific loss of proper morphology has been previously described in *V. cholerae* cells impaired in the PBP1A (Penicillin Binding Protein 1A) and associated regulatory proteins.

Objectives

Characterize the enzymatic activity and the biological function of the new protein found to be involved in PG homeostasis of *V. cholerae*.

Methods

A transposon insertion library of *V. cholerae* was used for the morphological screening using microscopy.
Analysis of the PG structure of the mutant and characterization of the enzymatic activity of the protein were performed.
Suppressor mutants were studied by: i) whole genome sequencing of isolated spontaneous suppressors; ii) transposon insertion sequencing of suppressors isolated under low osmolarity conditions.
To study the biological role of the protein of interest, a Tn-seq experiment was performed for the identification of synthetically lethal mutations.

Conclusions

A number of evidences suggest that the role of the protein under study in morphogenesis and PG homeostasis occurs in a PBP1A independent-fashion: i) is cytosolic protein; ii) development of spheres in the mutant is independent of NCDAA production; iii) its mutation is synthetically lethal with PBP1A; iv) the mutant exhibits a high generation rate of suppressor mutants.

IDENTIFICATION OF NOVEL INTERACTION PARTNERS OF THE PERSISTER REGULATOR OBG

P. Herpels[1], J. Rayo Company[2], A. Economou[2], N. Verstraeten[1], J. Michiels[1]
[1]KU Leuven, Department of Microbial and Molecular Systems M²S, Leuven, Belgium
[2]KU Leuven, Department of Microbiology and Immunology, Leuven, Belgium

Backgrounds

Chronic infections that are recalcitrant to treatment with antibiotics are posing a major threat to human health. This recalcitrance is partly caused by so-called persister cells. Persisters comprise a small (typically < 0.1%) fraction of transiently antibiotic-tolerant cells that are able to survive prolonged exposure to antibiotic treatment. Although the clinical importance has been demonstrated, the precise molecular mechanisms underlying persistence are not fully unravelled.

Objectives

Previous research in our group has demonstrated a central role for the conserved GTPase Obg in mediating persistence. In the current project, direct interaction partners of Obg are identified to further unravel the Obg-persistence pathway and select specific targets that influence persister formation.

Methods

An innovative photo-crosslinking technique is used to identify novel direct interaction partners of *Escherichia coli* Obg. The unnatural photo-reactive amino acid *p*-benzoyl-L-phenylalanine (*p*Bpa) is incorporated at specific locations on the surface of the Obg protein. Following UV radiation, the carbonyl oxygen of *p*Bpa crosslinks to carbon-hydrogen bonds of molecules within a radius of 3 angstrom. Interaction partners of Obg are identified using high resolution liquid chromatography-mass spectrometry. Subsequently, specific proteins and corresponding genes are tested for their involvement in persistence.

Conclusions

Identification of Obg-interaction partners contributes to the full understanding of the pathway. It is expected that targeting Obg-mediated persistence will significantly reduce the number of persister cells in bacterial populations, thereby facilitating clearing of infections by conventional antibiotics.

CAN THESE GENES STRETCH ANYMORE?! – ON EXPERIMENTAL EVOLUTION OF CHLAMYDIAE

P. Herrera[1], L.N. Schuster[1], M. Zojer[2], H. Na[1], J. Schwarz[1], F. Wascher[1], T. Rattei[2], M. Horn[1]
[1]University of Vienna, Division of Microbial Ecology, Vienna, Austria
[2]University of Vienna, Division of Computational Systems Biology, Vienna, Austria

Backgrounds

Experimental evolution approaches have been essential for understanding evolutionary mechanisms. However, our knowledge of evolutionary dynamics of strictly host-dependent bacteria is largely based on comparative genomics of closely-related species. The phylum Chlamydiae is comprised exclusively of bacteria with an obligate intracellular lifestyle. Their associations with eukaryotic hosts are remarkably diverse: They are major pathogens of many animals and occur ubiquitously as protist symbionts.

Objectives

Our laboratory has been conducting an ongoing long-term evolution experiment (LTEE) using the chlamydial symbiont *Protochlamydia amoebophila* and its amoeba host. The main aim is to improve our understanding of the evolutionary dynamics and genomic/molecular basis of the intracellular lifestyle of chlamydiae with respect to host adaptation, interaction, and character of the symbioses.

Methods

We have established replicate *Protochlamydia* populations thriving in their *Acanthamoeba* hosts under two temperature regimes for 500 generations (38 months). Pool sequencing was carried out at selected time points, and variant detection was performed using a novel work flow to detect low abundant variants in high-coverage sequence pools. Infectivity assays were carried out to compare ancestral and selected evolved populations.

Conclusions

The observed substitution rate was surprisingly similar to those of free-living microbes, with a significant increase at 30°C compared to 20°C incubation temperature. Non-synonymous substitutions were more frequent at 30°C, indicating a higher level of positive selection. Infectivity assays revealed that 30°C populations exhibited reduced virulence. In summary, we were able to track evolutionary dynamics of a chlamydia symbiont within its protected intracellular niche, providing a better understanding of their adaptation to elevated temperature.

DEVELOPMENT OF FLUORESCENCE BASED BIO-REPORTER SYSTEM FOR DETECTING ANTIBIOTIC-INDUCED MISTRANSLATION

M. Hinnu[1], *M. Putrinš*[1], *K. Kogermann*[2], *T. Tenson*[1]
[1]*University of Tartu, Institute of Technology, Tartu, Estonia*
[2]*University of Tartu, Institute of Pharmacy, Tartu, Estonia*

Backgrounds

Errors in protein translation are common and can be beneficial for bacteria. It has been shown that increased mistranslation can modify the susceptibility to antibiotics. On the other hand, antibiotics themselves can increase mistranslation.

Objectives

The aim of our study was to develop a fluorescence based bio-reporter strain, which could be used to estimate the prevalence of mistranslation during infection and antibiotic treatment. Possible future applications include guiding the development of better dosing regimens for existing antibiotics and the design and development of new antibiotics.

Methods

Fluorescence based mistranslation reporter system was developed and studied in uropathogenic *Escherichia coli* strain CFT073. The reporting system uses green fluorescent protein (GFP) as a mistranslation indicator, and red fluorescent protein mCherry as a control protein for expression. Therefore, the ratio of green and red fluorescence can be used as an indicator of mistranslation. Frameshift and nonsense mutants of GFP were constructed. Fluorescence of bulk bacterial cultures was measured by plate-reader and fluorescence of single cells by flow cytometer. Effects of different antibiotics were studied.

Conclusions

Our reporter enabled detecting frameshifting in stationary phase cells. With the addition of aminoglycosides, single cell analysis showed an increase in non-fluorescent bacterial population, which might indicate death of bacteria in sub-MIC antibiotic concentrations. The system still needs to be developed further for more extensive studies with antibiotics.

BIOCHEMICAL SURVEY OF THE RID PROTEIN FAMILY DEMONSTRATES DEAMINASE ACTIVITY IS CONSERVED AMONG SUBFAMILIES

K. Hodge-Hanson[1], *D. Downs*[1]
[1]*University of Georgia, Microbiology, Athens, USA*

Backgrounds

The Rid (YjgF/YER057c/UK114) protein family is conserved across the three domains of life and consists of eight subfamilies: RidA and Rid1-7. The archetypal member, RidA from *Salmonella enterica* is a **R**eactive **I**ntermediate **D**eaminase that hydrolyzes enamine/imine intermediates generated as catalytic intermediates in bacterial metabolism. The importance of RidA is reflected in the various processes affected in its absence in a number of organisms including bacteria, plants and yeast. Production of the reactive intermediates, as well as the consequences of lacking RidA are both linked to the essential cofactor pyridoxal 5'-phosphate (PLP). Our understanding of the remaining subfamilies is in its infancy. Some genomes encode multiple Rid proteins such as the opportunistic pathogen *Pseudomonas aeruginosa* with nine encoded Rid proteins, representing multiple subfamilies.

Objectives

This work was initiated to probe functional overlap between Rid proteins from subfamilies Rid1-3 in an effort to understand the role(s) of enamine/imine intermediates in bacterial metabolism.

Methods

A biochemical-genetic approach was taken; Rid1-3 subfamily proteins from various gamma-Proteobacteria were compared to RidA *in vivo* using the best-studied RidA paradigm in *S. enterica.* Purified Rid proteins were assessed for the ability to deaminate a wide range of short-lived intermediates generated *in situ* from both PLP-and FAD-dependent enzymes.

Conclusions

A biochemical-genetic approach was taken; Rid1-3 subfamily proteins from various gamma-Proteobacteria were compared to RidA *in vivo* using the best-studied RidA paradigm in *S. enterica.* Purified Rid proteins were assessed for the ability to deaminate a wide range of short-lived intermediates generated *in situ* from both PLP-and FAD-dependent enzymes.

CROSS-RECOGNITION OF PROMOTERS BY ALTERNATIVE STRESS-RESPONSE SIGMA FACTORS IN STREPTOMYCES COELICOLOR A3(2)

D. Homerova[1], B. Sevcikova[1], B. Rezuchova[1], R. Novakova[1], J. Kormanec[1]
[1]Institute of Molecular Biology Slovak Academy of Sciences, gene expression, Bratislava, Slovak Republic

Backgrounds

Bacteria are in their natural habitats exposed to various stresses. The stress response is regulated mainly by stress-response sigma factors of RNA polymerase. In *Bacillus subtilis*, the activity of such sigma factor SigB is regulated by the anti-sigma factor RsbW, anti-anti-sigma factor RsbV, and by two PP2C phosphatases, RsbP and RsbU. However, the genome of Gram positive soil bacterium *Streptomyces coelicolor* contains genes for 65 sigma factors including 9 close homologues of SigB (SigB, F, G, H, I, K, L, M, N), 45 homologues of RsbW, 17 homologues of RsbV, and 44 homologues of RsbU/RsbP that indicates rather complex picture of regulation comparing to *B. subtilis*. We previously characterised several of these SigB homologues in *S. coelicolor* and found their dual role in morphological differentiation and osmotic stress response [1].

Objectives

Characterization of the recognition of promoters by nine SigB homologues using two plasmid system. Verification of their dependence in sigma factor gene mutants using *lux* reporter system.

Methods

E. coli two plasmid system is described in [2]. *In vivo* activity of promoters was investigated using a *lux* reporter system [3].

Conclusions

1, *S. coelicolor* SigB homologues cross-recognize several promoters in *E. coli* two-plasmid system.

2, *In vivo* activity of the promoters was differentially dependent upon these sigma factors during differentiation and after osmotic stress conditions.

A COMPETITOR OR SCAVENGER: WHAT ROLE DOES GSKIP PLAYS IN THE WNT SIGNALING PATHWAY?

Y.R. Hong[1]
[1]*Kaohsiung medical university, Biochemistry, Kaohsiung, Taiwan R.O.C.*

Backgrounds

A-Kinase Anchoring proteins (AKAPs) are a family of PKA scaffolding proteins. It allows PKA to phosphorylate other signaling molecules and achieve spatiotemporal modulation of their activities through protein-protein interaction. GSKIP is an AKAP that promotes PKA phosphorylation of GSK3β.

Objectives

First, we found that wild-type GSKIP attenuates yeast growth but the process can be revoked by either PKA or GSK3β binding site mutants. Bioinformatics study, on the other hand, revealed that GSKIP contains the evolutionary conserved DUF727, which possesses both PKA and GSK3β binding sites in vertebrate, but only site for GSK3β in invertebrate. This could explain why human GSKIP significantly decrease growth rate might due to yeast lacking PKA binding site and affected. We also found that both PKA and GSK3βsites affect the binding, in various forms of GSK3β in yeast two-hybrid assays. However, pre-incubation of yeast cells with either PKA inhibitor H89 or GSK3βinhibitor LiCl had no effect on growth or binding. We also showed that the effect of GSKIP on β-catenin is highlighted by its functioning as a competitor or scavenger in a Wnt3a stimulus; it recruits the GSK3β away from the destruction complex and simultaneously brings PKA to form a new PKA/GSKIP/GSK3β/β-catenin complex.

Methods

GSKIP was studied through yeast growth upon GSKIP transfection, yeast two-hybrid, cell line-based assay, knock-out mice, 2D-DIGE combined mass spectrometry and bioinformatics.

Conclusions

Our findings highlight an essential complex of a cAMP/PKA/β-catenin axis by GSKIP- and GSK3β-mediated anchoring in modulating β-catenin phosphorylation via Wnt signaling.

Physiology / Biochemistry / Molecular Microbiology - Part II

CHARACTERIZATION OF THE SEVEN NAD+-DEPENDENT ALCOHOL DEHYDROGENASES IN ACINETOBACTER BAUMANNII

M.C. Hsieh[1], *G.H. Lin*[1]
[1]*Tzu Chi University, Department of Microbiology, Hualien, Taiwan R.O.C.*

Backgrounds

Acinetobacter baumannii is an aerobic Gram-negative bacteria, and this opportunistic human pathogen causes a seriously nosocomial infections. To prevent nosocomial infections, ethanol is commonly used for surface cleaning and disinfecting surgical devices. In previous study showed that low doses of ethanol not only as a carbon source but also as a bacterial signaling molecule which can enhance the bacterial growth and increase salt tolerance of *A. buamanii*.

Objectives

In alcohol metabolism, alcohol dehydrogenases (ADH) catalyze the reversible oxidation of alcohols to aldehydes or ketones. In order to understand the seven ADHs are functionally different and find out the different kinetic characteristics in *Acinetobacter baumannii*.

Methods

In silico analysis, *A. baumannii* contain seven ADHs which belong to NAD^+-dependent ADHs. We constructed *Abadh*s mutants by marker-less mutation and cultured *Abadh*s mutants in different concentration alcohols as sole carbon source. Although constructed *Abadh*s expression strain by *E.coli* and purified AbAdhs for enzyme activity.

Conclusions

AbAdh1, AbAdh2, and AbAdh7 are zinc-containing ADH. AbAdh3, AbAdh4, and AbAdh6 are iron-containing ADH. AbAdh5 is a short-chain ADH. *Abadh3* deletion mutants decrease 1-propanol metabolism. *Abadh4* deletion mutants cannot grow in ethanol, butanol, and 1-propanol as a single carbon source. These data seem like AbAdh4 is the most important ADH of alcohol metabolism in *A. baumannii*. Kinetics studies showed that iron-containing AbAdh3 are in need of iron for ethanol oxidation.

FUNCTIONAL STUDY OF ORF58 (MAB_2101 HOMOLOGUE) IN MYCOBACTERIUM MASSILIENSE

S.T. Hu[1], P.H. Lin[1]
[1]National Yang-Ming University, Microbiology and Immunology, Taipei, Taiwan R.O.C.

Backgrounds

Two strains, R49R (rough) and R49S (smooth), of *M. massiliense* isolated from same patient were identified derived from same pedigree and displayed different phenotypes. Whole genome sequences analysis of these strains showed a 54-kb deletion within R49R genome. This 54-kb region is flanked with 19-mer direct repeats and comprises of 58 open reading frames (ORFs) including a putative recombinase ORF58 (Mab_2101 homologue). It is possible that ORF58 acts as a recombinase to cause 54-kb deletion at the 19-mer direct repeats, resulting in the phenotypic differences of these strains.

Objectives

This study aims to determine the function of ORF58.

Methods

The *orf58* driven by *ptr* promoter was overexpressed in R49S, which indeed resulted in some phenotypic differences, but no deletion of 54-kb. The ORF58 contains the putative resolvase, recombinase, and zinc ribbon domains. To investigate which domain is essential for the function of ORF58, the plasmid containing full-length or truncated gene was overexpressed in R49S. The results showed that only resolvase and zinc ribbon domains were essential. The resolvase of transposon *3* also plays a role in transcriptional regulation, suggesting that ORF58 is more likely a regulator rather than a recombinase. Indeed, the transcriptome analysis of R49S gene expression revealed that the overexpressed ORF58 induced some interesting genes. In addition, when the plasmid containing *orf58* was cured from R49S, the bacterial phenotype switched back, indicating that the ORF58 might not cause recombination event in bacterium.

Conclusions

It is concluded that ORF58 may function as a transcriptional regulator rather than a recombinase.

DIET INDUCED MICROBIOTA AND M-CELL MODIFICATIONS IN RABBIT GUT ASSOCIATED LYMPHOID TISSUE (GALT)

R. Arrazuria[1], E. Molina[1], M. Serrano[1], M. Tello[1], I.A. Sevilla[1], E. Khafipour[2], V. Pérez[3], A. Hurtado[1], R.A. Juste[4], J.M. Garrido[1], N. Elguezabal[1]
[1]NEIKER-Tecnalia, Department of Animal Health, Derio, Spain
[2]University of Manitoba, Department of Animal Health, Winnipeg, Canada
[3]University of León, Department of Animal Health, León, Spain
[4]SERIDA, Department of Agriculture of the Regional Government of the Principality of Asturias, Deva, Spain

Backgrounds

The gut microbiome plays an important role in competitive exclusion of pathogens and in immunity development and maturation. Rabbit GALT is predominantly composed of two structures: the sacculus rotundus (SR) and the vermiform appendix (VA). M-cells are specialized epithelial cells covering the lymphoid follicles of the GALT that uptake antigens from the lumen and subsequently put them in contact with cells of the immune system.

Objectives

To evaluate modifications in the microbiota and in the M-cell population in GALT of rabbits fed regular or high fiber diet.

Methods

Microbial composition and the abundance of M-cells of VA and SR were studied in 10 New Zealand rabbits. Half of those rabbits were fed a regular diet during the whole experiment. In the remaining rabbits the regular diet was switched to a high fiber diet from weeks 7 to 11 and 23 to 27 of the beginning of the experiment. M-cells were identified by vimentin immunohistochemistry and analyzed using the IHC Profiler in ImageJ. The microbiota was studied by 16S rRNA sequencing. Data treatment was carried out following QIIME pipeline and analyzed in LefSe.

Conclusions

Immunohistochemistry analysis revealed that the number of M-cells was increased with dietary fiber in both sacculus rotundus and vermiform appendix ($p<0.05$). Analysis of microbial composition showed the overrepresentation of the family Dehalobacteriaceae in sacculus rotundus and the family Odoribacteriaceae and the genus *Butiricimonas* in vermiform appendix of animals fed with high fiber diet. These findings suggest that the hyperplasia of M-cells may be induced by dietary and microbial factors.

EVOLUTION OF GLOBAL MODULATORS: A NOVEL H-NS PARALOGUE IDENTIFIED IN THE ENTEROAGGREGATIVE E. COLI STRAIN 042 HAS EVOLVED TO SPECIFICALLY MODULATE HGT DNA

A. Prieto[1], M. Bernabeu[1], S. Aznar[2], M. Huttener[1], A. Juárez[1]
[1]Universitat de Barcelona,
Departamento de Genética- Microbiología y Estadística. Facultad de Biología. Universidad de Barcelona- Barcelona- Spain, Barcelona, Spain
[2]Instituto de Bioingeniería de Cataluña IBEC- Barcelona- Spain.,
Microbial Biotechnology and Host Pathogen Interaction, Barcelona, Spain

Backgrounds

Bacterial nucleoid-associated proteins contribute to nucleoid structure and modulate gene expression. The H-NS protein is widespread in Gammaproteobacteria and has been best studied in *E. coli* and related genera. H-NS binds to DNA in a non-sequence-specific manner. H-NS binds, mainly HGT DNA which, among others, encodes virulence determinants. StpA is an H-NS paralogue which in *E. coli* appears not to have a specific modulatory role out of functioning as an H-NS molecular backup.

Objectives

A recent genomic analysis performed by our group has shown that, unlike many other *E. coli* strains, the chromosome of the strain 042 encodes a new paralogue of the *hns* gene, *hns2*. We present in this communication information about the biological role of this new member of the H-NS family of proteins.

Methods

We performed RNAseq experiments with a set of EAEC 042 mutants: *hns*, *hns2* and *hnshns2.* We compared then the gene expression pattern to the wild type strain 042. In addition, we measured H-NS2 expression by qPCR as well as by immunodetection.

Conclusions

H-NS2 expression is significantly lower than that of H-NS. H-NS2 modulates a subset of the H-NS modulated genes, mainly HGT genes. The obtained data suggest a specialized role for H-NS2 modulating HGT DNA. The observed low expression levels of H-NS2 together with the likely enhanced sensitivity to proteolysis suggest that enterobacterial strains expressing this regulator may specifically derepress HGT genes under stress conditions without altering other H-NS specific functions such as chromosome architecture or modulation of core genes.

THE EFFECT OF PEROXISOME ON VARIOUS ENVIRONMENT BY CHANGE OF PEROXINS IN SACCHAROMYCES CEREVISIAE

H.J. Kang[1], B.H. Choi[1], P.C. Lee[1], H.J. Hwang[1]
[1]Ajou University, Department of Molecular Science and Technolgy, Woncheon-dong- Yeongtong-gu- Suwon, Republic of Korea

Backgrounds

In *S. cerevisiae*, the regulation of peroxisome, which has various metabolic processes, is tightly controlled by several peroxins depending on the environment. To date, 34 peroxins have been identified that are involved in the peroxisome biogenesis, proliferation and targeting and importing of peroxisomal matrix proteins. However, exact regulation mechanism of peroxin for number and size of peroxisome on various environment remain unclear.

Objectives

In this study, to determine the exact mechanism for the number and size regulation of peroxisome, we investigated the effect of *PEX34* and *PEX11*, which are known to be involved in the peroxisome population and size, on various environments in *S. cerevisiae*.

Methods

The CEN.PK2-1D *S. cerevisiae* strain and its derivatives were used in this study. To investigate changes for the number and size of peroxisomes in various environments, deletion or/and overexpression strains of peroxin gene were constructed. Morphology, size and abundance of peroxisome was observed by TEM (Transmission electron microscopy) and Pot1-GFP tagging or GFP-PTS1 (peroxisomal targeting signal 1) expression vector. RNA-Seq analysis was performed to determine the effect of changes on number and size of peroxisome in yeast cell.

Conclusions

In the present study, we confirmed the change in numbers and sizes of peroxisome by the regulation of *PEX34* and *PEX11*. Furthermore, it was observed that changes of peroxisome affected the stress response of yeast cells. The results of our study provide clues to understand the regulation mechanism for number and size of peroxisome by peroxins and may be useful for peroxisome utilization in metabolic engineering and synthetic biology.

GLYCAN-CONJUGATED FLUORESCENT AND MAGNETIC NANOPARTICLES FOR DETECTION OF HELICOBACTER PYLORI

J.Y. Hyun[1]
[1]*Yonsei University, Chemistry, Seoul, Republic of Korea*

Backgrounds

Helicobacter pylori is known to be a causative pathogen to induce chronic gastritis and gastric ulcers. It is also linked to the development of duodenal ulcers and stomach cancer.

Objectives

As a consequence, a sensitive method to detect *H. pylori* is crucial for diagnosis and treatment of *H. pylori*-associated diseases. It was reported that some strains of *H. pylori* express sialic acid-binding (SabA) and Le^b-binding adhesins (BabA) that recognize glycans on the human gastric mucosa for infection.

Methods

To sensitively detect *H. pylori* strains expressing BabA, fluorescent magnetic glyconanoparticles were prepared by conjugating aminoethylated Le^a, Le^b and H1 oligosaccharides to carboxy-containing fluorescent magnetic nanoparticles. The glycoclusters were characterized by using FT-IR, TEM and DLS/zeta potential techniques. They were then utilized to detect *H. pylori*. In this study, *H. pylori* J99 strain which expresses BabA was incubated with three kinds of glyconanoparticles.

Conclusions

The results of fluorescence microscopy analysis showed that Le^b and H1 conjugated but not Le^a conjugated nanoparticles bound to this strain. However, these glyconanoparticles did not recognize *H. pylori* strains lacking BabA. They were also employed to enrich BabA expressing *H. pylori* by using a magnet. It is anticipated that dual-mode glyconanoparticles will be powerful tools to sensitively detect pathogens including *H. pylori*.

THE CARBOHYDRATE MICROARRAY TECHNOLOGY IS A POWERFUL TOOL FOR SCREENING OF FUNCTIONAL GLYCANS

J.Y. Hyun[1], I. Shin[1]
[1]Yonsei University, Chemistry, Seoul, Republic of Korea

Backgrounds

It is well-recognized that carbohydrate-binding proteins (lectins) expressed on the cell surface are involved in a wealth of biological processes through interactions with free or conjugated glycans.

Objectives

For example, cell surface lectins in the immune system bind to microorganism glycans on the surface, an event which leads to stimulation of immune responses to microorganisms. Mouse SIGN-R1 (SIGN-related 1) is a homolog of human DC-SIGN (dendritic cell-specific ICAM-grabbing non-integrin) that is expressed largely on macrophages. This lectin recognizes mannose-rich or fucosylated glycans in a Ca^{2+}-dependent manner. When SIGN-R1 interacts with glycans expressed on microorganisms, glycan antigens are internalized into cells via lectin-mediated endocytosis to induce immune activation. Thus, it is of great importance to identify glycans that elicit immune cell response.

Methods

In this study, a carbohydrate microarray-based technology was utilized for the rapid screening of glycans that trigger production of reactive oxygen species (ROS) through binding to the cell-surface SIGN-R1. To identify functional glycans which enhance ROS production, a fluorescent ROS probe was employed. It was found that binding of SIGN-R1 expressing cells to several mannose and fucose containing glycans immobilized onto the microarrays generated ROS, whose levels were attenuated in the presence of a ROS scavenger or a NADPH oxidase inhibitor.

Conclusions

The findings indicate that glycan microarrays are applicable to the simultaneous screening of functional glycans whose binding to the cell-surface lectin elicits cellular response.

EPIDEMIOLOGY OF EXTENDED-SPECTRUM BETA LACTAMASES AND CARBAPENEMASES IN KLEBSIELLA PNEUMONIAE HOSPITAL ISOLATES FROM MOSTAR, BOSNIA AND HERZEGOVINA

A. Ibrahimagić[1], F. Kamberović[1], T. Petrović[2], S. Jakovac[2], D. Slačanac[3], S. Uzunović[1], B. Bedenić[4], J. Luxner[5], I. Barišić[6]
[1]Institute for Health and Food Safety, Department for Laboratory Diagnostics, Zenica, Bosnia - Herzegovina
[2]University Clinical Hospital, Department for Microbiology and Molecular Microbiology, Mostar, Bosnia - Herzegovina
[3]University of Zagreb, School of Medicine, Zagreb, Croatia
[4]Clinical Hospital Center, Laboratory for Molecular Microbiology- Department for Clinical Microbiology, Zagreb, Croatia
[5]Institute for Microbiology, Hygene and Environmental Medicine, Gratz, Austria
[6]Institute for Technology, Institute for Technology, Vienna, Austria

Backgrounds

Extended-spectrum beta lactamase (ESBL) producing isolates has become one of the most challenging agents of nosocomial infections in recent years.

Objectives

To determine antibiotic susceptibility and to characterize ESBL/carbapenem-resistance of eleven *Klebsiella pneumoniae* isolates collected in hospital, Mostar, Bosnia and Herzegovina.

Methods

Eleven *Klebsiella pneumoniae* isolates with reduced susceptiblity to cephalosporins and carbapenems were isolated. Antibiotic susceptibility was determined by broth microdilution method. Production of metallo-β-lactamases (MBLs) and ESBLs was detected by inhibitor-based tests with EDTA and clavulanic acid, respectively. Genes encoding OXA-23/OXA-24/40-/OXA-58-/OXA-143-like carbapenem-hydrolzing oxacillinases, in addition to MBLs of VIM, IMP and SIM series, SHV, CTX-M, PER-1 and TEM β-lactamases were detected by PCR.

Conclusions

All isolates were found to be multidrug resistant and ESBL producers. Cefuroxime, ceftazidime, cefotaxime and ceftriaxone were the least potent antibiotics with MIC_{90} >128 mg/L, cefepime MIC_{90} 64 mg/L, gentamicine MIC_{90} >128 mg/L and ciprofloxacin MIC_{90} 64 mg/L. Conjugation frequency was in the range 10^{-3}–10^{-5}. Resistance to gentamicin, sulphamethoxazole, and tetracycline in most cases were co transferred alongside with cefotaxime resistance. MBL fenotype test in one isolate was positive, but the PCR targeting common MBLs was negative. All strains were positive for TEM and CTX-M genes. Antimicrobial susceptibility testing and molecular characteristics of *K. pneumoniae* isolates showed a significantly high level and prevalence of resistance and high prevalence of both CTX-M and TEM genes. This is the first report of *Klebsiella pneumoniae* producing extended-spectrum beta-lactamases in Mostar, Bosnia and Hercegovina.

Physiology / Biochemistry / Molecular Microbiology - Part II

BORONATE CARRYING NANOPARTICLES FOR THE PURIFICATION OF RNA FROM ESCHERICHIA COLI

N. Idil[1], *I. Perçin*[1], *A. Denizli*[2]
[1]*Hacettepe University, Department of Biology, Ankara, Turkey*
[2]*Hacettepe University, Department of Chemistry, Ankara, Turkey*

Backgrounds

Boronate affinity chromatography has been exploited for the separation of a wide variety of cis-diol-containing compounds including RNA. In recent years, boronate affinity functionalized materials have attracted great interest in nucleic acid-based researches due to being effective sorbents. Nanoparticles have widespread use in many applications due to their unique chemical and physical properties and they are capable of reducing the purification time.

Objectives

The objectives of the study were to prepare boronate carrying nanoparticles in order to purify RNA from *Escherichia coli* and investigate RNA binding capacity of these nanoparticles at different experimental conditions.

Methods

Poly(hydroxyethyl methacrylate-co-vinylphenylboronic acid) [P(HEMA-VPBA)] nanoparticles were prepared for the purification of RNA from *Escherichia coli.* These nanoparticles were synthesized using vinylphenylboronic acid (VPBA) and 2- hydroxyethyl methacrylate (HEMA) via miniemulsion method. The RNA binding capacity of [P(HEMA-VPBA)] nanoparticles were examined in a batch system.

Conclusions

The prepared nanoparticles were selected as a boronic acid affinity system for the purification of RNA from *Escherichia coli.* In this manner, it was determined that [P(HEMA-VPBA)] nanoparticles had high efficiency when purifying RNA from a biological source. It can be concluded that these boronic acid carrying nanoparticles were capable of separate the bacterial RNA successfully and promising tools for the purification of RNA.

Physiology / Biochemistry / Molecular Microbiology - Part II

BORONATE AFFINITY NANOPARTICLES FOR IGG BINDING

N. Idil[1], I. Perçin[2], A. Denizli[3]
[1]Hacettepe University, Department of Biology- Biotechnology, Ankara, Turkey
[2]Hacettepe University, Department of Biology, Ankara, Turkey
[3]Hacettepe University, Department of Chemistry, Ankara, Turkey

Backgrounds

Immunoglobulins are glycoproteins which have crucial roles in immune system response. There have been many separation techniques for IgG including affinity chromatography. Boronate affinity adsorbents have been widely used for the separation of biomolecules such as glycoproteins by selective capturing of cis-diols. Nanosized particles provides high-capacity boronate affinity adsorbents with high surface areas.

Objectives

The objectives of the study were (i) to prepare boronate affinity nanoparticles for IgG binding, (ii) to characterize these nanoparticles by particle size distribution, Fourier transform infrared spectroscopy (FTIR) and atomic force microscopy (AFM), (iii) to investigate IgG binding capacity of prepared nanoparticles at different experimental conditions.

Methods

The phenylboronic acid (PBA) was preferred as a ligand due to the specific and reversible interaction with glycoproteins. Poly(hydroxyethyl methacrylate-co-vinylphenylboronic acid) [P(HEMA-VPBA)] nanoparticles were synthesized for IgG binding.

Conclusions

The proposed [P(HEMA-VPBA)] nanoparticles have the ability to bind IgG and they are promising candidates to be used in many biotechnological applications offering the advantage of high binding capacity.

TRANSCRIPTOMIC ANALYSIS ON THE RESPONSE OF PORCINE ADIPOCYTES TO COMMON MICROBIAL LIGANDS

M. Igata[1], A. Tada[1], A.H. Kober[1], L. Albarracín[2], W. Ikeda-Ohtsubo[1], H. Aso[1], K. Miyazawa[3], K. Yoda[3], F. He[3], T. Saito[1], J. Villena[2], H. Kitazawa[1]
[1]Tohoku University, Graduate School of Agricultural Science, Sendai, Japan
[2]CENTRO DE REFERENCIA PARA LACTOBACILOS CERELA-CONICET, Laboratory of Immunobiotechnology, San Miguel de Tucumán, Argentina
[3]Takanashi Milk Products Co.- Ltd, Technical Research Laboratory, Yokohama, Japan

Backgrounds

Previous we established a clonal porcine intramuscular preadipocyte cell line and a protocol to obtain functional porcine mature adipocytes (PMAs) from these cells.

Objectives

In this work, we investigated the immunobiology of PMAs in relation to their response to Toll-like receptor 2 (TLR2) or TLR4 stimulation by using a transcriptomic approach.

Methods

PMAs cells were stimulated with peptidoglycan or lipopolysaccharide (LPS), and the transcriptomic response was evaluated 12 h after the challenge using the Porcine (V2) Gene Expression Microarray (Agilent). Variations in transcript abundance with a t-test $p<0.05$, and a cutoff in abundance of at least 2-fold were considered statistically different. Changes in the expression of selected genes were confirmed by Real-Time RT-PCR.

Conclusions

Both, TLR2 and TLR4 activation increased the expression of inflammatory factors in PMAs including chemokines (*CCL2, CCL8, CXCL2*), adhesion molecules (*VCAM1*) and complement factors. However, the immunomodulatory effect was stronger in TLR2-stimulated PMAs than in those receiving LPS, since increased expression of *IL-1, CCL20, CXCL12, EPCAM, SELL*, and *NOS2* was found only in the first group. On the contrary, TLR4 activation had a stronger influence in lipid metabolism. Genes involved in lipid metabolism such as *APOB, APOM, FFAR2, MGPD*, and *PLA2G7* were up-regulated in LPS-treated PMAs but not in those stimulated with peptidoglycan. These results indicate that PMAs are able to generate complex metabolic/immune responses to common microbial ligands. Therefore, PMAs could be used for the *in vitro* screening and selection of new alternatives to beneficially modulate adipose tissue metabolism and/or inflammation such as probiotic treatments.

POPULATION STRUCTURE IN CAMPYLOBACTER JEJUNI ISOLATED FROM HUMANS, CHICKENS AND WILD BIRDS

Y. Iglesias[1], *E. Miro*[1], *C. Muñoz*[1], *T. Llovet*[1], *C. Madrid*[2], *C. Balsalobre*[2], *F. Navarro*[1]
[1]*Hospital de la Santa Creu i Sant Pau, Microbiology, Barcelona, Spain*
[2]*Universidad de Barcelona, Microbiology, Barcelona, Spain*

Backgrounds

Campylobacter jejuni is responsible for most foodborne bacterial infections worldwide. It is believed that the major source of contamination is caused by consumption of contaminated chicken meat.

Objectives

The objectives of this study were to compare the clonal diversity and population structure between *C. jejuni* strains from human, chickens and wild birds.

Methods

A total of 150 *C. jejuni* strains were analyzed, 50 from patients attended at Hospital de Sant Pau in 2014, 50 from broiler isolated from different farms in 2013 and 50 strains from five different species of wild birds obtained between 2014 and 2015. Identification at the species level was performed by MALDI-TOF. The population study was carried out by PFGE with *Sma*I and *Kpn*I, and MLST (http://Pubmlst.org/ campylobacter).

Conclusions

Among the 150 strains 60 ST were obtained (six of them for the first time in this study) grouped into 21 clonal complexes (CC) and 12 singletons (S). ST-45, ST-48 and ST-354 were present in the three collections. The CC-21, CC-1275, CC-45 and CC-257 were the most prevalent. By PFGE 143 restriction patterns were obtained. Only three clusters with more than one strain were obtained. One of them included six strains from chicken, whereas the other two clusters include two strains of wild bird each one. There is great genotype variability between the three collections. Analysis data using both methods classify clearly separates the bird population of human and chicken. Human and chicken population shared ST profiles but no PFGE .

Physiology / Biochemistry / Molecular Microbiology - Part II

INSIGHTS INTO THE ROLE OF FLUG IN THE REGULATION OF DEVELOPMENT IN ASPERGILLUS

M. Iradi[1], *M. S. Cortese*[1], *U. Ugalde*[1]
[1]*University of the Basque Country, Applied Chemistry, San Sebastian, Spain*

Backgrounds

FluG was recognized as an early regulator of asexual development over two decades ago. *fluG* null mutants show profuse aerial growth and no conidial production in minimal medium, but can display moderate sporulation under nitrogen limitation. Initial studies detected sequence homology of *fluG* with a prokaryotic glutamine synthetase (GS), but catalytic activity was not demonstrated. Other investigations placed FluG as a putative interactor of the Velvet complex.

Objectives

1) To perform a detailed and updated bioinformatic analysis of FluG sequence.
2) Make point mutations in predicted catalytic residues to confirm the functionalities of the predicted protein.

Methods

We conducted a sequence and crystal structure analysis of the FluG sequence, which yielded two clearly distinguishable regions: a N-terminal amidohydrolase (AH) coding region and a C-terminal GS or gamma-glutamyl synthetase region. Separate expression of these regions revealed that the C-terminal region was essential for asexual development. The N-terminal region, in turn, was required only under high nitrogen availability.
Selected point mutations directed at disabling catalytic residues with no major predictable structural changes caused severe developmental defects.

Conclusions

We have therefore concluded that FluG may act as a two-enzyme multifunctional protein. Given that intracellular glutamine levels are associated with growth of aerial hyphae and suppression of asexual development (fluffy phenotype), we hypothesize that FluG may scavenge nitrogen intermediates which could be otherwise destined for glutamine synthesis, thus preventing the formation of aerial hyphae. The product of the FluG enzyme would, instead, signal or metabolically channel the induction of asexual development.

Physiology / Biochemistry / Molecular Microbiology - Part II

GRAM NEGATIVE PROMISCUOUS LIPOPROTEINS KEEP SURFACE TOPOLOGY WHEN TRANSPLANTED FROM ONE SPECIES TO ANOTHER AND CAN DELIVER FOREIGN POLYPEPTIDES TO THE BACTERIAL SURFACE

C. Irene[1], L. Fantappie'[1], M. De Santis[1], A. Armini[2], A. Gagliardi[2], M. Tomasi[1], M. Parri[3], V. Cafardi[1], S. Bonomi[3], L. Ganfini[1], F. Zerbini[1], I. Zanella[1], C. Carnemolla[2], L. Bini[2], A. Grandi[3], G. Grandi[1]
[1]University of Trento, CIBIO, Trento, Italy
[2]University of Siena, Department of Life Sciences, Siena, Italy
[3]Toscana Life Science, Toscana Life Science, Siena, Italy

Backgrounds

In Gram negative bacteria outer membrane-associated lipoproteins can either face the periplasm or protrude out of the bacterial surface. The mechanisms involved in lipoprotein transport through the outer membrane are not fully elucidated. A group of lipoproteins reach the surface by using species-specific transport machineries. By contrast, a still poorly characterized group, we referred to as “promiscuous lipoproteins”, appears to cross the outer membrane using transport systems shared by different species.

Objectives

To provide further evidence of the existence of promiscuous lipoproteins, we tested the expression and compartmentalization in *E. coli* of three surface-exposed lipoproteins, two from *Neisseria meningitidis* (Nm-fHbp and NHBA) and one from *Aggregatibacter actinomycetemcomitans* (Aa-fHbp). We found that the three lipoproteins were lipidated and compartmentalized in *E. coli* outer membrane and in Outer Membrane Vesicles (OMVs). Furthermore, FACS analysis, proteolytic surface shaving, and confocal microscopy revealed that the three proteins were also exposed on the external side of the outer membrane. Removal or substitution of the first four amino acids following the lipidated Cysteine residue and extensive deletions of the C-terminal regions in Nm-fHbp did not prevent the protein from reaching the external side of the outer membrane. Heterologous polypeptides fused to the C termini of the proteins are efficiently transported to the *E. coli* surface and efficiently compartmentalized in OMVs.

Methods

Outer membrane vesicles preparation by ultracentrifugation, Triton-X114 phase fractionation, SDS-PAGE, FACS analysis, proteolytic surface shaving, confocal microscopy, Two-dimentional gel electrophoresis, protein identification by mass spectrometry

Conclusions

These data indicate that promiscuous lipoproteins travel from the cytoplasm to the cell surface using conserved mechanisms and when transplanted from one species to another they maintain their natural topology without the need of ancillary transport machineries. Furthermore such proteins can be exploited in biotechnological applications requiring the decoration of Gram negative bacterial surface with foreign polypeptides.

QUANTIFICATION OF CELL ADHESION OF ACINETOBACTER SP. TOL 5 VIA A TRIMERIC AUTOTRANSPORTER ADHESIN USING ATOMIC FORCE MICROSCOPY

S. Ishii[1], S. Yoshimoto[1], K. Hori[1]
[1]Nagoya University, engineering, Nagoya, Japan

Backgrounds

The bacterial adhesion to material surfaces or host cells is mediated by cell surface proteins called adhesins. Trimeric autotransporter adhesin (TAA) is one of the major non-fimbrial adhesins widely distributing in Gram-negative bacteria. *Acinetobacter* sp. Tol 5 shows autoagglutinating nature and noteworthy adhesiveness through its TAA, namely AtaA. We previously reported the unique adhesiveness of Tol 5 cells to various abiotic material surfaces from hydrophobic plastics to hydrophilic glass and metals. However, the adhesion force of Tol 5 cells via AtaA has only preliminary been investigated.

Objectives

In this work, we evaluated the strength and properties of adhesion of Tol 5 cells via AtaA using atomic force microscopy (AFM). We also attempted to quantify adhesion force of a single AtaA molecule.

Methods

We measured the interaction force between a cantilever probe and a cell surface of various bacteria including Tol 5, *Pseudomonas aeruginosa*, *Escherichia coli and Yersinia enterocolitica* in liquid. These cells were immobilized on the polyethyleneimine-modified glass plate by using aldehyde-cross-linkage before the measurement.

Conclusions

Tol 5 cells showed much stronger adhesion force than the D*ataA* mutant of Tol 5 and other typical bacteria did. The result revealed that AtaA confers not only high adhesiveness but also strong adhesion force to Tol 5 cells.

CHARACTERIZATION OF AN EPSILON/ZETA TOXIN-ANTITOXIN SYSTEM FROM THE CLINICAL STRAIN MYCOBACTERIUM SP. MHSD3, CLOSELY RELATED TO MYCOBACTERIUM CHELONAE.

D. Jaén-Luchoro[1], F. Aliaga-Lozano[2], R.M. Gomila[3], M. Gomila[4], F. Salvà-Serra[5], J. Lalucat[4], A. Bennasar-Figueras[4]
[1]University of the Balearic Islands, Biology, Palma de Mallorca, Spain
[2]Clínica Rotger, Laboratoy of Molecular Biology, Palma de Mallorca, Spain
[3]University of Balearic Islands, Serveis Cientifico-Tècnics-, Palma de Mallorca, Spain
[4]University of Balearic Islands, Biology, Palma de Mallorca, Spain
[5]University of Gothenburg, Infectious desease, Gothenburg, Sweden

Background

Mycobacterium chelonae, an emergent opportunistic pathogen, causes infections difficult to treat mainly due to its high antibiotic resistance, being necessary to find alternative targets for new treatments to fight against them. Toxin-antitoxin systems (TAS), small operons that can contribute to the virulence of the strain, are considered important potential targets.

Objectives

The main objectives are i) to identify the potential toxin-antitoxin systems (TAS) in the clinical strain Mycobacterium sp. MHSD3, and ii) to characterize the TAS from a genomic, functional and structural approach.

Methods

BLAST against TADB and GenBank databases were made to find potential TAS and possible homologues, respectively. Functional domains were searched in Pfam database. Antitoxinsand toxins were clonedseparately into expresion vectors: pBAD/HA (inducible with arabinose) and pRSF-DUET (inducible with IPTG), respectively. Constructions were transformed in Escherichia coli BL21 (DE3) pLysS and cultured on LB agar plates supplemented with kanamicin (pRSF-Duet), ampicilin (pBAD/HA) and cloramphenicol (pLysS). Positive clones were used for functional assays in four different conditions: control (no induction), antitoxin induction (arabinose),toxin induction (IPTG) and induction of both (arabinose+IPTG). Cells were grown to the stationary phase, maintaining the antibiotic presure. Absorbance at 600 nm and colony counting mesurements were made. Expresion of the protein was confirmed by MALDI-TOF MS analysis. Structure prediction was performed using I-TASSER.

Conclusion

A functional type II epsilon/zeta toxin-antitoxinsystem was found in Mycobacterium sp. MHSD3. The system was found close to genes codifying for proteins containing β-lactamases andintegrases/transposases domains, representing a potential mobile genetic element stabilizing antibiotic resistance genes.

UNVEILING THE HYBRID GENOME STRUCTURE OF ESCHERICHIA COLI RR1 (HB101 RECA+)

H. Jeong[1], Y.M. Sim[2], H.J. Kim[3], S.J. Lee[3]
[1]Korea Research Institute of Bioscience and Biotechnology, Infectious Disease Research Center, Daejeon, Republic of Korea
[2]Korea Research Institute of Bioscience and Biotechnology, Korean Bioinforation Center, Daejeon, Republic of Korea
[3]Korea Research Institute of Bioscience and Biotechnology, Metabolic Regulation Research Center, Daejeon, Republic of Korea

Backgrounds

There have been extensive genome sequencing studies for *Escherichia coli* strains, particularly for pathogenic isolates. For laboratory *E. coli* strains, however, genome sequence information is limited except for several well-known strains.

Objectives

The availability of accurate genome information for each strain is crucial to the success of a particular application. In this study, we determined the complete genome sequence of *Escherichia coli* RR1 (a *recA*+ derivative of HB101), a host suitable as a multipuprose cloning host.

Methods

A hybrid genome sequence of K-12 MG1655 and B BL21(DE3) was constructed based on the initial mapping of Illumina HiSeq reads to each reference, and iterative rounds of read mapping, variant detection, and consensus extraction were carried out. Finally, PCR and Sanger sequencing-based finishing were applied to resolve non-single nucleotide variant regions with aberrant read depths and breakpoints, most of them resulting from prophages and insertion sequence transpositions that are not present in the reference genome sequence.

Conclusions

We found that 96.9% of the RR1 genome is derived from K-12, and identified exact crossover junctions between K-12 and B genomic fragments. However, because RR1 has experienced a series of genetic manipulations since branching from the common ancestor, it has a set of mutations different from those found in K-12 MG1655. As well as identifying all known genotypes of RR1 on the basis of genomic context, we found new mutations. Our results extend current knowledge of the genotype of RR1 and its relatives, and provide insights into the pedigree, genomic background, and physiology of common laboratory strains.

WHOLE GENOME SEQUENCING INSIGHTS INTO THE POPULATION BIOLOGY AND SECONDARY METABOLITE CAPACITY OF PATHOGENIC BURKHOLDERIA GLADIOLI

C. Jones[1], M. Bull[1], M. Jenner[2], L. Song[2], Y. Dashti[2], G. Webster[1], T. Spilker[3], S.R. Harris[4], J. Parkill[4], T.R. Connor[1], G.L. Challis[2], J.J. LiPuma[3], M. Eshwar[1]
[1]Cardiff University, School of Biosciences, Cardiff, United Kingdom
[2]University of Warwick, Department of Chemistry, Warwick, United Kingdom
[3]University of Michigan Medical School, Department of Pediatrics, Ann Arbor, USA
[4]Welcome Trsut Genome Campus, Welcome Trust Sanger Institute, Cambridge, United Kingdom

Backgrounds

The *Burkholderia* genus encompasses diverse and versatile species, infection with which is associated with poor clinical outcome in persons with cystic fibrosis (CF). One such pathogen, *Burkholderia gladioli*, was responsible for between 15 – 18 % of *Burkholderia* CF infections annually between 1997 and 2016, and is also a pathogen of commercially important crops.

Objectives

The genome sequences of *B. gladioli* isolates from CF and environmental sources were sequenced in order for population biology and secondary metabolism to be investigated.

Methods

Draft genome sequences of over 200 *B. gladioli* isolates were assembled and their secondary metabolite capacity analysed using AntiSMASH. Core genome phylogeny was used to compare genomes.

Conclusions

A wealth of biosynthetic loci were identified, with around 18% of genomic capacity devoted to the production of secondary metabolites and between 15 and 25 biosynthetic gene clusters (BGC's) per isolates. Very few BGC's were found in all isolates, and the total biosynthetic potential of individual isolates was variable. Analysis of bioactive fractions yielded multiple known (e.g. Enacyloxin, Bongkrekic acid, and Toxoflavin) and novel secondary metabolites.

The population biology of this diverse species was brought up to date. Our genomic comparison of environmental and CF isolates confirms that there is no clear CF lineage. Mapping the distribution of biosynthetic loci against the core genome phylogeny has provided new insights into the evolution of *B. gladioli*. By combining genome mining and population biology we aim to exploit the secondary metabolite potential of *B. gladioli*, for the production of novel secondary metabolites.

COMPLETE GENOME SEQUENCE ANALYSIS OF PAENIBACILLUS KONKUKENSIS ISOLATED FROM PIG CONCENTRATE FEED

H.I. Jung[1], K. Yi[1], K. Niu[1], S.W. Lee[2], S.K. Kim[1]
[1]Konkuk University, Department of Animal Sciences and Technology, Seoul, Republic of Korea
[2]Konkuk University, College of Veterinary Medicine, Seoul, Republic of Korea

Backgrounds

Paenibacillus is a genus of Gram-positive, facultative anaerobic rod-shaped, and endospore-forming bacteria. *Paenibacillus* spp. have been detected in divergent environments such as soil, water, rhizosphere, vegetable matter, foods, tree roots, forage, and insect larvae. The main characteristics of *Paenibacillus* spp. is secretion of extracellular enzymes in neutral and alkaline growth conditions and production of polysaccharides, amino acids, and secondary metabolites such as antimicrobial agents, pigments, digestive enzymes, and growth promoters for vegetable and animal.

Objectives

In this study, we have completely sequenced for whole genome of a novel species *Paenibacillus konkukensis* SK3146 from pig concentrate feed and analyzed for beneficial genes as feed additive enzymes.

Methods

Complete genome sequencing of *P. konkukensis* SK3146 was performed using the PacBio® RS II system. Sequencing reads were *de novo* assembled using the PacBio SMRT analysis with default options. Annotation of open reading frames and functional gene analysis were carried out using the Prokka and the BASys softwares, respectively.

Conclusions

P. konkukensis SK3146 has a single circular form of genome that is 7,968,964 bp in size with 53.4% of GC contents. Presence of virulence factors, prophages, and the genes related in the CRISPER-Cas system and antibiotics resistance in the genome were analyzed. The genome encodes functional genes involved in various hydrolytic enzymes such as α-galactosidase, β-glucosidase, β-xylosidase, cellulase, lipase, protease, and xylanase etc. The results suggest that P. konkukensis SK3146 would be a valuable probiotic strain, which secrets variable digestive enzymes and could be used as feed additives in the animal industry.

A NOVEL MECHANISM OF INHIBITION OF TRANSLATION INITIATION PRESENTED BY ACETYLTRANSFERASE TOXIN FROM TA MODULE

D. Jurenas[1], S. Chatterjee[2], A. Konijnenberg[2], F. Sobott[2], L. Droogmans[3], A. Garcia-Pino[4], L. Van Melderen[1]
[1]Free University of Brussels ULB, Laboratoire de Génétique et Physiologie Bactérienne, Gosselies, Belgium
[2]University of Antwerp, Center for Proteomics, Antwerp, Belgium
[3]Free University of Brussels ULB, Laboratoire de Microbiologie, Gosselies, Belgium
[4]Free University of Brussels ULB, Laboratoire de Biologie Structurale et Biophysique, Gosselies, Belgium

Backgrounds

Toxin-antitoxin (TA) modules are small operons widely spread in bacteria. TA modules are believed to be involved in stress response and bacterial persistence. Toxins from type II TAs most commonly are translation inhibitors that act at different stages of translation. Their targets span mRNAs, tRNAs and their charging, rRNAs and translation factors. Small proteins possessing acetyltransferase domain from GNAT family were found to constitute active TA pairs in several pathogenic bacteria.

Objectives

We aimed to characterize at the molecular level the toxicity mechanism of AtaT toxin involved in TA system AtaR-AtaT from enteropathogenic *E. coli* O157:H7.

Methods

Translation was followed *in vivo* and *in vitro* to detect the target of AtaT toxin. Acetylated target and precise modification position was identified by *in vitro* acetylation reactions with isotope labelled acetyl-CoenzymeA and by mass spectrometry. We have further *in vitro* reconstructed the translation initiation events by incorporation of isotopes and by ITC, as well as assayed changes in ribosome profiles *in vivo*.

Conclusions

We have found that AtaT acetylates the free amine group of methionine charged on initiator Met-$tRNA^{fMet}$. Acetyl-Met-$tRNA^{fMet}$ fails to interact with initiation factor-2 thereby hindering 30S initiation complex formation and therefore leading to translation initiation inhibition. High specificity of AtaT for the Met-$tRNA^{fMet}$ in comparison to other charged tRNAs leads to efficient inhibition of translation initiation which is manifested by accumulation of ribosome assembly intermediates.

TOXIN-ANTITOXIN SYSTEM UNDER LAMBDOID PROPHAGE REGULATION

D. Jurenas[1], A. Vandervelde[2], P. De Bruyn[2], T. Jové[3], R. Loris[2], L. Van Melderen[1]
[1]Free University of Brussels ULB, Laboratoire de Génétique et Physiologie Bactérienne, Gosselies, Belgium
[2]Vrije Universiteit Brussel, Structural Biology Brussels- Department of Biotechnology, Brussels, Belgium
[3]Université de Limoges, INSERM- CHU Limoges, Limoges, France

Backgrounds

Bacterial Toxin-antitoxin (TA) modules of type II are typically small operons coding for two proteins: a bacterial cell growth inhibitor and its cognate antidote that binds toxin to form an inactive complex. Antitoxins usually present a DNA-binding domain and are also responsible for regulation of transcription of the TA operon. In several cases TAs are found in three component configurations where regulator and antitoxin are two separate proteins. PaaR2-PaaA2-ParE2 (RAE2) module from enteropathogenic *E. coli* O157:H7 is located in a lambdoid prophage region which provides possibility of complex regulation.

Objectives

We aimed to investigate the transcriptional regulation of *E. coli* O157:H7 CP993-P PaaR2-PaaA2-ParE2 system.

Methods

We used 5'RACE and N-terminal sequencing to detect transcription and translation start sites respectively. Promoter transcriptional activity cloned upstream of GFP was measured upon expression of different regulators. EMSA and DNA footprint assays were performed to confirm binding sites of regulators.

Conclusions

PaaR2 regulator shares several features with lambda cI regulator – localization, leaderless translation, multimerization, binding to additional promoter downstream of RAE2, but has different binding consensus than cI. YdaS-YdaT operon encoded upstream of RAE2 is implicated in transcriptional regulation of RAE2 with YdaS being a negative regulator and YdaT being a positive regulator of an alternative promoter for RAE2 located between YdaS and YdaT. Taken together our results provide an example of a TA module hijacked by a sophisticated transcriptional regulation of lambdoid prophage.

CHARACTERIZATION OF THE ROLE OF SPA33, A COMPONENT OF THE TYPE 3 SECRETION SYSTEM IN SHIGELLA FLEXNERI

M. Kadari[1], D. Lakhloufi[1], H. Koroglu[1], P. SMEESTERS[1], A. Botteaux[1]
[1]Université libre de Bruxelles ULB, Laboratoire de Bactériologie moléculaire, Brussels, Belgium

Backgrounds

Shigella uses a surface nano-syringe, called type 3 secretion system (T3SS), to enter enterocytes. Upon cell contact, T3 secreted proteins, called translocators, form a pore inside the host cell membrane allowing the secretion of proteins, called the effectors, directly into the cell cytoplasm where they interfere with multiple signalling cascades. Nevertheless, the mechanism underlying this T3SS activation is still poorly understood.

Objectives

We aimed to characterize the role of a T3S cytoplasmic component, Spa33, in the secretion activation

Methods

The role of Spa33 was studied by generating point mutations and analyzed their impact on T3S. Binding partners of Spa33 were also investigated by GST pull-down assays.

Conclusions

We have identified an alternative translation initiation site inside the *spa33* gene leading to the expression of a short C-terminal fragment ($Spa33^C$). The suppression of $Spa33^C$ expression totally impairs the proteins secretion by the T3SS. Nevertheless, the ectopic expression of $Spa33^C$ *in trans* restores the secretion of the translocators, but not the one of effectors. The phenotype was shown to be a consequence of the secretion defect of one of the regulator, MxiC. Interestingly, we have shown that MxiC interacts with $Spa33^C$ strengthening our model in which MxiC, in concert with Spa33, prevent early secretion of T3 effectors.

ENDOCYTIC PATHWAYS IN PLANT PATHOGENIC FUNGUS RHIZOCTONIA SOLANI

O.V. Kamzolkina[1], M.A. Kiselica[2], N.A. Krupenina[3], O.A. Kudryavtseva[2], O.V. Shtaer[2], I.S. Mazheika[2]
[1]Lomonosov MSU, Faculty of Biological- department of Mycology and Algology, Moscow, Russia
[2]Lomonosov MSU, Faculty of Biology- department of Mycology and Algology, Moscow, Russia
[3]Lomonosov MSU, Faculty of Biology- department of Biophysics, Moscow, Russia

Backgrounds

Endocytosis is a complex process of transport into the cell and further distribution of soluble substances and macromolecules with the participation of the plasma membrane forming vesicles. Nowadays it is described about ten different types of endocytosis in animals according to the differences in the initial stages. Endocytosis in filamentous fungi is not studied enough. Investigation of endocytic mechanisms in fungi of such kind is a relevant and promising area for fungal cell biology, fundamental and applied mycology.

Objectives

Inhibitory analysis of endocytosis dynamics in plant pathogenic fungus *Rhizoctonia solani.*

Methods

We used methods of tagging endocytic membrane with a fluorescent AM4-64.

Conclusions

We demonstrated that: a) actin cytoskeleton plays a key role in endocytosis; b) microtubular cytoskeleton plays an unusual role in endocytosis. It affects formation of primary vesicles that has not been shown for other organisms; c) inhibitors of different types of endocytosis (clathrin-dependent, dynamin-dependent and lipid-blast) decelerate or completely block it. Our results indicate the existence of conservative endocytic mechanisms in *R. solani* as well as in other eukaryotes. On the other hand, some features of endocytosis in *R. solani* suggest the presence of specific endocytic mechanisms in filamentous fungi.This work was supported by the Russian Foundation for Basic Research (RFBR) project № 16-04-00814.

THE SMALL RNA CHAPERONE HFQ REGULATES QUORUM SENSING AND PATHOGENICITY OF PANTOEA ANANATIS

B. Kang[1], O. Choi[2], J. Park[1], Y. Lee[1], J. Kim[3]
[1]Gyeongsang National University, Division of Applied Life Science BK21 Plus, Jinju, Republic of Korea
[2]Gyeongsang National University, Institute of Agriculture & Life Science, Jinju, Republic of Korea
[3]Gyeongsang National University, Institute of Agriculture & Life Science- Division of Applied Life Science BK21 Plus, Jinju, Republic of Korea

Backgrounds

Hfq is an abundant bacterial RNA binding protein which has many important physiological roles that are usually mediated by interacting with Hfq binding small RNA (sRNA). *Pantoea ananatis* PA13, our model bacterium, causes bacterial rice sheath rot and onion center rot diseases.

Objectives

The objective of this study was to assess the contribution of the sRNA chaperone Hfq of *P. ananatis* to quorum sensing and pathogenicity.

Methods

Several phenotypes of Δ*hfq* mutant including carotenoid pigmentation, swimming motility, EPS production, HR in tobacco leaves, and virulence in rice and onion were assessed.

Conclusions

Δ*hfq* mutant exhibited the deficiency in carotenoid pigmentation, swimming motility, EPS production, HR in tobacco leaves and virulence in rice and onion. All phenotype deficiencies of Δ*hfq* mutant were recovered by genetic complementation with intact *hfq*(pCOK335; pLAFR3::*hfq*). A screen for additional circuits of the *Pantoea ananatis* QS revealed the protein Hfq. We showed that Hfq regulates the transcription of *eanI*(QS signal synthetic gene) and QS signal production. A small regulatory RNA (sRNA) SraH is known to bind Hfq and increase translation of sigma factor RpoS. Δ*sraH* mutant of *P. ananatis* exhibited deficiencies in EPS production, HR and virulence in rice and onion. All phenotypes deficiencies of Δ*sraH* mutant were recovered by genetic complementation with intact *sraH*(pBS28; pLAFR3::*sraH*), indicating SraH controls pathogenicity of PA13.

IDENTIFICATION, BIOSYNTHESIS AND CHARACTERIZATION OF A NOVEL BACTERIOCIN ENCODED IN THE GENOME OF THERMOPHILIC BACTERIA AERIBACILLUS PALLIDUS

A. Kaunietis[1], *A. de Jong*[2], *A. Buivydas*[2], *O. Kuipers*[2]
[1]*Vilnius University, Life Sciences Center, Vilnius, Lithuania*
[2]*University of Groningen, Molecular Genetics, Groningen, The Netherlands*

Backgrounds

Bacteriocins are ribosomally synthesised antimicrobial peptides. Part of them can undergo post-translational modifications. It is a heterogeneous group of small (<10 kDa) peptides that kills other bacteria. They can have narrow or broad range of antibacterial activity spectrum. Producer strain has immunity mechanism to its own synthesised bacteriocin. The current increase of antibiotic resistance among bacteria requires new alternatives to traditional antibiotics. Bacteriocins have many properties like high activity, stability or low toxicity which suggest them as viable alternative. They can be used not only in treatment of human pathogens but also in food-safety applications.

Objectives

The aim of this study was to find genes coding new bacteriocins in the genome of thermophilic bacteria *Aeribacillus pallidus*.

Methods

Genomic DNA of bacteria was sequenced (NGS) on Illumina platform. Velvet algorithms set was used for *de novo* paired-end assembly, resulting draft genome sequence. The RAST, BAGEL3 and antiSMASH servers were used to annotate the genome and to identify putative gene clusters coding bacteriocins which subsequently were cloned to vectors and overexpressed in heterologous host *E. coli*. One of the synthesised antimicrobial peptide was purified using MPLC and HPLC systems and analysed in mass spectrometry methods.

Conclusions

BAGEL3 and antiSMASH observed that genome of *Aeribacillus pallidus* codes several gene clusters of putative biosynthetic machineries of antimicrobial compounds. One of these gene clusters was successfully overexpressed in *E. coli* and a novel active bacteriocin with post-translational modifications was synthesised.

Physiology / Biochemistry / Molecular Microbiology - Part II

TRANSFER OF PLASMIDS FROM ESCHERICHIA COLI TO CLOSTRIDIUM DIFFICILE IS SENSITIVE TO DNASE.

L. Khodadoost[1], *P. Mullany*[1]
[1]*Eastman Dental Institute- University College London, Microbial Diseases, London, United Kingdom*

Backgrounds

Background

Horizontal gene transfer (HGT) between bacterial cells is an important mediator of bacterial evolution and adaption to various environments. In the clinical setting it is a major player in the spread of antibiotic resistance. Three mechanisms of HGT in bacteria are known: conjugation, transduction and transformation. HGT is also used to transfer genetic constructs made in organisms that have relatively advanced genetic technologies, such as *Escherichia coli,* to organisms that are not as amenable to genetic manipulation. Commonly plasmid RK2 is used to mobilise plasmids having a compatible origin of transfer *oriT*. This system is used for genetically modifying the important human pathogen *Clostridium difficile.* In this work we demonstrated *oriT* is not required for transfer between *E. coli* and *C. difficile* and that transfer is abolished in the presence of DNase indicating that a possible cell-to-cell transformation-like mechanism is responsible for transfer.

Objectives

Objectives

To investigate the mechanisms of transfer of plasmids between *E. coli* and *C. difficile*

Methods

Methods

E. coli donor strain CA434 (HB101 carrying the IncPß conjugative plasmid, R702) was transformed with pMTL9301 or pMTL9301Δ*oriT*. *E. coli* donors containing the plasmids was mixed with *C. difficile* CD37 and incubated anaerobically without selection for 18 hours then transferred onto selective plates, supplemented with the antibiotic to select for the plasmid-encoded resistance, with counter-selection against the *E. coli* donor.

Conclusions

Conclusions

Deletion of *oriT* lowered the transfer frequency of pMTL9301 but did not stop it showing that pMTL9301 can be transferred by a mechanism different from conjugation. In support of this pMTL9301Δ*oriT* could not transfer to *C. difficile* in the presence of DNase. We hypothesize that an unknown and undefined DNA uptake system, possibly a cell-to-cell transformation-like mechanism is involved.

DEVELOPMENT OF A HOME BREW REAL-TIME PCR METHOD FOR RAPID DETECTION OF TOXIGENIC CLOSTRIDIUM DIFFICILE FROM CLINICAL SAMPLES

S. Khodaparast[1], A. Mohabati Mobarez[1], M. Mohammad Vasei[2], M. Mahmood Naderi[3], T. Tahereh Tohidi Moghadam[4], F. Savaheli Moghadam[1]
[1]Tarbiat Modares University, Medical Bacteriology, Tehran, Iran
[2]Shariati Hospital- School of Medicine- Tehran University of Medical Sciences, Department of Pathology, Tehran, Iran
[3]Digestive Disease Research Institute- Tehran University of Medical Sciences, Liver and Pancreatobiliary Diseases Research Center, Tehran, Iran
[4]Faculty of Biological Science- Tarbiat Modares University, Department of Nanobiotechnology, Tehran, Iran

Backgrounds

Qualification of *Clostridium difficile* DNA toxins (tcdA&tcdB) is used to monitor *C.difficile* infections. Although several commercial Real-time PCR methods are available for qualification of *C. difficile*, their major disadvantage is the sensitivity and accuracy of the assay.

Objectives

In the present study, an internally controlled qualificative Home brew multiplex Real-time PCR assay based on fluorescent labeled probes technology was developed for detection and qualification of *C. difficile* DNA toxins in stool samples.

Methods

To demonstrate its performance characteristics, a total of 186 stool samples were tested from patients hospitalized in gastroenterology, ICU and Bone marrow transplantation wards. Home brew multiplex Real-time PCR method and the commercial Real Star® altona.
Clostridium difficile PCR Kit assays were performed.TC using CCFA agar (MAST Group,England) was used a reference method.

Conclusions

The assay showed good accuracy and reproducibility. Total of 34 (18.3%) toxigenic *C.difficile* in stool samples were detected. Based on toxigenic culture, sensitivity and a specificity of Home brew method were 100% and 96.6% respectively.

Analysis of a panel containing potentially interfering bacteria demonstrated no cross reactivity with the assay. A strong correlation was observed between this Home brew multiplex Real-time PCR method and the commercial RealStar® altona Clostridium difficile PCR Kit (P = 0.000).
These results indicate that the affordable internally controlled Home brew multiplex Real-time PCR method described will be useful for monitoring and rapid detection of toxigenic *Clostridium difficile* from clinical samples of colitis patients.

METAGENOMICS ANALYSIS OF THE GUT MICROBIAL POPULATION AND FUNCTIONALITY OF THE GRASSHOPPER, OXYA CHINENSIS SINUOSA

S.H. Hong[1], M. Shim[1], B.R. Kim[1], J. Shin[1], J. Lee[1], R.B. Guevarra[1], H.B. Kim[1]
[1]Dankook University, Animal Resources Science, Cheonan, Republic of Korea

Backgrounds

The gut microbiome of insect is known to play pivotal roles in its growth and development. In addition, the genetic diversity of the insect gut microbiota has recently been recognized as potential genetic resources for bioprocessing industry. However, limited information is available regarding the insect gut microbiome.

Objectives

The aim of this study was to get insight into the gut microbial population and functionality of the grasshopper, *Oxya chinensis sinuosa*.

Methods

Fecal samples from individual *O. c. sinuosa* (n = 10) were collected. The V5-V6 hypervariable regions of 16S rRNA genes and the whole metagenome were sequenced by using the Miseq chemistry. Sequences were quality assessed. A phylogenetic assessment was conducted using RDP classifier, and diversity indices were generated using QIIME with an Operational Taxonomic Unit definition at a similarity cutoff of 97%. Functional analysis of gut-derived microbiota was conducted by using the Microbial Genomics Module of CLC Genomics Workbench using the GO Term database Amigo2.

Conclusions

At the phylum level, the gut bacterial communities of *O. c. sinuosa* were dominated by *Firmicutes* and *Bacterioidetes* accounting for > 90% of total sequences. At the genus level, *Weissella, Acinetobacter, Arthrobacter, Lactococcus, and Pantoea* were dominant. The GO term analysis showed that functional properties related with xylan, cellulose, pectin catabolism of the gut-derived microbiota were abundantly present. The results from this study showed gut microbial populations and functionality of the *O. c. sinuosa*. These results establish a baseline toward the understanding of the insect gut microbiome, and provide us with fundamental knowledge for later studies.

THE LAG PHASE OF E. COLI BL21(DE3) IN SUCCINATE MINIMAL MEDIUM SHORTENED BY MUTATIONAL ADAPTATION

H.J. Kim[1], H. Jeong[2], S.J. Lee[1]
[1]Chung-Ang University, Department of Systems Biotechnology, Anseong, Republic of Korea
[2]Korea Research Institute of Bioscience and Biotechnology, Infectious Disease Research Center, Daejeon, Republic of Korea

Backgrounds

As programmed in the genome, bacterial cells can adapt instantly and grow optimally under various environmental conditions. When cells encounter environmental stress, cellular growth will be delayed or lag phase will be prolonged. What happened in cells during the lag phase has been rarely studied, because enough cellular samples could not be obtained from the beginning stage of broth cultures. It has been just noted that the period of lag phase depends on the size and history of inoculum.

Objectives

The aim of this study was to confirm the microbial cellular systems can be reprogrammed by short-term adaptation via genomic mutations.

Methods

It was observed that the aerobic culture of BL21(DE3) cells in succinate minimal medium showed the extended lag phase compared to K-12 cells. We isolated large colonies in succinate minimal agar, which showed higher growth rates in succinate minimal broth. Next, genome sequencing characterized that such adaptations result from single genomic mutations in the regulatory region of a gene encoding a membrane protein. Seed dilution experiments showed those adaptive mutations occurred during the flask culture containing succinate minimal medium.

Conclusions

Accordingly, cellular system could be reprogrammed by adaptation via genomic mutations to change metabolic or regulatory network for optimal cellular growth when appropriate methods are not available in the genome information.

WHOLE GENOME AMPLIFICATION AND SEQUENCING USING THERMOPHILIC DNA POLYMERASE

S. Kim[1]
[1]*korea Research Institute of Standards and Science, Center for bioanalysis, Daejeon, Republic of Korea*

Backgrounds

Whole genome amplification is a method of amplifying small amount of genomic material and used in a variety of applications such as single cell genomics, forensic science and etc. Currently, most of whole genome amplification is carried by the phi29 DNA polymerase which is derived from *Bacillus subtilis* bacteriophage. The phi29 DNA polymerase has exceptional processivity and strand displacement property and the genome can be amplified rapidly and isothermally by multiple displacement amplification. However, the phi 29 DNA polymerase has relatively high error rate and may introduce some errors during the whole genome amplification

Objectives

Investigation of whole genomic amplification using high-fidelity thermophilic DNA polymerase with bacterial genomic DNA and assessment of the amplified genomic materials.

Methods

The bacterial genomic DNA was extracted from *Escherichia coli* KCTC2441T and *Bacillus subtilis* 3135T using GenElute Bacterial Genomic DNA Kit (Sigma-aldrich). The amplification of the bacterial genome was carried out various condition and the amplified genome was sequenced using Illumina sequencer. The sequences reads were assembled using SPAdes and the assembly was assessed with QUAST.

Conclusions

The result suggested that whole genome amplification using high-fidelity thermophilic DNA polymerase can be used de novo single cell genomics or error-sensitive genomic analysis.

DRUG DESIGN FOR HEPATITIS C VIRUS TREATMENT BASED ON SIRNA TECHNOLOGY

O. Koloskova[1], I. Shilovskiy[1], M. Khaitov[1]
[1]NRC Institute of Immunology FMBA Russia, Nanobiomedical Technologies, Moscow, Russia

Backgrounds

hepatitis C virus (HCV) affects about 3% of the world population. The disease is accompanied by damage to the liver and can lead to the death. Existing treatments have drawbacks, so new approaches for HCV treatment are an urgent task. A detailed study of the HCV life cycle molecular mechanisms has led to the possibility of design new gene therapeutics for this pathology treatment.

Objectives

design the novel complex based on siRNA for HCV treatment.

Methods

bioinformatics, PCR, in vitro gene silencing experiments.

Conclusions

there are three HCV genome regions (5'-UTR, NS2 and NS5B genes) which are the most conserved and involved in genome replication. So, these regions were chosen as a target sites for design of siRNA molecules. More than 100 different variants of siRNA molecules against these sites were predicted by OligoWalk program. 14 variants of designed siRNAs were synthetized and significantly downregulated the expression of these targets in vitro. The most potent siRNA targeted to 5'-UTR exhibited up to 90% suppression level.

For drug design the developed siRNA against 5'-UTR was encapsulated in cationic liposomes, modified by lactose derivative for the targeted delivery into the liver cells.

PRELIMINARY FUNCTIONAL CHARACTERIZATION OF PUTATIVE TRANSCRIPTIONAL REGULATORS PA3027, PA3458 AND PA3973 FROM PSEUDOMONAS AERUGINOSA

K. Kotecka[1], *A.A. Bartosik*[1]
[1]*Institute of Biochemistry and Biophysics- Polish Academy of Sciences, Microbial Biochemistry, Warsaw, Poland*

Backgrounds

Pseudomonas aeruginosa is an opportunistic human pathogen, causing nosocomial infections. It is known for metabolic versatility, tolerance to a wide variety of physical conditions, antibiotic resistance mechanisms and complex regulatory systems. ParA and ParB proteins encoded by the majority of bacterial genomes are involved in chromosome segregation. In *P. aeruginosa* ParA and ParB are also directly or indirectly engaged in regulation of gene expression. PA3027, PA3458 and PA3973 are putative transcriptional regulators (TRs) from ParA/ParB regulon.

Objectives

The aim of this work was a functional characterization of PA3027, PA3458 and PA3973. One of the tasks was construction of chromosomal mutants and their phenotypic analysis. Another task concerned analysis of proteins and their regulatory properties *in vivo* and *in vitro*.

Methods

We applied: site-directed mutagenesis, phenotypic characterization (growth, morphology, motility, phenotype microarrays, biofilm formation), protein overproduction and *in vitro*/*in vivo* regulatory experiments.

Conclusions

The chromosomal single deletion mutants in TR genes and double mutants in one of TR gene and *parB* are not lethal for *P. aeruginosa.* The TR mutants do not show significant differences in tested phenotypes when compared to the wild type *P. aeruginosa*. The purified HIS-tagged proteins form dimers *in vitro*. The *PA3458* has the strongest promoter out of three included in the analysis, active in *P. aeruginosa* and *E. coli*. Overproduction of PA3458, but not PA3027 or PA3973 has the negative impact on the growth of *P. aeruginosa*, but not *E. coli.*

ADAPTATION OF SINORHIZOBIUM MELILOTI TO NCR PEPTIDES COUPLED WITH INCREASED RESISTANCE TO ANTIMICROBIAL AGENTS

E. Kovács[1], *É. Kondorosi*[1], *A. Kereszt*[1]
[1]*Biological Research Center, Biochemistry Institute, Szeged, Hungary*

Backgrounds

Since the occurrence of antibiotic-resistant superbugs resulting from the widespread use of conventional antibiotics is multiplying, numerous studies have focused on the use of antimicrobial peptides (AMPs) as therapeutic agents.

A large group of AMP-like molecules with up to 600 different members is the nodule-specific cysteine-rich (NCR) peptide family, which is produced almost exclusively in the infected cells of the nitrogen-fixing nodules of *Medicago truncatula*.

Objectives

Cationic NCR peptides have been found to have antimicrobial activity, killing *Sinorhizobium meliloti* (and other Gram-negative and Gram-positive bacteria as well as fungi) when applied at high concentration.

Methods

We evolved increased tolerance against a peptide in the wild-type and the *bacA* mutant strains of *S. meliloti* 1021 by increasing gradually the concentration of NCR335 in the growth medium. The lines became tolerant not only towards the NCR335 peptide but also against other cationic peptides such as NCR247 and indolicidin isolated from bovine neutrophils. Genome sequencing of the peptide-tolerant lines revealed that they accumulated 5-10 mutations during their evolution. To test the effect of the individuals mutations on peptide sensitivity both in free-living state and *in planta*, they have been transferred into the genome of parental strains as well as the mutant genes cloned in a plasmid have been expressed from the *bacA* promoter.

Conclusions

The mutations can render the cells to tolerate 2-3 times higher concentration of NCR peptides and other antimicrobial drugs than the wild type strain.

FEMS7-1057
Physiology / Biochemistry / Molecular Microbiology - Part II

NEW IMPORTANT GENES IN CHRONIC INTRACELLULAR INFECTION OF SINORHIZOBIUM MELILOTI

E. Kovács[1], *É. Kondorosi*[1], *A. Kereszt*[1]
[1]*Biological Research Center, Biochemistry Institute, Szeged, Hungary*

Backgrounds

Sinorhizobium meliloti differentiates nitrogen-fixing bacteroids in root nodules of the legume *Medicago truncatula*. Nodule-specific cysteine-rich antimicrobial peptides (NCR AMPs) and the bacterial BacA protein are crucial for bacteroid development. Cationic NCR peptides have been found to have antimicrobial activity in vitro, killing *S. meliloti* when applied them at high concentration. To counteract this antimicrobial activity, rhizobia requires the BacA protein. In the absence of this protein, the bacteroids do not differentiate, rather they are immediately killed by the NCR peptides in the nodule as soon as they are released in the symbiosomes. In vitro *bacA* deficient cells were hypersensitive to NCRs.

Objectives

It seemed to be relevant question that NCR-tolerance affected bacteroid development.

Methods

We evolved increased tolerance against NCR335 in *bacA* mutant strain using 10 parallel lines. These mutant lines became tolerant to NCR335, polimyxin B, indolicidin and NCR247. After genome sequencing of the peptide-tolerant lines, the effects of six different mutations were tested in vitro and in planta. A few among these mutations could help *S. meliloti bacA* deficient cells to survive in the milieu filled with antimicrobial peptides which means that the bacteroid differentiation and the formation of nitrogen-fixing nodules were complete.

Conclusions

The mutations can render the cells to tolerate high antimicrobial drug concentration and help rescue *S. meliloti bacA* deficient cells.

INVESTIGATION OF THE ROLE OF BFMR REGULATOR IN CLINICALLY IMPORTANT FEATURES OF OPPORTUNISTIC PATHOGEN ACINETOBACTER BAUMANNII

R. Krasauskas[1], J. Skerniškytė[1], J. Armalytė[1], E. Sužiedėlienė[1]
[1]Life Sciences Center- Vilnius University, Institute of Biosciences, Vilnius, Lithuania

Backgrounds

In recent years, *Acinetobacter baumannii* emerged as an important Gram-negative opportunistic pathogen that plays a great role in hospital-acquired infections. Previously, it has been shown that one of the clinically relevant traits – biofilm formation – of *A. baumannii* is controlled by the response regulator BfmR which, along with histidine kinase BfmS, comprises the two-component signal transduction system BfmRS. However, data on the precise role of BfmR in the regulation of biofilms and other clinically important features is in scarce.

Objectives

To assess the role of BfmR in *A. baumannii* physiology using various mutant alleles.

Methods

Whole *bfmRS* operon was deleted in a clinical strain of *A. baumannii* after which the strain was complemented with various mutant alleles of *bfmR* regulator placed under an inducible promoter. Clinically important phenotypes such as motility, biofilm and pellicle formation were assessed using various inducer concentrations.

Conclusions

We determined, that wild type *bfmR* allele (WT) displays concentration independent biofilm and pellicle induction. However, surface associated motility of *A. baumannii* was variable and was completely abolished under high *bfmR* induction. We also obtained a mutant of *bfmR* which behaves more like an attenuated WT allele – biofilms, pellicles, and motility are complemented only at a particular inducer concentration. The results suggest that the role of BfmR in *A. baumannii* physiology might be concentration-dependent and that we may have obtained at least a fraction of its activity spectrum. They also provide us with the tools to investigate the BfmRS regulon under different biofilm inducing conditions.

CATALYTIC PROPERTIES OF S1-LIKE AND DNASE II-LIKE NUCLEASES FROM ACANTHAMOEBA CASTELLANII.

R. Krela[1], M. Węglewska[2], E. Poręba[2], K. Leśniewicz[1]
[1]Adam Mickiewicz University in Poznan, Department of Molecular and Cellular Biology, Poznan, Poland
[2]Adam Mickiewicz University in Poznan, Department of Molecular Virology, Poznan, Poland

Backgrounds

Free-living amoeba *Acanthamoeba castellanii* is an opportunistic animal pathogen, causal agent of amoebic keratitis and granulomatous amoebic encephalitis (GAE). It is ubiquitous in environment and play crucial role in nitrogen and carbon flow in soil, where it grazes on bacteria. The life cycle of *A.castellanii* is divided into vegetative trophozoite stage and dormant cystic stage. Due to such diverse mode of action and food source, it is important to examine enzymes involved in feeding of this protozoa. Recently there was a many reports on different proteins crucial for phagocytosis, encystation and pathogenicity. Although any nuclease has not been examined, despite fact that high nucleolytic activity of *Acanthamoeba castellanii* was shown as a characteristic trait of this organism.

Objectives

Analysis of *Acanthamoeba castellanii* nuclease activity during life cycle and characterization of involved enzymes.

Methods

Using nuclease activity in-gel assay we examined cell lysate and medium of different time points of *Acanthamoeba castellanii* culture. Based on genome sequence we determined genes and possible proteins responsible for high nucleolytic activity of *A.castellanii*. We overexpressed DNAse II-like and S1/P1-like nucleases using mammalian cells system. Analyzed activity and catalytic properties of this distinct nucleases by zymography.

Conclusions

Acanthamoeba castellanii has two distinct groups of DNA-degrading nucleases. S1/P1-like enzymes with homology to fungi and plants nucleases involved in PCD, and DNAse II-like nucleases with homology to animals enzymes. It is first reported organism with nucleases from both families. Although their functions in *Acanthamoeba castellanii* still remain unclear.

This research is supported by the Dean of the Adam Mickiewicz University Faculty of Biology, grant GDWB 10/2016.

Physiology / Biochemistry / Molecular Microbiology - Part II

COPPER NANOPARTICLES EXERT THEIR ANTIMICROBIAL PROPERTIES BY PREVENTING Z-RING FROMATION

G. Kumar[1], S.D. Pandey[1], S. Mallick[1], S. Ghosh[1], P. Pramanik[1], A. Ghosh[1]
[1]Indian Institute of Technology Kharagpur, Biotechnology, Kharagpur, India

Backgrounds

In recent years, copper nanoparticles (CuNPs) have been used as alternative to challenge the menace of MDR bacteria to prevent nosocomial infections. Though the cost effectiveness and low dosage requirement CuNPs has gained importance in antimicrobial applications, insight in its mode of action remains unknown.

Objectives

1. Assessment of antimicrobial activity of newly synthesized CuNPs
2. Understanding the bactericidal mechanism of CuNPs.

Methods

The stable CuNPs of size 5-45 nm were synthesized by chemical reduction method and characterized physio-chemically using XRD and TEM. The antimicrobial and anti-biofilm properties of CuNPs were assessed (MIC and MBEC) where it showed the ability to sensitize bacterial cells and reduced biofilm formation. Localization studies with ectopically expressed GFP-tagged FtsZ and FtsI in *E. coli* in presence of CuNPs revealed the appearance of elongated cells without Z-rings or medially localized FtsI, indicating the possible involvement of CuNPs in preventing the Z-ring formation. The CuNPs were also able to degrade DNA from both mammalian and bacterial origin possibly due to generation of reactive oxygen species (ROS) as the expression of oxidative stress defence genes,e.g., *ahpC* of *Mycobacterium smegmatis* was significantly high in CuNPs treated cells as revealed by synthesized cDNA by semi quantitative RT-PCR and observing its degradation. However, cytotoxicity (Methyl Tri Chloro Trifluoro Tetrazolium Bromide or MTT) assay of CuNPs showed toxicity towards the RAW 264.7 cells.

Conclusions

The CuNPs synthesized have significant anti-microbial and anti-biofilm activities. Here, we hypothesize that CuNPs might prevent Z-ring formation to inhibit bacterial division and causesDNA degradation possibly through ROS generation.

IMPACT OF POINT MUTATION S191A OF NDM-7 OF KLEBSIELLA PNEUMONIAE ON ITS ANTIMICROBIAL SUSCEPTIBILITY AND PROTEIN STABILITY

G. Kumar[1], I. BAGRE[2], D. Kar[1], S. Biswal[1], A.S. Ghosh[1]
[1]Indian Institute of Technology Kharagpur, Biotechnology, Kharagpur, India
[2]Université Félix Houphouët-Boigny, UFR Biosciences, Abidjan, Ivory Coast

Backgrounds

New Delhi Metallo beta-lactamase (NDM) is of significant public health concern due to its enormous potential to hydrolyse all major beta-lactams including carbapenems. Amino acid substitutions outside the active site reportedly affect NDM beta-lactamase activities.

Objectives

In this work, we attempt to identify specific mutations that can influence the beta-lactam hydrolysing ability of NDM-7.

Methods

bla$_{NDM-7}$ was cloned from clinical isolates in pET and pBAD vectors, and mutated *bla*$_{NDM-7}$ constructs were created by site-directed mutagenesis. Recombinant NDM-7 and its mutant were purified via Ni-NTA metal based affinity chromatography. The differences in proteins *in vitro* biochemical and biophysical properties were analysed via steady state kinetics studies with various beta-lactams and analysed through mass spectroscopy and circular dichroism spectra analysis. The cellular effects of the mutated proteins were investigated by determining the beta-lactam sensitivity alterations in presence and absence of ethylenediaminetetraacetic acid (EDTA) as EDTA chelates zinc ions that are required for NDM-7 activity.

Conclusions

Among the different substitution mutations, serine at position 191 is identified as the most influencing residue for NDM-7. The beta-lactam resistance of NDM-7 is remarkably affected upon S191A substitution and the results are in synchrony with the modulations in kinetic parameters. Normally, NDM-7 hydrolyzes beta-lactams efficiently, but NDM-7_S191A has lost its ability to hydrolyze the beta-lactams tested, especially penicillins and carbapenems. Though, the substitution did not affect the overall folding pattern of the NDM-7, substantial differences in thermal stabilities are observed. Therefore, we hypothesize that Ser191 plays a crucial role in exhibiting beta-lactamase nature of NDM-7.

Physiology / Biochemistry / Molecular Microbiology - Part II

OUTER MEMBRANE VESICLE PRODUCTION IN BACTEROIDES FRAGILIS IS REGULATED BY DNA INVERSION

T. Kuwahara[1], *H. Nakayama-imaohji*[1]
[1]*Kagawa University, Microbiology- Faculty of Medicine, Kagawa, Japan*

Backgrounds

Phase changes in gut microbe *Bacteroides fragilis* mediate variations in a vast array of cell surface molecules. Three master DNA invertases that globally control promoter inversions at many distant regions have been identified in *B. fragilis*: Mpi, Tsr0667 and BF2766. BF2766 inverts two distantly localized promoters, IVp-I and IVp-II.

Objectives

BF2766-regulated invertible promoters of *B. fragilis* were further analyzed to determine the role of their associated proteins in surface structure modification.

Methods

A series of BF2766 mutants were constructed in which the two promoters were locked in different configurations (IVp-I/IVp-II=ON/ON, OFF/OFF, ON/OFF or OFF/ON). DNA microarray analysis was performed with these mutants to identify genetic regions whose alterations in expression were specifically associated with ON/ON genotype. We compared the survival of the four mutants following contact with antimicrobial compounds (bile, LL-37 and human defensins).

Conclusions

ON/ON *B. fragilis* mutants exhibited hypervesiculating, whereas the other mutants formed only a trace amount of outer membrane vesicles (OMVs). By comparing the transcriptomes of the four BF2766 deletion mutants, we found that the transcription of the genes downstream of IVp-II markedly elevated in a hypervesiculating ON/ON strain. The ON/ON mutants showed higher resistance to treatment with bile, LL-37, and human b-defensin 2. Incubation of wild-type cells with 5% bile increased the population of cells with the ON/ON genotype. These results indicate that *B. fragilis* regulates the formation of OMVs through DNA inversions in response to membrane stress.

EXPRESSION OF GROEL PROTEIN OF BURKHOLDERIA MALLEI USING A SYNTHETIC DNA FRAGMENT

S. Kye[1], J. You[1], J. Ha[1]
[1]Animal and Plant Quarantine Agency, Infectious Diseases Department, Seoul, Republic of Korea

Backgrounds

Burkholderia mallei is a gram-negative bacterium that causes glanders, a disease primarily affecting Equidae, which is also a fatal zoonotic infectious disease. Current veterinary diagnosis relies on the crude preparation of the B. mallei antigen. This reagent not only poses a category B biothreat during its preparation, but also causes a considerable number of false results. The preparation of an alternative reliable antigen will improve the diagnosis of glanders.

Objectives

We attempted to produce the GroEL protein of B. mallei, which is easily accessible in diagnostic laboratories and of diagnostic value.

Methods

We synthesized in vitro DNA fragment of the B. mallei GroEL gene based on the sequences previously published. The synthetic DNA fragment was expressed in a baculovirus expression system. Antigenic property of the expressed protein was investigated using the positive sera.

Conclusions

The recombinant GroEL protein produced in this system shared the similar antigenicity to the existing crude antigen of B. mallei, displaying its diagnostic value for the detection of B. mallei. However, further validation using a large number of field sera is needed to be employed in the diagnostic program.

FEMS7-0592
Physiology / Biochemistry / Molecular Microbiology - Part II

TAXOGENOMIC STUDY OF MARINE BACTERIA BELONGING TO THE FAMILY RHODOBACTERACEAE

A. La Mura[1], *M.J. Pujalte*[1], *D. Ruiz*[1]
[1]*Universitat de Valencia, Departamento de Microbiología y Ecología, Valencia, Spain*

Backgrounds

Comparative genomics holds great potential for prokaryote systematics since it allows to perform phylogenetic analyses based on the whole genome content. Furthermore it might assist to improve the general biological knowledge of the organisms through the reconstruction of metabolic pathways. However, and spite considerable progress in recent years many prokaryotic lineages still lack sequenced genomes, which is desirable, at least for the type strain of each species. And for the genomes that are available there is a bias toward organism of medical importance.

Objectives

In this project we want to obtain draft genomes of 50 type strains from the Spanish Type Cultures Collection CECT, all of them related to the marine environment and belonging to different genera of the family *Rhodobacteraceae*. A second aim is to make comparative analysis together with genomic sequences and assemblies from public repositories. As part of these analyses we want to explore phenotypic inferences.

Methods

The methods include laboratory and bioinformatic work:

1. Laboratory techniques: cultivation of strains, extraction and purification of DNA.
2. Bioinformatics work: raw data processing, quality control, de novo assembly, calculation of similarity indexes, functional annotation and search of metabolic pathways.

Conclusions

The present work is intended for the Doctoral Thesis of the presenting author. At present only the selection of strains and a first batch of next generation sequencing has been undertaken. We expect to communicate more results during the event.

FEMS7-3144
Physiology / Biochemistry / Molecular Microbiology - Part II

CHARACTERIZATION OF THE CONTAMINANT BACTERIAL COMMUNITIES IN SUGARCANE FIRST GENERATION (1G) INDUSTRIAL ETHANOL PRODUCTION

C. Labate[1], M.L. Bonatelli[1], M.C. Quecine-[1], M.S. Silva[1]
[1]University Of Sao Paulo / Luiz de Queiroz College of Agriculture, Departamento de Genética, Piracicaba, Brazil

Backgrounds

The industrial ethanolic fermentation process is operated in distilleries, either in fed-batch or continuous mode. A consequence of the large industrial production of ethanol is bacterial contamination in the fermentation tanks, which is responsible for significant economic losses. Thus, we accessed the profile of bacterial communities from two distilleries in Brazil; one operating in fed-batch and another in continuous mode to ethanol production. Both ethanol production mode showed similar bacterial density, around 10^5 gene copies/mL.

Objectives

This work focused on the cultured-independent assessment and characterization of contaminant bacterial community from sugarcane ethanol fermentation process. To this purpose, two distinct distilleries in the state of São Paulo were sampled during the harvest season of 2012-2013. To our knowledge, this is the first cultured-independent assessment of this microbiota.

Methods

Both ethanol production mode showed similar bacterial density, around 10^5 gene copies/mL. However, 16S rDNA sequencing showed differences in the bacterial profile between the two distilleries. It was reported 219 genera that belong to 12 different phyla, several of them never described in this environment. As expected, 91% to 99% of the sequences were affiliated to the *Lactobacillus* genus. Alpha diversity only showed a correlation through the fermentation tanks in continuous mode. Beta diversity clearly separated the two distilleries and the operational taxonomy units (OTU) that were differentially represented belonged mainly to *Lactobacillus*, whereas several of them were unique to the continuous mode.

Conclusions

The *Lactobacillus* genus may be even more important to this environment than ever thought, that each distillery appears to have a distinct microbiome, considering both OTU and predictive gene families, and that this community seems to persist a long time. These results suggest that the study of the contaminant microbiota, from a particular distillery, may be the way to find customized and less expensive solutions to control them.

Physiology / Biochemistry / Molecular Microbiology - Part II

ISCR1 CONTRIBUTES TO ANTIBIOTIC RESISTANCE

C. Lallement[1], *T. Jové*[1], *M.C. Ploy*[1]
[1]*UMR Inserm S-1092, Université de Limoges, Limoges, France*

Backgrounds

The IS*CR* family of bacterial insertion sequences (IS) consists in a group of poorly characterized IS related to IS*91*. They encode an HUH transposase though to catalyze the rolling circle transposition of these families. It is admitted that these elements contribute to dissemination and contribution to the expression of the antibiotic resistance. The prevailing IS*CR*, IS*CR1,* shows a large repertoire of combinations of genes downstream and particularly, antibiotic resistance genes. Moreover, this element provides two outward-oriented promoters suggested in literature, located in a region at the 3' of the element (*ori*IS). The role of IS*CR1* in antibiotic resistance contribution is yet to be clarified.

Objectives

The aims of the study is to investigate (I) if IS*CR1* element contributes to the antibiotic resistance and (ii) to characterize of promoter(s) involved.

Methods

Three antibiotic resistance genes (*qnrA1*, $bla_{CTX\text{-}M\text{-}9}$ and *dfrA19*) located at different distance from IS*CR1* 3' end, were studied. For each of them, *lacZ* transcriptional fusions of their intergenic region with or without *ori*IS region (IS*CR1*) were performed. Promoters activity were measured by β-galactosidase assays. Besides, in parallel, phenotypic assays were performed with each genes and +/- *ori*IS region.

Conclusions

*ori*IS region increases to the expression of those three genes (4-15 fold). When *lacZ* gene was replaced by the *blaCTX-M-9* gene, the presence of *ori*IS presence was essential to provide a resistance phenotype. Therefore, IS*CR1* is involved in process of antibiotic resistance which may explain the epidemiological success of IS*CR1* in bacteria.

BIOCHEMICAL AND FUNTIONAL ANALYSIS OF THE RECOMBINANT ZUR MAP3773C OF MYCOBACTERIUM AVIUM SUBSP. PARATUBERCULOSIS

B. Landeros Sanchez[1], G. Ibarra Molina[1], J.A. Gutierrez-Pabello[2], L.A. Hurtado Ayala[1], M.D.C. Brito Perea[1], A. Fernandez Otal[3], M. Fillat[4]
[1]Universidad Autonoma de Baja California, Facultad de Ciencias Quimicas e Ingenieria, Tijuana- B.C., Mexico
[2]Universidad Nacional Autónoma de Mexico, Facultad de Medicina Veterinaria y Zootecnia, Mexico, Mexico
[3]Instituto Aragonés de Ciencias de la Salud,
Department of Biochemistry and Molecular and Cell Biology. Faculty of Sciences and Institute for Bioc omputation and Physics of Complex Systems, Zaragoza- Spain, Spain
[4]University of Zaragoza,
Department of Biochemistry and Molecular and Cell Biology. Faculty of Sciences and Institute for Bioc omputation and Physics of Complex Systems, Zaragoza- Spain, Spain

Backgrounds

Paratuberculosis (PTB) is caused by *Mycobacterium avium subsp. paratuberculosis* (MAP). The study of protein functionality and characterization is an important issue to elucidate its possible use in vaccine design.

Objectives

This study was designed to characterize the functionality and biochemical properties of the Zur MAP3773c protein

Methods

We performed the purification of the recombinant protein using a zinc-loaded IMAC column, and determined its structural content of zinc, using PAR staining. Oligomeriztion properties were analysed by, crosslinking with gluraldehyde and its self-regulation was assesed by EMSA. Partial structure of Zur MAP3773c was investigated by circular dichroism using DicroWeb.
Results. The recombinant MAP3773c protein presented the following biochemical characteristics: Absence of prosthetic group, non-formation of intramolecular bond oligomers according to DTT analysis, no formation of intermolecular bond oligomers after glutaraldehyde crosslinking, absence of structural zinc and Zn^{2+} dimerization. For secondary structure, the predominance alpha helix constituted around 50%, versus the 20% of the folded beta sheet. Around 23% corresponded to structurally disordered regions, in good concordance with the characteristics of crystal structures available from other FUR proteins. Furthermore, MAP3773c is a self-regulated protein.

Conclusions

MAP3773c is a Zur protein that is able to bind to *E. coli* iron boxes. Interaction of MAP3773c with the mycobacterial box found in its own promoter indicates that the MAP3773c protein is self-regulated.

Physiology / Biochemistry / Molecular Microbiology - Part II

SYNTHESIS OF AMONABACTINS BY AEROMONAS CATALYZED BY A NONRIBOSOMAL PEPTIDE SYNTHETASE WITH UNIQUE ITERATIVE-ALTERNATIVE-OPTIONAL MECHANISM

Q. Esmaeel[1], M. Chevalier[1], P. Jacques[1], V. leclere[1]
[1]Univ Lille - Sciences et technologies, Institut Charles Viollette, villeneuve d'ascq, France

Backgrounds

Aeromonas are Gram negative bacteria, fish pathogens, commonly found in aquatic environments. Pathogenicity and virulence of *A*. *hydrophila* and *A*. *salmonicida* strains are related to the ability to produce virulence factors as siderophores. Amonabactins represente a family of 4 peptide-based siderophores co-produced by *Aeromonas*. They are composed of 5 or 6 monomers including 2 DhB, 2 Lys, an aromatic residue (either D-Trp or D-Phe), and an optional Gly. As many bacterial siderophores, they are synthesized by a non-ribosomal peptide synthetase (NRPS).

Objectives

The objective was to understand how a single NRPS can lead to the co-production of 4 amonabactins

Methods

The domain architecture of proteins constituting the nonribosomal assembly line was determined using specific bioinformatics tools. Hypothesized mechanism of biosynthesis was deciphered by analyzing the production of the 4 different amonabactin forms from mutants deleted in different domains.

Conclusions

From *A. hydrophila* genome sequence, the amonabactin synthesis operon was identified. It is constituted of 7 genes we have named *amo*CEBFAGH, including 4 NRPS genes. The same *amo* cluster was found widespread among most of the *Aeromonas* species. Knockout mutants in *amo*G and *amo*H genes were constructed allowing the deciphering of a unique mode of synthesis, the most complex described so far for NRPS. It was qualified of i) alternative as Phe or Trp can be equally recruited by the same A-domain of AmoG, ii) iterative as AmoE and AmoF work twice to assemble two [Dhb-Lys], iii) optional as Gly incorporated by AmoH is only present in 2 over the 4 amonabactins.

Physiology / Biochemistry / Molecular Microbiology - Part II

CHARACTERIZATION OF A THERMOSTABLE A-GALACTOSIDASE INVOLVED IN RAFFINOSE FAMILY OLIGOSACCHARIDE UTILIZATION FROM CALDICELLULOSIRUPTOR BESCII

A. Lee[1], S. Suzy[1], L. Junho[1], C. Jaeho[1]
[1]Pusan National University, Microbiology, Busan, Republic of Korea

Backgrounds

Caldicellulosiruptor bescii, which belongs to Gram-positive and thermophilic bacteria, was isolated from hot spring in Russia. *C. bescii* has a high capacity to utilize various carbohydrates and harbors 88 genes related to carbohydrate utilization. Among them, the gene cluster proposed to be involved in the degradation of the raffinose family oligosaccharides (RFO) were detected. The RFO, which are α-(1,6) galactosyl derivatives of sucrose, play role in storage or transportation of carbohydrates in mature seeds and leaves of the plants. The bacteria capable of utilization of RFO has rarely studied in environmental sources, but *C. bescii* showed growth on raffinose as carbon source.

Objectives

To understand how *C. bescii* can utilize the RFO, we decided to investigate the proteins related to raffinose transport and hydrolysis.

Methods

As the first step, the gene encoding a putative α-galactosidase (CbAga36) was cloned and expressed in *Escherichia coli*. Size exclusion chromatography of the purified rCbAga36 indicated that the native form was a tetramer. The purified rCbAga36 was optimally active at pH 5.0 and 70°C and had a half-life of 15h at 70°C. rCbAga36 exhibited high activity with artificial substrate compared to the natural substrates such as melibiose and raffinose. rCbAga36 exhibited preferential activity toward the raffinose and stachyose, but did not degrade the galactomannans.

Conclusions

Our results imply that CbAga36 may play a role for degradation of RFO into galactose, further utilized as an energy source in *C. bescii*. Furthermore, its ability for synthesizing novel oligosaccharides by transglycosylation reaction makes it potentially useful for functional food.

SCOLOPENDIN LEADS CA2+-MEDIATED MITOCHONDRIAL DYSFUNCTION AND CASPASE DEPENDENT APOPTOTIC DEATH IN CANDIDA ALBICANS

H. Lee[1], *D.G. Lee*[1]
[1]*Kyungpook National University, School of Life Sciences, Daegu, Republic of Korea*

Backgrounds

Centipedes, a kind of arthropod, reportedly produce antimicrobial peptides as part of an innate immune response. Scolopendin (SRSEKAGLQFPVGRIGRMLKK) is a novel antimicrobial peptide derived from the body of *Scolopendra subspinipes mutilans* centipede by using RNA sequencing.

Objectives

Many antifungal agents have more than one type of cell death mechanism. Although scolopendin is involved in membrane perturbation, the corresponding intracellular changes require further investigation. To address the critical need for novel antimicrobial therapeutics, we have rationally investigated induction of yeast apoptotic death of scolopendin.

Methods

We assessed the cell morphology and calcium ion concentration of the cytosol and mitochondria of scolopendin-treated cells. To investigate the intracellular responses induced by scolopendin, ROS accumulation were monitored. Cells exposed to scolopendin were identified using diagnostic markers of apoptotic response including phosphatidylserine externalization, DNA fragmentation, and nuclear condensation.

Conclusions

Treatment of *Candida albicans* with scolopendin induced the apoptotic response, which in turn led to mitochondrial dysfunction, metacaspase activation, and cell death.The elucidated mechanisms responsible for the antifungal activity of scolopendin provide possible applications in fighting clinical fungal infections.

GLUCOSE-DEPENDENT REGULATION OF THE STRINGENT RESPONSE IN ESCHERICHIA COLI

J.W. Lee[1], Y.H. Park[2], Y.J. Seok[3]
[1]Seoul National University, Biophysics and Chemical Biology, SEOUL, Republic of Korea
[2]Seoul National University, Biological Sciences and Institute of Microbiology, SEOUL, Republic of Korea
[3]Seoul National University,
Biophysics and Chemical Biology- Biological Sciences and Institute of Microbiology, SEOUL, Republic of Korea

Backgrounds

Bacteria respond to various stresses by modulating the level of alarmone (p)ppGpp (guanosine tetraphosphate and pentaphosphate) through a process called the stringent response. In *Escherichia coli*, the level of (p)ppGpp is regulated by stringent factors, RelA and SpoT proteins. RelA catalyzes the synthesis of (p)ppGpp, whereas SpoT catalyzes both the synthesis and hydrolysis of (p)ppGpp, serving as a bifunctional enzyme.

Objectives

SpoT is particularly important in balancing the intracellular level of (p)ppGpp since it is the only enzyme responsible for (p)ppGpp hydrolysis. However, the underlying mechanisms for the (p)ppGpp hydrolase activity regulation of SpoT still remain unknown in *E. coli*. In this study, we conducted ligand-fishing experiment and found Rsd as a novel interaction partner of SpoT.

Methods

We identified specific interaction between SpoT and Rsd using ligand-fishing experiment and BACTH (Bacterial Two Hybrid) assay.

Measuring intracellular (p)ppGpp concentration using TLC analysis in Rsd overexpressing strain.

Growth test under starvation condition.

Conclusions

HPr is a general PTS component and participates in the phosphorylation-coupled transport of numerous sugars. We recently reported that HPr is dephosphorylated and interacts with Rsd when a favorable carbon source, such as glucose, is available. In this study, we demonstrate that only dephosphorylated form of HPr, but not phosphorylated HPr, can sequester Rsd from SpoT to antagonize its stimulatory effect on SpoT. Based on these data, we suggest that SpoT-mediated stringent response can be regulated by Rsd in a glucose-dependent manner, proposing a novel stringent response mechanism in *E. coli*.

FRAS (FERMENTATION-RESPIRATION SWITCH) EXPRESSION IS INDUCED UNDER ANOXIC CONDITION VIA OXYGEN-FNR-SRNA REGULATORY PATHWAY

K.H. Lee[1], B.R. Jang[1], K.J. Lee[1], S.J. Park[2]
[1]Sogang University, Department of Life Science, Seoul, Republic of Korea
[2]Yonsei University College of Medicine, Department of Environmental Medical Biology, Seoul, Republic of Korea

Backgrounds

An enzyme, FrsA converting pyruvate to acetaldehyde and carbon dioxide has been identified in *Vibrio vulnificus*. Since FrsA protein was rarely detectable in cells grown under oxygen-rich condition, the *in vivo* activity of FrsA was observed in cells grown under anaerobic condition.

Objectives

To investigate the regulatory mechanism for anaerobic induction of FrsA, *frsA* transcription was monitored, but no significant difference in its transcription was observed in the cells grown under aerobic or anaerobic conditions, suggesting the involvement of posttranscriptional regulation in FrsA expression.

Methods

In silico analysis of *V. vulnificus* genome showed a tentative sRNA whose sequence is complementary to 5'-UTR of *frsA* mRNA. A northern blot revealed the presence of 350 nucleotide-long sRNA. Regulatory role of this sRNA was examined using the mutant deficient in the sRNA. The mutant showed high level of FrsA protein and activity of pyruvate decarboxylase even under the aerobic condition. Thus, it was named as the regulatory sRNA for FrsA expression (Rsf). Regulatory dependency of Rsf on oxygen was further examined in repressing FrsA expression. *rsf* gene expression was repressed by a transcription factor FNR under anaerobic condition, whereas repression of *rsf* transcription by FNR was relieved in the presence of oxygen.

Conclusions

Therefore, this study demonstrates that the cellular content of FrsA is minimized during aerobic growth period via repression of its expression by Rsf. Under anaerobic condition, however, FrsA expression is derepressed due to repression of *rsf* transcription by FNR, resulting in increased fermentative metabolism(s) of *V. vulnificus*.

ACETATE FLUXES IN ESCHERICHIA COLI ARE DETERMINED BY THE THERMODYNAMIC CONTROL OF THE PTA-ACKA PATHWAY

B. Enjalbert[1], P. Millard[1], M. Dinclaux[1], J.C. Portais[1], F. Letisse[1]
[1]Laboratoire d'Ingénierie des Systèmes Biologiques et des Procédés, Metasys, Toulouse, France

Backgrounds

It is known that *Escherichia coli* excretes acetate when growing on excess fermentable sugars. It is consumed once the glucose is totally depleted in the medium. This diauxic behavior is due to the catabolite repression exerted by glucose on acetate utilization. Acetate consumption is prevented by the repression of acetyl-coA synthetase (*acs*) expression, considered as the main pathway for acetate metabolization. However, it was recently observed that acetate can be taken up and metabolized during exponential growth of *E. coli* K-12 strains on a mixture of glucose and acetate[1]. The ability of *E. coli* to consume acetate in such conditions is highly intriguing since *acs* is not expressed due to catabolite repression. This observation suggests that acetate can still be utilized by another pathway upon glucose excess.

Objectives

We first aimed to clarify the pathway by which acetate is consumed upon growth on excess glucose and then to identify the mechanism(s) that control(s) acetate metabolism in such conditions.

Methods

To address these questions, we designed and carried out dynamic ^{13}C-labeling experiments to quantify acetate production and consumption fluxes individually, and to identify the metabolic pathways supporting the fluxes.

Conclusions

The results pointed out that the constitutive Pta-AckA pathway (*pta*, phosphate acetyl-transferase; *AckA*, acetate kinase) was responsible for both fluxes, and thermodynamic and *in silico* kinetic analyses suggested this pathway is thermodynamically controlled *in vivo* by extracellular acetate level. Catabolite repression is hence not the unique determinant of acetate utilization. The regulatory mechanism proposed was validated experimentally on glucose and two other glycolytic substrates.

Physiology / Biochemistry / Molecular Microbiology - Part II

DICEPHERING THE ROLE OF MULTIPLE THIOREDOXINS FOLD PROTEINS OF LEPTOSPIRILLUM SP. CF-1 IN OXIDATIVE STRESS TOLERANCE

G. Levicán[1], D. González[1], P. Álamos[1], O. Orellana[2], R. Chávez[1]
[1]Universidad de Santiago de Chile, Biología, Santiago, Chile
[2]Universidad de Chile, Instituto de Ciencias Biomédicas, Santiago, Chile

Backgrounds

One of the main target of reactive oxygen species (ROS) are the thiols group of proteins, which upon oxidation are regenerated through activity of thioredoxins. *Leptospirillum* spp. is a bioleaching microorganism that is naturaly exposed to conditions as acidic pH and high concentrations of metals, that contribute to ROS generation and consequently induction of oxidative stress and biomolecule damage. Bioinformatic studies in *Leptospirillum* sp. CF-1 allowed to identify multiple thioredoxin coding genes (*trx)*. However, it is unknown what is the contribution of each *trx* gene to tolerate oxidizing conditions

Objectives

In this research, we analyzed the individual participation of 13 *trx* genes from *Leptospirillum* sp. CF-1 in response to oxidative stress

Methods

Role of the thioredoxins was addressed by using a bioinformatic approach in combination with genetic complementation assays carried out in Escherichia coli, and evaluating mRNA levels of *trx* genes from *Leptospirillum* sp. CF-1 exposed to ferric sulfate and diamide.

Conclusions

Analysis revealed that predicted thioredoxins can be assigned to functional categories including thioredoxins, peroxiredoxins, and disulfide oxidoreductases, among others. The 13 *trx* genes were transcriptionally active, although they responded differentially to ferric sulfate or diamide stress. Moreover, there was one *trx* gene that was fulfilling a more general role responding to both oxidative agents. It was demonstrated that some of these genes conferred oxidative protection to a thioredoxin-deficient strain of *E. coli* by restoring the wild-type phenotype under oxidative stress conditions. These findings can be the basis to understand the adaptations of acidophilic microorganisms to extremely oxidative bioleaching environments, with a possibility for an improvement of the bioleaching industrial process.

Physiology / Biochemistry / Molecular Microbiology - Part II

A PHAGE PROTEIN INTERACTS WITH TYPE IV PILI FOR SUPERINFECTION EXCLUSION

Y. Li[1], X. Wang[1]
[1]Chinese Academy of Sciences- South China Sea Institute of Oceanology, LMB, Guangzhou-, China

Backgrounds

Filamentous prophage Pf4 in *Pseudomonas aeruginosa* PAO1 plays an important role in biofilm development, Pf4 was able to convert into superinfective phage during the biofilm formation of PAO1, and the released Pf4 phages were capable of re-infecting the PAO1 host, The underlying mechanism of Pf4 superinfection remains largely unknown.

Objectives

A small protein PA0721 encoded by Pf4 plays an important role in Pf4 superinfection exclusion.

Methods

Overexpression of PA0721 in the PAO1 and Pf4 deletion mutant strains resulted in the abortion of Pf4 superinfection and the loss of twitching motility. Twitching motility allows *Pseudomonas aeruginosa* to respond to stimuli by extending and retracting its *type IV pili*. PilJ is a protein necessary for this surface-associated twitching motility and bears high sequence identity with the methyl-accepting chemotaxis proteins in *E. coli*. Since the uptake of Pf4 requires the type IV pili, we reasoned that PA0721 might interact with the components of type IV pili to block twitching motility. GFP-fused PA0721 was localized to the cell poles and it interacted with PilJ via the periplasmic domains of PilJ. Furthermore, the minor coat protein PA0724 of Pf4 also interacts with PilJ.

Conclusions

The entry of Pf4 into PAO1 might be mediated by the interaction of PA0724 and PilJ, and PA0721 might disrupt this interaction to inhibit Pf4 superinfection. Additionally, genes encoding PA0721 and PA0724 are conserved among Pf filamentous phages. Therefore, PA0721-mediated inhibition of twitching motility may reveal a common mechanism for the superinfection exclusion of Pf filamentous phages.

Physiology / Biochemistry / Molecular Microbiology - Part II

AN IMPROVED CRIB REPORTER ENABLES THE IDENTIFICATION OF INDIVIDUAL HYPHAE OF TRICHODERMA ATROVIRIDE ENGAGED IN MYCOPARASITIC ATTACK

A. Lichius[1], *L. Salzmann*[1], *D. Moreno-Ruiz*[1], *S. Zeilinger*[1]
[1]*University of Innsbruck, Institute of Microbiology, Innsbruck, Austria*

Backgrounds

Launching a mycoparasitic attack depends on the perception of host-derived signals by individual hyphae of the mycoparasite. However, not all hyphae constituting the colony periphery execute the same cellular programs at the same time. Therefore, a principal difficulty for researching host-parasite interactions on the cellular and molecular level is the identification of individual hyphae that at the time of observation are actively engaged in mycoparasitic signalling. This becomes specifically important for single-molecule imaging techniques where pinpointing such active hyphae is a prerequisite for efficient data acquisition.

Objectives

Our rational was to establish a fluorescently-labelled CRIB reporter to visualise those peripheral hyphae of the mycoparasite *Trichoderma atroviride* that grow positively chemotropic towards a host fungus, and thus most likely execute mycoparasitic cellular programs.

Methods

Fluorescent CRIB reporters exclusively associate with active, i.e. GTP-bound, Cdc42 and Rac1 GTPases, and specifically label hyphae that show active polarised tip growth. Using site-directed mutagenesis we generated an EGFP variant with 20-fold increased brightness which significantly improved CRIB detection. To allow a clear distinction between parasite and host hyphae in the contact zone we used as confrontation partner and prey *Botrytis cinerea* expressing cytoplasmic mCherry.

Conclusions

The novel *T. atroviride* CRIB-mbasicGFP reporter localises inside the Spitzenkörper and as apical crescent/cap in growing hyphae. Repositioning of apical GTPase activity precedes and thus regulates tip growth directionality. Hence, the analysis of CRIB reporter dynamics allows differentiation and prediction of positively chemotropic hyphae, and therefore enables a quantitative approach on mycoparasitic signaling in relation to host-parasite distance and different host species.

Physiology / Biochemistry / Molecular Microbiology - Part II

SPOT 42 BINDING TO DIFFERENT GAL MRNAS RESULTS IN DIFFERENTIAL CONSEQUENCES

H. Lim[1], Y. Lee[1], H.J. Jeon[1], X. Wang[1]
[1]Chungnam National University, Biology, Daejeon, Republic of Korea

Backgrounds

Most of small RNAs (sRNA) in *Escherichia coli* work by binding to target mRNA through base-pairing. Spot 42, a sRNA of 109 nucleotide-long, harbors 3 regions in its 5' half, about 10 nucleotide each for binding to target mRNAs. The *gal* operon has 4 structural genes in *E, T, K* and *M* order and harbors a Spot 42 binding site at *T-K* junction. Out of 6 *gal* mRNAs, 4, mT1, mK2, mK1, and mM1 have the same Spot 42 binding site, thus, in different locations relative to their 3'ends.

Objectives

In this study, we investigated molecular consequences of Spot 42 binding to these *gal* mRNAs.

Methods

3' Race (Rapid Amplification of cDNA End) assay and Northern blot analysis.

Conclusions

We found that Spot 42 binding to mT1 causes mT1 production, but that to mK2, mK1, and mM1 leads to degradation. Spot 42 binds to a transcript between RNA polymerase (RNAP) and leading ribosome (LR), causing 1) RNAP to pause transcription and 2) blocking translation initiation of LR. These two events, respectively, produce the 2 clusters of mT1 3'ends. These results suggested that if Spot 42 binding occurs to emerging transcript, the binding leads to production of target mRNA, but if that occurs to existing transcript, i.e. post-transcriptionally, the binding leads to degradation of target mRNA.

FUNCTIONAL ANALYSIS OF INDOLE-3-ACETIC ACID METABOLIC GENES IN ACINETOBACTER BAUMANNII

G.H. Lin[1]
[1]Tzu Chi University, Microbiology, Hualien, Taiwan R.O.C.

Backgrounds

Indole-3- acetic acid (IAA) plays an important role in crop development. Bacteria in rhizosphere such as *Pseudomonas* or *Acinetobacter* evolved with the ability to degrade and product IAA.

Objectives

In order to understand the biological function of IAA metabolic genes in rhizosphere, both of IAA degradation and synthesis genes will be studied in detail.

Methods

Marker-less and insertional method were conducted to product mutants for the study of biological and biochemical of those genes. A modified rapid method employed LC/MS-MS was used to analyze the concentration of IAA was established by our group. Quantitative RT-PCR was carried out to determined transcription of different genes.

Conclusions

The *iac* gene cluster contributes to the regulation and degradation of IAA in *A. baumannii.* IacR, a MarR family regulator represses *iac* operon expression in the absence of IAA. In the presence of IAA, IAA served as a ligand to remove IacR from the promoter and RNA polymerase promote the expression of *iac* operon for IAA degradation. Culture experiment, qRT-PCR and GC/MS-MS results determined that *A. baumannii* produced IAA via indole pyruvate (IpyA) route. In summary, IacR regulates *iac* operon expression which is functions for IAA degradation. IpyA is the major route for IAA production via a tryptophan-dependent pathway. *A. baumannii* manipulates IAA concentration in rhizosphere by equipping production and degradation machinery with differential regulatory mechanisms.

Physiology / Biochemistry / Molecular Microbiology - Part II

THE SELF-IMMUNE RESPONSE OF TRICHODERMA TO ITS OWN SECONDARY METABOLITES

C.M. Liu[1], S.Y. Liu[2], C.K. Liao[1], H.L. Peng[2], N.R. Vaikar[1], K.C. Peng[1]
[1]National Dong Hwa University, Department of Life Science and Institute of Biotechnology, Hualien, Taiwan R.O.C.
[2]Da-Yeh University, Department of Molecular Biotechnology, Changhua, Taiwan R.O.C.

Backgrounds

Alternative approaches, such as biological control, have been employed to manage soil-borne plant pathogens. Several *Trichoderma* spp. have been shown to reduce the severity of plant diseases by inhibiting plant pathogens through their highly potent antagonistic and mycoparasitic activity. Plant growth promotion, defenses and tolerance to biotic & abiotic stress benefit from *Trichoderma* as well. The biocontrol activities are driven by variety of secondary metabolites secreted by *Trichoderma*.

Objectives

Previously we identified several metabolites involved in *Trichoderma*'s biocontrol mechanism, by inducing mitochondria-mediated apoptosis in phytopathogens and lead to deadly lysis in the end. In this study, we further investigate the self-immune response induced by *Trichoderma*'s own metabolites.

Methods

MALDI-TOF and LC-MS/MS analysis identified four significantly up-regulated expressed proteins: HEX1 , nitroreductase, transaldolase, and serine hydroxymethyltransferase. Quantitative PCR analysis indicated the up-regulated expression of corresponding mRNA as well. Apparently certain metabolic pathways and signaling were accelerated to protect *Trichoderma* itself from oxidative burst. Four ROS-related enzyme activities were also measured following 3-day treatment with 30 ppm of specific metabolites. SOD was significantly increased, PEX slightly increased, and GST showed no variation. However, CAT exhibited about 25% decrease instead. The escalated ROS level within *Trichoderma* hyphae seemed scavenged by highly induced SOD.

Conclusions

The highly expressed HEX1, NTR, TRAD, SHMT, and SOD following 3-day treatment with its own secondary metabolites definitely involved in self-immune response of *Trichoderma*. The investigation of specific roles played by these proteins and signaling network within is underway.

Physiology / Biochemistry / Molecular Microbiology - Part II

CABBAGE RESISTANCE AGAINST PHYTOPATHOGENS INVOLVING TRICHODERMA METABOLITES

C.K. Liao[1], S.Y. Liu[2], H.L. Peng[2], K.C. Peng[1]
[1]National Dong Hwa University, Department of Life Science and Institute of Biotechnology, Hualien, Taiwan R.O.C.
[2]Da-Yeh University, Department of Molecular Biotechnology, Changhua, Taiwan R.O.C.

Backgrounds

It is well known *Trichoderma* spp contribute crucial benefits to the host plant through variety of proposed mechanisms such as boosting host plant defense responses against phytopathogens. The underlining mechanism of induced systemic resistance and systemic acquired resistance in primed plants provoked by *Trichoderma* spp remained an interesting issue.

Objectives

Previously, we showed two major *Trichoderma* secondary metabolites, namely chrysophanol and anthraquinone, exhibited significant antimicrobial activities. In this study, we further investigate any beneficial effect of these two compounds to the host plants and their intervention during phytopathogen infection.

Methods

Cabbage was mainly used as the host plant in this study. The seed germination rates were calculated following chrysophanol/anthraquinone treatment. The whole plant development, as well as susceptibility to phytopathogen infections, was assessed following chrysophanol/anthraquinone treatment or *Trichoderma* colonization. Further investigation with q-PCR to learn the variation of pathogenesis related proteins (PR-1), cell wall degrading enzymes, and reactive oxygen species scavenging enzymes were also conducted. The leaf infected area can be reduced significantly either by the presence of *Trichoderma* in rhizosphere or chrysophanol/ anthraquinone treatment prior to phytopathogen challenge. In addition, DNA fragmentation was inhibited, PR-1 suppressed, while GST, SOD, and ascorbate peroxidase induced.

Conclusions

Both compounds at the concentration of 1,000 ppm, better effectiveness of chrysophanol than pahybasin, dramatically reduced the susceptibility of cabbage to phytopathogen infection. Through scavenging cytotoxic reactive electrophiles, induced GST, SOD, and ascorbate peroxidase significantly reduced the oxidative tissue damage in phytopathogen-infected cabbage. Both compounds indeed promoted the defense response of cabbage against phytopathogens tested.

Physiology / Biochemistry / Molecular Microbiology - Part II

FUNCTIONAL AND GENETIC ANALYSIS OF A SYSTEM THAT RAISES THE FITNESS LOCATED ON THE NATIVE BACILLUS SUBTILIS PLASMID PLS20.

A. López Pérez[1], *W. Meijer*[1]
[1]*Centro Biología Molecular Severo Ochoa, Virology and Microbiology, Madrid, Spain*

Backgrounds

The emergence of (multidrug) resistant bacteria (MRB) is one of the main clinical problems today. There are at least three different strategies to combat the increasing problems associated with MRB. First, identifying novel cellular targets for the development of new potential antibiotics, second, identifying and developing new antibiotics or/and new antibiotic-strategies against existing cellular targets, and third, studying the mechanisms responsible for the dissemination of antibiotic resistances and use the information to develop drugs to interfere with these processes

Objectives

Studying the mechanisms responsible for the dissemination of antibiotic resistances and use the information to develop drugs to interfere with these processes

Methods

Bacteria evolve rapidly which is especially due to their ability to exchange genetic material, which can occur via different processes, collectively named Horizontal Gene Transfer (HGT). Most bacteria contain plasmids that can be transferred to plasmid-free bacteria in a process called conjugation. Antibiotic resistance genes are often located on conjugative plasmids. Therefore, plasmid conjugation plays a major role in the spread of antibiotic resistance.

Conclusions

Our results indicate that, besides of conjugation, pLS20 has another mechanism that allows most of the cells in an ecological niche to have the plasmid. We have focused on the functional and genetic analysis of a cassette of two plasmid gene. These genes constitute a functional module that together raise the fitness of *Bacillus subtilis* cells harboring the plasmid.

TRANSMEMBRANE REDOX AND PROTEOLYSIS CONTROL OF C-DI-GMP SIGNALING IN BACTERIAL BIOFILM FORMATION

M. Lorkowski[1], S. Herbst[1], O. Sarenko[1], K. Nguyen[1], T. Jaenicke[1], R. Hengge[1]
[1]Humboldt-University of Berlin, Biology/Microbiology, Berlin, Germany

Backgrounds

The nucleotide second messenger c-di-GMP nearly ubiquitously promotes bacterial biofilm formation, with enzymes that synthesize and degrade c-di-GMP being controlled by diverse N-terminal sensor domains.

Objectives

Here we describe and compare members of a novel class of widely occurring c-di-GMP phosphodiesterases that feature a periplasmic 'CSS domain' flanked by two transmembrane regions (TM1/TM2) and followed by a cytoplasmic EAL domain with phosphodiesterase activity.

Methods

Using PdeC of *E. coli* as a model, we show that DsbA/DsbB-promoted disulfide bond formation in the CSS domain inhibits activity. By contrast, the free-thiol form is enzymatically active, which depends on TM2 as a dimerization domain. Moreover, this form is processed by periplasmic proteases DegP and DegQ, yielding an irreversibly activated TM2+EAL fragment slowly removed by further proteolysis.

Conclusions

This versatile interplay of redox control and proteolysis of PdeC controls cellular c-di-GMP and thereby the production of amyloid curli fibres and cellulose, i.e. major biofilm matrix polymers.

Physiology / Biochemistry / Molecular Microbiology - Part II

DISTRIBUTION OF FITNESS EFFECTS OF RANDOM MUTATIONS IN THE SALMONELLA TYPHIMURIUM LT2 GENOME

U. Lustig[1], D.I. Andersson[1]
[1]Uppsala University, Department of Medical Biochemistry and Microbiology, Uppsala, Sweden

Backgrounds

The distribution of fitness effects (DFE) of random mutations for a whole genome is a key determinant of how evolution progresses in response to mutation, selection and drift. Few studies have directly measured the fitness effects of random single mutations in the genome in their native context with high sensitivity. New techniques like whole genome sequencing (WGS) and Magnetic-Activated Cell Sorting (MACS) allow us to study the distribution of mutations and fitness changes in detail.

Objectives

To determine the DFE and identify the types of mutations that are accumulated in the *Salmonella typhimurium* genome under conditions when genetic drift is high.

Methods

We serially passaged *Salmonella typhimurium* LT2 on solid rich media for 2000 generations under conditions expected to result in a high genetic drift (i.e. one cell bottleneck). The 200 evolved lineages were whole genome sequenced (Illumina MiSeq) and analysed for SNPs, insertions, deletions, amplifications and compared to the ancestral parental strain. Fitness measurements were performed by competing the evolved lineages (YFP-labelled) with an isogenic ancestral strain (BFP-labelled), using Magnetic-Activated Cell Sorting (MACS). The selection coefficients were calculated for the evolved lineages and compared to the ratio of the ancestral YFP/BFP strains.

Conclusions

The whole genome sequence data revealed that the majority of the evolved lineages had acquired between 1 and 4 mutations. The main fraction of the mutations were SNVs and 80% were located in coding regions. The fitness data show a distribution of selection coefficients between -0.6809 and 0.0687 for all lineages and an average change in fitness of -0.031.

Physiology / Biochemistry / Molecular Microbiology - Part II

WHEN ANTISENSE MAKES SENSE: EXPLORING THE ROLE OF RNA POLYMERASE-BINDING RNA APTAMERS IN CONTROL OF BACTERIAL ANTISENSE TRANSCRIPTION

A. Magan Garcia[1], N. Sedlyarova[1], R. Schroeder[1]
[1]Max F. Perutz Laboratories, Department of Biochemistry and Cell Biology, Vienna, Austria

Backgrounds

RNA polymerase (RNAP) is the enzyme responsible for transcription in *Escherichia coli*. Its activity is tightly controlled by multiple factors, such as proteins, RNAs and small molecules. We have identified a new class of RNA regulatory elements that modulate transcription in *cis*, either by leading to premature termination or antitermination. RNAP-binding RNA aptamers (RAPs) are relatively short RNA sequences (30-100 nucleotides) binding to the RNAP with high affinity. There are approximately 15,000 RAPs 'encoded' in the *E. coli* genome and the majority (~60%) is found antisense to annotated genes (asRAPs). Since the *E. coli* genome is pervasively transcribed from both strands, we hypothesised that antisense RAPs play a significant role in controlling antisense transcription, both positively and negatively.

Objectives

We studied the potential role of asRAPs in modulating antisense transcription. We particularly focused on how RAPs modulate transcriptional interference (TI) happening from two convergent promoters.

Methods

Differential expression analyses of the *E.* coli transcriptome were performed and several datasets were obtained (i.e. RNA 3' end mapping and RNA deep-sequencing). Combining these data, we were able to identify several asRAP candidates with regulatory potential. The activity of these candidates was studied in depth on TI plasmid-based reporter systems by diverse methods (RT-qPCR, Northern blotting, and fluorescence reporter assays).

Conclusions

Our preliminary data suggest that certain asRAPs are able to terminate transcription from the antisense strand, reducing TI and increasing the expression level of genes expressed from the sense promoter. We therefore suggest that asRAPs are widespread modulators of transcription interference.

MUTATIONS IN GENES OF 3R SYSTEM OF NEISSERIA GONORRHOEAE AS THE CAUSE OF THE 1901ST CLONE SUCCESS

N. Bodoev Ivan[1], M. Malakhova[1], I. Alexander Manolov[1], I. Karpova[2], E. Kostryukova[2], E. Ilina[1], M. Vadim Govoruna[1]
[1]Federal Research and Clinical Center of Physical-Chemical Medicine, Laboratory of Molecular microbial genetics, Moscow, Russia
[2]Federal Research and Clinical Center of Physical-Chemical Medicine, Laboratory of Postgenomic Research in Biology, Moscow, Russia

Backgrounds. The expansion of drug resistant bacteria is one of the global contemporary problems. *N. gonorrhoeae* (NG) is a gram-negative bacterium which causes common sexually transmitted diseases gonorrhea and easy acquires various mechanisms of drug resistance (DR). Recent studies of DR evolution were considered in the context of the high rates of recombination within the *Neisseria* genus. It was shown that NG strains of sequence type 1901ST are very successful in DR developing and spreading. However, not all of 1901ST strains bring the known DR determinants.

Objectives. In this work we tried to establish the relationship between the unique set of mutations in 3R (Repair, Replication, and Recombination) system genes of 1901ST strains and their successfulness.

Methods.

83 NG strains with known susceptibility to the cefixime, azithromycin and tetracycline including both our 1901ST strains NG51 and NG0705 and whole genome sequenced strains from the NCBI database were selected for the cluster analysis based on the 3R system genes polymorphism. Mutation rates in NG51 and NG0108 (ST 12443) strains were estimated by fluctuation test.

Conclusions.

It was shown that 1901ST strains form a distinct phylogenetic cluster on the tree built on a set of 3R system gene polymorphism. It could assume higher mutation rates in successful 1901ST NG strains; however, this assumption was not confirmed by the results of the fluctuation test.

Physiology / Biochemistry / Molecular Microbiology - Part II

HOW CAN TYPE IV SECRETION SYSTEM SECRETE INTEGRAL MEMBRANE PROTEINS?

S. Malmsheimer[1], *L. Krampen*[1], *S. Wagner*[1]
[1]*Institut für Medizinische Mikrobiologie und Hygiene, Sektion Zelluläre & Molekulare Mikrobiologie, Tübingen, Germany*

Backgrounds

During the course of infection, *L. pneumophila* and *C. burnetii* translocate a large number of effector proteins in a type IV secretion system (T4SS)-dependent manner into the host cell to promote intracellular survival and colonization. Among these effector proteins are integral membrane proteins that find their final destination in one of the host cell's membranes. Transmembrane domains (TMDs) within T4SS substrates create a targeting conflict within the secreting bacterium because signals for two different incompatible secretion pathways are interlinked in the same protein: Transmembrane helices are by themselves a membrane targeting and integration signal while the C-terminal translocation signal destines proteins for secretion through T4SSs.

Objectives

We aim to understand how the bacterial cell discriminates between inner membrane targeting and secretion by the T4SS.

Methods

We studied the membrane targeting and integration potential of four out of 90 TMD-containing T4SS substrates of *Legionella pneumophila* and *Coxiella burnetii* in different *in vivo* model systems.

Conclusions

We noticed that some proteins avoid inner membrane insertion by a fine-tuned lower hydrophobicity of their TMDs, which is similar to what we observed for T3SS substrates in *Salmonella Typhimurium*. Other T4SS substrates, however, show a markedly high hydrophobicity of their TMDs. While these effectors have been reported to be *bona fide* T4SS substrates, we observe that their TMDs are able to promote inner membrane insertion. Either these substrates take a novel T4SS pathway that involves inner membrane intermediates or a so far unknown mechanism exists that prevents futile membrane targeting of these T4SS substrates in *Legionella* and *Coxiella*.

EVOLUTION OF GENE CLUSTERS IN FUNGI

M. Marcet-Houben[1], T. Gabaldón[1]
[1]Center for Genomic Regulation, Bioinformatics and Genomics, Barcelona, Spain

Backgrounds

Although to a lesser extent than in prokaryotes, eukaryotes also show some level of conservation of gene order among functionally related genes. An illustrating example are the gene clusters responsible for the synthesis of secondary metabolites in fungi. Such clusters are present across different fungal genomes, often showing sparse distributions and being present in very divergent species.

Objectives

We aim to detect gene clusters conserved among divergent fungal species and asses which evolutionary processes drive such distributions.

Methods

We developed a new method to detect gene clusters across genomes based on a comparative genomics approach. We used this method on 280 diverse fungal species and detected 189,000 gene clusters, which could be grouped in 25,689 families. Based on a phylogenomics approach we established the most likely evolutionary scenario for the formation of the clusters involving several mechanisms such as vertical evolution, horizontal gene transfer, or convergent evolution.

Conclusions

We established that most cluster families present in divergent species owed their presence to the independent formation of the cluster (71% of the cases). Surprisingly horizontal gene transfer events of whole gene clusters seem to play only a secondary role in the formation of cluster families (1.3% of the cases).
This study provides a novel methodology to detect gene order conservation and answers the question on how gene clusters in fungi have evolved. Yet it opens new questions on the mechanisms that allow the same cluster to be formed multiple times in divergent fungal species.

RELEVANCE OF MIXED FUNGEMIA BY CANDIDA PARAPSILOSIS AND CANDIDA ORTHOPSILOSIS

C. Marcos Arias[1], E. Cantón[2], N. Pena-Fernández[1], E. Mateo[1], J. Pemán[2], E. Eraso[1], G. Quindós[1]
[1]Universidad del País Vasco UPV/EHU, Inmunología- Microbiología y Parasitología, Bilbao, Spain
[2]Hospital Universitari i Politécnic La Fe, Servicio de Microbiología, Valencia, Spain

Backgrounds

Incidence of *Candida parapsilosis* invasive candidiasis is increasing. However, *Candida parapsilosis* is a complex of cryptic species phenotipically undistinguishable that hinders the diagnosis.

Objectives

To evaluate the incidence of mixed fungemia by *Candida parapsilosis* and *Candida orthopsilosis*.

Methods

Identification of 96 *Candida parapsilosis* complex clinical isolates from 93 patients suffering candidaemia at the Hospital Universitario y Politécnico La Fe (Valencia, Spain) was performed by two RFLP-PCR methods. Restriction patterns of the secondary alcohol dehydrogenase gene (*SADH*) and *FKS1* gene were analyzed in a complementary way. When both methods failed to reach an agreement on the species identity, analysis of the D1/D2 domain of 26S LSU gene sequence was performed.

Conclusions

Seventy eight isolates out of 96 of *Candida parapsilosis sensu stricto* (81.2%), 15 of *Candida orthopsilosis* (15.6%) and three of *Candida metapsilosis* (3.1%) were identified. Mixed cultures were observed in Candida Chromogenic Agar (Laboratorios Conda, España) from 3 out of 93 patients (3.2%): the presence of *Candida parapsilosis sensu stricto* and *Candida orthopsilosis* in the same blood specimen was confirmed by molecular methods. Concordance between the two RFLP-PCR methods was good (89.6%), although the method involving *SADH* gene misidentified four isolates (4.2%).

Candida orthopsilosis, *Candida parapsilosis* and mixed *Candida parapsilosis* complex candidaemias are not uncommon and careful selection of molecular identification methods is recommended.

A FASCINATING EXAMPLE OF CONVERGENT EVOLUTION INVOLVES STAPHYLOCOCCUS AUREUS PHAGE ENCODED DIMERIC AND TRIMERIC DUTPASES IN SIGNALLING

J. Donderis[1], E. Maiques[1], J.Z. Bowring[2], J.R. Ciges[1], M.M. Neamah[2], C. Alite[1], M.A. Tormo-Mas[3], J.R. Penadés[2]
[1]Institute of Biomedicine of Valencia CSIC, Genomic and Proteomic, valencia, Spain
[2]University of Glasgow, Institute of Infection- Immunity and Inflammation., Glasgow, United Kingdom
[3]Instituto Investigación Sanitaria La Fe, Grupo Infección Grave, Valencia, Spain

Backgrounds

The dUTPase (Dut) enzymes prevent the misincorporation of uracil into the DNA and are encoded by almost all free-living organisms and some viruses. We have previously showed that phage-encoded trimeric Duts mediates the *Staphylococcus aureus* pathogenicity island (SaPIs) transfer by interacting to the SaPI-encoded repressor Stl, proposing that these Duts are regulatory proteins. Some S. aureus phages encode structurally unrelated dimeric Duts instead trimeric Duts. Surprisingly, a recent work, has involved one of these predicted dimeric Duts in the transfer of SaPIs by interacting with the same Stl repressor.

Objectives

To analyse the molecular basis of SaPI induction by dimeric Duts and to compare with the mechanism reported for trimeric Duts.

Methods

Using sequence analysis we have divide S. aureus phage-encoded Duts in six families. The SaPI mobilization capacity of one representative dimeric Dut from each family was examined *in vivo* as well as its binding capacity to Stl repressor *in vitro*. We analysed the effect of the dUTP in the Stl-Dut interaction. Finally, we solved the 3-D structure by X-ray crystallography of several dimeric Duts in different activation states

Conclusions

The results that will be presented in the communication show that dimeric and trimeric Duts from *S. aureus* phages present a striking parallelism in the mechanism of SaPI mobilization. These similarities would confirm the role of dUTP as new nucleotide with second messenger function. However, some differences suggest peculiarities in the molecular mechanism of Stl recognition and binding for each type of Duts. Our results support the idea that the signalling role of the Dut proteins is an important force driving evolution and speciation

THE TWO AAA+ ENHANCER-BINDING PROTEINS (BEBPS) REDR1 AND REDR2 FORM HETEROHEXAMERS TO ACTIVATE TRANSCRIPTION OF AZOARCUS ANAEROBIUS 1,3-DIHYDROXYBENZENE ANAEROBIC DEGRADATION PATHWAY

D. Pacheco[1], *P. Marín*[1], *M. Grifé-Ruíz*[1], *S. Marqués*[1]
[1]*Estación Experimental del Zaidín-Consejo Superior de Investigaciones Científicas, Environmental Protection, Granada, Spain*

Backgrounds

The two homologous bacterial AAA+ enhancer-binding proteins RedR1 and RedR2 of the obligate anaerobe *Azoarcus anaerobius* activate transcription at three promoters controlling the anaerobic degradation of 1,3-dihydroxybenzene (1,3DHB, resorcinol). Despite 97% identity between the two bEBPs, they are controlled by different activation mechanisms: RedR1 becomes fully active when repression by its N-terminal domain (NTD) is released after effector binding (negative control), whilst RedR2 requires its NTD to be constitutively active (positive control) and is kept inactive in the cell through binding to the membrane protein BtdS.

Objectives

The two bEBPs are required for full activity of the promoters, and bEBPs must oligomerize into hexamers to activate transcription. The aim of this work was to analyze the promoters driving expression of the three operons and to determine if the two regulators were able to form heterohexamers. The activation mechanism of each regulator was further analyzed.

Methods

Transcription analysis, bacterial adenylate cyclase two-hybrid (BACTH) assays, protein pull-down and site-directed mutagenesis were used to identify the interactions and analyze the activation mechanisms.

Conclusions

Only P_{orf14} promoter was active in the heterologous host *E. coli*. Transcription activation required the active form of either RedR1 (the NTD-truncated protein) or RedR2 (the whole-length regulator); the promoter was strictly dependent on σ^{54} and IHF. BACTH assays showed interaction between RedR1 and RedR2 central domain, partially stabilized by their C-terminal domain. No self-interaction of either regulator was observed. This interaction pattern was confirmed in pull-down experiments. We conclude that redR1 and RedR2 form hetero-hexamers to activate transcription of the pathways. The RedR2 residues involved in the interaction with BtdS have been identified.

Physiology / Biochemistry / Molecular Microbiology - Part II

LIKE THE AIR WE BREATHE: THE ROLE OF UROPATHOGENIC ESCHERICHIA COLI TERMINAL REDUCTASES DURING INFECTION IN VITRO AND IN VIVO

A.J. Martín-Rodríguez[1], *K. Melican*[1], *A. Richter-Dahlfors*[1]
[1]*Karolinska Institutet, Swedish Medical Nanoscience Center, Stockholm, Sweden*

Backgrounds

Urinary tract infections follow an ascending path from the urethra to the bladder (cystitis) and the kidneys (pyelonephritis). The urinary tract is a moderately oxygenated environment in which a variety of niches exist. For instance, the oxygen concentration in the bladder is reported to be around 4-7 %, whereas local fully anoxic conditions have been found in the renal tubule lumen during bacterial infection.

Objectives

Our goal is to explore the role of UPEC anaerobic respiration during host colonization and the expression of infection-relevant phenotypes. Specifically, we aim to understand the contribution of individual respiratory terminal reductases to an array of infection phenotypes *in vitro* and *in vivo*.

Methods

In this work, which is presented as part of ongoing research, we use *E. coli* CFT073 as a protoypic uropathogenic *Escherichia coli* (UPEC) strain. Using lambda red-mediated recombineering, we have systematically knocked out all the operons encoding anaerobic terminal reductases in this strain, as well as *fnr* whose gene product, the global transcriptional regulator FNR, is required for the switch from aerobic to anaerobic metabolism in *E*. *coli*. We are analyzing the effect of these deletions on biofilm formation, motility, antimicrobial susceptibility and *in vitro* infection. Subsequently, we aim to move beyond the bench and validate our findings using ascending infection and intravital animal models.

Conclusions

Our results shed light on the role of alternative electron acceptors as key fitness factors for UPEC infection, including the modulation of virulence-relevant phenotypes.

AMRZ IS A GLOBAL ENVIRONMENTAL RESPONSE REGULATOR INVOLVE IN C-DIGMP TURNOVER IN PSEUDOMONAS FLUORESCENS F113

M. Martín[1], C. Muriel[1], E. Arrebola[1], F. Martínez-Granero[1], E. Blanco-Romero[1], D. Garrido-Sanz[1], M. Redondo-Nieto[1], R. Rivilla[1]
[1]Universidad Autónoma de Madrid, Biología, Madrid, Spain

Backgrounds

AmrZ, alginate and motility regulator Z, is a regulator protein belonging to the Arc family that contains a Ribbon-Helix-Helix (RHH) DNA binding domain. AmrZ is a master regulator of gene expression across Pseudomonads. The expression of *amrZ* depends on the environmental stress sigma factor AlgU which itself has been implicated in alginate production, regulation of virulent factors and adaption traits. *Pseudomonas fluorescens* F113 is a Plant Growth Promoting Rhizobacteria (PGPR) which has been considered as a model strain for rhizosphere colonization studies. In this strain, AmrZ regulates swimming motility through the repression of FleQ.

Objectives

To investigate the c-diGMP related regulon of AmrZ in *P. fluorescens* F113

Methods

A ChIP seq analysis of AmrZ in P. *fluorescens* F113 revealed that this protein is involve in environmental sensing and adaption.

Conclusions

AmrZ regulates not only the motility but also the iron uptake, the cell wall maintenance and the virulence among other traits. However, most of these phenotypes are influenced by the AmrZ dependent changes in c-diGMP. In this work we have analyze the phenotype of 15 mutants in genes codifying phosphodiesterases and diguanylate cyclases regulated by AmrZ. The implication of these enzymes in *P. fluorescens* F113 ability to form biofilms will be discussed.

CM was granted by FPI fellowship program (BES-2013-063189). EBR is the recipient of a fellowship from Fundación Tatiana Pérez de Guzmán el Bueno, Spain. UBIQUITINATION: IMPLICATIONS IN THE REGULATION OF GENE EXPRESSION THROUGH THE CWI PATHWAY IN YEAST

R. García[1], V. Mascaraque[1], A.B. Sanz[1], S. Díez-Muñiz[1], C. Nombela[1], J.M. Rodríguez-Peña[1], J. Arroyo[1]
[1]Facultad de Farmacia. Universidad Complutense de Madrid and Instituto Ramón y Cajal de Investiga ciones Sanitarias, Departamento de Microbiología II, Madrid, Spain

Backgrounds

Signal transduction pathways mediated by MAPKs play an essential role in cellular homeostasis and survival. In *Saccharomyces cerevisiae*, stress conditions perturbing cell wall integrity trigger the activation of the cell wall integrity MAPK pathway (CWI) whose result is a transcriptional response controlled by the MAPK Slt2 and the transcription factor Rlm1. In the last years, ubiquitination system has emerged as an important regulator of signal transduction pathways.

Objectives

It has consisted of the identification and functional characterization of elements of the ubiquitination/deubiquitination machinery potentially involved in the regulation of the gene expression through the CWI pathway.

Methods

Ubiquitin-ligases and deubiquitinating enzymes related to cell wall stress (Congo Red and Zymolyase) were identified using phenotypic and transcriptional studies. Chromatin immunoprecipitation (ChIP) was used to study ubiquitination/deubiquitination of promoters and ORFs of CWI-responsive genes under different growth conditions and yeast mutant backgrounds.

Conclusions

Ubiquitin-ligases Rad6, Dia2, Slx8, Mms1, Pep3, Rcy1, Ubr2 and deubiquitinating enzymes Ubp3 and Ubp8 were involved in the regulation of expression of CWI-responsive genes (*MLP1/KDX1, SRL3, PRM5, CWP1*) under cell wall stress. Additionally mutants *dia2*Δ, *slx8*Δ, *mms1*Δ, *pep3*Δ, *rcy1*Δ and *ubp3*Δ were sensitive to Congo Red and/or Zymolyase. Ubiquitination in the ORF of CWI-responsive genes described above was observed as well as a dependence on Dia2, Rad6, Slt2 and Rlm1 in this process. Moreover, Rad6 bound to the ORF of MLP1. These results point to ubiquitination as an additional regulatory mechanism involved in the response to cell wall stress in yeast.

EXPRESSION OF THE GLOBAL REGULATOR CSRA IS REGULATED BY THE CPXRA TWO-COMPONENT SYSTEM IN E. COLI

C. Masson[1], *L. VAN MELDEREN*[1]
[1]*Free University of Brussels ULB, département de biologie moleculaire, Gosselies, Belgium*

Backgrounds

Global regulators play major roles in response to a variety of intracellular and extracellular signals, allowing bacteria to adapt to environmental changes. Lack of global regulators generally leads to strong defects. We are interested in CsrA, a post-transcriptional global regulator acting by binding target mRNAs and modulating their translation. This regulator is important for cell growth and regulates central carbon metabolism and social behavior pathways.

Transcriptional regulation of *csrA* expression remains largely unknown although it was shown that Sigma70 and RpoS directly regulate *csrA* transcription.

Objectives

The objective is to identify two-component system (TCS) involved in regulation of *csrA* expression.

Methods

Transcriptional fusion was used in different mutant strains to identify *csrA* regulators. Confirmation and characterization of the *csrA* regulation by *cpxRA* were obtained by western blot, mobility shift assays and footprint experiments

Conclusions

We focus our study on the *cpxRA* system, a TCS sensing periplasm and inner membrane stresses through various signals. *cpxRA* regulate pathways notably involved in envelop repair and homeostasis. Our results show that *csrA* promoter activity is dependent on CpxRA. Phosphorylation state of CpxR is important for *csrA* regulation *in vivo*. We showed that acetyl-phosphate plays an important role in the CpxRA-dependent regulation of *csrA* expression by phosphorylating CpxR independently of CpxA, and that CpxA phosphatase activity counteracted it thanks to its phosphatase activity. Finally, we defined the location and sequence of the two CpxR binding sites on the *csrA* promoter region.

SPIROPLASMA POULSONII AS A NEW MODEL FOR ENDOSYMBIONT GENETICS

F. Masson[1], F. Schüpfer[1], B. Lemaitre[1]
[1]EPFL, EPFL-SV-GHI-UPLEM, Lausanne, Switzerland

Backgrounds

Spiroplasma are widespread arthropod-associated bacteria. They exhibit a wide range of interactions with their hosts, from parasitism to mutualism. All species are helical, motile, and do not possess a cell wall, which makes them outstanding with regard to their interaction with other organisms. Some species, like *Spiroplasma citri*, are pathogens with a cyclic lifestyle between an insect host and another environment (plants). Other species are insect endosymbionts: they thrive in the insect body cavity and are transmitted from females to offspring, often during oogenesis. This is the case of *Spiroplasma poulsonii* that infects *Drosophila melanogaster*, causing variety of phenotypes.

Objectives

Pathogenic *Spiroplasma* species have generally been cultivable *in vitro* for a long time, and most of them can be readily transformed. Endosymbiotic *Spiroplasma* however do not develop in general *Spiroplasma* media. Furthermore, they are fragile and unable to perform homologous recombination, which stalls most of the mainstream genomic modification techniques. The bacterial side of their interaction with their host has thus never been approached and required the development of new ways to cultivate and modify them.

Methods

By using a step-by-step optimization process, we developed a cell-free medium where *S. poulsonii* can be maintained for several months out of its host. We then set-up integrative plasmids to genetically modify the endosymbiont genome *in vitro* and to re-implant it in the host.

Conclusions

These technical breakthroughs make *S. poulsonii* one of the very few genetically tractable endosymbionts, paving the route for functional studies of the bacterial determinants of its interaction with its host.

HIGH MOLECULAR WEIGHT PROTEINS FROM L. RHAMNOSUS GG MODULATE PRO-INFLAMMATORY RESPONSES IN VITRO

M. Mata Forsberg[1], S. Björkander[1], M. Ndi[2], E. Sverremark-Ekström[1]
[1]Stockholm University, Department of Molecular Biosciences- The Wenner-Gren Institute, Stockholm, Sweden
[2]Stockholm University, Department of Biochemistry and Biophysics, Stockholm, Sweden

Backgrounds

Probiotic lactobacilli reduce the risk of immune related diseases by strengthening the gut epithelium, outcompeting pathogens and modulating the immune system. We, and others, have shown that early-life lactobacilli colonization correlates with a reduced risk to develop allergy. Recently we demonstrated that lactobacilli cell free supernatants (CFS) contain factors able to dampen *Staphylococcus aureus* (*S. aureus*) induced T-cell proliferation and pro-inflammatory cytokine production *in vitro*.

Objectives

To investigate how secreted soluble factors from *Lactobacillus rhamnosus* GG (LGG) modulate immune cell activation and to identify specific factors with the capacity to regulate pro-inflammatory immune responses.

Methods

Human peripheral blood mononuclear cells were stimulated in the presence or absence of whole or size fractionated LGG-CFS. Spin column fractionation generated fractions ranging from 3 to 100 kDa in size and the >100 kDa fraction was further fractionated using high performance liquid chromatography (HPLC). Flow cytometry was used to evaluate cell proliferation and ELISA was used to quantify cytokines in cell culture supernatants.

Conclusions

We conclude that LGG secretes factors of low molecular weights that dampen interferon-γ (IFN-γ) production as well as high molecular weight factors that dampen both IFN-γ and interleukin-17A (IL-17A). The HPLC analysis revealed the presence of one or several heat sensitive proteins with IFN-γ and IL-17A dampening activity. With future sequencing analysis we intend to further describe the characteristics of these proteins.

Physiology / Biochemistry / Molecular Microbiology - Part II

THE ROLE OF INDOLE IN ANTIMICROBIAL RESISTANCE AND BACTERIAL PERSISTER FORMATION IN ESCHERICHIA COLI.

M. Matuszewska[1], S. Forrest[1], S. David[1]
[1]University of Cambridge, Department of Genetics, Cambridge, United Kingdom

Backgrounds

Indole is a widespread biological signalling molecule that affects a range of cellular processes in *Escherichia coli* including plasmid stability, extracellular signalling, virulence control and biofilm formation. Recently, indole has been shown to be involved in the formation of antibiotic persisters as well as being a key player in antimicrobial resistance through upregulation of drug efflux pumps.

Objectives

The aim of this study was to further investigate these two aspects of antibiotic resistance. Wild-type and indole-deficient (ΔtnaA; tryptophanase knockout) strains of *E. coli* BW25113 were compared to determine the influence of indole on the minimum inhibitory concentration (MIC) of a range of antibiotics in clinical use

Methods

Both strains were treated with the same antibiotics at 100x MIC and persister cells were enumerated. Pre-treatment and supplementation of the culture with exogenous indole were used in an attempt to repair the effect of the tryptophanase knockout.

Conclusions

A difference in MIC between the strains was observed for a variety of antibiotics, including Aztreonam, Ceftriaxone and Phosphomycin; indicating a role for indole in resistance. For persister formation the results were more complex. During the exponential phase of growth wild-type cultures gave rise to a higher frequency of persisters than tryptophanase knockout cultures. Stationary phase cultures behaved differently, showing a higher frequency of persisters for the tryptophanase mutant. However, colonies formed by persisters derived from the tryptophanase mutant grew more slowly than wild-type persisters after the antibiotic was withdrawn.

THE INFLUENCE OF CULTIVATION MEDIUM COMPOSITION ON ESCHERICHIA COLI BIOFILM FORMATION ON NANOCRYSTALLINE DIAMOND SURFACE

P. Matyska Liskova[1], J. Budil[1], J. Beranova[1], R. Fiser[1], O. Romanyuk[2], E. Ukraintsev[2], A. Kromka[2], I. Konopasek[1]
[1]Charles University- Faculty of Science, Dpt of Genetics and Microbiology, Prague 2, Czech Republic
[2]Institute of Physics of the Czech Academy of Sciences, Department of Optical Materials, Prague 6, Czech Republic

Backgrounds

Nanocrystalline diamonds (NCD) belongs to the materials recently widely investigated for antibacterial potential. Published studies include both bacteria survival tests in suspension with NCD nanoparticles and investigation of the antibacterial potential of NCD films on the surfaces. As NCD films seems to exhibit good biocompatibility with tissue cultures, the NCD based surfaces might be promising for bacterial biofilm growth restriction. Further studies must be performed in order to trace the conditions under which NCD limits the growth of bacterial biofilm.

Objectives

We employed NCD deposited on glass with various termination (H-NCD, O-NCD, F-NCD) and *E. coli* as a representative biofilm producer for testing the ability of bacteria to adhere and to establish and mature the biofilm. We analyzed the conditioning film that develops on the surfaces in different cultivation environments and which can substantially influence the consequential biofilm growth.

Methods

E. coli culture was grown in complex LB and mineral M9 media as a batch culture at low rotation rate in presence of tested material. The resulting biofilm quantified using crystal violet assay. We compared the biofilm mass formed in complex and mineral medium.

Conclusions

We discuss the biofilm growth produced by *E. coli* on glass and glass covered with NCD films. The ability of *E. coli* to form biofilm was shown to depend on the NCD surface treatment, its roughness and chemical composition. We also observed the influence of cultivation medium composition which is directly related to the the conditioning film formation which mediates the further bacterial attachment.

Physiology / Biochemistry / Molecular Microbiology - Part II

SECONDARY GENOME PARA PROTEINS OF DEINOCOCCUS RADIODURANS ARE FUNCTIONALLY SIMILAR AND INTERACT TO EACH OTHER

G. Maurya[1], S. Kota[2], H.S. Misra[1]
[1]BHABHA ATOMIC RESEARCH CENTRE- HBNI- Mumbai, Molecular Biology Division- Life sciences, Mumbai, India
[2]BHABHA ATOMIC RESEARCH CENTRE- Mumbai, Molecular Biology Division, Mumbai, India

Backgrounds

Deinococcus radiodurans, a radiation-resistant bacterium, shows ploidy with four genome replicons viz. chromosome I, chromosome II, a megaplasmid and a small plasmid. The genome is annotated with putative *parA-parB* operons. Except small plasmid, other replicons have their own ParA and ParB proteins. The presence of multiple sets of 'Par' proteins in bacteria harboring multipartite genome system, raises the question on their possible functional redundancy and roles in genome segregation.

Objectives

Functional characterization of ParA2 and ParA3 proteins encoded on chromosome II and megaplasmid in *D. radiodurans,* respectively.

Methods

ParA2 and ParA3 proteins were purified and their interaction with DNA was monitored in absence and presence of ADP, ATP or ATPγS using electro-mobility shift assay and fluorescence anisotropy. Polymerization of both proteins in absence and presence of DNA and nucleotides was monitored using sedimentation assay and light scattering. ATP binding and hydrolysis were compared using [α^{32}P]-ATP and fluorimetry. The bacterial two-hybrid system used for interaction in synthetic *E. coli*. Effects of ParA2 and ParA3 mutation on growth and genome maintenance were studied in *D. radiodurans*.

Conclusions

Both ParA2 and ParA3 bind to DNA and polymerize in similar fashion. These activities improved further in the presence of ATP and both are ATPase *in vitro*. Interestingly, both proteins interact to self as well as each other and their mutant can complement the function of each other in *D. radiodurans* indicating functional redundancy among both proteins.

Physiology / Biochemistry / Molecular Microbiology - Part II

MOLECULAR TYPING OF METHICILLIN RESISTANT STAPHYLOCOCCUS AUREUS COMING FROM SCREENING OF MULTI-RESISTANT BACTERIA OF VERONA, ITALY

A. Mazzariol[1], *L. Galia*[1], *M. Ligozzi*[1]
[1]*University of Verona, Diagnostic an Public Health- Microbiology section, Verona, Italy*

Backgrounds

Methicillin-resistant *Staphylococcus aureus* (MRSA) is a major cause of hospital-and communities acquired infections

Objectives

The aim of the study was to characterize MRSA isolated during the screening of multi-resistant bacteria and check if there is a prevalent clone.

Methods

A total of 110 *S. aureus* isolates originating from patients at hospital admission in high risk wards were obtained from throat

MRSAs were confirmed by detection of the *mecA* gene by PCR that also included primers to detect *spa, scn, lukS-PV* (PVL) and *mecC.*

spa and SCC*mec* typing was performed by Sanger sequencing and the multiplex PCR protocol by Kondo et. al., respectively

All 110 strains of MRSA were *mecA* positive. 8 strains resulted SCCmec type I (7,27%), 102 are type IV (92,7%) and all 110 strains of class B.

Only 6 strains are positive for *pvl* gene and belong to SCCmec IV.

The 6 *spa type* "representative" of 110 MRSA strains have these results: 38% Spa t032 CC22 (clonal complex), 14% Spa t1036 CC22; 8% Spa t1214 CC22; 7% Spa t022; 7% Spa t041 CC5; 5,4% CC8 Spa t121 (*pvl*-positive).

The t032-IV type resulted the most frequent and belong to the clone type EMRSA15.

Conclusions

92,7% of the strains are SCCmec type IV normally associated with CA-MRSA. Only 7,27% are SCCmec type I normally associated with strains HA-MRSA. The 5,4% of cases are PVL positive.

EMRSA-15 clone has been detected in this study belonging to type more frequently t032-IV CC22.

Physiology / Biochemistry / Molecular Microbiology - Part II

MRNA HOMEOSTASIS IS MAINTAINED AS CELL VOLUME CHANGES IN SACCHAROMYCES CEREVISIAE

A. Mena[1], D.A. Medina[1], J. Garcia-martinez[1], G. Ayala[2], J.E. Perez-ortin[1]
[1]University of Valencia, Biochemistry and Molecular Biology, Burjassot, Spain
[2]University of Valencia, Stadistics and Operations Research, Burjassot, Spain

Backgrounds

Different cell size is found among *Saccharomyces cerevisiae* yeast strains depending on their ploidy or on gene mutations that increase or decrease it with regard to wild type median size and also along the cell cycle, size increases up to a maximum size in mitosis and then abruptly the volume splits into two cells. Thus, control of the mRNA concentrations is required to keep cell homeostasis. Although there is a compartmentalization of mRNA synthesis and degradation activities, a cross-talk between both has been proposed

Objectives

In order to determine if volume influences transcription and mRNA stability in *S. cerevisiae* we analyzed several mutant strains and BY4741 isogenic diploid, triploid and tetraploid strains

Methods

To asses our hypothesis, poly-A signal was measured by dotblot and flux cytometry and poly-A mRNA stability for each population was obtained by transcriptional shut-off and dot blot hybridization. Moreover Genomic-Run-On was performed to obtain RNA nascent transcription.

Conclusions

We found that total RNA (rRNA and tRNA mainly) and mRNA concentrations maintain homeostasis but whereas total nascent transcription (RNA pol I+III mainly) scales with volume, the mRNA turnover (both mRNA synthesis and degradation) is reduced. This last result is also seen in a meta-analysis of the mutant datasets from other group

FEMS7-2183
Physiology / Biochemistry / Molecular Microbiology - Part II

3'UTRS: THE NEW POST-TRANSCRIPTIONAL REGULATORS IN BACTERIA

P. Menendez-Gil[1], *C. Caballero*[1], *A. Toledo-Arana*[1]
[1]*Instituto de Agrobiotecnología, Laboratory of Bacterial Gene Regulation, Mutilva, Spain*

Backgrounds

A messenger RNA comprises a coding sequence flanked by two untranslated regions (UTRs), the 5'UTR (from the transcription initiation to the start codon) and the 3'UTR (from the stop codon to the transcriptional terminator). In eukaryotes, 3'UTRs are essential elements for modulating protein translation by interacting with RNA-binding proteins and microRNAs. Dysregulation of genes whose 3'UTRs suffer mutations or shortening can lead to diseases such as cancer. Recent studies showed that bacterial 3'UTRs are also involved in regulatory functions by controlling biofilm formation, virulence or iron-homeostasis. Moreover, genome-wide transcriptomic analyses revealed that bacteria express hundreds of long 3'UTRs for which a specific role has not yet been discovered.

Objectives

We aimed to perform a high-throughput functional study of bacterial 3'UTRs to decipher new mechanisms driven by these non-coding regions.

Methods

Therefore, we analyzed the transcriptomes of several *Staphylococcal* species that were phylogenetically associated to understand the conservation of 3'UTRs. In addition, we constructed chimeras of genes lacking their 3'UTR or carrying the 3'UTRs of other species and tested how different 3'UTRs affect the protein expression of the same gene.

Conclusions

Transcriptomes showed that one third of *S. aureus* genes contain 3'UTRs longer than 100-nt. However, we found that 3'UTRs are not conserved among *Staphylococcal* species. Western-blot analysis from different chimeras showed that lacking of 3'UTRs changes protein expression, indicating the presence of regulatory elements, and that protein expression differs when carrying different 3'UTRs of the same gene. These results suggest that the post-transcriptional regulation mediated by 3'UTRs has differentially evolved among bacterial species.

WHEN SUB-INHIBITORY CONCENTRATIONS OF ANTIBIOTICS PROMOTE THE DISSEMINATION OF UNSELECTED RESISTANCE GENES

H. Scornec[1], H. Guilloteau[1], G. Groshenry[1], C. Pradalier[2], X. Bellanger[1], C. Merlin[1]
[1]CNRS / Université de Lorraine, LCPME, Vandoeuvre-les-Nancy, France
[2]UMI 2958 GT-CNRS, Georgia Tech-Lorraine, Metz, France

Backgrounds

Beyond their selective properties, some antibiotics have been shown to induce the dissemination of their own resistance genes by interfering with the regulation of specific mobile genetic elements (MGEs) once at sub-inhibitory concentrations. Demonstrating such a stimulating effect remains quite difficult because there is no obvious way to identify an active antibiotic and its working concentration.

Objectives

The aim of this study was to screen and identify antibiotics for their ability to activate the transfer of known MGEs.

Methods

Inspired by J. Davies and co-workers, we developed a promoter-fusion-based screening approach where full gradients of antimicrobials can be tested instead of arbitrarily defined concentrations. To do so, bacterial laws of *lux* reporter strains are exposed on plates to a gradient of antibiotic provided by disk diffusion assays, while light emission is recorded by a CCD camera to reveal the activity of the promoters. Induction profiles are finally extracted using a homemade automated image processing software.

Conclusions

Sixty molecules, covering most classes of antibiotics, were screened for their ability to interfere with the expression of MGEs mobility functions. For MGEs such as Tn916, we could identified several modulating antibiotics for which the elements does not provide any resistant determinant, and their ability to trigger the transfer of the elements was further confirmed with standard mating assays. This observation clearly disconnects the inducer molecules from the selective advantage provided by the disseminated resistance genes, and raises the question of the risks posed by some antibiotic therapies.

MORE THAN A GAME OF NUMBERS: BACTERIAL PERSISTENCE ACCELERATES THE EMERGENCE OF ANTIBIOTIC RESISTANCE BY INCREASING MUTATION RATES

J.E. Michiels[1], E.M. Windels[1], B. Van den Bergh[1], T. Wenseleers[2], M. Fauvart[3], J. Michiels[1]
[1]KU Leuven, Centre of Microbial and Plant Genetics, Leuven, Belgium
[2]KU Leuven, Laboratory of Socioecology and Social Evolution, Leuven, Belgium
[3]imec, Smart Systems and Emerging Technologies Unit, Leuven, Belgium

Backgrounds

Persisters are transient, antibiotic-tolerant variants that complicate the treatment of bacterial infections, and constitute a reservoir of viable cells in the presence of antibiotics from which resistant mutants can emerge. Moreover, stress responses implicated in persistence are also known to increase mutation rates and horizontal gene transfer. Thus, the processes of persistence and genetic adaptation could be positively coupled through common stress response mediators, fuelling the supply of resistance-conferring mutations in the persister reservoir.

Objectives

Our goal was to investigate how persistence influences the evolution of genetic resistance.

Methods

We monitored resistance by tracking (1) the development of resistant colonies on ciprofloxacin-containing agar plates, and (2) the time until the emergence of resistant mutants in liquid broth. We used natural strains from the ECOR collection and well-described high- and low persistence mutants.

Conclusions

We found a positive correlation between persister levels and the formation of resistant colonies in a collection of environmental *E. coli* strains. Additionally, we found that the size of the persister cell reservoir could only partially explain differences in resistance development. We discovered that mutation rates are pleiotropically linked with persistence and affect the likelihood that an individual persister acquires a resistance-conferring mutation. Together, our findings show that persistence shapes the evolution of genetic resistance by modulating both the number of cells surviving antibiotic treatment and the mutation rate. To conclude, we suggest that anti-persister therapies should be implemented in the ongoing battle against antibiotic resistance.

H2 PRODUCTION BY ESCHERICHIA COLI BATCH CULTURES DURING FERMENTATION OF GLYCEROL AND LACTOSE AT DIFFERENT PHS

S. Mirzoyan[1], A. Poladyan[1], K. Trchounian[1], A. Trchounian[1]
[1]Yerevan State University, Biochemistry- Microbiology and Biotechnology, Yerevan, Armenia

Backgrounds

Molecular hydrogen (H_2) can be produced by microbes during utilization of cheap sources of carbon. *Escherichia coli* produces H_2 from different carbon substrates like sugars, glycerol and some organic acids.

Objectives

In this study H_2 production in batch cultures during mixed carbon sources (glycerol 10 g/l and/or lactose 1-5 g/l) fermentation at different pHs has been investigated.

Methods

H_2 generation was detected by a pair of Ti-Si and Pt redox electrodes.

Conclusions

Wild type specific growth rate on mixed carbon sources was ~1.3 fold more, compared to single carbon sources. Moreover, pH monitoring during mixed carbon fermentation showed that medium was acidified while during single lactose fermentation no pH decrease was determined.

H_2 production in wild type was detected at pH 6.5 during the utilization of lactose at various concentrations. Interestingly, no H_2 production was detected at pH 7.5 and pH 5.5. Moreover, in the mixture of glycerol and lactose at all concentrations and pHs tested H_2 generation was observed. In *hycE* (lacking large subunit of hydrogenase 3) mutant no H_2 production was detected. During growth on mixed carbon at pH 5.5, 6.5 or 7.5 in *hycE* and *hyfG* (lacking large subunit of hydrogenase 4) mutants H_2 production rate was decreased ~2.5 and ~1.5 fold, respectively, compared to wild type.

Summarizing it might be suggested that H_2 generation during the utilization of mixed carbon depends mainly on hydrogenase 3 and growth pH. These data can be applied to use different organic wastes containing glycerol and lactose and further stimulate H_2 production.

CHARACTERIZATION OF A SEQUENCE-SPECIFIC CUTTER CONSERVED IN THE NITROSOMONAS EUROPAEA CHROMOSOME

T. Miyamoto[1], A. Yokota[2], Y. Ota[1], S. Tsuneda[1], N. Noda[2]
[1]Waseda University, Department of life science and medical bioscience, Tokyo, Japan
[2]National Institute of Advanced Industrial Science and Technology, Biomedical research institute, Tsukuba, Japan

Backgrounds

Toxin-antitoxin (TA) systems are small genetic modules that modulate microbial cell fates in stressful environments. Previously, bioinformatics analysis revealed that these TA pairs abound in some free-living microorganisms, including some chemolithotrophic prokaryotes, e.g., *Nitrosomonas europaea*. Interestingly, *N. europaea* is predicted to carry more than 50 TA pairs in its chromosome, indicating their use in coping with versatile environmental changes. However, their molecular functions are largely unknown.

Objectives

We attempted to characterize a representative TA family, the MazEF system, composed of a MazF toxin and a MazE antitoxin. Given that MazF toxins are known to be sequence-specific endoribonucleases, we isolated a putative MazF toxin encoded in the *N. europaea* chromosome and sought to identify their target sequence(s).

Methods

Unbiased RNAs were cleaved by MazF, and the position of the RNA-cleavage sites were analyzed using a specialized RNA-Seq. Subsequently, short oligonucleotides containing specific sequences inferred to be necessary for MazF cleavage were incubated with MazF, and the cleavages were monitored using a fluorometric assay.

Conclusions

We showed that a MazF homologue predicted in the *N. europaea* chromosome is a functional endoribonuclease and that it forms a canonical TA pair with its cognate MazE. Additionally, we demonstrated that the MazF toxin recognizes and cleaves a specific 3-nt motif. Our results indicate that *N. europaea* alters the translation profile and regulates its growth using this enzyme under certain stressful conditions.

EXPRESSION PATTERNS OF ABC TRANSPORTER GENES IN FLUCONAZOLE-RESISTANT CANDIDA GLABRATA

M. Moazeni[1], M. Nabili[2], H. Badali[1], T. Shokohi[1], A. Abdollahi Gohar[1]
[1]Department of Medical Mycology and Parasitology- School of Medicine- Mazandaran University of M edical Sciences- Sari- Iran, Department of Medical Mycology and Parasitology, Sari, Iran
[2]Department of medical sciences- Sari Branch- Islamic Azad University- Sari- Iran, Department of medical sciences, Sari, Iran

Backgrounds

Clinical management of fungal diseases is compromised by the emergence of antifungal drug resistance in fungi, which leads to elimination of available drug classes as treatment options. An understanding of antifungal resistance at molecular level is, therefore, essential for the development of strategies to combat the resistance.

Objectives

This study presents the assessment of molecular mechanisms associated with fluconazole resistance in clinical *Candida glabrata* isolates originated from Iran.

Methods

Taking seven distinct fluconazole resistant *C. glabrata* isolates, real time PCRs were performed to evaluate the alternations in the regulation of the genes involved in drug efflux including *CgCDR1*, *CgCDR2*, *CgSNQ2,* and *CgERG11.* Gain-of-function mutations in *CgPDR1* alleles were determined by DNA sequencing.

Conclusions

Cross-resistance to fluconazole, itraconazole and voriconazole was observed in 2.5% of the isolates. In the present study, six amino acid substitutions were identified in Cgpdr1, among which W297R, T588A, and F575L were previously reported whereas D243N, H576Y, and P915R are novel. *CgCDR1* overexpression was observed in 57.1% of resistant isolates. However, *CgCDR2* was not co-expressed with *CgCDR1*. *CgSNQ2* was up-regulated in 71.4% of the cases. *CgERG11* overexpression does not seem to be associated with azole resistance, except for isolates that exhibited azole cross-resistance. The pattern of efflux pump gene upregulation was associated with gain-of-function (GOF) mutations observed in *CgPDR1*. These results showed that drug efflux mediated by adenosine-5-triphosphate (ATP)-binding cassette transporters, especially *CgSNQ2* and *CgCDR1*, is the predominant mechanism of fluconazole resistance in Iranian isolates of *C. glabrata*. Since some novel gain-of-function mutations were found here, this study also calls for research aimed at investigating other new GOF mutations to reveal the comprehensive understanding about efflux-mediated resistance to azole antifungal agents

[5]Pharmaceutics Research Laboratory- School of Life Sciences- University of Sussex- Arundel Building- Brighton BN1 9QJ- UK, Pharmaceutics Research Laboratory, Brighton, United Kingdom

Backgrounds

Despite the growing trends in the number of patients at risk for invasive fungal infections, management with current antifungal agents results in complications due to changes in the epidemiology and drug susceptibility of invasive fungal infections.

Objectives

In the present research fluconazole-loaded nanostructured lipid carriers were prepared and the efficacy of the optimal formulation on a large number of Candida species was investigated.

Methods

Fluconazole-loaded nanostructured lipid carriers were prepared using probe ultrasonication technique. The morphology of the obtained nanostructured lipid carriers was characterized by transmission-electron microscopy. The minimum inhibitory concentrations (MIC) for the new formulations against strains of Candida were investigated using the Clinical and Laboratory Standards Institute document M27-A3 and M27-S4 as a guideline.

Conclusions

The fluconazole-loaded nanostructured lipid carriers presented a spherical shape with a mean diameter, zeta potential and entrapment efficiency of 126.4 ± 15.2 nm, -35.1 ± 3.0 mV, and 93.6 ± 3.5%, respectively. The drug release from fluconazole-loaded nanostructured lipid carriers exhibited burst-release behavior at the initial stage followed by sustained release over 24 hours. Using a new formulation of fluconazole led to a significant decrease in MICs for all Candida groups ($P < 0.05$). Furthermore, C. albicans isolates showed more susceptibility to fluconazole-loaded nanostructured lipid carriers than C. glabrata and C. parapsilosis ($P < 0.05$). The MIC50 drug concentration was obtained as 0.0625, 0.031 and 0.25 µg/ml for fluconazole-resistant strains of C. albicans, C. glabrata, and C. parapsilosis, respectively. In this study, we evaluated a novel delivery system which can be used as part of a strategy to improve the antifungal activity of fluconazole against various Candida strains with different susceptibilities to conventional formulations of fluconazole.

ANALYSIS OF THREE PUTATIVE TRANSCRIPTIONAL REGULATORS PA1196, PA2121 AND PA2577 FROM PSEUDOMONAS AERUGINOSA PROTEOME

M. Modrzejewska[1], *A.A. Bartosik*[1]
[1]*Institute of Biochemistry and Biophysics- Polish Academy of Sciences, Department of Microbial Biochemistry, Warsaw, Poland*

Backgrounds

Pseudomonas aeruginosa, a human opportunistic pathogen, is a common cause of nosocomial infections. Its high adaptability relies on a complex network of overlapping regulatory circuits. Over 30% of its genome remains annotated as hypothetical, unknown orfs, among them many genes encoding putative transcriptional regulators (TRs). PA1196, PA2121, PA2577 belong to different families of prokaryotic-type TRs: NtrC/NifA, LysR and AsnC, respectively, with identified *in silico* HTH (helix-turn-helix) motifs, involved in DNA binding, and potential dimerization domains.

Objectives

The aim of this study was characterization of *PA1196*, *PA2121* and *PA2577*, the putative regulatory genes from *P. aeruginosa*, initially established as a part of ParA/ParB regulon.

Methods

The chromosomal deletion mutants of PAO1161 strain were constructed by allele exchange due to the homologous recombination. The *PA1196*, *PA2121*, *PA2577* genes and their promoters were cloned in appropriate vectors and used in *in vivo* experiments. The HIS-tagged TRs were overproduced and purified for *in vitro* studies.

Conclusions

PA1196, *PA2121* and *PA2577* are not indispensible for *P. aeruginosa* PAO1161 strain under tested conditions. The chromosomal mutants do not show significant differences in the growth rate, ability to metabolize different carbon sources, motility and biofilm formation in comparison to the reference strain. The purified HIS-tagged PA1196, PA2121 and PA2577 form dimers *in vitro*. The *PA2121* gene has the strongest promoter from three included in the analysis. Overproduction of PA2577, but not PA1196 or PA2121 leads to strong inhibition of *P. aeruginosa* growth.

Physiology / Biochemistry / Molecular Microbiology - Part II

CHARACTERISATION OF THE PUTATIVE TERMINATOR LOCATED UPSTREAM OF THE TN916 CONJUGATIVE MODULE

N. Mohamad Jamil[1], *P. Mullany*[1], *A.P. Roberts*[1]
[1]*UCL Eastman Dental Institute, Microbial Diseases, London, United Kingdom*

Backgrounds

Tn*916* is a clinically important conjugative transposon as it is a vector for the dissemination of antibiotic resistance among a broad range of bacteria. We identified a putative *rho*-independent terminator, 170 bp from the end of Tn*916* and upstream of the conjugation genes. The predicted termination efficiency was 31%.

Objectives

To evaluate the activity of the putative Tn*916* terminator by using *in vitro* reporter system.

Methods

To verify this experimentally, the terminator was cloned in between the *tet*(M) promoter and a *gusA* reporter gene in a pHCMCO5 shuttle vector. The termination efficiency was determined by measuring the β-glucuronidase activity of *Bacillus subtilis* containing the constructs,

Conclusions

We demonstrated the level of enzyme activity decreased by 90% when comparing the construct containing the terminator to the construct containing the promoter only, confirming termination activity. We hypothesized that the terminator is preventing the transcription of the conjugation genes when Tn*916* is integrated in the host genome. To test this, we cloned the terminator region into pHCMCO5 plus either the flanking DNA (representing the linear, integrated form) or the ligated ends of Tn*916* (representing the excised and circularized form).

The enzyme activity observed is twofold higher in the construct representing the circularized form compared to the construct representing the linear, integrated form.This data supports our hypothesis that the terminator efficiency is modulated upon excision and circularization of Tn*916*, which is the exact time when Tn*916* would require expression of its conjugation genes.

REFUGEE FLOWS AND WARNING OF EMERGING RESISTANT CLONE OF MYCOBACTERIUM TUBERCULOSIS IN WEST ASIA

I. Mokrousov[1], E. Shitikov[2], Y. Skiba[3], S. Kolchenko[4], E. Chernyaeva[5], A. Vyazovaya[1]
[1]St. Petersburg Pasteur Institute, Laboratory of Molecular Epidemiology and Evolutionary Genetics, St. Petersburg, Russia
[2]Federal Research and Clinical Centre of Physical-Chemical Medicine, Laboratory of Molecular Genetics of Microorganisms, Moscow, Russia
[3]Aitkhozhin Institute of Molecular Biology and Biochemistry, Laboratory of Genome, Almaty, Kazakhstan
[4]Moscow Institute of Physics and Technology, Department of Biological and Medical Physics, Dolgoprudny, Russia
[5]St. Petersburg State University, Theodosius Dobzhansky Center for Genome Bioinformatics, St. Petersburg, Russia

Backgrounds

Mycobacterium tuberculosis has clonal population structure and some of its global lineages (e.g., Beijing, LAM) have been extensively studied. In contrast, some other remained overshadowed but the situation is changing. The underestimated NEW-1 family (prototype spoligotype SIT127), placed under the umbrella of heterogeneous Euro-American superlineage, presents a hot example. Until recently, it was endemic and prevalent in southern Iran and its historical eastwards propagation via Silk Road was hypothesized (Mokrousov, 2012). However, its multidrug resistant (MDR) subtype appears to have started a wider propagation in the region.

Objectives

We sought to correlate classical markers and whole genome sequencing (WGS) data, assess dynamic changes in phylogeography and drug resistance of NEW-1 family of *M. tuberculosis*, define its phylogeny and detect pathobiologically relevant genetic variation.

Methods

Spoligotyping, VNTR and WGS analysis was performed on DNA available in our laboratories. Published literature and databases were searched and (re)analyzed to retrieve information about SIT127 and derived strains. All data were analyzed by bioinformatics tools.

Conclusions

NEW-1 family is a part of the larger sublineage defined by RD122 deletion. In the last 15 years, NEW-1's prevalence increased significantly in North Iran, Afghanistan (proxied by data on Afghan immigrants in Iran) and Pakistan. The circulating strains are MDR-associated and this trend is also observed in farther countries, such as Bulgaria. Ongoing migration within and outside of West Asia, especially, Afghan refugees flows emphasize a risk of the wider spread of this potentially epidemic strain with arguably adverse impact on TB control in concerned countries.

EFFECT OF ALLELIC DIVERSITY IN THE SIGNALING PATHWAY TORC1 ON THE NITROGEN CONSUMPTION IN SACCHAROMYCES CEREVISIAE DURING ALCOHOLIC FERMENTATION

J. Molinet[1], *F. Cubillos*[2], *C. Martínez*[1]
[1]*Universidad de Santiago de Chile, Departamento de Ciencia y Tecnología de los Alimentos, Santiago, Chile*
[2]*Universidad de Santiago de Chile,*
Centro de Estudios en Ciencia y Tecnología de Alimentos CECTA, Santiago, Chile

Backgrounds

Nitrogen is the second nutrient assimilated by yeast during alcoholic fermentation, its consumption is key for *Saccharomyces cerevisiae* to carry out this process. Deficiencies in nitrogen sources correlate with sugglish fermentation and becoming one of the main problems in the wine industry. Studies in this area have shown that different strains of *S. cerevisiae* present different levels of ammonium and amino acid consumption during fermentation. On the other hand, it is known that the TORC1 signaling pathway is responsible for detecting nutritional signals and to coordinate cell growth. Among its targets are genes related to nitrogen transport and metabolism, however, it is unknown how TORC1 can impact on the different strains generating differences in nitrogen consumption. This variability could be the result of the differences in the signaling pathway by the allelic diversity in this.

Objectives

Identify allelic variants of the TORC1 pathway involved in nitrogen consumption.

Methods

Candidate genes participating in this pathway were selected from a QTL mapping performed on a tetraparental population (SGRP-4X). The allelic variants were validated by reciprocal hemizygosity assay, which were fermented in synthetic must and determined the nitrogen content by HPLC.

Conclusions

Seven genes were selected: *GTR1, TOR2, SIT4, SAP185, EAP1, NPR1* and *SCH9*; these were validated in relation to their nitrogen consumption during fermentation process. In conclusion, allelic variants were identified in genes with different functions in the TORC1 pathway, whose allelic diversity may explain the differences in arginine, glutamic, glutamine, alanine, tryptophan and ammonium consumption.

Single molecule science- EMBL Node- School of Medical Sciences, Sydney, Australia
[2]Lowy Cancer Research Centre - University of New South Wales,
Single molecule science- EMBL Node. School of Medical Sciences, Sydney, Australia

Backgrounds

Enteropathogenic *Escherichia coli* (EPEC) are gram-negative bacteria that can be found in the lower intestine of humans and are associated with acute gastroenteritis. EPEC relies on the type III secretion system (T3SS) or injectisome to deliver effector proteins directly into the host cells. The T3SS is distinguished by three different regions: the basal structure, the needle complex and the translocation pore.

The needle complex is responsible for bacterial attachment to the outer membrane of the host cell, after the translocation pore is inserted into the cell membrane.

Objectives

We aim to understand the way in which the needle complex is assembled and the binding steps of the formation of the translocation pore.

Methods

We use a bottom-up *in vitro* approach, where we can express the individual proteins and assess their propensity to oligomerise or fibrillate using single molecule confocal microscopy. We studied the different components of the needle and mapped their protein-protein interaction using a nanobead assay (AlphaScreen proximity assay). We then used this map to co-express protein pairs and reassemble step-by-step the full complex.

Lastly, we focus on the translocation pore and the role of EspB/EspD in attaching the tip of the needle. Here we use single-molecule Total Internal Reflection Microscopy (TIRF) to observe binding and oligomerisation on liposomes with different lipid compositions and human cell membranes. We are also studying the role of chaperones and tip attachment on the opening of the pore.

Conclusions

Eventually, we will be able to reconstruct the whole needle complex and to understand the pore formation mechanism.

THE ENTEROPATHOGENIC E. COLI EFFECTORS: SWISS-ARMY KNIVES AND PATHWAY HIJACKERS

A. Monserrat-Martínez[1], A. O'Carrol[2], A. De-Andres-Murillo[2], E. Sierecki[2], Y. Gambin[2]
[1]Lowy Cancer Research Centre - University of New South Wales,
Single molecule science- EMBL Node- School of Medical Sciences, Sydney, Australia
[2]Lowy Cancer Research Centre - University of New South Wales,
Single molecule science- EMBL Node. School of Medical Sciences, Sydney, Australia

Backgrounds

Enteropathogenic *Escherichia coli* (EPEC) are gram-negative bacteria that can be found in the lower intestine of humans and are associated with acute gastroenteritis. EPEC is a highly evolved organism that only needs around 20 effectors and 20 other structural proteins to colonize a foreign environment causing disease on-set, thanks to the ability of EPEC effectors to disrupt multiple pathways in the host cell.

These effector proteins are structurally small in size (15kDa) but possess the ability to bind multiple targets associated with inflammatory response, actin reorganization, cell-to-cell junction formation and apoptosis pathways. Once in the host cells, EPEC effectors interact with some important proteins involved in innate immune system pathways, so the host cell cannot fight the invasion, eventually leading to the effective colonization of the gut.

Objectives

The aim of this project is to know what exactly the effectors are doing to immune pathways, especially the TLR, NLR and apoptotic pathways.

Methods

For that, we express the proteins of the innate immune system and systematically check whether EPEC effectors bind to them. Thanks to the cell-free expression system we use to express all the proteins, we can screen the interaction of multiple protein combinations *in vitro* using a nanobead assay (AlphaScreen proximity assay) and single molecule confocal microscopy.

Conclusions

Overall, we will establish a complete map of interactions between effectors and innate immune system proteins. The most potent effectors in terms of disruption protein-protein interactions will be studied in more detail to understand the molecular determinants of EPEC effectors versatility.

SOURCE OF CARBON MAY MODULATE INDOLE-3-ACETIC ACID PRODUCTION IN ENDOPHYTIC BACTERIAL ISOLATES FROM MAIZE

A. Montanez[1], S. Vico[1], N. Rigamonti[1], A. Rodriguez[2], C. Rufo[2]
[1]Facultad de Ciencias, Montevideo, Montevideo, Uruguay
[2]Instituto Polo Tecnológico de Pando, Canelones, Pando, Uruguay

Backgrounds

Indole-3-acetic-acid (IAA) is an important phytohormone with the capacity to control plant-development in both beneficial and deleterious ways. The ability to synthesize IAA is an attribute that many bacteria including both plant growth-promoters and phytopathogens possess. Also a given bacterial species may use more than one pathway. The different IAA biosynthesis pathways using tryptophan as a precursor have been reported to be affected by environmental and genetic factors. Carbohydrate source is an important environmental factor that regulates microbial genetic expression.

Objectives

The objective of this research was to investigate the effect of different carbohydrates on the biosynthesis of IAA by endophytic bacteria isolates from maize.

Methods

Seven different carbohydrate sources were supplied to bacteria growing in minimal medium containing tryptophan. The bacteria selected for this study were: EMA68-*Pseudomona flourescens, EMA83-Rhanella* spp, EMA171-*Burkholderia cepacia*, EMA175-*Rhanella* spp, EMA176-*Rhizobium* spp**.** Filtrated supernatant samples were analyzed for IAA and biosynthetic intermediates by HPLC-MS. In order to elucidate the genes involved in IAA synthesis of our collection of IAA-producing strains, three set of primers were proposed for PCR-amplification of the genes-fragments encoding tryptophan-2-monooxygenase (*iaa*M) and IAM-hydrolase (*Iaa*H) corresponding to the indole-3-acetamide pathway and for the indole-pyruvate-pathway two set of primers were proposed for PCR-amplification of indol-pyruvate-descarboxilase (*ipd*C) gene-fragments.

Conclusions

Preliminary results showed that the regulatory mechanism controlling bacteria production of IAA biosynthesis and modulation is affected by carbohydrate source and bacteria genotype. Thus, microbial production of IAA, its impact on plant and its regulatory mechanisms represent an interesting case of plant-microbe communication and need further investigation.

[4]French National Institute for Agricultural Research - INRA, PFEM, Saint-Genès Champanelle, France

Backgrounds

Enterohaemorrhagic *E. coli* (EHEC) are anthropozoonotic agents that range third among food-borne pathogens respective to their incidence and dangerousness in Europe. The ability of *E. coli* to colonize different environments and to cause a wide range of disease is partly due to its capability to secrete effectors at the cell surface or in the extracellular milieu. However, their expression varies tremendously depending on the environmental conditions.

Objectives

This study aims to identify surface proteins involved in colonization by EHEC O157:H7 under intestinal conditions for future vaccination targets, following, for the first time, an analysis of the bacterial proteosurfaceome *in vivo*.

Methods

EHEC O157:H7 were cultured in BHI up to mid-exponential phase and bacterial cells were injected in the mice intestine and colon, separately. After 3 or 10 hours of incubation, EHEC cells were recovered from both intestinal sections and the bacterial proteins were tagged with Sulfo-NHS-SS biotin. Biotin-labeled surface proteins were trapped in a neutravidin column. All samples were separated by nano-HPLC and identified by high-resolution mass spectrometry.

Conclusions

The analysis of the surface-exposed proteome allowed uncovering proteins differentially expressed by EHEC during early and late state of infection and also in the different compartments of the intestinal tract. The identification of those proteins permits to understand the adaptation of EHEC, as well the proteome changes that occurs during an *in vivo* infection and leads to a successful colonization. The integration of these results with the genomic information available will help to find strategies to fight against EHEC intestinal colonization.

SYNONYMOUS MUTATIONS IN THE 3-PHOSPHOGLYCERATE KINASE GENE IN SCHIZOSACCHAROMYCES POMBE ALTER PROTEIN EXPRESSION AND CELL GROWTH

S. Moreira[1], *L. Arias*[1], *O. Orellana*[1]
[1]*Universidad de Chile, Biología Molecular y Celular, Santiago, Chile*

Backgrounds

Folding of many proteins is a co-translational process, where the exit speed of the nascent peptide from the ribosome is critical. This process might be controlled by translation efficiency of the mRNA. Due to the redundancy of the genetic code, it is believed that codon bias is a relevant factor that control translation rate. So far, the rules that govern translational rate by synonymous codons and the effects on cell fitness are unknown.

Objectives

The purpose of this work was to study the effect of synonymous mutations in the gene encoding the highly expressed enzyme 3-phosphoglycerate kinase 1 (Pgk1) on protein levels and folding as well as on cell fitness of *S. pomb*e.

Methods

To study the effect of synonymous mutations, eleven segments of *pgk1* were randomly mutated for synonymous codons and each variant was introduced in the chromosome by homologous recombination. Then, we measured cell growth in minimal medium and protein aggregation.

Conclusions

We determined that some mutations in the boundaries of Pgk1 domains altered yeast growth. A concomitant alteration of protein aggregation and sensitivity to proteasome inhibitors was observed, suggesting a role of these codons in the modulation of translation and folding. These data suggest that codon usage bias is an important regulator of proteostasis.

EFFECT OF THE HFQ AND CRC PROTEINS ON THE TRANSCRIPTION, PROCESSING AND STABILITY OF THE PSEUDOMONAS PUTIDA CRCZ SRNA

S. Hernández-Arranz[1], D. Sánchez-Hevia[1], R. Fernando[1], R. Moreno[1]
[1]Centro Nacional de Biotecnología, Biotecnología Microbiana, Madrid, Spain

Backgrounds

In *Pseudomonas putida*, the Hfq and Crc proteins regulate the expression of many genes in response to nutritional and environmental cues, by binding to mRNAs that bear specific target motifs and inhibiting their translation. The effect of these two proteins is antagonized by the CrcZ and CrcY small RNAs (sRNAs), the levels of which vary greatly according to growth conditions. The *crcZ* and *crcY* genes are transcribed from promoters *PcrcZ* and *PcrcY*, respectively, a process that relies on the CbrB transcriptional activator. We found that *crcZ* can also be transcribed from the promoter of the immediate upstream gene, *cbrB*, a weak constitutive promoter. The *cbrB-crcZ* transcript originated at promoter *PcbrB* was processed to render a sRNA very similar in size to the CrcZ produced from promoter *PcrcZ*.

Objectives

We analysed whether the processed sRNA, termed CrcZ*, was functional, and its possible biological role.

Methods

Using diverse approaches we determined the processing site of the *cbrB-crcZ* transcript, the amounts of CrcZ*, and its ability to antagonize the effect of Hfq and Crc.

Conclusions

The processed CrcZ* sRNA was able to antagonize Hfq/Crc since, when provided *in trans*, it relieved the deregulated Hfq/Crc-dependent hyperrepressing phenotype of a CrcZ/CrcY-null strain. CrcZ* may help attaining basal levels of CrcZ/CrcZ* that are sufficient to protect the cell from an excessive Hfq/Crc-dependent repression. In addition, we found that Crc and Hfq increase CrcZ stability, which supports the idea that these proteins can form a complex with CrcZ and protect it from degradation by RNases.

TOXIN Z TRIGGERS A SURVIVAL RESPONSE TO COPE WITH STRESS BY ALTERING THE ATP, GTP, (P)PPGPP AND C-DI-AMP POOLS

M. Moreno-del Álamo[1], *M. Tabone*[1], *V. S. Lioy*[1], *J.C. Alonso*[1]
[1]*Centro Nacional de Biotecnología-CSIC, Microbial Biotechnology, Madrid, Spain*

Backgrounds

The ζ/PezT superfamily of protein toxins are found in major human pathogens and in environmental important bacteria. ζ interacts with UNAG/ATP/GTP nucleotides, and with their antitoxin protein ε_2/PezA$_2$. The toxin-antitoxin interaction leads to the formation of a biological non-toxic $\zeta\varepsilon_2\zeta$ complex that could still interact with UNAG. Transient expression of ζ triggers a reversible state of dormancy, but a small subpopulation of persisters.

Objectives

To elucidate the connection between ζ-mediated growth-arrest and the alteration on the ATP/ GTP/(p)ppGpp/c-di-AMP/UNAG pool in the presence/absence of the second stressor ampicillin (Amp).

Methods

By means of (d)NTP/NADH-linked assay we have measured the ATPase/dATPase/GTPase activities of ζ and how ε_2 affected them. We have selectively expressed ζ/ε_2 to address whether the toxin induces tolerance/persistence and if any biological noise affected our studies. To test whether the susceptible populations were death/growth-arrested, we expressed ζ for 15-900 min, and after that ε_2. We have expressed a short-living ζ variant (ζY83C) in a set of *B. subtilis* isogenic strains (Δ*relA*, Δ*gdpP*, Δ*codY*, Δ*disA*) to test how the nucleotide signalling integrates and coordinates the toxin mode of action *in vivo.*

Conclusions

We show that ζ is a (UNAG)-dependent ATPase whose activity is inhibited by stoichiometric ε_2 concentrations. ζ promotes a multi-level response, by altering the control of the signalling purine nucleotide pool, leading to growth-arrest. ζ and Amp persisters show a different sensitivity to variations in the c-di-AMP/(p)ppGpp pools. The Amp-persisters are still susceptible to toxin action, and this additive effect is still sensitive to variations in the signalling nucleotide pool.

EVALUATION OF DIFFERENT DNA EXTRACTION METHODS FOR THE DETECTION OF BOTH BACTERIA (HELICOBACTER PYLORI) AND PROTOZOA (ACANTHAMOEBA CASTELLANII) IN THE SAME SAMPLE

L. Moreno-Mesonero[1], J.L. Alonso[1], I. Amorós[1], M.A. Ferrús[2], Y. Moreno[1]
[1]Instituto Universitario de Ingeniería del Agua y Medio Ambiente- IIAMA, Universitat Politècnica de València, Valencia, Spain
[2]Departamento de Biotecnología, Universitat Politècnica de València, Valencia, Spain

Backgrounds

Large sample volumes are frequently required for the analysis of waterborne pathogens, which are usually in low numbers. This fact limits the number of samples to be processed, so, a simultaneous concentration method for all types of microorganisms is used. Consequently, it is of high importance to have an optimized DNA extraction method capable of extracting high amounts of good quality DNA from all types of microorganisms present in such samples.

Objectives

In this study, ten different DNA extraction methods were evaluated for the detection of *Helicobacter pylori* and *Acanthamoeba castellanii* in the same inoculated sample to apply the best one in concentrated water samples containing bacteria and protozoa.

Methods

Ten DNA extraction methods were evaluated [(1,2): addition of PVP solution prior to FastDNA™ SPIN Kit for Soil with (1) 4 m/s 3x30s or (2) 6.5 m/s 2x60s bead-beating; (3): addition of PVP solution prior to the mammalian cells protocol of GeneJET™ Genomic DNA Purification kit; (4,5): FastDNA™ SPIN Kit for Soil with (4) 4 m/s 3x30s or (5) 6.5 m/s 2x60s bead-beating; (6,7,8): mammalian cells protocol of GeneJET™ Genomic DNA Purification kit with incubation times at 56ºC of (6) 30min, (7) 2h and (8) 24h; (9,10) UNEX buffer protocol with (9) 4 m/s 3x30s or (10) 6.5 m/s 2x60s bead-beating]. Final DNA was subjected to qPCRs of *A.castellanii* and *H. pylori,* gel electrophoresis and measure of DNA concentration and purity.

Conclusions

Overall, the best DNA extraction method was GeneJET™ Genomic DNA Purification kit with 2h of incubation time.

MEMBRANE SUGAR TRANSPORTERS IN THE YEAST KLUYVEROMYCES MARXIANUS

J. Morrissey[1], J. Varela[1], N. Montini[1], M. Oreb[2], E. Boles[2]
[1]University College Cork, Microbiology, Cork, Ireland
[2]Goethe-Universität Frankfurt, Institut für Molekulare Biowissenschaften, Frankfurt, Germany

Backgrounds

Kluyveromyces marxianus is a yeast of industrial importance because of traits such as a rapid growth rate, thermotolerance and QPS/GRAS status. The yeast is used commercially for production of enzymes, bioethanol and bioflavours.

Objectives

Our overall aim is to increase the knowledge of the genetics and metabolism of this yeast to facilitate applications as a microbial cell factory. The focus in this study is sugar transporters.

Methods

We have carried out extensive comparative genomics, expression analysis and kinetic studies to understand sugar transport and metabolism. One of the most notable findings is that, compared to its relative *K. lactis,* there are many more potential sugar transporters, mainly arising from tandem gene duplications. The role of these transporters is under investigation. Not all wild strains of *K. marxianus* are equally efficient at sugar utilisation and our data indicate that, at least in part, this is due to polymorphisms in sugar transport genes. For example, we have established that although *K. marxianus* carries 4 copies of the *LAC12* gene, which encodes a lactose permease, only one of these is a functional lactose transporter. Furthermore, *K. marxianus* strains that are unable to efficiently utilise lactose carry an allelic variant of *LAC12*. This may reflect niche specialization.

Conclusions

In *K. marxianus*, there has been a major expansion of sugar transport genes and this confers this yeast with broad metabolic flexibility. Increasing knowledge will give new insights into this family of transport proteins and open up new possibilities for strain engineering for biotechnology.

FEMS7-2155
Physiology / Biochemistry / Molecular Microbiology - Part II

DEVELOPMENT OF BACTERIOCINS AS THERAPEUTIC ANTIBIOTICS

K. Mosbahi[1]
[1]*Infection Immunity & Inflammation, Bacteriology, Glasgow, United Kingdom*

Backgrounds

In the past few years there has been a worldwide rise of antibiotic resistance. New therapeutic agents are now urgently needed to treat multi-resistant and chronic bacterial infections. Amongst those threats, *Pseudomonas aeruginosa* is a Gram-negative pathogen frequently resistant to conventional antibiotics and responsible for severe hospital-acquired blood and lung infections. A promising alternative strategy is the development of bacteriocins, potent narrow spectrum protein antibiotics as novel therapeutic antibiotics.

Objectives

Our current goal is to test the efficacy of pyocins, protein antibiotics that selectively target *P. aeruginosa*, in *in vivo* disease models. Additionally we will map the uptake pathways of pyocins to enable us to rationally design pyocin combination therapies to mitigate against the development of resistance.

Methods

Our work has demonstrated pyocin efficacy in a model of acute lung infection on post-infection administration and we are currently testing these antibiotics in a chronic infection model. Mapping the uptake pathways of pyocins is currently in progress using whole geneome sequencing of isolated pyocin resistant mutants.

Conclusions

Pyocins show efficacy in an acute model of *P. aeruginosa* lung infection and testing in a chronic model is currently underway. Our current knowledge of the uptake pathways of pyocins suggests that combinations of pyocins could be designed to prevent the development of resistance. These early stage data suggest that pyocins may make good candidates to treat highly drug-resistant *P. aeruginosa* isolates.

Physiology / Biochemistry / Molecular Microbiology - Part II

CHARACTERIZATION OF A ZINC ABC TRANSPORTER OF STREPTOCOCCUS AGALACTIAE

P. Moulin[1], A. Rosenau[1,2], L. Mereghetti[1,3], A. Hiron[1]
[1]UMR 1282 Université de Tours/Inra - ISP, Bactéries et Risque Materno-Foetal, Tours, France
[2]Hôpital Trousseau-CHRU de Tours, Service de Bactériologie et Hygiène Hospitalière, Tours, France
[3]Hôpital Bretonneau-CHRU de Tours, Service de Bactériologie-Virologie-Hygiène Hospitalière, Tours, France

Backgrounds

Streptoccocus agalactiae is a versatile pathogen that can infect a broad diversity of hosts ranging from human to fish. Among *S. agalactiae* virulence factors, we are particularly interested in the *lmb-sht* locus which is mainly found in human strains. In association with five others proteins we have shown that the Lmb and Sht proteins are a part of an ABC transporter involved in zinc import.

Objectives

We wanted to study the impact of zinc on bacterial metabolism and the role of the Lmb/Adc transporter in *S. agalactiae*.

Methods

Growth assays with the different mutants for genes encoding the transporter in chemically defined medium with zinc restriction showed that the Lmb/AdcA/AdcAII and the Sht/ShtII proteins are redundant as zinc suppliers. Moreover, microscopy analyzes revealed that the absence of the transporter affects the cell morphology. Finally, competition assays between the wild type and mutant strains in human biological fluids showed that the transporter is needed for the growth and survival of the bacterium. In another part we are studying a second potential role of the Sht and ShtII proteins in the resistance to complement by survival assays in whole and decomplemented human blood.

Conclusions

We characterized in *Streptococcus agalactiae* a zinc-ABC transporter and shown that it is essential for bacterial growth and morphology in zinc-restricted environments, including human biological fluids. Experiments to determine if there is a link between the two identified roles of the Sht and ShtII proteins as zinc suppliers and in the resistance to complement are ongoing.

Physiology / Biochemistry / Molecular Microbiology - Part II

MODULATION OF HOST-CELLULAR RESPONSES BY A BACTERIAL LIGAND VIBRIO CHOLERAE PORIN OMPU

A. Mukhopadhaya[1]
[1]*Indian Institute of Science Education and Research Mohali, Department of Biological Sciences, Mohali, India*

Backgrounds

Porins represent one of the major classes of proteins present in the outer membrane of the gram-negative bacteria. Porins primarily act as channels for solute transport. However, owing to their abundance in the bacterial outer membrane, porins are capable of performing various functions modulating bacterial as well as host cell responses. OmpU, one of the major porins of gram negative bacterial pathogen *Vibrio cholerae*, helps bacteria to survive well in the gut of the human host.

Objectives

To explore whether *Vibrio cholerae* OmpU as a bacterial ligand can modulate host's innate and adaptive responses and to study the underlying mechanism.

Methods

We have done several in vitro and ex vivo studies using ELISA, western blotting, flow cytometry.

Conclusions

We have shown that OmpU is able to induce pro-inflammatory responses through TLR-mediated pathway via the recruitment of MyD88 and NF*k*B. Further, MAP kinase pathway and AP-1 transcription factors are also involved in OmpU-mediated proinflammatory responses. Further, we also observed that OmpU can induce inflammasome activation leading to the production of IL1b. Furthermore, we observed that OmpU can induce dendritic cell activation and Th1 polarization of CD4 T cells. Another interesting observation we have made that OmpU can translocate to host cell mitochondria and can induce apoptosis like programmed cell death.

PROTECTIVE EFFECTS OF MELATONIN AGAINST UV IRRADIATION AND OXIDATIVE STRESS IN SACCHAROMYCES CEREVISIAE

S. Muñiz Calvo[1], R. Bisquert[2], J.M. Guillamon[2]
[1]Instituto de Agroquímica y Tecnología de los Alimentos, Biotecnología de Alimentos, Valencia, Spain
[2]Instituto de Agroquímica y Tecnología de los Alimentos CSIC, Biotecnología, Paterna, Spain

Backgrounds

Melatonin (Mel) is considered a natural potent antioxidant molecule due to its role as a free radical scavenger. Its origin is traced back to the origin of aerobic life as an early defense against oxidative stress and radiation. More complex functions have been attributed to Mel as a result of evolution in the different biological kingdoms, comprising gene expression, enzyme activity and mitochondrial homeostasis regulation processes among others.

Objectives

We tested the antioxidant and UV protective effect of Mel in *Saccharomyces cerevisiae (Sc)* since its presence has been reported during wine fermentation. As the optimal conditions for *Sc* to synthesize Mel remain unknown we developed an intracellular Mel-charging method to test its effect against stresses.

Methods

In order to assess the ability of Mel to protect *Sc* from both stresses we performed growth tests in liquid media and viability assays by colony count after a Mel treatment, followed by stress. We also performed gene expression analysis by RT-qPCR on a selection of antioxidant genes in response to the Mel treatment under oxidative stress and UV radiation

Conclusions

Our results show a significant shortening on Mel-treated cells' lag phase over control cells under stress conditions and under normal growth conditions. Viability after an H_2O_2 stress in Mel-treated cells is 26% greater than non-treated ones, while for 15 s UVC pulse (254 nm), stress amelioration reaches 28%. Gene expression analysis showed Mel significantly modulates gene expression in unstressed cells during exponential growth phase and after 30 min of both stresses.

MOLECULAR DETECTION OF TREPONEMA PALLIDUM SUBSPECIES PALLIDUM FOR THE DIAGNOSIS OF CONGENITAL SYPHILIS

G. Pinilla[1], L. Campos[1], A.T. Duran[1], J. Navarrete[1], L. Munoz[1], M.Y. Cifuentes[2]
[1]Universidad Colegio Mayor de Cundinamarca, Bogota, Bogota, Colombia
[2]Universidad Nacional de Colombia, Bogotá, Bogotá, Colombia

Backgrounds

Syphilis is a disease produced by Treponema pallidum subspecies pallidum, which impacts approximately 12 million people worldwide every year. Of these, more than 2 million are pregnant women which results in congenital syphilis, the worst form of this infection.

Objectives

Detect the presence of *Treponema pallidum* subspecies *pallidum* in clinical samples in order to diagnose congenital syphilis by means of nested PCR, PCR-RT and its concordance with serological testing.

Methods

Purified DNA from a rabbit testicle and clinical samples from patients presumptively diagnosed with congenital syphilis were used.

Three target genes (*polA, 16S ADNr y TpN47*) were amplified by conventional nested PCR and PCR-RT. The results from the amplification of the *TpN47* and *polA* genes were confirmed by sequencing. The serological tests used were VDRL, RPR y TPPA.

Conclusions

By using the *TpN47* gene, the sensitivity was 52 pg for the conventional PCR, 0.52 pg for the nested PCR, and 8,4 fg for the PCR- RT . The specificity for primer TpN47 and polA was 100%; the results of the sequencing showed a 97% identity with *Treponema pallidum*. Of the samples, 70% showed concordance between the serology and the nested PCR.

The *TpN47* gene demonstrated to be the best molecular target for the identification of *Treponema pallidum*, and PCR-RT presents itself as a promising molecular diagnosis alternative for the diagnosis of congenital syphilis.

THE FIRST-DEMONSTRATED SODIUM-MOTIVE CYTOCHROME-C OXIDASE OPERATES IN NATRONOPHILIC BACTERIA

M. Muntyan[1], A. Malinen[2], D. Sorokin[3], T. Ivashina[4], D. Cherepanov[1], R. Lahti[2], G. Muyzer[5], V. Skulachev[1]
[1]Belozersky Institute of Physico-Chemical Biology- Lomonosov Moscow State University, Bioenergetics, Moscow, Russia
[2]University of Turku, Biochemistry, Turku, Finland
[3]Delft University of Technology, Biotechnology, Delft, The Netherlands
[4]Skryabin Institute of Biochemistry and Physiology of Microorganisms- Russian Academy of Sciences, Molecular Biology, Pushchino, Russia
[5]Institute for Biodiversity and Ecosystem Dynamics- University of Amsterdam, Aquatic Microbiology, Amsterdam, The Netherlands

Backgrounds

The natronophilic chemolithoautotrophic bacteria *Thioalkalivibrio* inhabit alkaline (pH 10) soda lakes at saturating salt concentrations. Like all alkaliphilic microorganisms they have an inverted pH gradient across their membranes that decreases the $\Delta\mu H^+$. For many years Na^+-pumping NADH-CoQ reductase (NQR) was the only respiratory chain enzyme shown to solve this problem. *Thioalkalivibrio versutus* has no NQR and employs cytochrome oxidases (Coxs) as terminal components of its aerobic electron transport chain.

Objectives

The aim of our study was to find out how these bacteria effectively provide themselves with energy under low $\Delta\mu H^+$.

Methods

Direct Na^+ transport measurements were performed with bacterial cells and subcellular membrane vesicles loaded with $^{22}Na^+$. Sequence data were received from Genome databank and our experiments. Phylogenetic and molecular dynamic analyses were used to predict Na^+-translocating pathways.

Conclusions

The results include observation of (i) specific Na^+ dependence of Cox activity, (ii) protonophore- or valinomycin-stimulated Na^+ pumping in cells and vesicles, (iii) no H^+ pumping in them (iv) expression of the *T. versutus cbb*$_3$ in *P. denitrificans* cells with the result of Na^+ pumping in membranes of this bacterium, and (v) a Na^+-binding coordination shell in the active center of Cox.

We provide the first direct demonstration that the *T. versutus* cytochrome *cbb*$_3$ (Cox) is a primary Na^+ pump. The Na^+-pump sequence motive has been found in several bacterial strains related to *T. versutus*. Our findings are consistent with the hypothesis of using Na^+-motive energy transducers in organisms living under low ΔpH and high salinity.

Physiology / Biochemistry / Molecular Microbiology - Part II

THE EFFECT OF FLHDC HOMOLOGS OF INCOMPATIBILITY GROUP A/C PLASMIDS AND SALMONELLA GENOMIC ISLAND 1 ON ACACD-RESPONSIVE PROMOTERS

G. Murányi[1], *M. Szabó*[1], *J. Kiss*[1]
[1]*NARIC, Agricultural Biotechnology Institute, Gödöllő, Hungary*

Backgrounds

The Salmonella Genomic Island 1 (SGI1) was first described in *Salmonella enterica* serovar Typhimurium DT104 in the 80's. Since then several SGI1 variants have been recognized in *Salmonella* serovars and recently in a few *Proteus* and *Acinetobacter* strains. SGI1 contains a complex In104 integron region encoding resistance for ampicillin, chloramphenicol, florphenicol, streptomycin, spectinomycin, sulphonamides and tetracycline. Furthermore, different variants encode diverse resistance patterns, which imply serious health risk for humans and livestocks. Most of the variants share common backbone. Some ORFs of the conserved backbone of SGI1 have been proved to participate in the site-specific excision and integration of the genomic island, however majority of ORFs have unknown functions. The large conjugative plasmids of Incompatibility group A/C (IncA/C) take part exclusively in the conjugal transfer of SGI1 as particular helper.

Objectives

Aims of this work are to define the essential ORFs and non-coding sequences involved in the horizontal transfer of SGI1 and to analyse the AcaCD-responsive promoters of SGI1.

Methods

Consecutive directed deletions have been generated in the conserved backbone of SGI1 by one-step gene inactivation method. Quantifying activity of activators occurred by measuring ß-gal activity. Transcription start sites were determined by primer extension analysis.

Conclusions

We found an SGI1-encoded *acaCD* homolog activator, $flhDC_{SGI1}$, which induces SGI1 excision and activates all SGI1 promoters containing predicted AcaCD binding sites. Moreover, it can complement the transfer deficiency of the *acaCD* deletion mutant IncA/C plasmid. ß-gal assays proved that overexpression of $FlhDC_{SGI1}$ has weaker effect on these promoters than AcaCD expression.

FEMS7-2226
Physiology / Biochemistry / Molecular Microbiology - Part II

BIOCHEMICAL AND GENETICAL ANALYSIS OF THE BETA-CAROTENE SYNTHESIS IN MYCOBACTERIA OF CLINICAL INTEREST

A.M. Murillo[1], B. Luz Elena[1,2], Z. Juan David[2,3], G. Verónica[1], R. Jaime[1], R. Francois[1,4]
[1]Corporación para Investigaciones Biológicas, Bacteriología y Micobacterias, Medellín, Colombia
[2]Universidad Pontificia Bolivariana, Biología de Sistemas, Medellín, Colombia
[3]Corporación para Investigaciones Biológicas, Unidad de Micología Médica y Experimental., Medellín, Colombia
[4]Equal Opportunity Life Sciences, Molecular Biology- Genetics- Cell Biology, Saint-Etienne, France

Backgrounds

Scotochromogenic mycobacteria produce pigments either in the presence or absence of light while photochromogenic ones do so only upon photoactivation. Beta-carotene is an orange-red carotenoid of the terpenoid pigment family that has been described in mycobacteria for several decades, however very little is known about its detectable levels or about the regulation of the *crt* genes encoding its biosynthesis enzymes.

Objectives

To compare the constitutive expression levels of the *crt* genes as well as the basal beta-carotene yields in 6 mycobacterial species before and after exposure to UVB light.

Methods

Clinical isolates of *Mycobacterium tuberculosis (3), M. marinum (*3*), M. avium (*3*), M. abscessus (*3*), M. bovis (*3*) and M. kansasii (*3*)* were cultivated in Middlebrook 7H9 medium until a growth to McFarland scale 1.0 was obtained. Cultures were subsequently divided into 2 identical groups, one of which was subjected to a time course exposure to UVB light. Then, bacterial pellets were divided and processed for RNA isolation and beta-carotene extraction. *Crt* genes expression levels were assessed by semi-quantitative real time RT-PCR using SYBRGreen and beta-carotene yields were measured by HPLC-DAD at 450 nm.

Conclusions

HPLC-DAD analysis showed detectable levels of beta-carotene for all species but *M. abscessus*. Exposure to UVB rays over time shows increased coordinated expression of the *crt* genes, suggesting that carotenoid pigmentation could be part of a defense mechanism triggered by mycobacteria to protect themselves against the harmful effects of UVB rays.

Physiology / Biochemistry / Molecular Microbiology - Part II

MODULARITY OF PLASMID REPLICONS IN PSEUDOMONAS

L. Bardaji[1], M. Añorga[1], J.Á. Ruiz-Masó[2], G. del Solar[2], J. Murillo[1]
[1]Universidad Pública de Navarra, Departamento de Producción Agraria, Pamplona, Spain
[2]Centro de Investigaciones BIológicas, Molecular Biology of Gram-Positive Bacteria, Madrid, Spain

Backgrounds

Many bacterial traits of importance for humans, such as resistance to antibiotics, pathogenicity and degradation of pollutants, are carried by plasmids, facilitating their distribution among bacterial populations by lateral gene transfer. Plasmid doubling and bacterial host range depend on its replicon, usually comprising a DNA region controlling the replication rate, a replication gene and an origin of replication.

Objectives

We wanted to evaluate the organization and functionality of replicons from virulence plasmids of *Pseudomonas*.

Methods

Different replicons from the public databases were compared and aligned *in silico*. To study their functionality, we constructed appropriate deletion derivatives, mutants and chimeric replicons, and tested their ability to autonomously replicate in plasmidless strains of *P. syringae.* Incompatibility between chimeric replicons and native plasmids was assayed in wild type strains of *P. syringae*.

Conclusions

Here we propose a conceptual advance, with a paradigm shift in the genetics and biology of replicons, by showing that four replicon families from diverse species of *Pseudomonas* are organized as combinations of functionally independent control (REx-C) and replication (REx-R) modules. Modularity of replicons fosters evolutionary innovation and likely facilitates adaptation to the bacterial host and the acquisition of complexity; we also show avoidance of plasmid incompatibility by swapping REx-C modules. Notably, a REx-C module conferred replication ability to a chromosomal region from *P. syringae* containing replicon features but unable to replicate, suggesting that modularity could enable the co-option of appropriate genes into novel replicons.

Physiology / Biochemistry / Molecular Microbiology - Part II

A NITROGEN-REGULATED SMALL RNA CONTRIBUTES TO POST-TRANSCRIPTIONAL CONTROL OF THE STRESS-ACCLIMATION PROTEIN NBLA IN CYANOBACTERIA

I. Álvarez-Escribano[1], *A. Vioque*[1], *A.M. Muro-Pastor*[1]
[1]*Instituto Bioquímica Vegetal y Fotosíntesis, CSIC-Universidad de Sevilla, Sevilla, Spain*

Backgrounds

Photosynthetic cyanobacteria contain light-harvesting protein complexes called phycobilisomes (PBS). Several stress situations, including nutritional deficiencies or strong light exposure, lead to PBS degradation, either to protect the photosynthetic apparatus from excess light or to recycle the amino acids resulting from proteolysis. NblA is a protein adaptor that participates in degradation of PBSs. Transcription of *nblA* is induced upon nitrogen deficiency and controlled by NtcA, a CRP-family transcriptional regulator.

Objectives

We are interested in identifying NtcA-regulated small RNAs that could participate in the regulation of adaptation to nitrogen deficiency in the model heterocystous cyanobacteria *Nostoc* sp. PCC7120. In particular, we are analyzing the possible targets of NsrR1 (nitrogen stress-repressed RNA 1).

Methods

We have verified the presence of sequences encoding NsrR1 in the available genomes from heterocystous cyanobacteria and analyzed transcription of NsrR1 in response to different nitrogen regimes and transitions both in a wild-type strain and in an *ntcA* mutant. The *nblA* mRNA is computationally predicted to be regulated by NsrR1. We have verified the interaction using a GFP-based heterologous system in *E. coli*. We have analyzed the post-transcriptional regulation of *nblA* in cyanobacterial strains with altered levels of NsrR1.

Conclusions

We show that transcription of NsrR1 is regulated by NtcA, that NsrR1 interacts with the *nblA* mRNA at positions that overlap the translation initiation region, and that NsrR1 affects the accumulation of NblA mRNA and protein in *Nostoc* sp. PCC7120. Therefore, we conclude that NsrR1 contributes to the NtcA-operated control of nitrogen metabolism in cyanobacteria via *nblA*.

Physiology / Biochemistry / Molecular Microbiology - Part II

A CO-EXPRESSION NETWORK TO DISSECT THE TRANSCRIPTOMIC CHANGES TAKING PLACE DURING HETEROCYSTS DIFFERENTIATION IN THE CYANOBACTERIUM NOSTOC SP. PCC 7120

M. Brenes-Álvarez[1], A. Vioque[1], A. Sousa-Ortega[1], J. Georg[2], W.R. Hess[2], A.M. Muro-Pastor[1]
[1]Instituto Bioquímica Vegetal y Fotosíntesis, CSIC-Universidad de Sevilla, Sevilla, Spain
[2]University of Freiburg, Faculty of Biology, Freiburg, Germany

Backgrounds

Nostoc sp. PCC 7120 is a filamentous cyanobacterium that, in response to nitrogen deprivation, differentiates heterocysts (specialized cells devoted to fixation of atmospheric nitrogen). Because several cell types coexist at any given time in nitrogen-fixing filaments (vegetative cells, immature heterocyst and mature, nitrogen-fixing heterocysts), their global transcriptome is complex.

Objectives

We are interested in dissecting the complex transcriptome of *Nostoc* in order to identify genes (as well as antisense RNAs) differentially expressed at successive stages of the transformation of a vegetative cell into a nitrogen-fixing heterocyst. We expect those elements to be involved in development, maturation or function of this specialized cell type.

Methods

We have built a co-expression network using transcriptomic data from microarrays (corresponding to 56 samples from different strains growing under alternative nitrogen regimes). In this network, genes and antisense RNAs with similar expression patterns are grouped together. We have used the network to identify groups of genes specifically expressed in heterocysts. The differential expression of some of these genes has been verified by fluorescence confocal microscopy of strains bearing fusions of the corresponding promoters to the *gfp* gene encoding green fluorescent protein.

Conclusions

The co-expression network allows us to identify genes differentially expressed in specific cells of the filament during their transformation into heterocysts. Some of the products of these genes are well-known but others are annotated as unknown or hypothetical. Therefore, this network could help us to identify new genes (and antisense RNAs) potentially involved in the differentiation of heterocysts.

Department of Medical Microbiology, Nijmegen, Netherlands Antilles

Backgrounds

Because of the growing incidence of *Aspergillus* infection, typing methods of *Aspergillus* species are increasingly being used, i.e., phenotypic and genotypic analysis to study the spread and population dynamics in clinical and environmental settings, at levels ranging from a single host to large-scale ecosystems.

Objectives

So, we carried out a genetic study based on the analysis of nine microsatellite loci in a large sample of isolates from different regions of Iran to explore the genetic diversity between azole resistant and susceptible environmental and clinical *A. fumigatus* strains and to compare the data with isolates from other continent.

Methods

Sixty-six clinical and environmental strains were collected from ten provinces of Iran. The collection consisted of 43 clinical isolates from a variety of specimens, in addition 23 environmental isolates collected from soil and Hospital air samples. All strains were initially identified as *A. fumigatus* based on macroscopic and microscopic characters, the ability to grow at above 45°C, and finally reconfirmed by DNA sequencing of the partial b-tubulin gene. All *A. fumigatus* strains were subjected to microsatellite typing using three separate multiplex PCRs with a panel of nine short tandem repeats (STR) to evaluate the genetic relatedness between the isolates. The genetic relationship between the *A. fumigatus* isolates was established by comparing the profiles with BioNumerics v6.6 software.

Conclusions

The Simpson's index of diversity for all nine markers combined was calculated to be less than 0.9. The STR typing of 66 *A. fumigatus* isolates revealed 38 distinct genotypes distributed among environmental and clinical isolates. We identified 12 clones including 40 different isolates representing 60% of all isolates tested, which each clone included 2–7 isolates. In concordance with previous studies, STR typing provided to be a valuable tool for studying the molecular epidemiology and genotypic diversity of clinical and environmental *A. fumigatus* isolates with excellent discriminatory power.

HIGH PREVALENCE OF CLINICAL AND ENVIRONMENTAL TRIAZOLE RESISTANT ASPERGILLUS FUMIGATUS IN IRAN: IS IT A CHALLENGING ISSUE?

M. Nabili[1], T. Shokohi[2], M. Moazeni[2], S. Khodavaisy[3], H. Badali[4]
[1]Department of Medical Sciences- Sari branch- Islamic Azad University- Sari- Iran., Department of Medical Sciences, Sari, Iran
[2]Department of Medical Mycology and Parasitology/Invasive Fungi Research Center- School of Medic ine Mazandaran University of Medical Sciences Sari- Iran, Department of Medical Mycology, Sari, Iran
[3]Department of Medical Mycology and Parasitology- Kurdistan University of Medical Sciences- Sanan daj- Iran, Department of Medical Mycology and Parasitology, Tehran, Iran
[4]Department of Medical Mycology and Parasitology/Invasive Fungi Research Center- School of Medic ine Mazandaran University of Medical Sciences Sari- Iran, Department of Medical Mycology and Parasitology, Sari, Iran

Backgrounds

Triazole antifungal agents are the mainstay of aspergillosis treatment. As highlighted in numerous studies, the global increase in the prevalence of triazole resistance could hamper the management of aspergillosis

Objectives

we aimed to study the epidemiology of triazole-resistant *A. fumigatus* and the underlying *cyp51A* mutations in viable clinical and environmental isolates in Iran during 2013-2015.

Methods

In the present three-year study, 513 samples (213 clinical and 300 environmental samples) from 10 provinces of Iran were processed and screened in terms of azole resistance (4 and 1 mg l-1 of itraconazole and voriconazole, respectively), using selective plates. Overall, 150 A. fumigatus isolates (71 clinical and 79 environmental isolates) were detected. The isolates were confirmed by partial sequencing of the β-tubulin gene. Afterwards, in vitro antifungal susceptibility tests against triazole agents were performed, based on the Clinical and Laboratory Standards Institute (CLSI) M38-A2 document. The CYP51A gene was sequenced in order to detect mutations.

Conclusions

The MIC of itraconazole against 10 (6.6 %) strains, including clinical (n=3, 4.2 %) and environmental (n=7, 8.8 %) strains, was higher than the breakpoint and epidemiological cut-off value. Based on the findings, the prevalence of azole-resistant A. fumigatus in Iran has increased remarkablyfrom 3.3 % to 6.6 % in comparison with earlier epidemiological research. Among resistant isolates, TR34/L98H mutations in the CYP51A gene were the most prevalent (n=8, 80 %), whereas other point mutations (F46Y, G54W, Y121F, G138C, M172V, F219C, M220I, D255E, T289F, G432C and G448S mutations) were not detected. Although the number of patients affected by azole-resistant A. fumigatus isolates was limited, strict supervision of clinical azole-resistant A. fumigatus isolates and persistent environmental screening of azole resistance are vital to the development of approaches for the management of azole resistance in human pathogenic fungi.

A CRISPR/CAS9 SYSTEM FOR DISRUPTION OF CARB GENE IN MUCOR CIRCINELLOIDES

G. Nagy[1], C. Szebenyi[2], A. Vaz[2], E. Tóth[2], M. Homa[2], C. Vágvölgyi[2], T. Papp[1]
[1]Hungarian Academy of Sciences University of Szeged, Department of Microbiology, Szeged, Hungary
[2]University of Szeged, Department of Microbiology, Szeged, Hungary

Backgrounds

The CRISPR/Cas9 system offers a simple method for genome editing and RNA guided mutagenesis can be performed in several different organisms. The transformation strategy generally uses the crRNA and trans-activating crRNA (tracrRNA) together to guide CRISPR-associated (Cas) nuclease to cleave double-strand breaks in the targeted DNA sequence and the cell can repair this break with different repair mechanisms.

Objectives

Mucor circinelloides is a carotene producing Mucoromycotina fungus used as a model organism in studies of the carotenoid biosynthesis. Genetic manipulation of Mucoromycotina species, based on homologous recombination, is very difficult and frequently the mitotic stability of transformants is low.

Methods

In this study, CRISPR/Cas9 was used to disrupt the *carB* gene encoding phytoene dehydrogenase of *M. circinelloides*. PEG mediated protoplast transformation was used to introduce Cas9 enzyme and a synthesized *carB* gene specific gRNA with or without a deletion cassette into the fungus.

Conclusions

In the case of the usage of only the gRNA and cas9 without deletion cassette, the molecular analysis of transformant indicated a 2300 nl gap upstream from the PAM sequence by NHEJ. The colour of mutant strains was white. If we co-transformed Cas9 and gRNA with the deletion cassette the double-strand breaks of DNA was repaired by homologous recombination. After molecular analysis of these type mutants we could prove the presence of the *pyrG*, as selection marker into the coding sequence of *carB* gene.

The study was supported by the grants LP2016-8/2016 and GINOP-2.3.2-15-2016-00035.

MOLECULAR CHARACTERIZATION OF BETA-LACTAM RESISTANCE AND ASSOCIATED VIRULENCE GENES IN MDR GRAM POSITIVE AND GRAM NEGATIVE CLINICAL STRAINS ISOLATED FROM ONE BIG HOSPITAL IN BUCHAREST

H. Najee[1], I. Gheorghe[2], M. Popa[3], C. Chifiriuc[3], V. Lazar[3]
[1]Bucharest university-faculity of biology, microbiology department, Bucharest, Romania
[2]Bucharest university- Faculity of Biology, Microbiology, Bucharest, Romania
[3]Bucharest university-faculity of biology, Microbiology, Bucharest, Romania

Backgrounds

The purpose of the present study was aimed to identify the main genetic elements responsible for the beta-lactams resistance in *S. aureus* and Gram negative bacilli nosocomial recently isolated strains and to correlate their resistance profiles with the virulence genes spectrum.

Objectives

To correlate the resistance profiles with the virulence genes spectrum of clinical isolated bacteria

Methods

A total number of 27 isolates belonging to *S. aureus* (n=10), *P. aeruginosa* (n=10) and *E. coli* (n=107), clinical strains recovered from different sources (respiratory tract, wound and etc…) were collected in the Lab. of the "Prof.C. C. Iliescu" Institute of Cardiovascular Diseases, Bucharest, Romania. Strains identification was performed using automatic system Vitek2 Compact and the antibiotic susceptibility testing was investigated by agar disk diffusion (CLSI, 2016). Simplex and multiplex PCR were performed on genomic DNA in order to establish: the SCCmec type in *S. aureus* isolates; the genetic support of β-lactamases in *P. aeruginosa* (bla_{VIM}, bla_{IMP}, bla_{TEM}, bla_{CTX-M},$bla_{PER)}$ and respectively, in *E.coli* (bla_{IMP}, bla_{TEM}, bla_{CTX-M} bla_{NDM} and $bla_{OXA-48)}$ strains. The following virulence genes encoding for cell-associated and soluble virulence factors were investigated: plcH, plcN, protease IV, alginate, exotoxins (ExoU,T, and S) in *P. aeruginosa*, AggR, EAggE, VT1, VT2, pap, afa,sfa in *E. coli* and bbp, ebpS, fnbB, fnbA, fib, clfA, clfB, cna, luk-PV, hlg, tst and coagulase in *S. aureus.*

Conclusions

The microbial strains recovered from hospital environment proved to exhibit multiple drug resistance and virulence determinants, suggesting their potential to persist and initiate hospital-associated infections.

A MEMBRANE-TARGETING SMALL LIPOPROTEIN "KIL" INCREASED MEMBRANE PERMEABILIZATION AND BIOFILM FORMATION IN ESCHERICHIA COLI

R. Nakao[1], Y. Yoshimasu[1], S.N. Wai[2], B.E. Uhlin[2]
[1]National Institute of Infectious Diseases, Department of Bacteriology I, Tokyo, Japan
[2]Umeå University,
Department of Molecular Biology and Laboratory for Molecular Infection Medicine Sweden MIMS- Um eå Centre for Microbial Research UCMR, Umeå, Sweden

Backgrounds

Escherichia coli is one of the most prevalent microorganisms that cause catheter-associated infections in the urinary tract. Recently, we unexpectedly found that the biofilm formation of *E. coli* was enhanced by a commonly occurring plasmid gene called *kil*. The *kil* encodes small lipoprotein, however, it remains unknown the mechanism by which Kil increases the biofilm formation.

Objectives

In the present study, we addressed to understand the mechanism of Kil-dependent biofilm formation.

Methods

E. coli BW25113 strain and the derivatives were used in the present study. DNA cassetes of *kil* locus and *kil*-FLAG fusion were cloned into an arabinose-inducible expression vector pBAD33, resulting in pRN109 and pRN132, respectively. Membrane permeability and membrane potential (ΔΨ) were investigated by flow cytometry. Subcellular localization of Kil in BW25113/pRN132 was determined by a subcellular fractionation technique, followed by immunoblot using anti-FLAG antibody.

Conclusions

Supplementation with Mg^{2+} (5 mM) to the growth media dramatically inhibited membrane depolarization and increased the CFUs, suggesting its contribution to membrane stability. In the Mg^{2+}-enriched media, BW25113/pRN109 significantly increased biofilm formation as compared to BW25113/pBAD33. Induction of Kil increased membrane permeability, but not affect the ΔΨ. Most of Kil proteins translocated to the bacterial membrane but not in the cytoplasm or periplasm. We conclude that Kil inserted into the lipid bilayer enhances the biofilm formation probably due to increased membrane permeability without killing. We suggest possible roles of the Kil-encoding plasmids in spreading the *kil* locus via horizontal transfer among diverse Enterobacteriaceae, and therefore in enhancing biofilm formation.

ANTIMICROBIAL SUSCEPTIBILITY AND PHYLOGENETIC ANALYSIS OF PROPIONIBACTERIUM ACNES ISOLATED FROM ACNE PATIENTS IN A JAPANESE HOSPITAL

K. Nakase[1], *N. Hayashi*[2], *N. Noguchi*[1]
[1]*Tokyo University of Pharmacy and Life Sciences, Depertment of Microbiology, Tokyo, Japan*
[2]*Toranomon Hospital, Department of Dermatology, Tokyo, Japan*

Backgrounds

The prevalence of antimicrobial-resistant *Propionibacterium acnes* strains isolated from acne patients has been increasing in Japan.

Objectives

We should understand the current resistance rate for more effective acne treatment.

Methods

We tested antimicrobial susceptibility among *P. acnes* from acne patients having visited a specialized dermatology clinic between 2013 and 2015.

Conclusions

Rates of resistance to macrolides and clindamycin were 44.3 (31/70) and 38.6% (27/70), respectively. *erm*(X), which confers high-level clindamycin resistance (minimum inhibitory concentration ≥256 μg/ml), was detected in six isolates, whereas no resistance determinants were identified in eight strains showing high-level esistance to clindamycin. Using single-locus sequence typing, the *P. acnes* isolates were classified into five clades, with all high-level clindamycin-resistant strains lacking known clindamycin resistance determinants being grouped together (in clade F). *P. acnes* isolates from patients previously treated with macrolides and clindamycin exhibited a macrolide resistance rate (55.3%) significantly higher than that of those from patients not having received these treatments (21.7%, P <0.05). Furthermore, strains of clade F, which were very rarely isolated from healthy individuals, were more frequently recovered from patients with severe acne (40.0%) than those with mild acne (23.3%).
Our data revealed an increase in macrolide-resistant *P. acnes* prevalence in Japan due to the use of antimicrobial agents for acne treatment. Moreover, we identified strains of specific phylogenetic groups frequently associated with severe acne patients.

ROLE OF IRON AND FUR-FAMILY REGULATORS IN THE CONTROL OF ECTOINES SYNTHESIS GENES IN THE HALOPHILE CHROMOHALOBACTER SALEXIGENS

E. Naranjo[1], *M. Argandoña*[1], *C. Vargas*[1], *J.J. Nieto*[1]
[1]*University of Sevilla, Dpt Microbiology and Parasitology, Sevilla, Spain*

Backgrounds

Chromohalobacter salexigens is an halophilic microorganism that synthesizes ectoines as compatible solutes in response to osmotic stress, with important applications in Biomedicine. In this bacterium iron homeostasis is related with osmoadaptation, hence the synthesis of ectoines. In the genome of *C. salexigens*, two paralogs have been found, Fur1 (1) and Fur2, both involved in iron homeostasis and osmoadaptation.

Objectives

In this study we got insight into the role of both Fur regulators in the transcriptional control of genes involved in the synthesis of ectoine (*ectABC*) and hydroxyectoine (*ectD* and *ectE*), under iron limiting or iron supply conditions at different salinities.

Methods

Gene expression analysis of different mutants strains *(*Δ*fur1,* Δ*fur2 and* Δ*fur1fur2*) were performed by qPCR and compared with those of wild type strain. Besides, the intracellular content of ectoines was quantified by HPLC-MS as well as the intracellular iron content by ICP-OES.

Conclusions

Both regulators are involved in the transcriptional control of ectoines synthesis genes, albeit with different role (activator or inhibitor) depending on the environmental conditions. The existence of an additional iron-dependent but Fur-independent control mechanism was also suggested. On the other hand, the influence of iron in both the expression of ectoines synthesis genes and in its intracellular content was clearly shown. These results confirm the complex regulation of ectoine synthesis genes and the importance of iron in the osmoadaptation of this bacterium.

FREQUENCY OF GROUP B STREPTOCOCCUS CARRIAGE AMONG PREGNANT WOMEN IN SARI HOSPITALS,NORTHERN IRAN

M. Nasrolahei[1], M. Sharif[2]
[1], Sari, Iran
[2]Mazandaran University of Medical Sciences, Parasitology and Mycology, Sari, Iran

Backgrounds

Vaginal colonization with group B Streptococcus (GBS) is the predominant risk factor for the development of invasive neonatal GBS diseases.

Objectives

This study was undertaken to determine the prevalence of GBS colonization in pregnant women attending the antenatal clinic of Boo-Alicina hospital in Sari,northern Iran.

Methods

This cross-sectional study was conducted during June 2015 to April 2016 on 246 pregnant women admitted at term and in preterm labor. Socio-demographic information and clinical data pregnancy and neonatal-related complications such as previous pre-term delivery, PROM (Premature rupture of membrane), neonatal sepsis and maternal infection were collected using a structured questionnaire .Two recto-vaginal swabs were obtained from study subjects and standard microbiological methods were used to isolate GBS from specimens. The presence of the atr gene which is an essential gene and has to be expressed in all cells of this species was shown using PCR method. Statistical analysis was performed using Pearson's Chi square test.Two hundred and forty six women aged between 18-55 years (mean age of 30.73) were examined for GBS colonization. Culture and PCR positivity rate of recto-vaginal swabs were 20% and 27 % respectively. No significant difference was found in GBS colonization with mother's age, previous pre-term delivery, PROM (Premature rupture of membrane), previous neonatal sepsis and maternal Urinary tract infection. Only one risk factor has been seen in two GBS colonized mothers (i.e. in one cases premature delivery and in one other case premature rupture of membranes).

Conclusions

These results are the first record of the database in Sari which show high rate of vaginal colonization of GBS in Iranian women. However, further epidemiological investigations should be done in different parts of the country and accomplishment of routine GBS screening practices is also recommended.

GLYCOSIDE HYDROLASES ENCODED BY THE METHYLOFERULA STELLATA GENOME

D.G. Naumoff[1]
[1]*Winogradsky Institute of Microbiology - Moscow - Russia, Laboratory Of Wetland Microbiology, Moscow, Russia*

Backgrounds

Methyloferula stellata AR4 is an aerobic acidophilic methanotroph of the *Alphaproteobacteria* family *Beijerinckiaceae*. It is unable to grow on any multicarbon substrates, including carbohydrates. So, it is reasonable to conclude that all of its glycoside hydrolases use substrates synthesized intracellularly. The *M. stellata* draft genome sequence has been generated at the Joint Genome Institute (GenBank, ARWA00000000.1).

Objectives

Homology search of *M. stellata* genome allowed us to reveal 30 genes encoding putative glycoside hydrolases. Based on the catalytic domains, they belong to 14 different families: GH2, GH3, GH10, GH13, GH15, GH23, GH25, GH39, GH65, GH77, GH94, GH102, GH103, and PF06202. The PF06202 family is closely related to families GH63 and GH133 of glycoside hydrolases. We used each obtained glycoside hydrolase catalytic domain as a query for screening the protein database by blastp program. As a result, we found that in the vast majority of cases the closest homologue belongs to *Alphaproteobacteria*. The only exceptions are two *M. stellata* proteins representing GH39 and GH65 families of glycoside hydrolases. Eleven closest homologues of the GH39-family putative β-galactosidase (GenPept, WP_020173696.1) belong to bacteria from phyla *Actinobacteria* and *Firmicutes* (23%–31% of sequence identity). Five closest homologues of the GH65-family putative carbohydrate phosphorylase (WP_020177329.1) belong to *Betaproteobacteria* (60%–64%).

Methods

.

Conclusions

The data obtained suggest a low input of distant lateral transfer into evolution of glycoside hydrolase genes in the obligately methanotrophic bacteria. This is unusual for other bacteria and most probably is caused by the special role of their glycoside hydrolases not involved in environmental carbohydrate utilization.

Physiology / Biochemistry / Molecular Microbiology - Part II

PET TOXIN FROM ENTEROAGGREGATIVE E. COLI CAUSES EPITHELIAL CELL DEATH BY CLEAVING PROCASPASE-3 TO ACTIVATE CASPASE-3, INDEPENDENTLY OF CALPAIN AND CASPASE ACTIVITY

F. Navarro-Garcia[1], A. Serapio-Palacios[1], M. Rios-Vargas[1]
[1]CINVESTAV, Cell Biology, Cd. de México, Mexico

Backgrounds

Pet toxin secreted by Enteroaggregative *E. coli* (EAEC) has the ability to cause cytotoxic effects on epithelial cells, which leads to cell death. However, the cell death induced by Pet or its role on the cell death induced during EAEC infection has not been elucidated. Purified Pet and Pet-producing EAEC are able to cleave fodrin, paxillin and FAK, which are also cleaved by caspases and calpains during cell death by apoptosis and necrosis, leading to cell shrinkage, membrane blebbing and cell detachment.

Objectives

The aim of this study was to understand the role of Pet in cell death induced by EAEC

Methods

Here we have characterized the cell death induced by Pet by using confocal microscopy, flow cytometry and enzymatic activies. We found that Pet toxin is involved in the induction of cell death. Pet-induced cell death is independent of calpin and caspase activities since inhibition of these two activities did not block the cell death induced by Pet. Interestingly purified Pet induced cell death mainly by apoptosis. Pet-induced apoptosis was independent of caspases because Pet is able to cleave Procaspase-3 to produce caspase-3. This caspase-3 is active after its cleavage by Pet.

Conclusions

Thus our data indicate that Pet plays a relevant role in cell death induced by EAEC; Pet cleaves directly pro-caspase-3 for producing a specie of caspase-3 active, which leads epithelial cells to cell death by apoptosis.

Physiology / Biochemistry / Molecular Microbiology - Part II

CHARACTERIZATION OF THE VIBRIO CHOLERAE VC1636 PROTEIN: A NEW PARTNER IN DNA REPAIR MECHANISM?

V. Negro[1], *Z. Baharoglu*[1], *D. Mazel*[1]
[1]*Institut Pasteur, Genome and Genetics, Paris, France*

Backgrounds

The bacterial SOS response is a global stress response involved in DNA-damage repair. In *Escherichia coli* it is induced after DNA damage, for example after treatment with antibiotics that target DNA. The SOS response is also involved in genome plasticity and in the acquisition of resistance to antibiotics. Unexpectedly, the SOS response is induced in *Vibrio cholerae* by exposure to sub-inhibitory concentrations (sub-MIC) of different families of antibiotics that do not target DNA, such as aminoglycosides, chloramphenicol and tetracycline. The use of a genetic screen led to the isolation of mutants in which induction of the SOS response by sub-MICs of aminoglycosides is lost. One of these mutants is inactivated for the *vc1636* gene, which encodes a putative DNA/RNA helicase. We show that the overexpression of VC1636 in an *E. coli mfd* mutant, which is very sensitive to UV exposure, complements the viability of this mutant.

Objectives

The purpose of this project is to characterize the protein encoded by the *V. cholerae vc1636* gene and to understand the induction of the SOS response by antibiotics that do not target DNA in *V. cholerae.*

Methods

Towards this goal we use several bacterial genetic assays and biochemical tests *in vivo* and *in vitro* in order to study the helicase activity of this protein and the interaction with other complexes in *V. cholerae*.

Conclusions

The preliminary results show that VC1636 could play a role in the resolution of transcription and replication conflicts that can occur after a DNA damage.

Physiology / Biochemistry / Molecular Microbiology - Part II

DECIPHERING OMPR REGULATORY IMPACT ON THE EXPRESSION OF THE KDGR REGULON GENES INVOLVED IN PECTIN-DERIVATIVES TRANSPORT IN YERSINIA ENTEROCOLITICA

M. Nieckarz[1], *A. Raczkowska*[1], *K. Brzostek*[1]
[1]*University of Warsaw- Faculty of Biology, Department of Applied Microbiology, Warszawa, Poland*

Backgrounds

The outer membrane comparative LC-MS/MS analysis revealed oligogalacturonate-specific porin KdgM2 negatively regulated by OmpR protein in enteropathogenic *Yersinia enterocolitica.* Bioinformatic analysis of *Y. enterocolitica* genome revealed clusters of genes for a variety of pectinolytic enzymes and transport systems involved in pectin-derivatives translocation into the cells. The expression of pectin degradation and catabolism genes in plant pathogen *Dickaya dadantii* is controlled by the general repressor KdgR.

Objectives

The aim of this study was to reveal the role of OmpR in the regulation of genes involved in the pectate lyases production and transport of oligogalacturonates in *Y. enterocolitica* O:9.

Methods

The expression of *kdgM1*, *kdgM2-pelP-sghX*, *pehX* and *pelW-togMNAB* in the wild-type strain, Δ*ompR*, Δ*kdgR* and Δ*ompR*Δ*kdgR* mutants was studied by applying the translational/transcriptional fusions. The OmpR-dependent activity of the *kdgR* promoter was analyzed by qPCR. To verify whether OmpR directly regulates the expression of the particular genes the band-shift assays were performed. The pectate lyase activity in *Y. enterocolitica* strains was tested using enzyme activity plate assays.

Conclusions

OmpR was found to inhibit *kdgM2*, *kdgM1* and *kdgR* genes by binding to their promoters. In contrast, the activation of *pehX* and *pelW-togMNAB* expression by OmpR appears to be indirect. Moreover, the raised level of pectate lyase PelP in the *ompR* mutant, implying a negative role for OmpR in the enzyme production. Our data revealed that OmpR plays a dual role in controlling of genes of the KdgR regulon and support the importance of OmpR as a key regulator of pectin-derivatives transport in *Y. enterocolitica.*

Physiology / Biochemistry / Molecular Microbiology - Part II

COMPARATIVE ANALYSES OF BACTERIAL DNA FOUND IN JAPANESE RICE WINES

M. Terasaki[1], Y. Takahashi[1], H. Nishida[1]
[1]Toyama Prefectural University, Department of Biotechnology, Imizu, Japan

Backgrounds

Japanese rice wine, Sake, is a traditional Japanese alcoholic drink that is made by fermenting rice that has been polished to remove the bran. During Sake brewing, koji mold (*Aspergillus oryzae*) converts rice starch into sugars, and then Sake yeast (*Saccharomyces cerevisiae*) converts the sugars to alcohol.

Objectives

In addition to koji mold and Sake yeast, other microbes are most likely introduced during the process of Sake production. In this study, we identified and quantified bacterial DNAs found in various Sakes.

Methods

DNAs found in various Sakes were purified and concentrated. Bacterial DNAs were amplified and quantified using qPCR. In addition, massively parallel DNA sequencing was performed to clarify the origins of extracted DNAs.

Conclusions

Concentrations of bacterial DNA extracted from Sake that had been opened for 1 year was 32 times higher than those of bacterial DNA extracted from fresh Sakes. The massively parallel DNA sequence analysis showed that the old Sake included *Lactobacillus fructivorans* as the most dominant sequence, indicating that this bacterium was most likely responsible for the Sake becoming putrid. In addition, the analysis showed that, although concentrations of bacterial DNAs were similar among the fresh Sakes, variability among bacterial species was extensive. Fresh Sake includes a certain concentration of bacterial DNAs. Each Sake has a variety of bacterial DNAs, which is different from those observed in other Sakes. The variation in bacterial species may be caused by the process of Sake brewing. When bacterial species grows in Sake, the bacterial DNA can be measured as an increase.

VIRUSES TAKE ADVANTAGE OF THE CAPACITY OF STING ALTERNATIVE SPLICED ISOFORMS TO ALTER THE STABILITY OF WT STING

E. Nistal-Villán[1], E. Rodríguez García[2], C. Olagüe[2], R. Ferrero[2], P. Fortes[2], J. Prieto[2], G. González-Aseguinolaza[2]
[1]Universidad San Pablo CEU-Facultad de Farmacia.,
Secciíón de Microbiología. Dep. de Ciencias Farmacéuticas y de la Salud., Boadilla del Monte, Spain
[2]Centro para la Investigación Médica Aplicada CIMA, Terapia y Expresión Génicas, Pamplona, Spain

Backgrounds

The innate immune system provides the first line of defense against pathogens in higher eukaryotes. Stimulator of interferon genes (STING), codified by the TMEM173 gene, is a critical protein involved in IFN-β induction in response to cytoplasmic DNA detection resulting from the infection by different pathogens.

Objectives

To describe the expression and function of the different alternative spliced TMEM173 mRNA species in human cells.

Methods

Over-expression and silencing effects of the different alternative splicing isoforms in activating IFN-β and antiviral programs was tested. Reporter luciferase assays, endogenous gene expression by qPCR, Western blot, bioinformatics analysis as well as quantification of viral growth were used in order to test different hypothesis.

Conclusions

Three alternative spliced STING isoforms were discovered. They fail to induce IFN-β production and act as selective pathway inhibitors of full-length (Wt) STING. Truncated isoforms alter the stability of Wt STING reducing protein half-life. The underlying mechanism of this inhibitory effect indicates a proteasome dependent degradation. Knocking-down expression of truncated isoforms increases the capability of THP1 cells to produce IFN-β in response to intracellular DNA or HSV-1 infection. Viruses like HSV-1 or VSV early after infection reduce the Wt STING/ truncated STING isoforms ratio, suggesting a manipulation of STING alternative splicing as a strategy to evade antiviral responses. Finally, *in silico* analysis reveals that the human intron-exon gene architecture of TMEM173 (splicing sites included) is preserved in other mammal species, predominantly primates, stressing the relevance of alternative splicing in regulating STING antiviral biology.

PROBING THE ROLE OF CHROMATIN STRUCTURE IN THE EMERGENCE OF PATHOGENICITY IN CANDIDA GLABRATA

E. Hyland[1], C. O' Kane[2], F. Lundy[3], S. Gollogly[1]
[1]Queen's University Belfast, School of Biological Sciences, Belfast, Ireland
[2]Queen's University Belfast, School of Biological Sciences, Belfast, United Kingdom
[3]Queen's University Belfast, School of Medicine- Dentistry- and Biomedical Sciences, Belfast, Ireland

Backgrounds

The emergence of antimicrobial resistance in pathogenic fungi poses a growing threat to global public health, which is exacerbated by a limited range of antifungal therapies. Candidiasis accounts for 25% of fungal infections in the UK, and there is currently no successful treatment for this disease.

Objectives

Therefore, we aim to elucidate the molecular mechanisms behind the emergence of pathogenicity in the virulent yeast *Candida glabrata*. Using phylogenetic approaches, we have identified nineteen genes under positive selection in *C. glabrata* that regulate the post-translational modification (PTM) of histone proteins, and we hypothesize that these 19 genes are important for pathogenicity.

Methods

We are currently optimizing a two-plasmid CRISPR/Cas9 system for use in *C. glabrata* strains, in order to disrupt each of the 19 target genes, whereby, the Cas9 enzyme is maintained on one plasmid and specific guide RNA molecules are Gibson assembled into a second distinct plasmid. Once generated, these deletion strains will be assessed in clinically relevant phenotyping assays to determine the contribution of these histone PTM genes to *Candida* infections.

Conclusions

Preliminary data support our hypothesis as we have found that the deletion of either cg-*HAT1* (a histone H4 acetyltransferase) or cg-*SSP1* (a regulator of histone H3 methylation) promotes *C. glabrata*'s biofilm formation and resistance to fluconazole as determined using a crystal-violet microtitre assay and an antifungal sensitivity assay respectively. Future work involves using RNA-seq and ChIP-seq to determine the molecular basis of these phenotypic changes as well as increasing our *C. glabrata* deletion strain collection using CRISPR/Cas9.

EFFECTS OF FEED SUPPLEMENTATION WITH DRY WHEY POWDER AND CALCIUM BUTYRATE ON CAMPYLOBACTER COLONIZATION AND CAECAL MICROBIAL COMMUNITY COMPOSITION IN BROILERS

M. Ocejo[1], B. Oporto[1], A. Lanzen[2], R.A. Juste[3], A. Hurtado[1]
[1]NEIKER-Tecnalia, Department of Animal Health, Derio, Spain
[2]NEIKER-Tecnalia, Department of Conservation of Natural Resources, Derio, Spain
[3]SERIDA, Servicio Regional de Investigación y Desarrollo Agroalimentario, Villaviciosa, Spain

Backgrounds

Poultry is the principal reservoir and source for *Campylobacter* infections. Farm interventions based on chicken feed supplementation could elicit health benefits, improve production and reduce chicken colonization.

Objectives

To assess the effects of dietary supplementation of broilers with whey (prebiotic) and calcium butyrate (salt of a short-chain fatty acid) on productive traits, histological integrity, *Campylobacter* colonization and caecal microbiota during the 42-days rearing period.

Methods

One-day-old Ross-308 chickens were assigned to 4 diets (5replicates x 30chicks x 4diets): 1) control corn-soybean based diet; 2) 6% dry whey powder supplementation; 3) 0.1% coated calcium butyrate; 4) 6% whey and 0.1% calcium butyrate supplementation. At 15-days-old, *Campylobacter jejuni* was experimentally introduced into the flock. *Campylobacter* was monitored by culture and real-time PCR and, 16S rRNA high-throughput Illumina amplicons (2X250bp paired-end reads) were analysed with DADA2, QIIME and R.

Conclusions

Supplementation with 6% whey and 0.1% coated calcium butyrate improved growth and feed efficiency, had a beneficial effect on duodenal villus integrity and decreased mortality. Six days after oral challenge, *Campylobacter* was widespread in the flock, and infection remained until the end of rearing. *Campylobacter* was detected by real-time PCR in dust, air and drinkers while animals shed culturable *C. jejuni*. No differences were observed in *Campylobacter* colonization or shedding levels associated to diet suggesting that neither of these additives gave the chicks any differential degree of protection. Microbiome composition and complexity changed rapidly with age, with older chickens having higher phylogenetic diversity, but changes associated to diet were more subtle.

BIOLOGICAL VALIDATION OF PUTATIVE IRON-RELATED GENES IN STAPHYLOCOCCUS EPIDERMIDIS: HOW IRON INDUCES PHISIOLOGIC AND TRANSCRIPTOMIC CHANGES ON BIOFILM CELLS

F. Oliveira[1], *N. Cerca*[1]
[1]*Centre of Biological Engineering - University of Minho, Department of Biological Engineering, Braga, Portugal*

Backgrounds

Iron has been recognized as a key nutrient for bacterial proliferation. Regarding staphylococci, most of the knowledge on iron acquisition mechanisms comes from studies on *Staphylococcus aureus*, whereas studies on *Staphylococcus epidermidis* are still in their infancy. Despite its long-known commensal nature, *S. epidermidis* has emerged as a prominent nosocomial pathogen. Its ability to grow as a biofilm has been regarded as its major pathogenic feature. Recently, we found *S. epidermidis* biofilm formation to be highly modulated by iron availability.

Objectives

To understand the mechanisms by which iron modulates *S. epidermidis* biofilm formation.

Methods

Biofilms of three *S. epidermidis* isolates were grown under iron-deficient/enriched conditions and studied for cell cultivability, matrix composition/structure (CLSM), and gene expression (qPCR).

Conclusions

The expression of several putative iron-related genes (siderophore biosynthesis, ABC transporters) was found to be modulated by iron availability, providing a biological validation of their function on iron metabolism. Physiologically, iron excess induced changes in the cultivability of suspended but not of the biofilm-associated cells. Conversely, iron deficiency induced noticeable changes in the cultivability of both suspended and biofilm-associated cells. A temporal analysis (6-24h) revealed that iron excess/deficiency: i) impaired biomass accumulation from 6h onwards, ii) induced microcolony-like arrangements, and iii) interfered with the production of extracellular matrix, indicating that iron availability plays a pivotal role from an early biofilm development stage. This study therefore paves the way for further research on the molecular mechanisms behind *S. epidermidis* iron metabolism, while placing it as an interesting target for biofilm control purposes.

TRANSCRIPTIONAL REGULATORY NETWORKS INVOLVED IN PECTIN DECONSTRUCTION IN ASPERGILLUS NIDULANS

M. Orejas[1], *A. MacCabe*[1]
[1]*Instituto de Agroquímica y Tecnología de Alimentos IATA-CSIC, Departamento de Biotecnología, Paterna, Spain*

Backgrounds

The cell walls of higher plants are composed of proteins and four polymeric building blocks: the polyphenol lignin and the three polysaccharides cellulose, hemicellulose and pectin. The utilization of the complex sugar-containing constituents is a highly regulated event in both saprophytic fungi growing on dead plant material and phytopathogenic fungi when colonizing their hosts. Pectin's chemical composition comprising various monosaccharides (*e.g.* galacturonic acid and L-rhamnose) linked by a variety of bonds makes it the most structurally complex of the plant cell wall polysaccharides, and as such its efficient degradation requires the action of a range of diverse enzyme activities.

Objectives

Using *Aspergillus nidulans* as a model, we are characterizing how filamentous fungi respond to pectin and its sugar components.

Methods

A genome-wide expression study is being performed under different growth conditions with wild type and loss-of-function mutants in two activators (RhaR and PecR; the latter was identified in this work) and the wide-domain repressor CreA.

Conclusions

RNAseq analyses reveal that: (i) regulation of the pectinolytic machinery is a highly coordinated process, (ii) L-rhamnose induces enzymes appropriate for the degradation of rhamnogalacturonan I, and (iii) RhaR and PecR have key roles in the degradation/utilization of the pectic polysaccharides rhamnogalacturonan I and II, respectively. The knowledge obtained could be used to modify the expression of sugar transporter genes, rhamnose catabolic genes and/or rhamnosidase regulatory genes with a view to modulating (up or down) the production of pectin-acting enzymes.

MODULAR STRUCTURE OF SRNAS AND CODON PREFERENCE OF TARGET REGIONS IN ESCHERICHIA COLI.

O. Orellana[1], F. Avalos[2], J.P. Maldonado[3], M. Tello[2]
[1]Facultad de Medicina -Universidad de Chile, Programa de Biología Celular y Molecular- ICBM, Santiago, Chile
[2]Facultad de Química y Biología- Universidad de Santiago de Chile.,
Laboratorio de Metagenómica Bacteriana- Centro de Biotecnología Acuícola, Santiago, Chile
[3]Facultad de Medicina- Universidad de Chile,
Laboratorio de Biología Molecular Bacteriana- Instituto de Ciencias Biomédicas, Santiago, Chile

Backgrounds

Small RNAs (sRNA) are a type of non-coding RNA that control bacterial translation process modifying ribosome binding, translation progression or degradation of mRNA. sRNAs may interact with one or more mRNAs mainly in the 5'UTR and/or in coding regions (CDS). However, it is unknown whether there is a conservation of the interaction regions in the target mRNAs. It is also unknown whether the interaction is associated to some specific codons

Objectives

To assess these questions we identified in *E. coli* sRNAs with multiple target mRNAs and characterized the interacting regions.

Methods

To achieve these goals bioinformatic approaches were used. Experimental data of sRNA-mRNA interactions were obtained from RNATarBAse and BSRD databases. Uncharacterized interactions were predicted using IntaRNA software. The regions of interaction in sRNA were identified mapping the density of sRNA-mRNA interactions over the sRNA sequence. The mRNA interacting regions were characterized at the codon level using CAI and tAI indexes.

Conclusions

18 sRNAs were found with 2 to 6 interacting regions. Spot42 and other sRNAs interact manly with CDS while others with the 5'UTR, suggesting a modular structure. Although there is no preference for biased codons, most sRNAs interact in regions with lower tAI compared to the rest of mRNA, suggesting a connection between sRNA regulation and translation efficiency. Experiments to validate the bioinformatic predictions are currently in progress.Our results suggest that sRNAs show a modular structure, interacting in many cases with coding regions with low codogenic preference and tAI.

[4]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRST IRCCS, Department of Medical Oncology, Meldola, Italy

Backgrounds

Colorectal cancer (CRC) development is a multistep process by which healthy gut epithelium slowly develops into adenomas, which in turn progress into malignant carcinomas over time. This pathogenic progression is known as the adenoma–carcinoma sequence. The formation of intestinal preneoplastic lesions and CRC are associated with several risk factors such as the microbial gut dysbiosis, supporting the concept that changes in the microbiota precede the progression into adenocarcinomas.

Objectives

This study aims to identify specific bacterial associations in adenoma-carcinoma sequence.

Methods

Faecal samples from a cohort of about 100 samples coming from healthy people (18) and patients with low-risk adenomas (LRA, 19), high-risk adenomas (HRA, 21), hyperplastic polyps (HP, 14) and with adenocarcinomas (ADK, 22) were collected. DNA was extracted and purified from all samples using QIAamp DNA stool kit (Qiagen) and was used for 16S metagenomic library preparation. These libraries were sequenced using HiSeq 2500 Illumina platform and *in silico* analysis of metagenomics data was performed. Interesting results were obtained at each taxonomic level. Some data obtained at phylum level can be summarized as follows:

- There is an increase of *Proteobacteria* in the adenoma-carcinoma sequence, confirmed also at genus level;

- In HRA and ADK samples there is a decrease in *Actinobacteria*, confirmed by a decrease in *Bifidobacterium* genus;

- *Fusobacteria,* a possible CRC driver, are more abundant in HRA.

Conclusions

Taking advantage of metagenomics approach, by this multidisciplinary study we identified specific microbial associations that can be potentially used as biomarkers during neoplastic progression.

EXPRESSION AND PURIFICATION OF A RECOMBINANT THIOSULFATE DEHYDROGENASE FROM AZOSPIRILLUM THIOPHILUM BV-S AND ITS STRUCTURAL CHARACTERISATION

M. Orlova[1], E. Rogozhin[2], A. Fomenkov[3], M. Grabovich[1]
[1]Voronezh State University, Department of Biochemistry and Cell Physiology, Voronezh, Russia
[2]Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry- Russian Academy of Sciences, Department of Molecular Neurobiology, Moscow, Russia
[3]New England Biolabs, Genome Biology, Massachusetts, USA

Backgrounds

The activity of thiosulfate dehydrogenase (Tsd) from *Azospirillum thiophilum* was shown previously, but its gene was not found in the genome by automatic annotation.

Objectives

Our task was to find *Tsd* gene in the genome of *A. thiophilum*, to clone it into the plasmid and to measure the properties of the appropriate protein.

Methods

The gene encoding a full-length sequence of the hypothetical protein from GenBank Database (WP_052710250) was expressed in *Escherichia coli* BL21 (DE3) cells with induction by 0.2% arabinose. The enzyme was purified by consistent hydrophobic, size-exclusion and affinity liquid chromatography procedures of medium and high pressure. Structural identification of the isolated protein was conducted by SDS gel-electrophoresis, electro transferring to PVDF membrane, N-terminal automated Edman degradation, MALDI-TOF mass spectrometry and chemical cleavage by cyanogen bromide.

Conclusions

The analysis of sequences in the NCBI database revealed a homologous gene for *tsd* (*cytc*), encoding a protein from the family of cytochromes (WP_052710250) in the genome of *A. thiophilum*. The alignment of Tsd from *A. thiophilum* with homologous proteins revealed the conserved motifs typical for previously characterized Tsd.

Tsd gene was cloned into the plasmid pBAD34 at sites for restriction endonucleases *NcoI* and *XbaI*. After purification the active protein was obtained (concentration 0.46 mg/mL, 10-20% of the total activity). Two N-terminal amino acid residues (Met and Ala) of the recombinant protein were hypothetically cleaved by bacterial amino peptidases. Identity of three peptide fragments, resulting from chemical hydrolysis and separated by reversed-phase high performance liquid chromatography, was confirmed by MALDI-TOF MS and Edman microsequencing.

THE ROLE OF LMO1216 IN GROWTH AND BIOFILM FORMATION OF LISTERIA MONOCYTOGENES

R. Ostrowski[1], M. Popowska[1]
[1]University of Warsaw - Faculty of Biology, Department of Applied Microbiology, Warsaw, Poland

Backgrounds

L. monocytogenes is a gram-positive, foodborne pathogen causing listeriosis. This species is widespread in nature which is connected with a high number of surface proteins. Very important class of these proteins are murein hydrolases (autolysins), involved in several processes, including cell growth, separation and division, biofilm formation, turnover of cell wall components, protein secretion, autolytic activity and pathogenicity. Lmo1216 is one of the hypothetical autolysins of *L. monocytogenes.* It comprises two domains: FlgJ (Flagellum-specific peptidoglycan hydrolase) and SH3 (containing GW repeat).

This work was supported by National Center of Science grant nº 2013/09/B/NZ6/00710.

Objectives

Determination of the impact of Lmo1216 autolysin on growth rate and biofilm formation in *L. monocytogenes* EGD*.*

Methods

A deletion in *lmo1216* gene was obtained by cloning its fragments in tandem in pMAD plasmid. Using this construct, a mutagenesis procedure was performed according to standard protocol. Optical density was measured in 30 minutes intervals to estimate growth rate in BHI medium at 20ºC, 30ºC, 37ºC with shaking at 120 rpm. Level of biofilm formation by bacteria was assessed by staining with 1% crystal violet. In both experiments the impact of SDS, Triton X-100, EDTA was also investigated. We performed standard motility tests and cell morphology was checked by transmission electron microscopy.

Conclusions

The *lmo1216* gene takes part in growing of *L. monocytogenes* significantly decreasing the growth rate. Lack of *lmo1216* gene influences the level of biofilm formation by this bacterium. We also observed changes in morphology and motility of the mutant.

PROTEIN ARGININE PHOSPHORYLATION IN STAPHYLOCOCCUS AUREUS

S. Junker[1], S. Maass[1], A. Otto[1], M. Hecker[2], D. Becher[1]
[1]Institute for Microbiology, Microbial Proteomics, Greifswald, Germany
[2]Institute for Microbiology, Microbial Physiology, Greifswald, Germany

Backgrounds

As human pathogen known to be the causative agent of a high number of nosocomial infections worldwide, *Staphylococcus aureus* is regarded a severe threat. One approach in research to understand pathogenesis and virulence on molecular level is the investigation of the phosphoproteome revealing central hubs of regulation. This has already been done for well-known o-phosphorylations and phosphorylations on cysteine, histidine and aspartate residues, and has recently been applied also to phosphorylations at arginine residues. It is likely that the latter play an essential, but mostly still unknown role in Gram positive bacteria.

Objectives

In *S. aureus* COL, the protein PtpB is assumed to be an arginine phosphatase. Hence, in the present work, we applied a gel-free method to analyze the changes in the phosphoproteome of the deletion mutant Δ*ptp*B and the wild type, focusing on analysis of arginine phosphorylations.

Methods

With the help of spectral library enhanced processing of LC-MS/MS datasets acquired from phosphoenriched samples, we are able to identify 207 arginine phosphorylations exclusively within the Δ*ptp*B mutant. The spectral library used for both enhancing the number of identifications and reproducibility of data processing comprises 84% of the theoretically predicted proteome with a total of 396 arginine phosphopeptides. A subset of the analytically challenging arginine phosphopeptides used for library building was verified by complementary analysis of chemically synthesized phosphopeptides.

Conclusions

The identification of putative targets of PtpB allows for further investigations of the physiological relevance of arginine phosphorylations and provides the basis for reliable quantification of this protein modification in *S. aureus*.

BIOCHEMICAL CHARACTERIZATION OF N-TERMINALLY TRUNCATED FTSH PROTEASE OF GEOBACILLUS KAUSTOPHILUS

I. Ozdemir[1], S.S. Ramadhan[1], A. Tulek[1]
[1]Gebze Technical University, Molecular Biology and Genetics, Kocaeli, Turkey

Backgrounds

In both eukaryotic and prokaryotic cells, protein degradation is largely conducted by ATP-dependent proteases such as Lon, FtsH, ClpAP, ClpXP and HslUV. Among these proteases, FtsH is unique as a membrane-bound ATP-dependent zinc-metalloprotease that degrades integral membrane proteins as well as cytoplasmic proteins. It spans the cytoplasmic membrane twice and has a large cytoplasmic C-terminal with a putative ATP binding domain.

Objectives

We studied ATPase and proteolytic activity of soluble FtsH protease from thermophilic *Geobacillus kaustophilus* strain DSM 7263^T which lack the transmembrane helices.

Methods

The 1530 bp gene was cloned in expression vector pET14b and expressed in BL-21(DE3) host cells. The recombinant protein contained hexahistidine tag at N-terminus and was purified using nickel-NTA chromatography. The molecular weight of N-terminally truncated *G.k*-FtsH was determined by SDS-PAGE and Western Blotting as ~58 kDa. Optimum temperature for ATPase activity was observed at 55˚C and the enzyme retained 60% activity after half-hour incubation at 55-60˚C. *G.k*-FtsH protease requires both ATP and Mg^{2+} for its ATPase activity, 3.4 U/µL. The enzyme is also capable of hydrolyzing CTP and slightly GTP but not UTP and ADP. ATPase activity of *G.k*-FtsH is inhibited by 10 mM metal-chelating agents EDTA and O-phenanthroline, 65% and 48% respectively and markedly inhibited in the presence of 1 mM lactacystin and PMSF. Purified *G.k*-FtsH degraded α-casein efficiently in the presence of 4 mM ATP at up to 96-98% of the starting concentration.

Conclusions

These results showed that without N-terminal transmembrane domain *G.k*-FtsH successful expressed and showed efficient ATPase activity and protease activity.

FEMS7-0999
Physiology / Biochemistry / Molecular Microbiology - Part II

PHYSIOLOGICAL ROLE OF THE LOW-MOLECULAR-MASS PENICILLIN-BINDING PROTEIN DACC IN ACINETOBACTER BAUMANNII

S. Pal[1], D. Kar[1], G. Kumar[1], A. Kumar[1], A.S. Ghosh[1]
[1]Indian Institute of Technology Kharagpur, Biotechnology, Kharagpur, India

Backgrounds

Multi-drug resistant *Acinetobacter baumannii* has emerged as an important nosocomial pathogen. As some low-molecular-mass penicillin-binding proteins are known to possess intrinsic β-lactam resistance properties, it would be interesting to unravel the physiological role of DD-Carboxypeptidases in *Acinetobacter baumannii*.

Objectives

In this study we aimed to characterize the physiological role of DacC of *A. baumannii* in β-lactam resistance, biofilm formation and cell shape maintenance.

Methods

The *dacC* gene was deleted from the genome of *A. baumannii* ATCC19606 and the membrane-bound form of the protein was cloned in pBAD18-Cam for expression in *Escherichia coli* and pABBR-MCS for *A. baumannii*). Biofilm formation was assessed by crystal violet staining. The minimum inhibitory concentrations of the β-lactams were determined using broth micro-dilution method. Cell morphology was analysed by phase contrast microscopy. To confirm the biochemical reason behind the physiological behaviours, the soluble form of the protein was created, expressed and purified. Steady state kinetic studies were done with the β-lactams and the peptide substrates.

Conclusions

The deletion of *dacC* resulted in reduced biofilm formation and also led to an abnormal cell shape. It also made the cells sensitive to some β-lactam antibiotics. Ectopic complimentation restored the lost phenotypes. The soluble protein exhibited DD-Carboxypeptidase activity against peptidoglycan-mimetic DD-Carboxypeptidase substrates as well as showed efficient β-lactam hydrolysis. Our hypothesis is that *A. baumannii* DacC is a dual enzyme, possessing both DD-Carboxypeptidase and β-lactamase activities, that is involved in biofilm formation and helps in maintaining cell shape.

LIFE WITHOUT CROSSING-OVER: GENOME EVOLUTION AND MECHANISMS OF MEIOSIS IN THE NEW MODEL YEAST SACCHAROMYCODES LUDWIGII

I.A. Papaioannou[1], N. Delhomme[2], F.A. Peltier[1], A. Bardhan[1], W. Wu[3], L. Steinmetz[3], M. Knop[1]
[1]University of Heidelberg,
Zentrum für Molekulare Biologie der Universität Heidelberg - ZMBH - ZMBH-DKFZ Alliance, Heidelberg, Germany
[2]University of Umeå, Department of Plant Physiology - Umeå Plant Science Center, Umeå, Sweden
[3]European Molecular Biology Laboratory - EMBL, Genome Biology Unit, Heidelberg, Germany

Backgrounds

The paradox of sex, i.e., its ubiquity despite its biological costs, is one of the most persistent conundrums in biology. Most relevant hypotheses focus on the roles of meiotic recombination in handling mutations, e.g., purging of the deleterious load and generation of new combinations of beneficial alleles. However, the impact of recombination on genome evolution is still poorly understood.

Objectives

To analyze the diploid yeast *Saccharomycodes ludwigii* as an ideal candidate for the study of genome evolution and the mechanisms of meiosis in the absence of crossing-over. This species experiences a full sexual cycle but generally fails to recombine its genome during meiosis.

Methods

The genome of *S. ludwigii* was sequenced, assembled and annotated. Repetitive content in DNA and protein sequences was compared with 23 other sequenced yeast species. A mutation accumulation experiment and a variant segregation analysis in full sequenced tetrads of a hybrid diploid strain were performed. Deletion/tagging strains of important meiotic genes were constructed and analyzed for putative functionality in meiosis.

Conclusions

Saccharomycodes ludwigii was established as a particularly interesting organism for the study of genome evolution. We are proposing an evolutionary model entailing the shaping of a remarkably A/T-rich genome as a consequence of the absence of crossover-associated gene conversion and the biased nature of mutations; the accumulation of repetitive DNA elements including particular codon expansions in genes; and the significant predicted expansion of prion-like proteins as a conceivably efficient way to ensure adequate levels of adaptation potential despite the absence of meiotic recombination.

SEX IS NOT THE ONLY WAY: NEW INSIGHTS INTO PARASEX IN THE PLANT-PATHOGENIC FUNGUS VERTICILLIUM DAHLIAE

I.A. Papaioannou[1], V. Vangalis[2], M.A. Typas[2]
[1]University of Heidelberg, Zentrum für Molekulare Biologie der Universität Heidelberg - ZMBH, Heidelberg, Germany
[2]National and Kapodistrian University of Athens,
Faculty of Biology - Department of Genetics & Biotechnology, Athens, Greece

Backgrounds

Parasex, as an alternative to sex permitting genetic exchange between individuals, has been established and exploited for genetic analysis in several asexual fungi. However, the traditional assumption that vegetative incompatibility barriers generally hamper parasexual exchanges in natural populations, has discouraged the detailed characterization of the process in recent years, thus hindering a clear understanding of its significance in fungal evolution and population dynamics.

Objectives

(i) to elucidate poorly understood steps of the parasexual cycle in the important plant-pathogenic asexual fungus *Verticillium dahliae*, and (ii) to examine the potential impact of vegetative incompatibility on the parasexual process in this species.

Methods

Widely used tester strains of *V. dahliae* vegetative compatibility groups (VCGs) were labeled with complementary combinations of auxotrophic, drug-resistant and fluorescent markers, and used for heterokaryon synthesis tests. Hyphal fusion (anastomosis), nuclear migration, diploid formation and haploidization were observed microscopically, analyzed in terms of temporal patterns by time-lapse microscopy, monitored genetically with conidial analyses (FACS), and characterized with genomic approaches.

Conclusions

All phases of the parasexual cycle of *V. dahliae* were characterized in detail with a combination of different experimental approaches. Heterokaryon synthesis was found to be very frequent under proper, low-nutrient conditions, not only between “compatible”, but also between supposedly “incompatible” strains. Diploid formation and segregation into novel recombinant mycelia were also recorded in both “compatible” and “incompatible” combinations. These results imply that the parasexual cycle may be more important in nature than previously anticipated, and lay the foundation for detailed investigations of its evolutionary significance.

SCREENING OF FOOD LACTIC ACID BACTERIA LACCASES

I. Pardo[1], M. Abril[1], R. Sendra[2], S. Ferrer[1], S. Callejón[1]
[1]ERI BioTecMed, ENOLAB, Burjassot, Spain
[2]Facultat de Biologia, Departament de Bioquímica, Burjassot, Spain

Backgrounds

Laccases (EC 1.10.3.2) are copper-containing oxidases found in many plants, fungi, animals and microorganisms. Laccases catalyse the oxidation of a variety of substituted phenols and many other compounds without any other requirement than oxygen from the air. As a result, these enzymes are promising green biocatalysts for several industrial sectors such as textile, food, wood and pulp, bioremediation, organic synthesis or electrocatalysis.

Objectives

The search of laccase enzymes in food lactic acid bacteria (LAB). The most representative LAB species from food or beverages - such as cheese, meat, olives or wine - were analysed using a microplate method specifically developed.

Methods

Laccase activity was measured from cell-free extracts using ABTS as substrate. Cells from a MRS culture were mechanically disrupted and the resulting extract clarified by centrifugation and submitted to ammonium sulphate fractionation. Then, the 90% saturation-precipitate was dissolved and saved as crude cell-free extract. Aliquots of extracts were incubated in sodium acetate buffer, pH 4.0, containing $CuCl_2$ 0.1 mM, for 10 minutes and after centrifugation, the supernatant transferred to a multiwell microplate. ABTS was added at 5 mM and its oxidation was determined by absorbance increase at 420 nm ($\varepsilon 420$=36,000 M^{-1} cm^{-1}). The initial rates were deduced from the slope of plots of A_{420} versus time, and specific activity was calculated by dividing the slope between the total protein concentration.

Conclusions

A new multiwell microplate method has been developed to detect and quantify laccase activity in LAB.

We obtained laccase positive strains from several LAB species.

FUNCTIONAL CHARACTERIZATION OF ENVIRONMENTAL LACTATE AND SIALIC ACID UTILIZATION DURING NTHI IN VITRO INFECTION OF HUMAN EPITHELIA

C. Parillo[1,2], B. Baddal[3], C. Baldari[1], S. Rossi Paccani[2], A. Pezzicoli[2]
[1]Università degli studi di Siena, Biochimica e Biologia Molecolare, Siena, Italy
[2]Glaxo Smith Kline Vaccines, Antigen Identification & Molecular Biology, Siena, Italy
[3]Harvard Medical School,
Division of Infectious Diseases- Boston Children's Hospital and Department of Pediatrics, Boston, USA

Backgrounds

Non-typeable Haemophilus influenzae (NTHi) is a small acapsulate gram-negative coccobacillus and a human-restricted nasopharynx commensal. Nevertheless, it is the main cause of chronic obstructive pulmonary disease (COPD) exacerbation. A previous dual RNA-seq study showed the upregulation of *L-lactate permease* gene, suggesting a role for environmental lactate during the infection. Furthermore a strong downregulation of a *tripartite ATP-independent periplasmic transporter* was reported, while a *putative sialic acid transporter* gene was found to be upregulated during the infection.

Objectives

In order to clarify the impact of these transport systems on lactate and N-acetyl neuraminic acid (NANA) uptake, we produced the corresponding *knock out* strains and we are currently investigating their role in human bronchial epithelia infection.

Methods

Bacterial strains were grown in a chemically defined medium in order to control the lactate and NANA content. Then human bronchial epithelia were infected at different timepoints to analyse bacterial fitness and resistance to complement mediated killing.

Conclusions

Preliminary data obtained by comparing *wild type* strain with *lactate permease knock out* after 72 hours infection of a bronchial epithelium, showed an increased amount of mutant bacterial cells. We are currently investigating the mechanisms causing this apparent discrepancy. On the other hand the serum resistance of *putative sialic acid transporter knock out* is comparable to the *wild type* after the colonization of human bronchial epithelia. In conclusion our work is aimed to better characterize NTHi infection factors involved in the colonization of the human bronchial epithelium.

DUAL-SPECIFICITY LAMMER KINASE REGULATES THE G1/S CELL CYCLE PROGRESSION AT TRANSCRIPTIONAL AND POST-TRANSLATIONAL LEVEL IN FISSION YEAST

S.J. Kwon[1], S. Shin[1], H.M. Park[1]
[1]Chungnam National University, Microbiology & Molecular Biology, Daejeon, Republic of Korea

Backgrounds

A number of studies have reported that the dual-specificity LAMMER kinases regulate multiple cellular processes in higher eukaryotes. While LAMMER kinase-dependent phosphorylation of Thr110 residue on Rum1, a cyclin-dependent kinase inhibitor (CKI), is crucial for G1/S cell cycle progression (Yu et al, 2013), much remains to be determined in terms of the mode of Lkh1 action in regulating cell cycle of the fission yeast *Schizosaccharomyces pombe*.

Objectives

Testing the effect of Thr110 phosphorylation of Cdc2-inhibitor Rum1 on CKI activity and affinity to CDK

Identification and characterization of the additional LAMMER kinase target(s)

Methods

CKI activity of Rum1 proteins was measured by using Cdc2-cyclin and Histone H1 assay system.

Affinity of Rum1 proteins to cyclin-dependent kinase Cdc2 was measured by pull-down assay.

Microarray analysis was performed to identify the LAMMER kinase target genes.

Kinase assay and PMF were applied to identify the LAMMER kinase target site(s) on the MBF components.

Conclusions

Kinas assay with phospho-mimic and phospho-defective Rum1 indicated that LAMMER kinase-dependent phosphorylation of Thr110 was pivotal for its CKI activity. No significant difference in affinity to Cdc2, however, was observed among Rum1 proteins. Microarray analysis with the *lkh1*$^{+}$ deletion mutant revealed four cell cycle genes up-regulated, of which expression are known to be modulated by the G1/S specific MBF (*Mlu*1 box binding factor). Modulation of MBF activity by LAMMER kinase-dependent phosphorylation of a negative regulator for MBF was also indicated. Results presented here indicate a potential dual action of LAMMER kinase in G1/S progression of *S. pombe* cell cycle: activation of Cdc2-inhibitor Rum1 and of the MBF-repressor.

TLR2 INDUCTION OF NF-KB SIGNALLING PATHWAY WITH LACTOBACILLUS FERMENTUM L930BB AND BIFIDOBACTERIUM ANIMALIS SUBSP. ANIMALIS IM386 AND THEIR PROPHYLACTIC EFFECT IN DSS-INDUCED COLITIS

D. Paveljšek[1], K. Ivičak-Kocjan[2], R. Jerala[2], B. Bogovič Matijašić[1], I. Rogelj[1]
[1]Biotechnical Faculty- University of Ljubljana, Department of Animal Science, Domžale, Slovenia
[2]National Institute of Chemistry, Department of Synthetic Biology and Immunology, Ljubljana, Slovenia

Backgrounds

Intestinal epithelial cells express several pattern recognition receptors (PRR), including Toll-like receptors (TLR), which initiate signalling cascades that lead to activation of NF-κB and other pro- and anti-inflammatory pathways. Commensal and probiotic bacteria can regulate the level of NF-κB activity at the intestinal epithelial border and affect the mucosal immune balance.

Objectives

The current study was designed to characterise TLR2 signalling in human cell lines, triggered by isolates from bioptic samples of human colonic mucosa, *Lactobacillus fermentum* L930BB (L930BB) and *Bifidobacterium animalis* subsp. *animalis* IM386 (IM386), and to evaluate their possible beneficial effects in dextran sulphate sodium (DSS) – induced colitis in mice.

Methods

Dual luciferase NF-κB inducible reporter assay was conducted on HEK293 cells that were transiently transfected with TLR1/2, TLR2/6 and different ratios of TLR10. After transfection, cells were stimulated with different concentrations of live and heat killed L930BB, IM386 and also their conditioned media. Female C57BL/6JOlaHsd mice, pre-treated with live L930BB and IM386, were exposed to DSS for 5 days. For histological assessments the colon was cut longitudinally and the sections were stained.

Conclusions

TLR10 is the only PRR within the TLR family that is able to dampen TLR2 signalling through NF-κB and suppress immune response. We discovered that strains L930BB and IM386 beside TLR1/2 and TLR2/6 also induce signalling through TLR2/10 and reduce the NF-κB activation. Histological assessment revealed that pre-treatment with probiotic mixture results in decreased length of affected colon, reduced infiltration of neutrophils in mucosa and decreased depth of inflammation of the colon wall.

STRUCTURAL AND FUNCTIONAL ANALYSIS OF ESSENTIAL EXTRACHROMOSOMAL REPLICONS (CHROMIDS) OF PARACOCCUS SPP. (ALPHAPROTEOBACTERIA)

A. Pawłot[1], J. Czarnecki[1], R. Lasek[1], M. Szuplewska[1], E. Prochwicz[1], M. Puzyna[1], A. Brozio[1], K. Kotecka[1], P. Dymek[1], P. Decewicz[1], Ł. Dziewit[1], D. Bartosik[1]
[1]Institute of Microbiology, Department of Bacterial Genetics, Warsaw, Poland

Backgrounds

Chromids are recently distinguished group of autonomous bacterial replicons, sharing some characteristics of both chromosomes and plasmids. They comprise genetic information of adaptive value as well as housekeeping genes, which make them essential for their hosts. The prevalence of chromids in bacteria and their conserved character within certain taxonomic groups suggests an important role for these replicons in the evolution of bacteria.

Objectives

The aim of the study is to identify chromids in bacteria of the genus *Paracoccus* (*Alphaproteobacteria*) and to analyze their variability and evolution.

Methods

Genomic sequencing of 13 strains of *Paracoccus* spp. was performed applying Illumina technology. Identification of essential replicons was performed using a target oriented replicon curing strategy, based on the replicon incompatibility phenomenon. Bioinformatic analyses included sequence annotation, comparative and phylogenetic analyses. Standard molecular procedures were employed for genetic characterization of the replication (REP) modules of chromids.

Conclusions

A characteristic feature of the identified *Paracoccus* spp. chromids was the presence of *dnaA*-like replication systems (REP), which are common within the large plasmids of bacteria of the *Roseobacter* clade. Two evolutionary lineages of dnaA-like REPs, which correlate with the genetic content of these replicons were distinguished. Interestingly, we found that several chromids harbored by a group of phylogenetically related *Paracoccus* species encode the DnaA protein, which is crucial for the chromosome replication initiation. Such chromid-dependent maintenance of bacterial chromosomes was not previously observed in any other bacteria.

TOWARD THE IN VITRO PRODUCTION OF MAGNETOSOME-LIKE MAGNETITES THROUGH THE COMBINED EFFECT OF THE MAGNETOSOME-ASSOCIATED PROTEINS MAMC AND MMS6 FROM MAGNETOCOCCUS MARINUS MC-1

A. Peigneux[1], Y. Jabalera[1], R. Zarivach[2], M.A. Fernandez-Vivas[1], C. Jimenez-Lopez[1]
[1]Facultad de Ciencias. Universidad de Granada., Departamento de Microbiología, Granada, Spain
[2]Ben-Gurion University of the Negev, Department of Life Sciences, Beer Sheva, Israel

Backgrounds

Magnetite nanoparticles (MNPs) are interesting in biotechnology as they can be manipulated by an external magnetic field and can be functionalized with different molecules. Magnetotactic bacteria produce magnetosomes, which are the ideal single magnetic domain particle (SDP). Scaling-up magnetosome production is still challenging due to difficulties in magnetotactic bacteria growth, so protein-mediated magnetite crystals synthesis is being explored. Several magnetosome-associated proteins have already been studied, but their effect in the *in vitro* magnetite formation has been assayed by only using one at the time. This situation is probably far from what occurs in the magnetosome, in which a number of magnetosome-associated proteins are involved in the biomineralization process.

Objectives

In vitro magnetite precipitation experiments were performed in the presence of recombinant Mms6 or/and MamC from *Magnetococcus marinus* MC-1 to check the individual and combined effect of the proteins in the *in vitro* magnetite formation.

Methods

MamC and Mms6 proteins were expressed as recombinant proteins in *Escherichia coli* TOP10 strain. After their purification, *in vitro* magnetite precipitation experiments were carried out in the presence of each one and in mixtures at different concentrations.

Conclusions

Compared to magnetite crystals produced in the absence of any protein and under identical conditions, MamC controls the size of magnetite crystals and produces SDP (most of them > 30 nm) while Mms6 produces better faceted crystals. The combined effect of those proteins resulted in crystals both large in size (30 ± 10 nm) and with uniform 2D morphologies that were not obtained by using only one of the proteins.

Physiology / Biochemistry / Molecular Microbiology - Part II

GENOME-WIDE IDENTIFICATION AND DNA-BINDING ARCHITECTURE OF THE ORPHAN RESPONSE REGULATOR HP1043 OF HELICOBACTER PYLORI

S. Pelliciari[1], E. Pinatel[2], C. Peano[2], V. Scarlato[1], D. Roncarati[1]
[1]University of Bologna, Department of Pharmacy and Biotechnology FaBit, Bologna, Italy
[2]National Research Council, Institute of Biomedical Technologies, Milan, Italy

Backgrounds

In *Helicobacter pylori*, the *hp1043* gene is one of the transcriptional regulator essential for cell viability. As such, this gene could not be deleted, supporting the hypothesis that HP1043 could be involved in the regulation of crucial cellular processes. The impossibility of generating a knock-out mutant for *hp1043* gene, or modulate the amount of HP1043 protein in the cell, has hampered the detailed characterization of its regulatory function.

Objectives

Discover all promoters bound *in vivo* by HP1043 and understand it's biological function.

Methods

Using Chromatin Immunoprecipitation-sequencing (ChIP-seq), we were able to identify genome-wide at least 37 new HP1043 binding sites. Moreover, *in vitro* DNaseI protection assays (footprints) enabled mapping of the HP1043 binding sites on a subset of the new targets, revealing the presence of a conserved nucleotide sequence motif consisting of a direct repeat. Furthermore, hydroxyl-radical probing allowed to refine the positions of HP1043 binding, suggesting that the proposed consensus motif is recognized by HP1043.

Conclusions

A significant fraction of newly identified binding sites overlaps promoter regions of genes involved in translation. Accordingly, arrest of protein translation determined induction of almost all HP1043 target genes. These observations prompted us to propose HP1043 as key regulator in *H. pylori*, likely involved in sensing and in coordinating the response to environmental stress inducing an arrest of protein synthesis. Experiments aimed to elucidate the role of each base of the consensus motif in the protein-DNA binding are in progress as well as experiments aimed to modulate its amount and/or activity *in vivo* in *H. pylori*.

COMPARATIVE ANALYSIS OF GROWTH, DEVELOPMENT AND OTC PRODUCTION OF VARIOUS S. RIMOSUS PRODUCERS

T. Paradžik[1], E. Šarić[1], G. Quinn[1], M. Roje[2], M. Jurin[3], I. Hunter[4], P. Herron[4], D. Vujaklija[1]
[1]Ruđer Bošković Institute, Department for molecular biology, Zagreb, Croatia
[2]Ruđer Bošković Institute, Division of Organic Chemistry and Biochemistry, Zagreb, Croatia
[3]Ruđer Bošković Institute, Division of Materials Chemistry, Zagreb, Croatia
[4]University of Strathclyde, Strathclyde Institute Of Pharmacy And Biomedical Sciences, Glasgow, United Kingdom

Backgrounds

Streptomycetes are multicellular bacteria that exhibit a complex developmental program and morphological differentiation. The great majority of natural products, including clinnicaly important antibiotics, immunosuppressants and anti-cancer drugs; are synthesized by these bacteria. The tetracyclines are one of the most successful classes of antibiotics that include oxytetracycline (OTC) produced by *S. rimosus*. It has been reported that protein phosphorylation has an important role in the regulation of metabolism and antibiotic production in strepomycetes.

Objectives

Bioinformatic analysis of the *S. coelicolor* genome predicted 47 eukaryotic-like protein kinases and 49 eukaryotic type protein phosphatases in this species. This number of kinases, although larger than other bacteria is not surprising as the average Streptomyces genome size is almost twice that of *E.coli*. Based on the phosphoproteome reported for *S. coelicolor* we predict that the effect of the OTC overproduction in *S. rimosus* is a consequence of alteration in posttranslational modification (PTM) of regulatory and/or OTC biosynthesis proteins.

Methods

Different *S. rimosus* strains were tested for antibiotic production, and analysed using HPLC. Level of phosphorylation during growh was inspected by Western blot and morphology was observed applying viability staining to each strain.

Conclusions

Inspected strains showed great variations in OTC production. Western blot analyses showed different phosphorylation patterns for each strain. Confocal microscopy revealed different morphological features and viability of tested strains.

DIFFERENCES IN THE NEONATE MICROBIOME AFTER HOME OR HOSPITAL DELIVERY

J. Combellick[1], S. Hakdong[2], S. Dongjae[3], H. Hagan[1], M.G. Dominguez Bello[4]
[1]New York University, Rory Meyers College of Nursing, New York, USA
[2]Sejong University- South Korea,
College of Life Science- Department of Food Science and Biotechnology, Seoul, Republic of Korea
[3]Sejong University, College of Life Science- Department of Food Science and Biotechnology, Seoul, Republic of Korea
[4]New York University, School of Medicine, New York, USA

Backgrounds

Hospitalization for delivery is considered a foundation of obstetric care. In the U.S. more than 99% of deliveries occur in the hospital. However in many countries—notably those in Scandinavia—home birth is recognized as a safe alternative for low-risk women. Currently there is limited investigation of how the neonatal microbiome develops in the absence of all interventions, including hospitalization. We hypothesize that hospital exposure at birth affects the neonate intestinal microbiota.

Objectives

To characterize the intestinal microbiota of newborns following home and hospital delivery and to investigate differences related to hospitalization during the first month of life.

Methods

A prospective cohort study was conducted to compare breast-fed vaginally delivered infants born at home (n=10) or in the hospital (n=10). Consecutive sampling was performed on infant feces at 7 time points from delivery through day 28. The V4 region of the 16S rRNA gene of 212 samples was sequenced using Illumina MiSeq platform. Sequences were analyzed using the QIIME pipeline.

Conclusions

Hospitalization for birth alters the microbiome of neonates. The gut microbiome differed significantly between home and hospital born neonates (PERMANOVA p=<0.005), with babies born at home showing higher fecal *Bacteroides*, and *Bifidobacterium*, *Streptococcus*, and *Lactobacillus*, at one or more time points after the first week of birth, and lower proportions of *Clostridium* (Day 21), Enterobacteriaceae family (Day 28). More research is needed to determine the health significance of these differences. These results are relevant to health care system policies that support home birth in low-risk women.

MEMBERS OF THE CMAX-CFRX-CMPX OPERON ARE DIFFERENTLY REGULATED BY ALGU AND SIGX IN RESPONSE TO HEAT AND COLD SHOCKS IN PSEUDOMONAS AERUGINOSA

E. Bouffartigues[1], I. Si Hadj Mohand[1], D. Tortuel[1], O. Maillot[1], B. Xu[2], A. Bazire[3], A. Dufour[3], D.J. Wozniak[2], N. Orange[1], M.G. Feuilloley[1], P. Cornelis[1], S. Chevalier[1], M. Gallique[1]
[1]University of Rouen Normandy, Laboratory of Microbiology Signals and Microenvironment LMSM, Evreux, France
[2]Center for Microbial Interface Biology- Ohio State University, Departments of Microbial Infection and Immunity- Microbiology, Columbus, USA
[3]Institut Universitaire Européen de la Mer- Université de Bretagne-Sud, Laboratoire de Biotechnologie et Chimie Marines LBCM, Lorient, France

Backgrounds

P. aeruginosa is a highly adaptable opportunistic pathogen, a phenotype that is mainly related to its large number of transcriptional regulators, including 19 extracytoplasmic function (ECF) sigma factors. The well-known RpoE-like ECF sigma factor AlgU is involved in alginate biosynthesis and cell wall stress response. Interestingly, the newly characterized ECF SigX emerged as a second sigma factor responding to envelope stress, controlling in particular membrane composition remodelling. However the functional interactions that may exist between SigX and AlgU to maintain envelope homeostasis remain to be discovered.

Objectives

To this aim, the regulation of a putative operon located directly upstream of *sigX* was studied according to temperature variation, a key parameter affecting the membrane state.

Methods

This predicted operon forms a cluster of three genes, *cmaX-cfrX-cmpX*, among which *cmaX* on one side, and *cfrX* and *CmpX* on the other side, were proposed to belong to AlgU and SigX regulons, respectively. Accordingly, we have identified an internal SigX-dependent promoter region upstream *cfrX*, in addition to the AlgU-dependent promoter region upstream *cmaX*. We show that expression of *cmaX* is increased in response to a heat shock through an AlgU-dependent mechanism that does however not involve RpoH. Remarkably, *cfrX* and *cmpX* expression is up-regulated *via* a SigX-dependent mechanism in response to a cold shock, and it requires also the AlgU-dependent alginate and motility regulator AmrZ, whose expression is partly controlled by SigX in this condition.

Conclusions

Taken together, these data give further insights into the highly complex networks that are involved in maintaining membrane homeostasis in *P. aeruginosa*.

LOMENTOSPORA PROLIFICANS RESISTANCE MECHANISMS TO THE ANTIFUNGAL DRUG VORICONAZOLE

A. Pellon[1], L. Martin-Souto[1], I. Buldain[1], A. Antoran[1], A. Rementeria[1], F.L. Hernando[1], A. Ramirez-Garcia[1]
[1]University of the Basque Country UPV/EHU,
Fungal and Bacterial Biomics Research Group. Dept. of Immunology- Microbiology & Parasitology, Leioa, Spain

Backgrounds

The filamentous fungus *Lomentospora* (*Scedosporium*) *prolificans* is an opportunistic pathogen that is intrinsically pan-resistant to available antifungal compounds, including to the first option to treat these mycoses, namely voriconazole. Thus, there is an urgent need for novel truly-effective therapies.

Objectives

To discover the unknown mechanisms involved in the voriconazole resistance in this pan-resistant filamentous fungus.

Methods

To delve into this, we performed an integrated study of *L. prolificans* responses to voriconazole using a wide range of techniques, including fluorescence and electron microscopy to study morphological alterations, ion chromatography to measure changes in cell wall carbohydrate composition, and proteomics-based analyses to identify differentially expressed proteins.

Conclusions

We showed drastic changes occurring in cell shape after voriconazole exposure, *L. prolificans* hyphae being shorter and wider than under control conditions. Interestingly, we proved that the architecture and carbohydrate composition of the cell wall were modified in the presence of the drug. Specifically, *L. prolificans* constructed a more complex organelle with a higher presence of glucans and mannans, among other carbohydrates. In addition, we observed 72 differentially expressed cell surface proteins, being Srp1 and heat shock protein 70 (Hsp70) as the most overexpressed under voriconazole-induced stress conditions. The mechanisms described in this study, which may be related to *L. prolificans* antifungal resistance, could be used as targets to improve existing therapies or to develop new ones against these mycoses.

Funding: GIU15/36 from the Basque Government. AP (postdoctoral), IB and AA (predoctoral) are recipients of fellowships from the UPV/EHU or the Basque Government, respectively.

STRUCTURE AND CELL INTERACTION ARE ALTERED IN MEMBRANE VESICLES RELEASED BY A HYPERVESICULATING ESCHERICHIA COLI NISSLE 1917 TOLR MUTANT

C. Perez Cruz[1], M.A. Cañas[2], R. Giménez[2], J. Badía[2], L. Baldomà[2], L. Aguilera[2], E. Mercadé[1]
[1]University of Barcelona, Department of Biology- Healthcare and the Environment, Barcelona, Spain
[2]University of Barcelona, Department of Biochemistry and Physiology, Barcelona, Spain

Backgrounds

Membrane vesicles (MVs) produced by Gram-negative bacteria are being explored for clinical applications. MVs from the probiotic *Escherichia coli* Nissle 1917 (EcN) are good candidates for testing such applications. A drawback is the low level of MV isolation from in vitro culture supernatants, which may be overcome by the use of mutants in cell envelope proteins that yield a hypervesiculation phenotype

Objectives

To confirm that a *tolR* mutation in EcN increases MV production, and to analyze if their composition, ultrastructure and interaction with target cells can be modified by the mutations in the cell envelope proteins.

Methods

EcN *tolR* MVs were analyzed by protein, LPS and fluorescent lipid measurements. Structure was determined by TEM after high-pressure freezing and freeze substitution of bacterial samples, together with cryo-TEM observation of plunge frozen hydrated isolated MVs. Time-course experiments of MV uptake in Caco-2 cells were done using rhodamine- and DiO-labelled MVs.

Conclusions

The *tolR* mutation in EcN induces a hypervesiculation phenotype. MVs showed alterations in composition and in their ability to interact with host cells, which can be explained by significant modifications in MV structure. Production of different types of vesicles by *tolR* mutants cannot be detected by TEM of negatively stained MVs, although this heterogeneity may have a major impact on vesicle functionality. This study evidences the need for conducting a detailed structural analysis by high resolution TEM techniques when working with hypervesiculating mutants. This analysis is crucial to improve and standardize the vesicles used for vaccine and therapy purposes.

CHARACTERIZATION OF SMALL RNAS DELIVERED BY MEMBRANE VESICLES FROM PSEUDOMONAS AERUGINOSA PAO1

C. Perez Cruz[1], *E. Mercade*[1]
[1]*University of Barcelona, Department of Biology- Healthcare and the Environment, Barcelona, Spain*

Backgrounds

Membrane vesicles (MVs) are spherical structures (20-200 nm) that are secreted from the membrane of Gram-negative bacteria to deliver bacterial effectors to distant cells. They are implicated in several functions: pathogenesis, horizontal gene transfer and quorum sensing. Recent publications, reported the presence of regulatory small RNA (sRNA) inside MVs although their role it is unknown.

Objectives

The aim of the current work is to identify and determine the function of sRNAs associated with MVs from *Pseudomonas aeruginosa* PAO1.

Methods

RNA and MVs isolation, pico-RNA Bioanalyzer, Qubit RNA HS, RT-qPCR, high-resolution flow cytometry, sRNA RNA-seq, transfer experiments.

Conclusions

To date, we have determined that MVs package sRNAs (25-100 nt) and we confirmed that sRNAs were encapsulated inside MVs through RNase protection assay. By high-resolution flow cytometry, we have quantified MVs during bacterial growth, finding that MVs concentration increases during the transition to stationary phase, while it decreases in the later stationary phase. We have monitored the expression of three PAO1 sRNAs (PhrS, CrcZ and RsmZ) during growth and we found that they were differentially packaged inside MVs. To identify the sRNAs in PAO1 MVs, sequencing of total RNA extracted from MVs obtained at different growth points have been performed. Studies to demonstrate that functional sRNA can be delivered to PAO1 cells by MVs were conducted. The differentially encapsulation of sRNAs inside PAO1 MVs, confirms it is not a random process and opens up to study whether MV-associated sRNAs could play a role in cell-to-cell communication.

Physiology / Biochemistry / Molecular Microbiology - Part III

FUNCTIONAL PROTEINS OF LACTOBACILLUS CASEI BL23 RECOGNIZE SURFACE ELEMENTS OF HUMAN EPITHELIAL CELLS AND REGULATE CELL PROLIFERATION AND INFLAMMATORY RESPONSES

C. Bäuerl[1], M. de la Cruz[2], J.M. Coll[1], M.C. Collado[1], V. Monedero[1], J. Rodriguez Diaz[3], G. Perez Martinez[1]
[1]Instituto de Agroquímica y Tecnología de Alimentos CSIC, Food Biotechnology, Paterna, Spain
[2]Universidad Católica de Valencia, Facultad de Veterinaria y Ciencias Experimentales, Valencia, Spain
[3]Faculty of Medicine, Department of Microbiology, Valencia, Spain

Backgrounds

In order to shed light on probiotic/host interactions, we have studied p40 and p75, two cell wall bound muraminidases (*cmu*A, *cmu*B), from *L. casei* BL23 that contain a conserved C-terminus NLPC/P60 domain for which antiapoptotic and IgA stimulating activity has been reported.

Objectives

To determine differences in the interaction of p40 and p75 with epithelial cells.

Methods

Both proteins bind to the surface of epithelial cells and they are subsequently internalised; however, the binding affinity for extracellular matrix proteins and glycosaminoglucans (GAGs), as determined by surface plasmon resonance (SPR), indicated a different binding profile. p40 showed a very high affinity for heparin and chondroitin sulphate A, suggesting a powerful interaction due to the highly positively charged NH-region of p40. On the other hand, using pNIFTY transfected HT29 cells, both proteins had pro-inflammatory effect, but NF-KB stimulatory effect of p75 was remarkably higher. Protein phosphorylation assays carried out on T-84 epithelial cells confirmed that they activate the epithelial grow factor receptor (EGFR) and *Akt*; however the inducing effect of both proteins may course through alternative metabolic pathways, as demonstrated by the phosphorylation of ERK1/2 intermediate, suggesting that both proteins may interact with different receptors or mediators.

Conclusions

Conclusions:family of NLPC/P60 carrying domain cell surface lysins (muraminidases), their biological properties are different and could be conferred by the amino acid sequences located toward the NH-terminus of the proteins.

Physiology / Biochemistry / Molecular Microbiology - Part III

TRANSCRIPTIONAL RESPONSE OF MUTANTS LACKING THE MRNA DEGRADATION FACTORS XRN1 AND DHH1 DURING OSMOTIC STRESS

M.E. Perez-Martinez[1], D.A. Medina[1], T. Li[1], J.E. Perez-Ortin[1], P. Alepuz[1]
[1]Universitat de Valencia, Facultad de Biologia, Valencia- Burjassot, Spain

Backgrounds

Recent studies strongly suggest that regulation of gene transcription at the nucleus is mechanistically connected, not only with nuclear mRNA processing, but also with cytoplasmic mRNA decay. The crosstalk between degradation and synthesis would serve to maintain proper mRNA levels in the cell. In this context, factors of the mRNA decay machinery, such as the 5'-3' exonuclease Xrn1, have been found to bind chromatin. Under steady-state conditions, deletion of Xrn1 decreases mRNA synthesis and increases mRNA half-life in an approximately compensatory manner.

Objectives

We asked about the role of these crosstalk factors under osmotic stress conditions in which mRNA levels are quickly, profoundly and transiently changed

Methods

We studied the osmotic stress-response in mutants lacking the 5' to 3' mRNA exonuclease Xrn1 and the decapping activator factor Dhh1. For this, we measured the changes in transcription rates, RNA polymerase association to chromatin and mRNA amounts and stability during the stress response at global and mRNA specific levels

Conclusions

Our results show that Xrn1 and Dhh1 are involved in the regulation of the transcription and degradation of up-regulated mRNAs during the response to osmotic stress. Interestingly, although transcription is reduced upon stress in *xrn1Δ* and *dhh1Δ* mutants, we observed high levels of RNA polymerase II binding to osmo-gene promoters. Moreover, the RNA polymerase II bound to osmo-responsive genes appears to be highly phosphorylated. These results suggest that the lack of co-transcriptionally binding of the decaysome to chromatin affects the transcription elongation capacity of the RNA polymerase II. Our results show that the lack of a proper transcriptional induction of osmo-mRNAs in *xrn1Δ* and *dhh1Δ* mutants is compensated by the over-stabilization of the osmo-mRNAs. This result could explain the resistance of *xrn1Δ* and *dhh1Δ* mutants in high osmolarity

FEMS7-3021

AN ADH2 GENE CONVERSION DROVE THE ADAPTIVE EVOLUTION OF WINE SACCHAROMYCES CEREVISIAE YEASTS

R. Pérez-Torrado[1], *A. Querol*[1], *E. Barrio*[2]
[1]*Institute of Agrochemistry and Food Technology, Food Biotechnology, Paterna Valencia, Spain*
[2]*Universitat de València, Department of Genetics, Burjassot- Valencia, Spain*

Backgrounds

One of the most important microorganism along human history, *Saccharomyces cerevisiae,* was domesticated to produce wine. However, the key genetic event responsible of its origin is unknown.

Objectives

In this study, we unveiled an *ADH2* allele, derived form an *ADH1-ADH2* gene conversion, which is fixed in wine yeasts and confers a specific metabolic signature.

Methods

This converted Adh2p shows similar ethanol affinity than Adh1p and allows a significant selective advantage in wine fermentations.

Conclusions

Therefore, this study demonstrates that the acquisition of a recombinant *ADH2* allele was a key step in the origin and adaptive evolution of a differentiated wine yeast population.

SUBFUNCTIONALIZATION INFLUENCES THE EXPANSION OF BACTERIAL ANTIBIOTIC RESISTANCE SYSTEMS

E. Perrin[1], M. Fondi[1], E. Bosi[1], A. Mengoni[1], S. Buroni[2], G. Riccardi[2], M. Valvano[3], R. Fani[1]
[1]University of Florence, Department of Biology, Sesto Fiorentino Florence, Italy
[2]University of Pavia, Department of Biology and Biotechnology "Lazzaro Spallanzani", Pavia, Italy
[3]Queen's University of Belfast, 3Centre for Experimental Medicine. The Wellcome-Wolfson Institute for Experimental Medicine, Belfast, United Kingdom

Backgrounds

Multidrug resistance (MDR) efflux pumps, in particular those belonging to the RND family, are mainly responsible of antibiotic resistance in Gram-negative bacteria. Their genomes often contain several copies of the different classes of MDR, and the role of gene duplication and the consequent assumption of new functions by the duplicate copies has a key role in the expansion of drug-resistance.

Objectives

The aim is to provide computational and experimental evidence on the evolution and functional diversification of two members of the RND superfamily in *Burkholderia* to understand how these events could have an effect on antibiotic resistance.

Methods

We assessed the conservation and distribution of these two systems together with their regulation mechanisms. This information was then used to design and perform genetic manipulation of these strains aimed at identifying both the exact substrate range of these transporters and their (eventual) interchangeability. Finally, the possible role of antibiotics in the activation of expression of these systems was evaluated, through a direct evolution experiment combined with NGS.

Conclusions

Changes in the regulatory circuit seem to be the first step to diversify the functions of different RND paralogs rather than functional mutations. This agrees with the low substrate specificity of these systems. Moreover, they could also rapidly rewire their regulation to respond to the presence of antibiotics, maintaining a high genomic plasticity. The knowledge of the regulatory network underlying the expression of the RND complexes has important implications in the understanding of the evolution of drug resistant phenotypes and in the fight for their eradication.

ALTERNATIVE SCENARIOS OF STARVATION-INDUCED ADAPTATION IN PECTOBACTERIUM ATROSEPTICUM

O. Petrova[1], V. Gorshkov[1,2], I. Sergeeva[3], A. Daminova[1], M. Ageeva[4], Y. Gogolev[1,2]
[1]Kazan Institute of Biochemistry and Biophysics - RAS, Laboratory of Molecular Biology, Kazan, Russia
[2]Kazan Federal University, Botany and Plant Physiology, Kazan, Russia
[3]Kazan Federal University, Genetics, Kazan, Russia
[4]Kazan Institute of Biochemistry and Biophysics - RAS, Laboratory of Microscopy, Kazan, Russia

Backgrounds

Bacteria have high adaptive potential that provides their survival during various environmental challenges. To adapt, bacteria activate a physiological program of stress-response that makes them able to persist under adverse conditions.

Objectives

The aim of this study was to check if the stress-response in a particular bacterial species could be realized according to alternative scenarios depending on the initial physiological status of the cells prior to stress effect.

Methods

As a model, cells of phytopathogenic microorganism *Pectobacterium atrosepticum* at different physiological states (actively growing exponential phase and stationary phase cells) were exposed to starvation and the resulting starving cultures were monitored using CFU counting, quantitative PCR and electron microscopy.

Conclusions

When exponential phase cells were subjected to starvation, the nucleoids of the cells became condensed, and their DNA was detected by qPCR less effectively than the one of the cells growing in nutrient-rich medium or stationary phase cells encountered starvation. Exponential phase cells subjected to starvation were characterized by the increased expression level of genes encoding DNA-binding histone-like proteins. In turn, cell wall deficient forms that were inefficient in their colony forming ability and, thus, had non-culturable phenotype, were formed in the starving cultures inoculated by stationary phase cells. Cell wall deficient forms displayed reduced expression level of genes, encoding synthases of cell-wall components. Our results demonstrated that alternative strategies of adaptation could be employed by *P. atrosepticum* depending on the initial physiological state of bacteria at the time of exposure to stress factor. This study was supported by RFBR 15-04-02380.

Physiology / Biochemistry / Molecular Microbiology - Part III

REGULATION OF K+ HOEMEOSTASIS BY THE NITROGEN PTS (PTS(NTR)) OF PSEUDOMONAS PUTIDA

K. Pflüger-Grau[1], *A. Kremling*[1]
[1]*Systems Biotechnology, Mechanical Engineering, Garching, Germany*

Backgrounds

The nitrogen branch of the phosphotransferase system (PTS^{Ntr}) of *Pseudomonas putida* is a multicomponent regulatory device that participates in controlling a variety of physiological processes in a post-translational fashion. It consists of three proteins PtsP, PtsO, and PtsN, that transfer a phosphate moiety derived from phosphoenol pyruvate. The phosphorylation state of PtsN reflects various metabolic inputs, among them the PEP/Pyr ratio, the presence of fructose, or the nitrogen source.

Objectives

We set out to analyse in more detail the regulatory duties of the PtsN protein in *P. putida*.

Methods

A general survey of the genes regulated by PtsN revealed that transcription of the entire *kdpFABC* operon is influenced by this protein. By monitoring the activity of the *kdpF* promoter in various *pts* mutant strains, we could show that PtsN is responsible for both, repression and activation of the transcription of the *kdpFABC* genes, and that regulation depends on the phosphorylation state of PtsN, in a way that non-phsophorylated PtsN stimulates transcription whereas PtsN~P seems to have the opposite effect. We could show that the regulation is implemented through direct interaction of the PtsN protein with the sensor kinase KdpD of the KdpD/KdpE two-component system. The absence of PtsN led to high KdpFABC expression and reduced growth rates, but also gave rise to suppressor mutations that regained the fast growing phenotype.

Conclusions

Taken together these results suggest that the regulation of K^+-homeostasis is a general duty of the PTS^{Ntr} even though the mechanism does not seem to be conserved between different organisms.

REGULATED PROTEOMIC ANALYSIS REVEALS THE EXPORT OF BIOPHARMACEUTICAL PRODUCT VIA TAT PATHWAY IN E. COLI WITH THE EXPRESSION OF CYDISCO PROTEINS

T.K. Pham[1], K. Richards[2], J. Pandhal[1], C. Robinson[2], P.C. Wright[3]
[1]The University of Sheffield, Chemical and Biological Engineering, Sheffield, United Kingdom
[2]University of Kent, School of Biosciences, Canterbury, United Kingdom
[3]Newcastle University, Faculty of Science- Agriculture and Engineering, Newcastle, United Kingdom

Backgrounds

The *E. coli* Sec pathway transports only unfold proteins from the cytoplasm to the periplasm, whereas the TAT system can transport fully folded and assembled proteins. Therefore, we aim to improve/enhance the export of recombinant biopharmaceutical products *via* the TAT pathway by identifying bottlenecks and assessing cell health using a quantitative proteomic approach.

Objectives

Quantitative proteomic analyses were used to understand the responses of *E. coli* during expression of CyDisCo proteins and target biopharmaceuticals (HGH, scFv). Both global and target proteins' regulations were examined to identify key factors to improve the designs of promoters/systems to achieve high yields therapeutic protein production.

Methods

E. coli strains (with/without CyDisCo proteins) were grown on LB medium and collected at 3 h post recombinant protein induction for iTRAQ proteomic analyses performed on a QExactive HF Orbitrap MS (Thermo) coupled with MaxQuant software and our in-house proteomic pipeline for regulated proteome determination.

Conclusions

Of 1,706 quantified proteins, 281 differentially regulated proteins were observed in CyDisCo *E. coli* cells. These regulated proteins belonged to different protein classes and widely involved in a variety of cellular/biological processes. The regulation of some key factors/proteins affecting protein export to the periplasm and degradation of targeted proteins were identified. Furthermore, key proteins relating to various stress responses (induction) such as chaperon/oxidative helpers, sigma factors (eg. E, H, S), *etc.* were also identified. These findings have provided useful information for guiding the specific design of gene promoters and overall optimisation of the host cell system.

IDENTIFICATION OF A SUBSTRATE DOMAIN THAT DETERMINES SYSTEM SPECIFICITY IN MYCOBACTERIAL TYPE VII SECRETION SYSTEMS

T. Phan[1], R. Ummels[2], E. Houben[3], W. Bitter[4]
[1]Vrije Universiteit Amsterdam, Molecular Microbiology, Amsterdam, The Netherlands
[2]Vrije Universiteit Medical Center Amsterdam, Medical Microbiology and Infection Control, Amsterdam, The Netherlands
[3]Vrije Universiteit Amsterdam, Molecular Micorbiology, Amsterdam, The Netherlands
[4]Vrije Universiteit Medical Cnter Amsterdam, Medical Microbiology and Infection Control, Amsterdam, The Netherlands

Backgrounds

Type VII secretion (T7S) systems are specialized machineries used by mycobacterial pathogens to transport important virulence factors across their highly hydrophobic cell envelope. There are up to five mycobacterial T7S systems, namely ESX-1 to ESX-5, each of which specifically secretes a different subset of substrates.

Objectives

The T7S substrates or substrate complexes are defined by the general secretion motif YxxxD/E. However this motif does not determine system specificity.

Methods

We have used molecular cloning method to introduce the EspG1 and EspG5 chaperone binding domains into ESX-5 and ESX-1 PPE substrates, respectively. Secretion analysis was performed in different ESX-1 and ESX-5 mutant strains to define effect caused by the swapping of cheprone binding domains.

Conclusions

Here, we show that the substrate domain recognized by the EspG chaperone is the determinant factor for this specificity. We first show that the introduction of point mutations into the $EspG_1$-binding domain of ESX-1 substrate pair PE35/PPE68_1 affects their secretion. Subsequently, we demonstrate that replacing this domain by the $EspG_5$-binding domain of the ESX-5 substrate PPE18 resulted in $EspG_5$ dependence and exclusive rerouting to the ESX-5 system. This rerouting of PE35/PPE68_1 to the ESX-5 system had a negative effect on the secretion of endogenous ESX-5 substrates.

BIOFILM FORMATION BY CLOSTRIDIUM LJUNGDAHLII IS INDUCED BY SODIUM CHLORIDE: TRANSCRIPTOME ANALYSIS

J. Philips[1], K. Rabaey[1], D.R. Lovley[2], M. Vargas[3]
[1]Ghent University, Center for Microbial Ecology and Technology CMET, Ghent, Belgium
[2]University of Massachusetts, Department of Microbiology, Amherst, USA
[3]College of the Holy Cross, Department of Biology, Worcester, USA

Backgrounds

The acetogen *Clostridium ljungdahlii* is capable of syngas fermentation and microbial electrosynthesis. Both these applications could benefit from biofilm formation. We demonstrated before that *C. ljungdahlii* biofilm formation is induced by the addition of sodium chloride to the medium. The molecular mechanisms behind biofilm formation by *C. ljungdahlii*, however, remain to be unraveled.

Objectives

A transcriptome analysis was performed to compare the gene expression of planktonic (no NaCl) and biofilm (NaCl addition) cells of *C. ljungdahlii*.

Methods

The addition of NaCl clearly induced stress to the cells, as the general stress response genes were upregulated. In addition, *C. ljungdahlii* coped with the salt stress by the upregulation of Na^+ export and osmoprotectant accumulation. Flagellar motility was downregulated in the biofilm cells, while putative type IV pili biosynthesis genes were not expressed in both conditions. The D-alanine pathway was strongly upregulated and is potentially involved in giving a positive charge to cell wall techoic acids to improve attachment, similarly as in *Staphylococcus* species. In addition, the biosynthesis of UDP-N-acetylglucosamine was upregulated, which is the precursor for poly-N-acetylglucosamines, the extracellular polysaccharides potentially responsible for biofilm formation, as for *Bacillus* and *Staphylococcus* species. Moreover, the gene expression analysis suggested the involvement of the transcriptional regulators LexA, Spo0A and CcpA in the stress response and biofilm formation.

Conclusions

This work is the first to gain insight into the regulation and molecular mechanisms of *C. ljungdahlii* stress response and biofilm formation.

CHARACTERISTICS OF MOLECULAR-GENETIC STRUCTURE OF PHAGE PF-10

T. Pilipchuk[1], L. Valentovich[2], M. Titok[1], E. Kolomiets[1]
[1]Institute of Microbiology - Belarus National Academy of Sciences, Laboratory of Biological Control Agents, Minsk, Belarus
[2]Institute of Microbiology - Belarus National Academy of Sciences, Laboratory "Center of Analytical and Genetic Engineering Research", Minsk, Belarus

Backgrounds

Bacteriophages capable to lyse pathogenic bacteria constitute active principle of antimicrobial preparations and make an alternative to antibiotics. Search and characterization of bacteriophages lays the basis for their application directed at formulation of biological agents controlling microbial pathogens.

Objectives

Aim of study was to analyze genome nucleotide sequence of bacteriophage Pf-10 - key ingredient of biopesticide Multiphage owing to ability to lyse phytopathogenic bacteria of genus *Pseudomonas*.

Methods

Various microbiological and molecular-genetical methods were used: isolation of phage DNA, PCR, sequencing, annotation of genome.

Conclusions

The conducted investigations resulted in deciphering of full nucleotide sequence of phage Pf-10 isolated from common bean leaves in Belarus (GenBank registration number NCBI KP025626).

Analysis of full nucleotide sequence of phage Pf-10 genome allowed to refer this linear double-stranded DNA virus to T7 group of genus *Autographivirinae*, family *Podoviridae*, order *Caudovirales.*

Genome sequencing of phage Pf-10 has revealed 46 open reading frames determining synthesis of proteins governing stages of lytic cycle. The genes and encoded proteins showed the closest similarity to homologous nucleotide and amino acid sequences of phage phiIBB-PF7A infecting bacteria *Pseudomonas fluorescens* and phage Phi-S1 displaying a broad host specificity toward *Pseudomonas* bacteria. In particular, amino acid sequences of DNA-dependent RNA polymerase, DNA polymerase, amidase, primase, helicase, endo- and exonuclease, phage tail proteins are 98-99% identical with homologous polypeptides of phage Phi-S1, while DNA ligase, inhibitor of bacterial RNA polymerase, endopeptidase, capside proteins showed 90-99% identity with functionally related proteins of phage phiIBB-PF7A, evidencing mutational modifications occurring in the course of phage Pf-10 genome evolution.

[3]University of Bologna, DIMES Department of Experimental- Diagnostic and Specialty Me dicine, Bologna, Italy
[4]University of Milan, Doctoral School of Molecular and Translational Medicine, Milan, Italy

Backgrounds

Genome-wide approaches are becoming crucial to provide system-level comprehension of bacterial species and to obtain a landscape view of their transcriptional regulatory network. *Helicobacter pylori* is a human pathogen surviving in the prohibitive gastric environment where it can cause cancer. Its genome encodes for only 17 transcription factors (TF) whose rapid and fine-tuned expression orchestrates *H. pylori* ability to counteract environmental stresses and to perstist in the stomach despite host defence responses. The metal-dependent regulators NikR and Fur directly control metal ion homeostasis in *H. pylori* and indirectly impact on several processes involved in its virulence and survival.

Objectives

The aim of this work was to characterize the complete regulons of these two TFs, characterizing their putative cooperation or antagonism towards common binding sites.

Methods

ChIP-seq and RNA-seq experiments were performed in parallel on wild-type *H. pylori* G27 strain and on the knockout strain for each TF, both in standard growth conditions and in conditions inducing or repressing their activity. The results of ChIP-seq and RNA-seq studies were integrated to discriminate transcriptionally active DNA binding sites and, finally, network analysis was adopted to reveal Fur and NikR interaction on common binding sites.

Conclusions

Our study identifies new and known targets of Fur and NikR, improving the characterization of their biological role. Moreover it sheds light on the entire framework of dynamic interactions occurring between these TFs and between each TF and its regulatory targets. This integrated view can help in unraveling new strategies to counteract the persistence and pathogenicity of *H. pylori*.

LARS CONTROLS THE EXPRESSION OF THE AGR SYSTEM OF LISTERIA MONOCYTOGENES AND MEDIATES VIRULENCE

J. Pinheiro[1,2], A. Carreaux[1,3], F. Carvalho[1,2], S. Sousa[1], D. Cabanes[1]
[1]IBMC – Institute For Molecular and Cell Biology- i3S - Institute for Research and Innovation in Health , Group of Molecular Microbiology, Porto, Portugal
[2]University of Porto, ICBAS- Instituto de Ciências Biomédicas Abel Salazar, Porto, Portugal
[3]Université Paris Diderot-Paris 7, SDV - UFR Sciences Du Vivant, Paris, France

Backgrounds

To succeed as a pathogen, *Listeria monocytogenes* depends on the ability to cross physiologic barriers, invade diverse host cells and avoid phagocytosis by macrophages. Adaptation to the host environment is a critical factor that requires mechanisms of highly coordinated expression of virulence factors. We provided the first comprehensive view of the genome expression of a pathogen in deeper organs of infected mice, where we demonstrated that the analysis of genes differentially expressed during infection is a powerful tool for the identification of new virulence factors otherwise difficult to predict[1]. We observed that two major virulence regulators (PrfA/VirR), as well as their downstream effectors, were up regulated *in vivo*. However, other putative regulator-encoding genes that could be important for virulence are also differentially expressed by *L. monocytogenes in vivo*.

Objectives

To identify and characterize novel virulence regulators of the pathogen *L. monocytogenes.*

Methods

Through extensive analysis of our transcriptomic data and mutagenesis, we identified a novel regulator LarS involved in *L. monocytogenes* virulence*. In vitro* cell invasion assays and *in vivo* mice infections were performed to study the roles of LarS in *L. monocytogenes* virulence. An RNAseq transcriptomic approach was developed to characterize its regulatory network.

Conclusions

The Δ*larS* mutant shows impaired ability to invade specific human cell lines and shows defects in mouse infection. We identified the Agr System genes (*agrBDCA*) as targets of *larS* positive regulation and demonstrated how *L. monocytogenes* expresses this regulator to modulate chitinase activity and biofilm formation in order to achieve full virulence.

NOVEL DRUG DISCOVERY PLATFORM BASED ON TARGETING SENSORY PATHWAYS OF STAPHYLOCOCCUS AUREUS

J.M. Prieto[1], *D. Viana*[2], *J.R. Penadés*[3], *I. Lasa*[4], *C. Latasa*[5]
[1]*RecombinaSL, I+D, Mutilva, Spain*
[2]*Universidad Cardenal Herrera, Producción y Sanidad Animal, Valencia, Spain*
[3]*University of Glasgow, Institute of Infection Immunity and Inflammation, Glasgow, United Kingdom*
[4]*Navarrabiomed-Universidad Pública de Navarra-IdiSNA, Direction, Pamplona, Spain*
[5]*RecombinaSL, Direction, Mutilva, Spain*

Backgrounds

Biotech and pharmaceutical sectors are constantly seeking novel therapeutic approaches that might deliver us from a future where infections by resistant bacteria could pose a greater threat to human health than cancer itself. One of these strategies consists of targeting the bacterial signalling pathways known as Two Component Systems (TCSs). These systems synchronize gene expression with the different environments that bacteria might encounter, and thus regulate key biological traits as virulence or biofilm formation. Unlike the conventional antibiotics, which target essential functions, anti-TCS drugs disarm pathogens and let the immune system kill them, reducing the tendency to generate resistance and leading to less side effects towards neutral and beneficial bacteria.

Objectives

The main goal of our project is to develop a TCS-targeted drug-screening platform that might contribute to discover novel antibacterial compounds.

Methods

With a starting point of a unique *Staphylococcus aureus* strain in which all the 15 non-essential TCSs had been deleted, and upon deciphering the critical role of one of fifteen non-essential staphylococcal TCS in vivo, several reporter strains based in luminescence and fluorescence emission have been constructed.

Conclusions

The collections of reporter Staphylococcal strains developed in this project represent a promising tool for drug-discovery in functional and reporter screening assays.

CHARACTERISATION OF THE "VIABLE BUT NOT CULTIVABLE" STATE TRANSITION IN FOUR VIBRIO SPECIES

E. Prosdocimi[1,2], Z. Zeaiter[2], S. Arioli[2], F. Mapelli[2], E. Crotti[2], S. Borin[2]
[1]Queen Mary University of London, Blizard Institute, London, United Kingdom
[2]Università degli Studi di Milano,
Department of Food- Environmental and Nutritional Sciences DeFENS, Milan, Italy

Backgrounds

Vibrios are marine bacteria able to enter the Viable But Not Cultivable (VBNC) state. VBNC cells are no longer cultivable on plates, unless after a "resuscitation" process. VBNC transition was previously described in different *Vibrio* species but no direct comparison between them was tempted. H_2O_2 has a key role in the VBNC behaviour in *V. vulnificus*, but it is unclear if this is a universal mechanism.

Objectives

To characterise the morphological changes in four *Vibrio* strains during the VBNC transition and resuscitation, investigating in particular the role of oxidative stress.

Methods

Vibrio harveyi BAA-1117™*, V. fortis* UU24*, V. hepatarius* UU21 and *V. nereis* M5 cells were incubated in seawater at 4°C for 50 days. Their size, viability and cultivability were monitored by flow cytometry combined with the LIVE/DEAD-BacLight-kit and by plating. The first two strains became VBNC, and were resuscitated by incubation at 30°C. To assess H_2O_2 sensitivity, catalase-supplemented plates or broths containing different H_2O_2 concentrations were used.

Conclusions

Even though only two strains lost cultivability, all of them displayed cell dwarfing, decrease in DNA quantity and appearance of a peculiar fluorescence upon staining with propidium iodide. These features were partially or totally reverted with resuscitation. Cultivability was partially rescued by plating on catalase-supplemented media. VBNC cells of BAA-1117™ and UU24 were permanently damaged by 0.007 or 0.02 mM H_2O_2, respectively. Conversely, resuscitating cells gradually increased their resistance to H_2O_2. The details of the processes differed among strains. Therefore we suggest that there is no unique “VBNC-pathway", even within the same bacterial genus.

REFINEMENT OF THE REGULON OF THE PSEUDOMONAS AERUGINOSA VIRULENCE REGULATOR ΣVREI BY RNA-SEQ

J.M. Quesada[1], J.R. Otero-Asman[1], C. Civantos[1], L. Alted-Pérez[1], M.A. Llamas[1]
[1]Estación Experimental del Zaidín-Consejo Superior de Investigaciones Científicas, Environmental Protection, Granada, Spain

Backgrounds

Bacterial gene expression is controlled by modifying the promoter affinity of the RNA polymerase (RNAP). This control occurs through the substitution of the RNAP σ subunit and by the interaction with transcription factors. The pathogen *Pseudomonas aeruginosa* contains several σ factors, including σ^{Vrel}. This protein belongs to the extracytoplasmic function (ECF) group of the σ^{70} family. Expression and activity of σ^{ECFs} are tightly regulated and only occur in response to specific signals. σ^{Vrel} expression occurs in response to inorganic phosphate (Pi) limitation and requires the PhoB transcription factor. σ^{Vrel} activity is modulated by both the VreR anti-sigma factor, which keeps σ^{Vrel} inactive in absence of the inducing signal, and by PhoB. Upon activation of the cascade, likely in response to a still unknown host signal, VreR is proteolytically degraded and σ^{Vrel} released. σ^{Vrel} then interacts with the RNAP and with PhoB, and this transcription complex targets the expression of the σ^{Vrel} regulon, which includes virulent functions that increase *P. aeruginosa* pathogenicity.

Objectives

The σ^{Vrel} regulon was first identified by microarray of cells overexpressing σ^{Vrel}, a situation in which extremely high levels of σ^{Vrel} are produced bypassing some of the requirements needed *in vivo* for the σ^{Vrel}-mediated transcription. In this work we have refined the σ^{Vrel} regulon by RNA-seq upon activation of σ^{Vrel} in conditions that resemble the *in vivo* situation, *i.e.* Pi starvation and a *vreR* mutant to reach maximal σ^{Vrel} activity.

Methods

RNA-seq

Conclusions

Several potential new σ^{Vrel}-regulated genes have been identified, providing new insights into this important signaling cascade.

TRANSLATIONAL-REPRESSIVE REGULATION DURING IRON DEFICIENT CONDITIONS BY THE MRNA-BINDING PROTEIN CTH2 IN SACCHAROMYCES CEREVISIAE

L. Ramos-Alonso[1], A.M. Romero[1], M.À. Soler[2], P. Alepuz[3], S. Puig[1], M.T. Martínez-Pastor[2]
[1]Instituto de Agroquímica y Tecnología de Alimentos IATA-CSIC, Biotechnology Department, Paterna- Valencia, Spain
[2]Universitat de València, Departamento de Bioquímica y Biología Molecular, Burjassot- Valencia, Spain
[3]Universitat de València, Departamento de Bioquímica y Biología Molecular and ERI Biotecmed, Burjassot- Valencia, Spain

Backgrounds

Iron is an essential micronutrient and a valuable cofactor for its redox properties, although its bioavailability is frequently limited. Under iron deficient conditions, *Saccharomyces cerevisiae* activates the transcription of a group of genes collectively known as the iron regulon, which includes *CTH2*. Cth2 belongs to the tristetraprolin family of proteins that specifically interact through two $Cx_8Cx_5Cx_3Hx_{18}Cx_8Cx_5Cx_3H$ tandem zinc-fingers (TZF) with adenosine/uridine-rich elements (AREs) within the 3'-untranslated region of multiple mRNAs, usually related to iron-dependent pathways, to promote their degradation. Cth2-dependent regulation allows the proper redistribution of iron within the cell to optimize its utilization in essential processes.

Objectives

We aim to study whether Cth2 functions as a translational repressor of ARE-containing mRNAs during iron deficiency. We will determine the contribution of Cth2 and the AREs to the translational regulation of specific mRNAs, find out the region of Cth2 responsible of this regulation and discover possible new target mRNAs and molecular mechanisms implicated in this process.

Methods

The translation efficiency of Cth2-target mRNAs will be determined by two methods: (1) quantitation of the mRNA and protein levels of specific mRNAs, and (2) polysome profile analyses of the mRNAs associated with monosomes vs. polyribosomes.

Conclusions

In addition to promote mRNA decay, Cth2 represses the translation of multiple of its target mRNAs in response to iron deficiency. Both Cth2 TZFs and AREs within the target mRNA are essential for decay as well as for translational repression. Presumably, Cth2 acts as a translational repressor due to its interaction with a translation-repressive machinery through its carboxy-terminal region.

CSRA/RSMA FAMILY PROTEINS NEGATIVELY AFFECT GLOBAL C-DI-GMP POOLS AND BIOFILM FORMATION IN PSEUDOMONAS PUTIDA BY REGULATING CFCR

Ó. Huertas-Rosales[1], M. Romero[2], S. Heeb[2], M. Cámara[2], M. Espinosa-Urgel[1], M.I. Ramos-González[1]
[1]Estación Experimental del Zaidín-Consejo Superior de Investigaciones Científicas, Environmental Protection, Granada, Spain
[2]University of Nottingham, Life Sciences, Nottingaham, United Kingdom

Backgrounds

CfcR is a response regulator with an active GGDEF domain in *Pseudomonas putida*. Previous work has revealed that *cfcR* expression is regulated by RpoS, ANR and FleQ, and the functionality of the protein as a diguanylate cyclase requires an active multi-sensor (CHASE3/GAF) hybrid histidine kinase named CfcA.

Objectives

Our aims were i) to investigate an additional degree of regulation in *cfcR* expression by the three small RNA-binding proteins of the CsrA/RsmA family present in *P. putida*; ii) to evaluate the contribution of CfcR to the free pool of c-di-GMP and the augmented biofilm phenotype exhibited by a triple mutant with *rsmA*/*rsmE*/*rsmI* deleted (*ΔrsmIEA*).

Methods

Specific binding of the three Rsm proteins to *cfcR* mRNA, containing the leader sequence and initiation of translation, was analyzed using fluorescence-based gel shift assays. To evaluate gene expression and quantify the free pool of c-di-GMP “in vivo” we used gene fusions to reporter genes. Microtitter plate assays were used for biofilm quantification.

Conclusions

RsmA bound *cfcR* RNA with the highest affinity but deletion of *rsmA* alone, similarly to the single *rsmE* or *rsmI* deletions, did not cause *cfcR* induction, which was patent in the triple mutant *ΔrsmIEA*. CfcR is responsible for much of the free pool of c-di-GMP during the stationary phase, whose major depletion was caused by RsmA when it remained as the only Rsm protein in the mutant *ΔrsmIE.* A boost of c-di-GMP was observed in *ΔrsmIEA* and was dependent on CfcR, which is a key player for Rsm-controlled biofilm formation in *P. putida*.

PROTEOME CHARACTERIZATION OF THE WHOLE TWO-COMPONENT SYSTEM NETWORK IN STAPHYLOCOCCUS AUREUS

B. Rapún[1], B. García[1], J. Valle[1], J. Fernández-Irigoyen[2], X. Martínez[2], E. Santamaría[2], C. Solano[1], I. Lasa[1]
[1]Navarrabiomed.Universidad Pública de Navarra, Dpto. de Salud, Pamplona, Spain
[2]Navarrabiomed.Universidad Pública de Navarra, Unidad de Proteómica, Pamplona, Spain

Backgrounds

Bacteria use two-component systems (TCSs) to sense and respond to environmental changes. Each TCS senses an array of environmental stimuli and the number of TCS in a bacterial genome seems to be proportional to the amount of environments it encounters during life cycle. Current knowledge about TCS have been inferred from the analysis of recombinant bacteria that lack individual members, yet we know little about the regulated proteins by each individual TCS. Here, we use a collection of *S. aureus* strains containing an individual TCS to determine the sub-proteome of every TCS without interferences from other members of the family.

Objectives

To identify the sub-proteome that specifically depends on each TCS of *S. aureus*.

Methods

Protein extracts from *S. aureus* strains containing an individual TCS were prepared under the same growing conditions (TSB, 37ºC OD 0,8), and label-free differential proteomic assay was carried out. Results were compared with the protein extracts from the wild type and the mutant strain in all non-essential TCSs. Bioinformatics analysis identified the group of proteins differentially regulated by each TCS and specific proteomes have been validated using reporter systems.

Conclusions

We identified and validated the sub-proteome of each TCS of *S. aureus*. Our results indicate that the number of proteins specifically regulated by each TCS in a condition is low, with little overlapping between sub-proteomes. Results suggest that TCS network is organized as self-sufficient modules, each of them conferring the capacity to adapt to a different environmental conditions.

CLASSIFICATION OF ISOLATES FROM THE PSEUDOMONAS FLUORESCENS COMPLEX INTO PHYLOGENOMIC GROUPS BASED IN GROUP-SPECIFIC MARKERS

D. Garrido-Sanz[1], E. Arrebola[1], F. Martínez-Granero[1], S. García-Méndez[1], C. Muriel[1], E. Blanco-Romero[1], M. Martín[1], R. Rivilla[1], M. Redondo-Nieto[1]
[1]Universidad Autónoma de Madrid, Biology, Madrid, Spain

Backgrounds

The *Pseudomonas fluorescens* complex of species includes plant-associated bacteria with potential biotechnological applications in agriculture and environmental protection. Many of these bacteria can promote plant growth by different means, including modification of plant hormonal balance and biocontrol. The *P. fluorescens* group is currently divided into eight subgroups in which these properties and many other ecophysiological traits are phylogenetically distributed.

Objectives

To design a fast and cheap PCR based technique to obtain a rapid phylogroup assignation from any environmental sample

Methods

Using comparative genomics on 71 *P. fluorescens* genomes, we have identified nine markers which allow classification of any isolate into these eight subgroups, by a presence/absence PCR test. Primer pairs were developed for the amplification of these markers. Their specificity and were assessed on 28 field isolates, environmental samples from soil and rhizosphere and tested by *in silico* PCR on 421 genomes. Phylogenomic analysis validated the results: this PCR-based classification method has a 98.34% of accuracy.

Conclusions

Considering the phylogenetic distribution of biotechnology relevant traits, this assay could provide a new tool for Pseudomonads screening with putative biotechnological applications. Thus, this fast and cheap method could be one of the first steps in protocols that require the screening of many pseudomonads´ isolates to evaluate the potential of any *P. fluorescens* complex strain before going further on genomics analysis.

Research was funded by grant BIO2015-64480R from MINECO/FEDER EU. DGS was granted by FPU fellowship program (FPU14/03965) from MECD Spain. EBR is granted by a fellowship from Fundación Tatiana Pérez de Guzmán el Bueno, Spain.

PHENOTYPIC AND GENOTYPIC IDENTIFICATION OF URINARY TRACT INFECTIONS CAUSED BY EXTENDED-SPECTRUM-BETA-LACTAMASE PRODUCING E. COLI IN THE LEICESTERSHIRE AREA

R. Reid[1]
[1]*De Montfort University, Health and Life Sciences, Leicester, United Kingdom*

Backgrounds

Uropathogenic *E. coli* is one of the highest producers of ESBLs (Extended-spectrum β-lactamases), a major public health concern.

Objectives

This study aims to investigate the prevalence of ESBLs and plasmid types in Leicestershire.

Methods

380 urinary *E.* coli ESBL producing isolates were collected from the Leicester Royal Infirmary. Phenotypic analysis involved the MAST ESBL detection kit. Genotypic prevalence was investigated by using a multiplex PCR assay. Primers for blaCTX-M, blaSHV, blaOXA and blaTEM were designed. A second multiplex PCR assay was designed to identify blaCTX-M-1, blaCTX-M-2, blaCTX-M-8, blaCTX-M-9 and blaCTX-M-25. To investigate the relationship between plasmid type and ESBLs, a multiplex PCR-based replicon typing assay was designed[RR1] to detect IncFIA, IncI1, IncL/M, IncN and IncFII.

Conclusions

Phenotypic analysis showed blaCTX-M genes confer higher resistance to CTX, than CAZ and CPD. All isolates that showed resistance to CAZ and CPD, were also resistant to CTX. Prominence for ESBL genes was blaCTX-M (37%)> blaOXA (5%), blaTEM and blaSHV (2%). Associations between the ESBL groups were detected. In the second multiplex assay, the most prominent were blaCTX-M-1 (56%) and blaCTX-M-9 (11%), with associations between the blaCTX-M groups detected. blaCTX-M was found to be associated with all replicons other than L/M.

This is the first study to analyse the prevalence of uropathogenic ESBLs in Leicestershire. blaCTX-M is the most prominent ESBL in Leicestershire. blaCTX-M can be associated with other ESBLs. blaCTX-M-1 is the most common subgroup. Multiple associated plasmids can increase the spread of resistance, causing the epidemic we see today.

SUBTILIN CHALLENGE INDICATES CROSS-REGULATION OF BCE-LIKE MODULES IN LACTOBACILLUS CASEI

A. Revilla Guarinos[1], C. Alcántara Baena[2], S. Gehbard[3], T. Mascher[1], M. Zúñiga[2]
[1]Technische Universität Dresden- Institute of Microbiology, 'General Microbiology, Dresden, Germany
[2]Instituto de Agroquímica y Tecnología de Alimentos IATA-CSIC, Biotecnología de Alimentos, Valencia, Spain
[3]University of Bath, Department of Biology and Biochemistry, Claverton Down, United Kingdom

Backgrounds

Lactobacillus casei is a probiotic lactic acid bacterium exposed to environmental stresses such as antimicrobial peptides (AMPs). BceRSAB-like modules mediate resistance against AMPs in some Firmicutes bacteria. BceRSAB modules contain a signal transduction Two Component System (TCS), BceRS, functionally associated to an ABC transporter, BceAB. *L. casei* BL23 possesses two paralogous BceRSAB modules involved in AMP resistance, Module09 and Module12. In response to nisin, TCS09 induces the expression of the ABC09 whereas module 12 acts as a sensory system that regulates the expression of genes involved in controlling cell surface properties (the *dlt* operon and the *mprF* gene) as well as an orphan ABC transporter. Maintaining specificity in TCS signaling is often critical for survival. The protein sequence identity of HK09 - HK12, and RR09 - RR12 is 37% and 44%, respectively.

Objectives

In the current study, we delve in the function and regulation of the paralogous Module09 and Module12 aiming to determine if cross-regulation is possible between these highly similar signaling pathways.

Methods

To address these questions we created a collection of single and double mutants deficient in different combinations of Bce-like elements. These mutants were phenotypically characterized in response to AMPs and the expression of the genes of interest was monitored by RT-qPCR after nisin or subtilin challenges. We also performed bacterial two-hybrid assays to test protein interaction between non-cognate partners from both modules.

Conclusions

Our results indicate that cross-regulation between Module09 and Module12 is possible at least at the level of RR-promoter interaction, under the conditions tested.

ANTIBIOTIC SUSCEPTIBILITY AND VANCOMYCIN RESISTANCE OF STAPHYLOCOCCUS AUREUS STRAINS ISOLATED FROM PATIENTS IN IRAN

V. Alekhamis[1], S.E. Rezatofighi[1], H. Motamedi[1]
[1]Shahid Chamran University of Ahvaz, Biology, Ahvaz, Iran

Backgrounds

Empiric therapy for staphylococcal infections by penicillins led to spread of penicillin resistance throughout the world**.** Treatment of infections caused by methicillin-resistant *Staphylococcus aureus* (MRSA) is becoming complicated due to the formation of new antibiotic resistance.

Objectives

In this study, the antibiotic and vancomycin susceptibility pattern of *S. aureus* isolates was investigated by the phenotypic and molecular methods.

Methods

A total of 100 *S. aureus* isolates were collected from clinical specimens of patients in hospitals of Khuzestan province. These isolates were checked for the presence of vancomycin resistance genes (*vanA, vanB, vanC,* and *vanD*) by PCR. Phenotypic vancomycin-resistance pattern of isolates was checked by minimum inhibition concentration (MIC) and agar dilution methods. Also *S. aureus* isolates were investigated for resistance to various antibiotics by disc diffusion method.

Conclusions

Among the isolates, *vanA*, *vanB*, *vanC*, and *vanD* genes were found in 1, 0, 1, and 1 isolates respectively. The isolate that harbored *vanA* gene showed vancomycin resistance equal to 16 µg/ml; therefore, it was considered VRSA. Two other isolates that showed *vanC* and *vanD* genes, expressed resistance to vancomycin up to concentrations of 8 µg/ml and 4 µg/ml respectively. These isolates considered vancomycin-intermediate *S. aureus* (VISA). High resistance profiles were observed to penicillin (99%), followed by cefoxitin (95%), tetracycline (90%), kanamycin (87%), ciprofloxacin (78%), and amikacin (72%). In conclusion, detection of VRSA in this study emphasizes that careful surveillance and monitoring of vancomycin resistance with staphylococcal infections is needed.

STRUCTURAL BASIS OF QUORUM SENSING-DEPENDENT OXALATE PRODUCTION

J. Oh[1], S. Rhee[1]
[1]Seoul National University, Agricultural Biotechnology, SEOUL, Republic of Korea

Backgrounds

Bacterial quorum sensing (QS), a cell-to-cell communication process in many *Proteobacteria,* controls the gene expression for bacterial population-wide characteristics, including bioluminescence, motility, and virulence-related factors. Recently, QS has been recognized to provide further benefits at the population level by regulating the production of public goods, the function of which could be beneficial to all members of the group. In *Burkholderia* species, oxalic acid was recently identified as an excreted public good for the QS-dependent growth. In these species, QS-mediated oxalogenesis via the oxalate biosynthetic component (obc) is a cellular event indispensable for the survival of bacteria in the stationary phase. In *B. glumae*, obc consists of two genes encoding ObcA and ObcB for coordinating the production of oxalic acid, as well as acetoacetate and CoA, by using oxaloacetate and acetyl-CoA as substrates. Unlike *B. glumae*, there is a bi-functional enzyme Obc1 from *B.thailandensis.* Sequence analysis indicates that Obc1 has an ObcA-like N-terminal domain and shows ObcB activity in its C-terminal domain despite no sequence homology with ObcB.

Objectives

We are to understand structural and functional features of Obc1.

Methods

X-ray crystallography and enzyme kinetics were employed to investigate the catalytic residues and a possible mechanism of oxalate production.

Conclusions

In Obc1, the C-terminal domain has an α/β hydrolase fold that has a catalytic triad for oxalate production and a novel oxyanion hole distinct from the canonical HGGG motif in other α/β hydrolases. Functional analyses through mutagenesis studies suggested that His-934 is an additional catalytic acid/base for its lyase activity and liberates two additional products, acetoacetate and CoA. These results provide structural and functional insights into bacterial oxalogenesis. This work was supported by Next Generation BioGreen 21 program of Rural Development Administration (Plant Molecular Breeding Center) of Republic of KOREA.

INVESTIGATION OF LIPOPROTEINS TRANSLOCATION SYSTEM IN N. MENINGITIDIS

B. Ricchetti[1], M. Giuliani[1], M. Scarselli[2], V. Scarlato[3], I. Delany[1]
[1]GSK vaccine, AIMB, Siena, Italy
[2]GSK vaccine, Proteomic and antigen structure, Siena, Italy
[3]University of bologna, Pharmacy and biotechnology, Bologna, Italy

Backgrounds

Lipoproteins (LPs) of pathogenic Gram-negative bacteria are involved in different biological processes. For some Gram-negative bacteria, like *E. coli* (Ec), the lipoprotein translocation machinery is well characterized and, for *N. meningitidis* (*Nm*), homologues of these proteins can be identified from the genome. *Nm*, unlike *Ec*, displays many lipoproteins on its surface suggesting the presence of unknown factors involved in this mechanism. An additional translocation component, Surface lipoprotein assembly modulator (Slam), involved in the surface exposure of specific *Nm* lipoproteins has been recently identified.

Objectives

In this work we investigate the surface lipoproteins (SLPs) translocation mechanism mediated by Slam in different *Nm* strains and in heterologous systems.

Methods

We analyzed the surface exposure of NHBA (Neisserial-Heparin-Binding-Antigen) and fHbp (factor-H-binding-protein) as representatives of *Nm* SLPs by FACS. SLPs expression was confirmed by WB analysis of whole-cell lysate. We tested heterologous surface expression of *Nm* SLPs in the *E. coli (Ec)* background by generating expression plasmids carrying SLP and Slam.

Conclusions

Our results validated the role of Slam in outer membrane translocation mechanism in *Nm*. Slam was necessary for surface exposure of NHBA and had an impact in fHbp protein expression/stability in *Nm.* Co-expression of fHbp with functional Slam protein in *Ec* resulted in significantly higher levels of fHbp expression and its surface exposure.
In conclusion, we confirm the role of Slam in SLPs surface localization, furthermore our results suggest that Slam may play a differential role in the correct surface assembly of lipoproteins, depending on the nature of the lipoprotein.

Physiology / Biochemistry / Molecular Microbiology - Part III

DESCRIPTION OF THE FTSZ DISASSEMBLY PHENOTYPE

A.I. Rico[1], *D. López-Escarpa*[1], *M. Krupka*[1], *M. Vicente*[1]
[1]*Centro Nacional de Biotecnología CNB-CSIC, Microbial Biotechnology, Madrid, Spain*

Backgrounds

FtsZ, a cytoplasmic GTPase, is the major component of the ring-shaped cell division machinery (the divisome) of most bacteria. Its polymerization plays an important role in constriction. In *Escherichia coli*, alteration of the FtsZ lateral contacts modifies its behaviour *in vitro* and *in vivo*.

The FtsZ·E93C mutant, retaining 20% of GTPase activity, can partially rescue VIP2, a conditional FtsZ strain (Encinar *et al.,* 2013). Mutations in the nearby residue E38 (at 8.5 Å distance) showed abnormal pole morphology and twisted septa (Bi and Lutkenhaus, 1992).

Objectives

Analysis of the *in vivo* effects of the FtsZ E38 and E93 lateral area. Comparison with mutations D269A and D86K (Stricker and Erickson, 2003), having a lower GTPase activity but located at different sides than E38 and E93.

Methods

Scanning and transmission electron microscopy were used to visualize the morphology of *E. coli* VIP2 derivatives in which FtsZ$^+$ is replaced by point mutants in E38 and E93. Growth, morphological parameters and localization of division proteins were measured.

Conclusions

We found a negatively charged area of *E. coli* FtsZ comprising E38 and E93 involved in divisome disassembly but not in its formation. This evident “FtsZ disassembly phenotype” shows detachment of the envelope layers and persistence of abnormally wide Z-rings both at midcell and at cell poles. It suggests a unique role of this lateral side, differently from those containing D269A or D86K. Mutations in E38E93 showed reduced GDP/GTP exchange and low turnover in the divisome, likely caused by strong interactions among FtsZ protofilaments.

SYMBIOTIC PLANT DECOMPOSITION BY FUNGI AND GUT MICROBES ASSOCIATED WITH FUNGUS-GROWING TERMITES

R. Rodrigues da Costa[1], K. Sydow Krogh Pedersen[1], H. Hu[1], J. Schückel[2], S. Kresimir Kracun[2], S. Vreeburg[3], B. Pilgaard[4], L. Lange[4], J. Harholt[5], D.K. Aanen[3], P. Sapountzis[1], M. Poulsen[1]
[1]University of Copenhagen, Department of Biology, Copenhagen, Denmark
[2]University of Copenhagen, Department of Plant and Environmental Sciences, Copenhagen, Denmark
[3]Wageningen University, Laboratory of Genetics, Wageningen, The Netherlands
[4]Technical University of Denmark, Department of Chemical and Biochemical Engineering-, Lyngby, Denmark
[5]Carlsberg A/S- Group Research, Carlsberg Research Laboratory, Copenhagen, Denmark

Backgrounds

Fungus-growing termites are a paramount example of symbiotic association between insect hosts, a saprotrophic fungal cultivar (genus *Termitomyces*), and co-diversified gut microbial communities. Through an intricate and efficient decomposition process that involves plant biomass passing termite guts before decomposition in the external fungal gardens, these termites fully utilize a range of plant substrates and have become major decomposers in the Old World.

Objectives

Previous studies have proposed complementarity in enzyme provisioning between the partners in the symbiosis, but targeted expression analyses have been lacking. Here we characterise plant polymer decomposition and the expression of enzymes that are produced during the decomposition process in three fungus-growing termite species from two genera.

Methods

We performed plant polymer content analyses in forage substrate and fungal gardens, enzyme assays of fungal garden and termite guts, and RNAseq and subsequent carbohydrate-active enzyme characterisation of fungal enzymes within gardens.

Conclusions

We found a remarkable decrease in the amount of plant polymers from the start (forage substrate) to the end of the decomposition process (old worker guts). This supports the capacity of the tripartite symbiosis to utilize nearly any complex plant polymer. Enzyme assays and RNAseq analyses supported these findings, as a wide range of plant-degrading enzymes was identified. The enzyme assays further suggested that termite ingestion of fungal nodules from the mature fungal gardens leads to the transport of enzymes to the freshly inoculated parts of the garden. This process likely boosts plant degradation in parts of the fungus garden where *Termitomyces* is not yet fully grown.

PLASMID-MEDIATED HETEROZYGOSIS INCREASES PHENOTYPIC PLASTICITY IN BACTERIA

J. Rodríguez Beltrán[1], J. De la Fuente[1], J.C.R. Hernández[2], J.A. Escudero[3], R. Peña-Miller[2], C. MacLean[3], A. San Millán[1]
[1]IRYCIS. Ramon y Cajal Institute for Health Research, Plasmid Biology and Evolution lab, Madrid, Spain
[2]Center for Genomic Sciences UNAM, Microbial Systems Biology, Morelos, Mexico
[3]Oxford University, Department of Zoology, Oxford, United Kingdom

Backgrounds

Small multicopy plasmids are very frequent in prokaryotes. Their multicopy nature produces an increase in gene dosage for the resident loci that increases gene expression and the chances of acquiring beneficial mutations. However, once a mutation arises its fixation will be largely influenced, not only by its selection coefficient, but by the plasmid copy number, segregation and replication dynamics. Accordingly, plasmids carrying mutated genes will co-exist in the same cell with plasmids encoding the ancestral allele, under plasmid-mediated heterozygosis.

Objectives

In this work we aim to explore the consequences of plasmid-mediated heterozygosis. It is known that when proteins acquire a new function through mutation they usually lose effectiveness at their original activity. We predict that plasmid-mediated heterozygosis may alleviate these trade-off effects that occur during evolutionary innovation.

Methods

To test this hypothesis, we combined mathematical modeling with an experimental system using *Escherichia coli* and fluorescently-labeled multicopy plasmids carrying either TEM-1 or TEM-12 β-lactamases. TEM-1 and TEM-12 are separated by a single mutation and confer resistance to ampicillin and ceftazidime respectively, showing a good example of an evolutionary trade-off.

Conclusions

We show that strains carrying both TEM alleles under heterozygosis are able to withstand concentrations of ceftazidime and ampicillin, alone or in combination, better than any of their homozygotic counterparts. Moreover, plasmid-mediated heterozygosis confers phenotypic plasticity to bacterial populations, facilitating the adaption to a range of constant and fluctuating antibiotic selection regimes. We argue that multicopy plasmids alleviate evolutionary trade-offs by maintaining copies of ancestral and evolved alleles under heterozygosis.

HEME UPTAKE SYSTEMATIC FUNCTIONAL ANALYSIS IN NONTYPABLE HAEMOPHILUS INFLUENZAE IDENTIFIES A NOVEL FAMILY OF HEME BINDING-DONATION MOONLIGHTING PROTEINS

I. Rodriguez-Arce[1], F.C. Ariadna[1], A.J. Tamim[2], E. Begoña[3], M. Javier[1], C. Lucia[1], M. Sara[3], R. Kristian[4], G. Juncal[1,3]
[1]Instituto de Agrobiotecnología-CSIC, Animal Healthcare, Pamplona, Spain
[2]Lund University, Clinical Microbiology- Department of Translational Medicine, Malmö, Sweden
[3]Centro de Investigación Biomédica en Red de Enfermedades Respiratorias, CIBERES, Madrid, Spain
[4]Lund University, Clinical Microbiology- Department of Translational Medicine, Malmo, Sweden

Backgrounds

The respiratory pathogen nontypeable *Haemophilus influenzae* (NTHi) is an important cause of exacerbations in patients suffering from chronic obstructive pulmonary disease (COPD), a progressive disease involving airway restriction, alveolar destruction and loss of lung function, primarily due to cigarette smoke (CS) exposure. CS induces the cytoprotective enzyme heme oxygenase-1, which catalyzes heme degradation. The existence of multiple heme-uptake systems in NTHi may be a evolutionary adaptation to its naturally-acquired heme auxotrophy, and also to overcoming host nutritional immunity and heme limited availability in the airway. Moreover, several NTHi heme-uptake systems are multifunctional proteins involved not only in heme capture, but also in bacterial resistance to antimicrobial peptides or epithelial adhesion. Relative contribution of the repertoire of NTHi heme-uptake systems to its host interplay is currently unknown.

Objectives

Functional characterization of a panel of 8 NTHi heme-uptake systems and their contribution to this host-pathogen interplay.

Methods

NTHi mutants lacking the TonB, HgpB, HxuCBA, TbpAB SapABCDZ, HitABC, HbpA-DppBCDF or protein E iron/heme/haemoglobin/haemopexin-capture systems were generated, and characterized in terms of bacterial growth, heme-binding and inter-bacterial donation, antimicrobial resistance, resistance to oxidative stress, relative gene expression, bacterial interplay with airway epithelia and *in vivo* lung infection.

Conclusions

NTHi heme-uptake systems are not hierarchically organized neither gene expression- nor function-wise. SapA, HxuA, DppA and protein E, besides other functions, share their ability to bind and donate heme, therefore constituting a novel family of moonlighting proteins.

DESIGN OF A REAL-TIME PCR TOOL TO STUDY CELL WALL STRESS IN FUNGI

L. da Cruz Cabral[1], J. Delgado[1], M.J. Andrade[1], A. Patriarca[2], M.A. Asensio[1], A. Rodríguez[1]
[1]Meat and Meat Products Research Institute, Animal Production and Food science, Cáceres, Spain
[2]Buenos Aires University, Organic Chemistry, Buenos Aires, Argentina

Backgrounds

The cell wall integrity (CWI) pathway is responsible for the reparation and/or biosynthesis of the cell wall and is activated when changes on the cell surface occurred mainly under imposed stress. A new tool able to detect changes in stress-related genes would be useful to understand the action mechanism of some filamentous fungi against antifungal compounds.

Objectives

The objective was to develop a real-time PCR (qPCR) using SYBR Green to monitor changes in the *Rho1* gene expression levels in moulds.

Methods

Optimization of reaction conditions included evaluation of different primer pairs, primer concentrations and annealing temperatures/times. The final reaction mixture contained 200nM of each primer and an annealing temperature of 55ºC. The specificity of primers was demonstrated when amplified a unique qPCR product with a Tm value of 86ºC. The qPCR showed a R^2 value =0.9994 and amplification efficiency of 97.5%. The method was validated by treating *Aspergillus flavus* and *Penicillium polonicum* with the antifungal protein PgAFP. The PgAFP-resistant *P. polonicum* showed an overexpression of *Rho1*, while the opposite trend was detected in *A. flavus* with the antifungal treatment.

Conclusions

This qPCR assay is a valuable tool to analyse intracellular responses linked to CWI pathway activation. This provides data to in-depth understand the ability of fungi to colonise different environments and to develop new antifungals

Acknowledgements: L. da Cruz Cabral is recipient of a pre-doctoral fellowship (BEC.ar call 2015). Dr. A. Rodríguez is supported by a Juan de la Cierva senior research fellowship (IJCI-2014-20666)

PHOSPHORYLATION OF YEAST CTH2 PROTEIN AND ITS SUBSEQUENT DEGRADATION BY GRR1 ARE REQUIRED FOR OPTIMAL GROWTH IN IRON DEFICIENT CONDITIONS

A.M. Romero[1], M.M. Martínez-Pastor[2], N. Sanvisens[3], J.A. Wohlschlegel[4], D. Toczyski[3], M.T. Martínez-Pastor[5], D.J. Thiele[2], S. Puig[1], S. Vergara[6]

[4]University of California, Biological Chemistry, Los Angeles- California, USA
[5]University of Valencia, Biochemistry and Molecular Biology, Burjassot- Valencia, Spain
[6]Duke University, Biology, Duke, USA

Backgrounds

Iron is an essential micronutrient for most organisms because it participates as a redox cofactor in a variety of metabolic pathways. However, iron bioavailability for living organisms is highly restricted due to its low solubility at physiological pH. Upon iron scarcity, *Saccharomyces cerevisiae* Cth2 protein, characterized by the presence of two $Cx_8Cx_5Cx_3Hx_{18}Cx_8Cx_5Cx_3H$ tandem zinc fingers (TZFs), is expressed and binds to AU-rich elements (AREs) of many mRNAs encoding for iron-containing proteins, promoting their degradation. Thus, Cth2 optimizes iron utilization by repressing non-essential iron-consuming pathways (respiration) and activating indispensable iron-dependent processes (DNA synthesis). Yeast cells need to fine-tune the expression levels of Cth2 protein because its excess can be detrimental for growth. Previous studies have demonstrated that Cth2 limits its expression by binding to AREs within its own mRNA, promoting its auto-degradation.

Objectives

Our goal is to characterize the post-translational mechanisms that regulate Cth2 protein levels according to environmental iron bioavailability. Cth2 phosphorylation, ubiquitylation and degradation by the proteasome will be studied.

Methods

RNA (qPCR) and protein (Western blot, CoIP) analyses, yeast growth assays

Conclusions

Yeast Cth2 protein is phosphorylated at serine residues 65, 68 and 70 under iron-deficient conditions. Mutagenesis of these serine residues does not eliminate Cth2 targeted mRNA degradation function, but it increases Cth2 protein stability. Our data demonstrate that F-box E3-ligase protein Grr1 recognizes phosphorylated Cth2 and facilitates its degradation by the proteasome. Both mutagenesis of Cth2 serine residues and *GRR1* deletion cause significant growth defects under iron depletion, emphasizing the physiological relevance of regulating Cth2 protein levels.

PSEUDOMONAS AERUGINOSA IN CYSTIC FIBROSIS CHRONIC INFECTIONS: HOW THE AIRWAY ENVIRONMENT SHAPES THE BACTERIAL TRANSCRIPTOME

E. Rossi[1], S. Molin[2], H.K. Johansen[1]
[1]Rigshospitalet, Department of Clinical Microbiology, Copenhagen Ø, Denmark
[2]Technical University of Denmark, Novo Nordisk Foundation Center for Biosustainability, Kgs. Lyngby, Denmark

Backgrounds

Cystic fibrosis (CF) is a life-threatening disease associated with genetic mutations affecting the activity of the epithelial chloride transporter CFTR. This condition promotes the formation of a viscous mucus layer that covers epithelial tissues of airways, creating an optimal environment for bacterial growth and development of chronic infections. *P. aeruginosa* is a predominant pathogen in these infections, mostly due to its ability to survive and evolve in CF lungs. Although progress has been made in understanding *P. aeruginosa* adaptive strategies, little is known about its behaviour in human lungs. In particular, we known very little about the ways *P. aeruginosa* physiology is shaped by the unique chemico-biological environment of CF patients' airways.

Objectives

Using a meta-transcriptomics approach, we investigate the eco-physiology of *P. aeruginosa* communities directly in human CF sputum.

Methods

CF sputum is collected and the DNA/RNA content stabilized within less than a minute. After rRNA depletion, isolated RNA is used for the preparation of sequencing libraries. High-depth sequencing is performed on Illumina NextSeq platform. *In silico* analysis is carried out using a customized pipe-line.

Conclusions

Our preliminary results picture a highly dynamic transcriptionally-active microbial community in CF patients. From our high-resolution approach, we could quantitatively evaluate *P. aeruginosa* gene expression in the patient's lungs, disclosing a peculiar expression profile characterized by functions that reflect bacterial adaptation to CF airways (anoxia, metal ion limitation, oxidative and antibiotic stresses), and features typical for both fast-growing and slow-growing cells, underlining the evolved physiology of the bacterium at the stage of long-term chronic infections.

EVOLUTIONARY INFORMATION VALUE OF GENOMIC ISLANDS OF ROOT NODULE BACTERIA SINORHIZOBIUM SPP.

M. Roumiantseva[1], V. Muntyan[1], M. Cherkasova[1], A. Saksaganskaya[1], B. Simarov[1]
[1]ARRIAM, Laboratory of Genetics, Saint Petersburg Pushkin, Russia

Backgrounds

Genomic islands (GIs) are not the typical accessory elements of the bacterial genome. The spectrum of GIs is represented by classical types like “pathogenicity”(PAIs) or "symbiotic” (SI) islands up to islands inheriting an extent blocks of genes with unknown functions. GIs are site specific integrated units in sequences of tRNA or tmRNA. Typically they have direct repeats, phage integrase, abundant IS-elements, transposons, noncoding RNA (ncRNA), as well as a numerous "foreign" genes, repetitive sequences, plasmid DNA sequences of various species of microorganisms. Genes inherited by GIs can dramatically improve and expand bacteria habitats (fitness).

Objectives

We are going to present and discuss evolutionary information value of genomic islands in *Sinorhizobium spp*. and GIs distribution in *S. meliloti* populations native to geographically distant centers of alfalfa diversity impact by different abiotic stress factors.

Methods

New molecular genetic approaches in tight links with bioinformatics and synthetic methods are providing tremendous comparative evaluation of *Sinorhizobium spp*. genomes.

Conclusions

Chromosome of *S. meliloti* 2011 comprises at least three elongated areas that are considered as genomic islands. These regions were not previously investigated, but it is known that they contain at least 196 ORF, IS-elements 5 identified families and 6 unidentified types and genes responsible for at least 2 types of restriction-modification systems and 75 ncRNA. The geographical distribution of genomic islands in *S. meliloti* populations and thier evolutionary information value in *Sinorhizobium spp*. will be discussed.

IDENTIFICATION OF A UNIQUE GENETIC SIGNATURE IN A NOVEL COMPLEX RESISTANCE GENE LOCUS IN MULTIPLE DRUG RESISTANT UROPATHOGENIC ESCHERICHIA COLI ST405

P. Roy Chowdhury[1], *J. McKinnon*[1], *M. Liu*[1], *S. Djordjevic*[1]
[1]*University of Technology Sydney, The ithree institute- Faculty of Science, Sydney, Australia*

Backgrounds

Escherichia coli belonging to sequence type (ST) 405 is globally known for dissemination of $bla_{CTX\text{-}M15}$ and NDM-1 genes and is noted threat to human health. In the course of our routine surveillance of multiple drug resistant (MDR) *E. coli* strains circulating in hospitals in Sydney, Australia, we identified *E. coli* isolate 2009-27 from midstream urine of a patient with cystitis that was resistant to most first line antibiotics, including ampicillin, azithromycin, kanamycin, sulphafurazole and trimethoprim used in the treatment of urinary tract infections. It was however sensitive to extended spectrum betalactams. Our in-house targeted PCR screening data indicated that 2009-27 contained a complex resistance locus (CRL), which could serve as a hotspot for further accumulation of resistance genes.

Objectives

To characterize the CRL in MDR strain 2009-27 and identify genetic signatures to reliably track dissemination of this clonal ST405 lineage.

Methods

Strain 2009-27 was sequenced using PacBio technology and interrogated using online analysis tools including BLAST, ORF finder, RAST, eMLST and ISfinder.

Conclusions

Strain 2009-27 was identified as phylogenetic group B2, ST405 with serotype O102:H6. A laterally-acquired, chromosomally-located complex resistance gene locus, spanning almost 20 kb, was shown to contain a suite of resistance genes that was sufficient to account for the resistance phenotype of strain 2009-27. The CRL also included five copies of the insertion element IS*26*. IS*26* appears to have played a major role in the evolution of the CRL in 2009-27, including creation of a unique deletion which can be exploited to track this MDR lineage.

THE PANGENOME OF AN UNCULTURED NOVEL BACTEROIDETES SPECIES

M. Royo-Llonch[1], P. Sánchez[1], J.M. González[2], C. Pedrós-Alió[3], S.G. Acinas[1]
[1]Institut de Ciències del Mar- CSIC, Department of Marine Biology and Oceanography, Barcelona, Spain
[2]Universidad de La Laguna, Department of Microbiology, San Cristóbal de la Laguna, Spain
[3]Centro Nacional de Biotecnología- CSIC, Systems Biology Department, Madrid, Spain

Backgrounds

The uncertainty on the threshold that defines bacterial species induced the “Pan-genome” concept. It categorizes prokaryotic species as a group of genomes that share a "core genome" and differ in the “flexible pool genome”. The first one codes for central metabolism and highly conserved genes, while the second is the sum of dispensable genes of each genome’s taxa. The flexible pool varies within the species due horizontal gene transfer and other genome rearranging events. Traditionally, pangenomes have been produced with isolated bacteria. Nowadays, retrieval of diverse genomes from natural samples by Single Cell Genomics (SCG) allows the exploration of the pangenome of those abundant microbial genomes that elude cultivation.

Objectives

The aim of our research is to generate the Pangenome of a novel photoheterotrophic *Kordia* species (Bacteroidetes) through environmental genomes obtained by SCG.

Methods

We retrieved 98 apparently clonal *Kordia* Single Amplified Genomes (SAGs) from the Indian Ocean, 10 of which have been sequenced. Reconstruction of most of this *Kordia* sp. genome has been possible through a co-assembly. Their genomic comparison, together with two phylogenetically identical SAGs retrieved from the North Pacific Subtropical Gyre deep waters will help us to elude the size of this *Kordia* sp. core and flexible genomes, which processes may have generated the flexible genome, differences in genetic composition of each flexible genome, etc.

Conclusions

In conclusion, this work features two significant points in marine bacterial genomics: firstly, the assembly and functional annotation of 10 novel Bacteroidetes SAGs and secondly, the construction and analysis of this *Kordia* sp.’ Pangenome.

[3]CIBER de Epidemiología y Salud Pública- Instituto de Biomedicina de Sevilla- Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Departamento de Epidemiología, Sevilla, Spain
[4]Centro de Investigación Príncipe Felipe, Genomics of Gene Expression, Valencia, Spain

Backgrounds

Background

Pneumocystis species are ascomycete fungi that adapted to live inside the lungs of mammals. These ascomycetes show extensive stenoxenism, such that each *Pneumocystis* species can infect only a single host species, indicating a high level of adaptation to and co-evolution with its host.

Objectives

Objectives

The aim of this project is to study the pattern exerted by natural selection on functionally related sets of genes in the genome of *Pneumocystis carinii* (rats), *Pneumocystis murina* (mice) and *Pneumocystis jirovecii* (humans). In addition, we studied the extent of positive selection and recombination in the evolution of major surface glycoproteins (Msg).

Methods

Methods

Protein families were aligned with MUSCLE and for each gene family, we estimated synonymous (dS) and non-synonymous (dN) rates of substitution. To detect recombination in Msg proteins we used GARD from HyPhy 2.220 package and the episodic diversifying selection was detected with MEME on each of the recombinant segments identified with GARD.

Conclusions

Conclusions

We showed that genes with an increased rate of non-synonymous substitution compared to the rest of genes in the genome coding for glycosylphosphatidylinositol biosynthesis in *Pneumocystis jirovecii* and *Pneumocystis carinii*, and for complexes of the protein secretion apparatus in *Pneumocystis jirovecii*. Also, we found that between 12% to 30% of the sites in Msg proteins evolved by episodic positive selection and identified several recombination segments along coding genes. These data suggest strong selective pressure of the immune system of the host in shaping the evolution of Msg proteins and the cell machinery implicated in protein secretion in *Pneumocystis*.

Backgrounds

Gene and genome duplication are major sources of biological innovations in all kingdoms, including yeast, plants and animals. As an example, a whole-genome duplication event provided the genomic background for the evolution of an efficient anaerobic fermentation capacity and the respiro-fermentative life-style in Saccharomyces yeasts (budding yeasts). Functional and transcriptional divergence between the copies after gene duplication has been considered the main driver of innovations. However, the relative role of transcriptional evolution of duplicated genes in the origin of adaptations remains poorly characterized.

Objectives

Here, we study the phenotypic plasticity of duplicated genes and determine its role in the origin of adaptations in *S. cerevisiae*.

Methods

The unicellular eukaryote *Saccharomyces cerevisiae* Y06240 haploid strain was challenged with five different environmental stresses (oxidative, ethanol, glycerol, lactate and oxidative plus dextrose). Transcriptional alterations were determined by RNAseq and differential expression analyses. The transcriptional plasticity of singletons and duplicates was analyzed. We also analyzed the role of the mechanism of duplication (whole-genome vs small-scale) in the transcriptional plasticity of duplicates.

Conclusions

The transcriptional response of *S. cerevisiae* to environmental stresses was greater through the alteration of duplicates than singletons. Duplicated genes exhibited signatures of adaptive transcriptional patterns in response to stress. Whole genome duplicates were more transcriptionally altered than small-scale duplicates. Duplicates responded more specifically to stress than singletons, supporting the role of natural selection in the transcriptional plasticity of duplicates. Our results reveal the underlying transcriptional complexity of duplicated genes and its role in the origin of adaptations.

Systems Biology of Molecular Interactions and Regulation, Valencia, Spain
[4]*University of Valencia, Genetics, Valencia, Spain*
[5]*Instituto de Agroquímica y Tecnología de los Alimentos IATA CSIC, Biotechnology, Valencia, Spain*

Backgrounds

The populations of endosymbiotic bacteria of insects are subjected to strong bottlenecks during their transmission to the host offspring, making selection less efficient on purging deleterious mutations. General endosymbiotic symptoms include reduced bacterial genome sizes, novel biochemical adaptations and increased genome mutational load. Despite these detrimental evolutionary dynamics, endosymbiotic bacteria of insects have been preserved through millennia. The underpinnings of the successful endosymbiotic lifestyle remain unclear. Some evidence point, however, to a fundamental role of the molecular chaperonin GroEL in bufferring the effects of deleterious mutations and enabling the origin of adaptations in endosymbiotic bacteria.

Objectives

This work aims to determine the role of the chaperonin GroEL in the phenotypic evolution through conferring resistance to deleterious mutations in bacterial populations evolving under genetic drift.

Methods

Escherichia coli (MG1655 delta *mutS*) bacterial isogenic lines over-expressing the operon *groE* were subjected to 180 (~4000 generations) daily passages under strong genetic drift effects, resembling matrilines transmissions of endosymbiotic bacteria of insects. The genomes of the evolved populations were sequenced using Illumina technology. Mutations arising during the evolution experiments were determined by comparing the genomes of evolved populations with those of their ancestral population. The effects of the mutations were estimated by calculating the fitness of the evolved populations relative to their ancestral population.

Conclusions

GroE over-expression confers resistance to deleterious mutations. The return of *groE* to its wild type expression levels led to a decline in the fitness and increase in the number of aberrant phenotypes in the evolved population.

EVOLUTION OF STAPHYLOCOCCUS AUREUS IN A MURINE MODEL OF NASOPHARYNGEAL COLONISATION

B. Salgado[1], J. Moran[1], E. Waters[2], A. Kadiolgu[2], M. Horsburgh[1]
[1]University of Liverpool, Institute of Integrative Biology, Liverpool, United Kingdom
[2]University of Liverpool, Institute of Infection and Global Health, Liverpool, United Kingdom

Backgrounds

Staphylococcus aureus is a frequent member of the human nasopharyngeal microbiome. The features that contribute to colonisation and the selective pressures in the presence of competitor species aren't clear.

Objectives

To better understand how *S. aureus* both colonises and persists in the nasopharynx, we developed a long-term asymptomatic model of nasopharyngeal colonisation in mice.

Methods

A nasopharyngeal colonisation model was established using CD-1 mice with *S. aureus* USA300 LAC*. To examine the selective pressure of this infection model upon *S. aureus,* serial passages were performed over 7 days. Three separate consecutive passages were performed with *S. aureus* USA300 LAC* being isolated between passages and used to establish a repeat colonisation with identical load. Following each passage 10 *S. aureus* isolates were obtained and their genomes were purified, pooled and genome resequenced. A single clone from the second passage was randomly picked and sequenced. The genome sequences of each pool of 10-strains and the evolved isolate were compared with their isogenic parent to identify the identity and frequency of SNPs/indels. Complementary *in vivo* assays were performed to assess phenotype changes by the evolved strain.

Conclusions

Bioinformatics analysis revealed distinct patterns of genetic changes after each subsequent cycle of *S. aureus* colonisation. Sequencing revealed incremental numbers of SNPs/indels with successive passages. After three rounds of colonisation there was evidence of repeated selection at specific loci. The observed selection pressure outcomes were mapped to cellular pathways to identify *in vivo* adaptation. A clone from the second passage showed increased colonisation frequency relative to its isogenic parent.

TRANSCRIPTOME ANALYSIS OF TELOMERASE NEGATIVE STRAINS OF USTILAGO MAYDIS

M.P. Sánchez-Alonso[1], J.J. Jacinto Vázquez[2], E. Anastacio Marcelino[3], C. Vázquez Cruz[3]
[1]Instituto de Ciencias, Centro de Investigaciones en Ciencias Microbiológicas, Puebla, Mexico
[2]Instituto de Ciencias- Benemérita Universidad Autónoma de Puebla,
Posgrado en Microbiología- Centro de Investigaciones en Ciencias Microbiológicas, Puebla, Mexico
[3]Instituo de Ciencias- Benemérita Universidad Autónoma de Puebla,
Centro de Investigaciones en Ciencias Microbiológicas, Puebla, Mexico

Backgrounds

The *U. maydis trt1::hph* mutants lacking telomerase activity exhibit low replicative potential, delayed growth, short telomeres, and senescent traits in same way as *est2* mutants in yeasts. As in *est2* cells, survivors sporadically arise among telomerase-negative mutants that maintain telomere function by recombination-based mechanisms known as alternative lengthening of telomere (ALT). Molecular machinery of RNA metabolism is, at least in part, involved in these arising of survivors.

Objectives

In this work we initiate transcriptome analysis of telomerase-negative Type I-like and Type II-like survivor mutants of *U. maydis* in order to compare their global transcription profiles with that of the parental strain 521.

Methods

High-quality total RNA from all the three strains was extracted, and sent to LANGEBIO-CINVESTAV Campus Irapuato to be processed and sequenced in order to obtain poly (A) transcriptomes. Sequencing was performed by duplicate using the Ion-Torrent NGS platform of Life Sciences. Assemble was made using Trinity software (https://github.com/trinityrnaseq/trinityrnaseq/wiki).

Conclusions

Raw analysis render 73,623 potential transcripts from transcriptomes of 521 strain and from Type I mutants in independent experiments by duplicate; length of transcripts range from 201 to 4010 bp with a total of assembled bases of 40,304,870 and N50 = 752 bp, In similar analysis we found 70,828 potential transcripts form parental strain and Type II mutant from two independent replicates; here were assembled 29,396,441 bp. Length of transcripts ranged form 201 pb to 4254, N50 = 437. Preliminary differential expression analyses showed changes in gene expression in Type I and Type II ALT mutants respect to wild type strain.

Physiology / Biochemistry / Molecular Microbiology - Part III

EFFECT OF THE HFQ AND CRC PROTEINS ON THE TRANSCRIPTOME OF PSEUDOMONAS PUTIDA

D.L. Sánchez-Hevia[1], *R. Moreno*[1], *F. Rojo*[1]
[1]*Centro Nacional de Biotecnología, Department of Microbial Biotechnology, Madrid, Spain*

Backgrounds

In metabolically versatile bacteria such as *Pseudomonas putida*, catabolite repression facilitates the preferential assimilation of the most efficient carbon sources, optimizing metabolism and improving growth rate and fitness. In *P. putida*, catabolite repression is mediated by the Hfq and Crc proteins, which inhibit translation of target mRNAs. Two sRNAs, CrcZ and CrcY, can bind these proteins and antagonize their activity. Inactivation of the gene coding for Hfq leads to a much stronger phenotype than inactivation of *crc*, suggesting that while Crc needs Hfq, Hfq might regulate some genes independently of Crc. In other bacterial species in which Crc is not present, Hfq is involved in many post-transcriptional regulation processes.

Objectives

Our aim was to elucidate whether Hfq can regulate genes in the absence of Crc, and vice-versa, and identify those genes.

Methods

Previous studies have indicated that although Crc and Hfq are post-transcriptional regulators, their absence has a great effect on the cell transcriptome. Therefore, the transcriptome of wild type, Hfq-null, Crc-null, and Hfq/Crc-null strains cultivated in a mineral salts medium with succinate as carbon source was analysed using RNA-Seq.

Conclusions

The absence of Hfq had a much greater effect on the transcriptome than the absence of Crc. Genes regulated by Crc were also Hfq-dependent. However, many genes were regulated by Hfq but not by Crc. Among others, this includes the genes involved in iron homeostasis. Current understanding on the underlying reasons will be presented.

OSMOREGULATORY MECHANISMS OF THE SUCCESSFUL HALOPHILIC BACTERIA SPIRIBACTER

M.J. Leon[1], T. Hoffman[2], C. Sánchez-Porro[1], E. Bremer[3], A. Ventosa[1]
[1]Universidad de Sevilla, Microbiology and Parasitology, SEVILLA, Spain
[2]Philipps-University Marburg, Department of Biology-, Marburg, Germany
[3]Philipps-University Marburg, Department of Biology, Marburg, Germany

Backgrounds

Studies carried out in hypersaline environments focused on culture-independent techniques showed that microorganisms easily isolated in the laboratory do not constitute the predominant microbiota and therefore they are not the ideal models for understanding the relationships and functions of microbes in natural environments. Metagenomic-based studies in salterns have recently permitted the isolation of representatives of a dominant bacterial group at intermediate salinities (10-20 % salts) that have been named as a new genus, *Spiribacter.*

Objectives

We have combined a physiological approach and genome mining to derive a comprehensive picture of the molecular and cellular events that allow to the members of the genus *Spiribacter* to be successful bacteria in hypersaline environments.

Methods

We have used a qualitative and quantitative assessment by natural abundance ^{13}C-NMR spectroscopy and high performance liquid chromatography analysis, respectively, and a genomic analysis of the species of this genus.

Conclusions

The genus *Spiribacter* represents the first ecologically defined moderately halophilic bacteria, quite abundant at intermediate salinities. Our data show that newly synthesized ectoine and imported glycine betaine play key roles in the osmoregulation of *Spiribacter salinus* to the high salinity. Species of *Spiribacter* and taxonomically related species possess an unusual genetic organization of ectoine biosynthetic genes and notably they lacked the gene *ectD* for the ectoine hydroxylase. Experimental results showed that *Spiribacter* species are able to synthesize the compatible solute ectoine, showing a linear relationship between the synthesis of this compatible solute and the osmotic stress. *Spiribacter salinus* was also able to uptake glycine betaine from the environment and use it as a carbon and energy source.

INTEGRATING PROTEOMIC RESEARCH INTO DIFFERENT BACTERIAL SPECIES WITH GENOMIC DATA AND BIOINFORMATICS TOOLS

T. Santos[1,2], C. Marinho[1,2], P. Poeta[3,4], G. Igrejas[1,2,4]
[1]University of Trás-os-Montes and Alto Douro, Department of Genetics and Biotechnology, Vila Real, Portugal
[2]University of Trás-os-Montes and Alto Douro, Functional Genomics and Proteomics Unit, Vila Real, Portugal
[3]University of Trás-os-Montes and Alto Douro, Veterinary Science Department, Vila Real, Portugal
[4]Faculty of Science and Technology- University Nova of Lisbon, UCIBIO-REQUIMTE, Lisbon, Portugal

Backgrounds

Proteomes are dynamic, varying according to cell type, functional state and responses to stress, such as sensitivity or resistance to antibiotics. Antimicrobial resistance presents a challenge to scientists in the field of infectious diseases. The full knowledge of how antibiotic resistance is evolving and being transmitted between hosts in different ecosystems is taking on great importance. The Functional Genomics and Proteomics Unit has recently completed 10 years of proteomics research related to antimicrobial resistance. The evaluation of protein profiles related to antimicrobial resistance is a valid approach in the development of new therapeutic strategies.

Objectives

To clarify antibiotic resistance mechanisms of multiresistant bacterial strains by integrating genomics and proteomics in a multidisciplinary framework.

Methods

Five different bacterial species were studied by isolating 32 strains from clinical and wildlife samples. A total of 2770 protein spots were characterized through 2-DE and MALDI-TOF MS, and 392 proteins were identified by shotgun proteomics (LC-MS/MS).

Conclusions

Our group has evaluated ESBL-producing Escherichia coli strain protein profiles, compared proteomes of vancomycin-resistant Enterococcus spp. strains, analysed the whole proteome of quinolone-resistant Salmonella strains, analysed a sub-proteome of a methicillin-resistant Staphylococcus aureus strain and undertaken several other proteomic approaches. Our aim is to present the framework connecting this large protein database with other published results on antimicrobial resistance to elucidate the metabolic pathways that result in antimicrobial behaviour. The identification of protein determinants of resistance not only provides biomarkers for resistance to a particular drug, but also aids in the understanding of the mechanisms of antibiotic function and resistance.

NEW INSIGHTS INTO THE ROLE OF FURC IN NITROGEN METABOLISM AND HETEROCYST DIFFERENTIATION

C. Sarasa[1], E. Sevilla[1], E. Broset[1], M.F. Fillat[1], M.L. Peleato[1]
[1]Faculty of Sciences and Biocomputation and Complex Systems Physics Institute BIFI- University of Z aragoza,
Department of Biochemistry and Molecular and Cell Biology- Biochemical- Biophysical and Computati onal Biology Group - CSIC Joint Unit, Zaragoza, Spain

Backgrounds

FUR (ferric uptake regulator) proteins constitute a large family of transcriptional regulators that exhibit a wide range of functions. FurC from *Anabaena* sp. PCC 7120 participates in the modulation of other FUR paralogues and is related to the response to oxidative stress. Furthermore, overexpression of the master regulator of nitrogen control in cyanobacteria NtcA leads to an increase of the transcription of FurC, suggesting its relationship to nitrogen metabolism. NtcA also regulates several genes, such as *nblA, a* gene responsible for the degradation of phycobilisomes, an early response under nitrogen starvation.

Objectives

To gain more insights on the role of FurC in nitrogen metabolism in *Anabaena* sp. including heterocyst differenciation.

Methods

Transcriptional analysis were performed using real-time PCR in the *Anabaena* sp. PCC 7120 wild type strain and the FurC-overexpressing mutant EB2770C, In order to determine a direct interaction between FurC and the promoter regions, DNA-protein binding assays (EMSA) were performed. Bright-field microscopy was used to determine the frecuency of heterocysts under nitrogen starvation.

Conclusions

Transcriptional analysis combined with EMSA indicated that FurC is either directly or indirectly involved in the regulation of several key genes such as *ntcA* and *nblA*. In addition, the *furC*-overexpressing mutant was unable to differenciate heterocysts under nitrogen deficiency. These results suggest the existence of a cross-regulation between NtcA and FurC and point to FurC as a transcriptional regulator involved in nitrogen metabolism in cyanobacteria.

Physiology / Biochemistry / Molecular Microbiology - Part III

TRANSCRIPITONAL ANALISIS OF Γ-LINDANE INDUCED CHANGES IN MICROCYSTIS AERUGINOSA PCC7806 AND ANABAENA PCC7120

C. Sarasa[1], E. Sevilla[1], C. Castro[1], M.F. Fillat[1], M.L. Peleato[1]
[1]Faculty of Sciences and Biocomputation and Complex Systems Physics Institute BIFI- University of Z aragoza,
Department of Biochemistry and Molecular and Cell Biology- Biochemical- Biophysical and Computati onal Biology Group - CSIC Joint Unit, Zaragoza, Spain

Backgrounds

Cyanobacteria are organisms with an outstanding capacity to adapt and survive in extreme or highly degraded environments. Their metabolic plasticity includes the synthesis of a high level of potentially toxic secondary metabolites such cyanotoxins that cause serious health and environmental problems. Cyanobacteria are able to tolerate and even metabolize moderate doses of organochlorines pesticides, such as lindane (γ-hexachlorocychlohexane), one of the most persistent and used in recent decades. Previous work showed that *Microcystis aeruginosa* PCC7806 and *Anabaena* PCC7120 degrades lindane. While degradation routes of lindane are defined in *Sphingomonas*, in cyanobacteria remain unknown.

Objectives

Elucidate the genes involved in cyanobacteria in lindane degradative pathway, as well in its regulation.

Methods

In silico analysis of both *Microcystis aeruginosa* PCC7806 and *Anabaena* PCC7120 strains genomic sequences to identify homologies with the *lin* operon from *Sphingomonas.* Transcriptional analysis were performed using real-time PCR.

Conclusions

Transcripcional analysis of genes homologs of *lin* operon has been performed in *Microcystis* grown in the presence of lindane and in the *Anabaena furC*-overexpressing strain. Also, genes involved in the oxidative stress response and implicated in potential transcriptional regulation has been analysed. Among other changes, the presence of γ-lindane in the culture media induces *linE* expression as well as *prxA* gene transcription in *M. aeruginosa*. *Anabaena furC*-overexpression mutant showed a greater tolerance to γ-lindane, with a growth of approximately 90% respect to the control without lindane in all concentrations tested while the wildtype is about 75%. Transcriptional analysis of *lin* operon genes in *furC*-overexpression mutant will be presented.

Physiology / Biochemistry / Molecular Microbiology - Part III

ADAPTATION OF B. MARMARENSIS SP NOV TO EXTREME ALKALINE CONDITIONS

F.E. Altinisik[1], D. Kazan[1], B. Sariyar Akbulut[1]
[1]Marmara University, Bioengineering, İstanbul, Turkey

Backgrounds

Bacillus marmarensis sp nov is an extreme obligate alkaliphile which can grow in a broad range of pH values between pH 8.0-12.5. Ability to grow at high pH values makes it a valuable microorganism since very few microorganisms can tolerate extreme alkaline conditions. This property may be used to by-pass sterilization processes in industrial applications, significantly lowering process costs.

Objectives

In the current study, the adaptation strategy of *B. marmarensis sp nov* to alkaline conditions was investigated using proteomic tools.

Methods

The organism was grown in nutrient broth (NB) medium. The final pH was adjusted to 9.8 or 10.6 with Na-sesquicarbonate solution. For extraction of total cellular proteins, cells were disrupted with MP Bio Fast Prep device. The proteome maps were obtained. Extracted proteins were treated protease inhibitor mix and nuclease mix. Then proteins were separated by 2-dimensional gel electrophoresis (2-DGE) using immobilized pH gradient (IPG) strips (17 cm and pH 3-6 gradient, Bio-Rad) in the first dimension and SDS-PAGE in the second dimension.

Conclusions

The obtained proteome maps showed significant changes in protein expression. Identification of the differentially expressed proteins will provide further clues on microbial alkaliphilic adaptation. This information could be used for manipulating other organisms for survival under alkaline conditions.

Funding Marmara University, Scientific Research Projects Committee (FEN-C-YLP-250816-0419) is gratefully acknowledged.

Physiology / Biochemistry / Molecular Microbiology - Part III

STREPTOMYCES WERRAENSIS: A PROMISING CANDIDATE TO PRODUCE FERULOYL ESTERASE

A.K. Scheu[1], *J. Soliveri de Carranza*[1], *J.L. Copa-Patiño*[1]
[1]*Universidad de Alcalá, Biomedicina y Biotecnología, Alcalá de Henares, Spain*

Backgrounds

Feruloyl esterase (FAE) is an enzyme capable of hydrolysing the ester bond that links phenolic acids, such as ferulic acid (FA), to polysaccharides. In Nature, this enzyme plays a key role in plant cell wall biodegradation. FAE also finds application in many biotechnological processes in industry.

Objectives

Study of the production, purification, sequencing, and glucose repression of a FAE produced by *Streptomyces*.

Methods

The fermentation process has been optimized using a strain of *S. werranesis*. The FAE present in the culture broth has been purified and the gen sequenced using reverse genetics. Finally, glucose repression of the FAE encoding gene has been studied by transcriptional analysis.
In the present work, a new isolate of *S. werraensis* was selected for its FAE activity and the initial culture conditions optimized to quadruplicate FAE production. Purification and sequencing of the FAE protein allowed to approach PCR amplification of its genomic DNA and to sequence the FAE encoding gene. RT-PCR of total RNA revealed no other co-transcribed genes downstream or upstream of the FAE gene. Furthermore, different culture conditions gave an insight into transcriptional repression of the gene by glucose.

Conclusions

S. werraensis produces a FAE, which achieves maximal yields within shortest incubation times using inexpensive carbon and nitrogen sources, showing activity on natural substrates but no dimerization of FA. *S. werraensis* is an interesting candidate for upscaling fermentation aimed on benefiting from both, the broad range of applications of the enzyme itself and the production of FA for further processing.

FIGHTING BURKHOLDERIA CENOCEPACIA THROUGH A NEW PROMISING BACTERICIDAL MOLECULE

V.C. Scoffone[1], A.S. Gislason[2], A.M. Hogan[2], L.R. Chiarelli[1], M.S. Stietz[2], A. Azzalin[3], V. Makarov[4], S.T. Cardona[2], G. Riccardi[1], S. Buroni[1]
[1]University of Pavia, Biology and Biotechnology, Pavia, Italy
[2]University of Manitoba, Department of Microbiology, Winnipeg, Canada
[3]Università di Pavia, Neurosurgery- Dipartimento di Scienze Clinico-Chirurgiche e Pediatriche- Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy
[4]Research Center of Biotechnology of the Russian Academy of Sciences, Bach Institute of Biochemistry, Moscow, Russia

Backgrounds

The respiratory tract of Cystic Fibrosis patient can be colonized by *Burkholderia cenocepacia*, a Gram-negative opportunistic bacterium characterized by a high level of antibiotic resistance. Exploration of molecular mechanisms essential for pathogen survival are essential to identify new molecular targets and new drugs for the treatment of these infections.

Objectives

We previously identified a new molecule belonging to the 2,1,3-benzothiadiazol-5-yl family (C109) effective against *Burkholderia cenocepacia* (MIC = 8 µg/ml). The compound is active against clinical isolates and other members of the Bcc, as well as against other Gram-negative and -positive bacteria. Our aims are the characterization of this molecule, the identification of its target and the elucidation of the related molecular mechanism.

Methods

By a chemogenomic approach, time-lapse fluorescence microscopy and biochemical assays the mechanism of action of C109 was shown to rely on the inhibition of the divisome machinery. Toxicity experiments carried out on CF epithelial bronchial cells revealed low toxicity of the compound.

Conclusions

In summary, we characterized the molecular mechanism of a new compound active against *B. cenocepacia*, identifying the cellular target as the bacterial divisome.
The final aim of our work is to characterize the *B. cenocepacia* divisome machineries and to develop C109 derivatives more effective. This could improve and extend CF patient lives fighting infections due to *B. cenocepacia*, paving the way for the development of new therapies.

Physiology / Biochemistry / Molecular Microbiology - Part III

AMINO ACID CATABOLISM OF THERMOANAEROBACTER AND CALDANAEROBACTER SPECIES

S. Scully[1], *J. Orlygsson*[1]
[1]*University of Akureyri, Natural Resource Science, Akureyri, Iceland*

Backgrounds

Thermoanaerobacter strains have been widely investigated for biofuel production from carbohydrates while proteins and amino acids catabolism have received less attention. Amino acid catabolism is challenging under anaerobic conditions unless hydrogen is removed. Recent reports have demonstrated that *Thermoanaerobacter* strains can degrade branched-chain amino acids (BCAAs) to a mixture of their corresponding fatty acids (BCFAs) and alcohols (BCOHs) when thiosulfate is present.

Objectives

The aim of the presented work to evaluate the ability of these genera to degrade amino acids and better understand the mechanisms dictating the observed end product ratios.

Methods

The type species of the genera of *Thermoanaerobacter* and *Caldanaerobacter*, were investigated in batch culture for each of the proteogenic amino acids with and without the addition of thiosulfate as an electron acceptor.

Conclusions

Some strains in the genus could utilize serine and threonine without the addition of thiosulfate with acetate and ethanol being the dominate products while BCFA/BCOH ratios from BCAA were highly dependent on species and substrate when thiosulfate was added. BCAA catabolism resulted mixtures of the corresponding BCOH (0.5-5 mM) and BCFA (3.5-15.5 mM) with partial substrate utilization being observed in some cases. Altering the liquid-gas phase ratio had an impact on end product ratios; in the case of *C. subterraneus* subsp*. yonseiensis,* increasing the L-G ratio from 1.00 to 5.88, the BCOH formation increased more than 5-fold (with thiosulfate) and less BCFA were produced. Preliminary results on pathway elucidation studies using enzymatic assays and ^{13}C NMR studies will also be presented.

Physiology / Biochemistry / Molecular Microbiology - Part III

EFFECT OF QUINONE CONCENTRATION ON MEMBRANE FLUIDITY IN LISTERIA MONOCYTOGENES ISOLATES FROM FOOD AT LOW TEMPERATURES

W. Seel[1], A. Lipski[1]
[1]Institut für Ernährungs- und Lebensmittelwissenschaften, Lebensmittelmikrobiologie und -hygiene, Bonn, Germany

Backgrounds

Listeria monocytogenes is well known as a food pathogen capable of growing at a broad temperature range, from 50 °C down to refrigerator temperatures. A key function in bacterial survival at low temperatures is their ability to adjust lipid composition in order to maintain membrane fluidity. In *L. monocytogenes* this is accomplished by modification of fatty acid chain length. Preliminary analyses showed different extent of fatty acid profile adaption for *L. monocytogenes* strains, which indicates the presence of a second adaptation mechanism.

Objectives

For eight *L. monocytogenes* isolates from food and two reference strains from culture collections (*L. monocytogenes* DSM 20600^T and ATCC 19115) the fatty acid profiles were analyzed as function of growth temperature (37°C versus 6°C). In addition the quinone concentrations were determined.

Methods

Membrane fluidity was analyzed *in vivo* by measuring generalized polarization and anisotropy with the fluorescent dyes laurdan and TMA-DPH, respectively.

Conclusions

In this study, 7 out of 10 strains showed a strong increase of the ai-15:0/ai-17:0 ratio up to 20-fold at low temperature and a slight decrease in quinone concentration. Three strains showed, contrary to expectations, only a small shift in ai-15:0/ai-17:0 ratio but an increased quinone content at 6 °C. These strains with quinone-enriched membranes exhibited a significantly different membrane fluidity characteristic with a more expanded phase transition zone in contrast to the strains with decreased quinone content. The broadening of the phase transition zone by increasing of non-fatty acid membrane lipids is discussed as an additional adaptation mechanism to temperature shifts for *Listeria monocytogenes* strains.

REACTIVE OXYGEN SPECIES-INDEPENDENT ANTIBACTERIAL ACTIVITY OF SILVER NANOPARTICLES THROUGH INNER MEMBRANE DYSFUNCTION ON THE GRAM-NEGATIVE BACTERIUM SALMONELLA ENTERICA SP. TYPHIMURIUM

M. Seong[1], *D.G. Lee*[1]
[1]*Kyungpook National University, School of life sciences, Daegu, Republic of Korea*

Backgrounds

Silver nanoparticles (AgNPs) are one of silver substance that has been used as an antibacterial agent in various fields. Although the antibacterial activity of AgNPs against gram negative bacteria have been studied previously, the mechanism of AgNPs against *S. typhimurium* remains unclarified.

Objectives

We revealed the mode of action of AgNPs against gram-negative bacterium *S. typhimurium* through activity of cell death related experiments at various concentrations.

Methods

To evaluate the inhibitory effects on AgNPs induced bacterial cell death, reactive oxygen species (ROS) accumulation were monitored various range of concentrations using H_2DCFDA. Cell viability and the cellular response to calcium ion signaling was measured after pretreatment with N-acetylcysteine (NAC). N-phenyl-1-naphthylamine assay and *O*-nitrophenyl-β-D-galactopyranoside assay measured outer membrane and inner membrane permeability respectively by spectrofluorophotometer.

Conclusions

AgNPs induces ROS-independent antibacterial activity which is most affected by inner membrane dysfunction on gram negative bacterium *S. typhimurium.*

SALT STRESS AFFECTS COMPLEMENTATION OF THE SOLUBLE CYTOSOLIC PYROPOSPHATASE OF YEAST BY FUNCTIONALLY DIFFERENT MEMBRANE-BOUND ION-TRANSLOCATING PYROPHOSPHATASES

J.R. Pérez-Castiñeira[1], J.M. Madroñal[1], A. Hernández[2], A. Serrano[1]
[1]Inst. de Bioquímica Vegetal y Fotosíntesis- CSIC-Univ. de Sevilla, Bioenergética del Fosfato, Sevilla, Spain
[2]Instituto de Ciências Biomédicas- Universidade de São Paulo, Depto. Parasitologia, 05508-000 São Paulo SP, Brazil

Backgrounds

Overexpression of the membrane-bound K^+-dependent H^+-translocating inorganic pyrophosphatase (H^+-PPase) from higher plants has been reported to alleviate the sensitivity towards NaCl in these organisms (PNAS USA 2001, 98:11444). This strategy had been initially tested in *Saccharomyces cerevisiae* (PNAS USA 1999, 96:1480), thus confirming this microorganism as a good model to study and test solutions to this and other stresses in plants.

Objectives

We have previously shown that membrane-bound PPases can functionally complement the cytosolic soluble pyrophosphatase (Ipp1p) of the yeast *Saccharomyces cerevisiae* (Biochem J 2010, 42:147; PNAS USA 2002, 99:15914). Here, the capacity of the former proteins to complement Ipp1p under salt-stress has been studied using several yeast strains with different sensitivities towards NaCl.

Methods

Three membrane-bound PPases were tested: the vacuolar K^+-dependent H^+-PPase AVP1 from the higher plant *Arabidopsis thaliana* (AVP1), the K^+-dependent Na^+-PPase from the halotolerant methanogenic archaea *Methanosarzina mazei* (MVP) and the K^+-independent H^+-PPase from the photosynthetic proteobacterium *Rhodospirillum rubrum*. The archaeal Na^+-PPase consistently supported yeast growth more efficiently than both plant and bacterial H^+-PPases under salt stress. *In vitro* studies showed that both hydrolytic and H^+-pumping activities of AVP1 are remarkably sensitive to Na^+. Moreover, comparative studies of sensitivity of PPase activity to Na^+ showed that the archaeal Na^+-PPase was expectedly less sensitive to this cation than its H^+-pumping counterparts.

Conclusions

We propose that membrane-bound PPases may be direct targets of Na^+, consequently, the strategy of using these proteins in order to improve salt-tolerance in plants might be significantly improved if Na^+-PPases are utilised for this purpose.

WIDE OCCURRENCE AND PHYSIOLOGICAL RELEVANCE OF SODIUM-PUMPING PYROPHOSPHATASES IN MARINE PROTISTS

J.M. Madroñal[1], J.R. Pérez-Castiñeira[1], A. Serrano[1]
[1]Inst. de Bioquímica Vegetal y Fotosíntesis- CSIC-Univ. de Sevilla, Bioenergética del Fosfato, Sevilla, Spain

Backgrounds

Ion (H^+/Na^+)-translocating pyrophosphatases (m-PPases) are integral proteins of prokaryotic cellular and eukaryotic vacuo-lysosomal membranes coupling hydrolysis of energy-rich pyrophosphate, a ubiquitous subproduct of anabolism, to the generation of electrochemical gradients. Many protistan genomes have set of genes encoding functionally diverse m-PPase paralogs.

Objectives

We aim to identify and functionally characterize the putative Na^+-translocating m-PPases (Na^+-PPases) encoded by the genomes of phylogenetically diverse marine microalgae (prasinophytes, stramenopiles, haptophytes, chlorarachniophytes, rhodophytes, dinophytes).

Methods

Our studies with the diatom *Phaeodactylum tricornutum*, the prasinophyte *Ostreococcus tauri* and the rhodophyte *Porphyridium purpureum* indicate that do contain functional Na^+-PPases which are less sensitive to ionic stress than their H^+-pumping counterparts. An active role of Na^+-PPases in ion homeostasis of marine protists is consistent with the abundance of their transcripts in EST libraries and the Marine Microbial Eukaryotic Transcriptome Sequencing Project (MMETS). The subcellular location of microalgal Na^+-PPases is of paramount importance to discern if they are either the first primary sodium pumps found so far in endomembranes or the only sodium pumps of the eukaryotic cell membrane able to use a substrate alternative to ATP.

Conclusions

These m-PPases are the first Na^+-PPases reported in eukaryotes, and they probably arose via HGT given its remarkable amino acid sequence similarity to their prokaryotic orthologs of bacteria and archaea. Moreover, their wide distribution among marine protists suggests an important physiological role for these molecular pumps in saline habitats. Eukaryotic Na^+-PPases should play a pivotal role in cations homeostasis of marine protists, which are poikilosmotic organisms that use sodium-dependent co-transporters for nutrients uptake.

FURC OVEREXPRESSION LEADS TO VARIATIONS IN THE COMPOSITION AND EFFICIENCY OF PHOTOSYNTHETIC APPARATUS IN ANABAENA PCC7120

E. Sevilla[1], C. Sarasa[1], E. Broset[1], R. Cases[2], M.L. Peleato[1], M.F. Fillat[1]
[1]Faculty of Sciences and Biocomputation and Complex Systems Physics Institute BIFI- University of Z aragoza,
Department of Biochemistry and Molecular and Cell Biology- Biochemical- Biophysical and Computati onal Biology Group - CSIC Joint Unit, Zaragoza, Spain
[2]ICMA, Functional Organic Materials, Zaragoza, Spain

Backgrounds

Ferric uptake regulator (Fur) proteins are transcriptional regulators that play key roles in many prokariots. *Anabaena* PCC 7120 contains in its genome three paralogs of Fur proteins whose genes are called *all1691* (*furA*), *all2473* (*furB*) and *alr0954* (*furC*). Until now, little is known about the role of FurC in cyanobacteria.

Objectives

This work was focused on the study of the functions of FurC protein in *Anabaena* PCC7120. In order to achieve this goal, an overexpression mutant of FurC protein was constructed in *Anabaena* PCC7120 rendering the EB2770 strain.

Methods

Scanning electron microscopy (SEM) studies and growth curves were performed comparing the EB2770 and the wild type strains. Photosynthetic pigments were also determined. Whole-cell absorbance spectra and the fluorescence emission spectra at 77K were carried out in order to compare the composition and efficiency of photosynthetic apparatus in both strains. Finally, pull down experiments were performed with purified FurC protein to identify proteins that could interact with this protein.

Conclusions

SEM studies revealed changes in size, shape and roughness of the EB2770 cells. Pigment content and yield of energy transfer between the phycobilisome and the photosystem I and II was notably altered in the EB2770 mutant. Pull down results indicated that two linker proteins of phycobilisome interacted with FurC protein. These results suggest that FurC has a role regulating the final composition of photosynthetic pigments and therefore influencing the yield of energy transfer between the phycobilisome and the photosystem I and II although the detailed mechanism remains unknown.

AMINO ACID SUBSTITUTION OF ACRB CONTRIBUTES TO AZITHROMYCIN RESISTANCE IN HAEMOPHILUS INFLUENZAE

S. Seyama[1], T. Wajima[1], H. Nakaminami[1], N. Noguchi[1]
[1]Tokyo University of Pharmacy and Life Sciences, Microbiology, Tokyo, Japan

Backgrounds

Macrolides, including azithromycin (AZM) and clarithromycin (CAM), can be used as alternatives of β-lactams for the treatment of *Haemophilus influenzae* infections. However, CAM-resistant *H. influenzae* strains have been isolated frequently in Japan. We showed that a nonsense mutation in the negative regulator gene *acrR* of these isolates resulted in overexpression of chromosomal efflux pump AcrAB, which is the underlying mechanism of the resistance. A nonsense mutation of *acrR* conferred resistance to CAM but not AZM.

Objectives

In this study, we isolated AZM-resistant strains and analysed the mechanisms underlying AZM resistance.

Methods

A total of 155 *H. influenzae* isolated during 2010–2012 were used in this study. The *acr* operon of these isolates was analysed by DNA sequencing. The transcription levels of chromosomal multidrug efflux pumps were evaluated by semiquantitative reverse-transcription PCR. A transformation experiment was performed by electroporation using *H. influenzae* Rd. Antimicrobial susceptibilities of the isolates were tested using the broth-dilution method.

Conclusions

A strain (2012-42) resistant to both AZM and CAM was found by antimicrobial susceptibility testing. An elevated transcript level of *acrB* resulting from the nonsense mutation in *acrR* was observed in the strain 2012-42, as well as in the strain 2011-70 that was resistant to CAM but not AZM. We found by sequencing of the *acr* region that the strain 2012-42 had a specific amino acid substitution Arg327Ser in AcrB. To confirm that the amino acid substitution in AcrB contributes to AZM resistance, the *acr* region of the strain 2012-42 was introduced into *H. influenzae* Rd. The MICs of AZM for the transformants ($Rd_{2012\text{-}42}$) increased to the same level as that of the donor strain.
Our findings strongly suggested that the 327th amino acid substitution of AcrB contributes to AZM resistance, in addition to nonsense mutation in *acrR*.

ANTIMICROBIAL RESISTANCE AND MOLECULAR PREVALENCE OF EFFLUX PUMP ENCODING GENES (ADER, ADEB) IN ACINETOBACTER BAUMANNII STRAINS ISOLATED FROM HOSPITALIZED PATIENTS IN TEHRAN

S. Shabani[1], P. Saffarian[2], R. Mirnejad[3]
[1]Tehran University of Medical Sciences school of Nursing and Midwifery, science, Tehran, Iran
[2]Tehran Medical Branch- Islamic Azad University- Tehran- Iran., Microbiology, Tehran, Iran
[3]Baqiyatallah University of Medical Sciences, Molecular Biology Research Center, Tehran, Iran

Backgrounds

Acinetobacter baumannii causes variety of nosocomial infections which often lead to death. Because of wide range drug resistance amongst A. baumannii strains, it becomes a problem in clinical treatments. One of the main factors causing resistance in A. baumannii strains is the efflux pump.

Objectives

The aim of this study was to determine the prevalence of adeR and adeB genes encoding efflux pump between A. baumannii strains isolated from hospitalized patients in Tehran.

Methods

300 clinical samples were collected from some main hospitals in Tehran. After strain determination through biochemical and culture method, antimicrobial resistance of A. baumannii isolates was evaluated with dick diffusion agar. Finally, the presence of adeR and adeB genes were examined using molecular method, PCR.

Conclusions

Out of 300 clinical samples, 100 A. baumannii isolates were determined. 70% of A. baumannii isolates showed resistance against three or more antibiotics. Moreover, molecular method assessment revealed that the prevalence of either adeR or adeB genes among antibiotic resistance A. baumannii strains is 96%.
According to results of this study, the efflux pump encoding genes (adeR and adeB) are active in between antibiotic resistance A. baumannii strains.

ATP DEPENDENT PERSISTER FORMATION IN ESCHERICHIA COLI

Y. Shan[1], *K. Lewis*[1]
[1]*Northeastern University, Antimicrobial Discovery Center, Boston, USA*

Backgrounds

Persisters are a subpopulation of cells that are tolerant to antibiotics. Persisters have been shown to be responsible for recalcitrance of chronic infections. In *Escherichia coli,* one widely-accepted model of persister formation holds that stochastic accumulation of ppGpp causes activation of the Lon protease that degrades antitoxins; active toxins then inhibit translation, resulting in dormant, drug-tolerant persisters.

Objectives

In this study we systematically examined induction of mRNA interferase encoding toxin-antitoxin (TA) systems upon stress. We found that various stresses induce mRNA interferase encoding TA expression, however, induction of these TAs does not necessarily increase persisters. The 16S ribosomal RNA promoter *rrnB* P1 was proposed to be a persister reporter and an indicator of toxin activation. We investigated the role of toxin activation in persister formation.

Methods

Using FACS, we confirmed the enrichment for persisters in *rrnB* P1-*gfp* dim cells after antibiotic treatment, however, this is independent of toxin-antitoxins. *rrnB* P1 is co-regulated by ppGpp and ATP. We show that *rrnB* P1 can report persisters independent of ppGpp, suggesting that *rrnB* P1 is a persister marker responding to ATP.

Conclusions

Cells surviving antibiotic treatment exhibit lower intracellular ATP levels. Consistent with these findings, decreasing the level of ATP by arsenate causes drug tolerance. Lowering ATP slows translation and prevents formation of DNA double strand breaks upon fluoroquinolone treatment, indicating that decreased antibiotic target activity is the reason for persister formation. We conclude that variation of ATP levels leads to persister formation through decreasing antibiotic target activity.

Physiology / Biochemistry / Molecular Microbiology - Part III

INVESTIGATION OF ESCHERICHIA COLI PERSISTERS TOLERANT TO B-LACTAMS USING TN-SEQ

Y. Shan[1], *K. Lewis*[1]
[1]*Northeastern University, Antimicrobial Discovery Center, Boston, USA*

Backgrounds

Persister are dormant variants that form a subpopulation of drug tolerant cells largely responsible for recalcitrance of chronic infections. In *E. coli*, level of persisters tolerant to a β-lactam antibiotic increase dramatically upon reaching stationary phase due to a cessation of cell growth, however, the molecular mechanism of this phenotype is unknown.

Objectives

In this study, we applied transposon sequencing (Tn-Seq) to identify mutants with a low level of persisters tolerant to ampicillin in stationary phase.

Methods

We utilized a highly-saturated transposon library and exposed a stationary phase culture to a high dose of ampicillin.

Conclusions

We identified 28 mutants with significantly decreased survival after ampicillin treatment. One of the high hits is *murR*, a negative regulator for peptidoglycan recycling. Deletion of *murR* may decrease stationary phase survival by promoting cell wall remodeling in stationary phase, and thus serves as a positive control for the screen. We also identified five genes encoding enzymes involved in central metabolism and one gene encoding a periplasmic peptidase. These findings demonstrate that central metabolism reprogramming plays an important role in the complete tolerance of stationary phase *E. coli* to β-lactams. On-going work aims at elucidating the metabolic switch involved in the process and will lead to a comprehensive understanding of β-lactam tolerance.

UNSATURATATION OF MEMBRANE LIPIDS AND THEIR COMPOSITION OF YEAST WICKERHAMOMYCES ANOMALUS B59 A POSSIBLE KEY FACTOR IN RESPONSE TO FURFURAL STRESS

S.C. Sharma[1]
[1]*Panjab University, Biochemistry, Chandigarh, India*

Backgrounds

Most important biofuel at world level is ethanol. The latter derived from agricultural lignocellulosic residues is a promising alternative to fossil fuel for energy based needs Plasma membrane is the primary target of various stresses. Furfural is present in post harvest lignocellulosic materials after acid hydrolysis of xylan and has been shown to exert an inhibitory effect in the process of fermentation.

Objectives

To analyse lipid changes in response to furfural stress; a key bye product of lignocellulosic acid hydrolysates in yeast cells.

Methods

Isolated strain of Wickerhamomyces was grown in YPD medium with/without furfural 10mM. Lipids extracted by Bligh& Dyer; phospholipids;sterols; glycolipids; by Ames(1966) ; Sperry& Webb: Dubois(1950) procedures fatty acids by GCMS respectively. Individual phospholipids were separated by 2DTLC. Fluidity was determined by DPH and TMA-DPH probes

Conclusions

The amount of phospholipids decreased while that of glycolipids and total sterols increased. The increase in free sterol: phospholipid (molar ratio) and glycolipids : phospholipids ratio showed decrease in membrane fluidity. Among the individual phospholipids: phosphatidylethanolamine and phosphatidylcholine levels increased while that of phosphatidylserine showed an opposite trend. No change was observed in the amount of phosphatidylinositol. The ratio of unsaturated to saturated fatty acids decreased and that of short chain: long chain showed about 40% increase. The results showed importance and implications of unsaturated lipids molecules and thereby membrane fluidity changes not only in the presence of ethanol but to exposure to furfural also.

Department of Veterinary Biosciences- Division of Microbiology and Epidemiology, Helsinki, Finland
[4]Institute of Biotechnology- University of Helsinki, DNA Sequencing and Genomics Laboratory, Helsinki, Finland
[5]University of Helsinki,
RPU Immunobiology- Department of Bacteriology and Immunology- Faculty of Medicine, Helsinki, Finland

Backgrounds

Eubacterium hallii is an anaerobic butyrate-producing bacterium commonly found in the human gut and part of its core microbiome (*Shetty et al. FEMS Microbiol Rev 2017 in press*). Oral administration of *E. hallii* strain L2-7 has been found to improve insulin sensitivity in mice models and hence this is a candidate for next generation microbiome therapeutics (*Udayappan et al. NPJ Biofilms & Microbiome 2016, 16009*).

Objectives

To improve our understanding of the physiology and functional capabilities of *E. hallii* strain L2-7.

Methods

The genome was sequenced using PacBio RII and HiSeq2000 instruments, and its proteome was obtained by nLC–MS/MS with a Proxeon EASY nLC and a LTQ-Orbitrap XL mass spectrometer.

Conclusions

The 3.5 Mb-genome of *E. hallii* strain L2-7 is predicted to encode 3226 proteins and 89 RNAs. The latter includes eight 16S rRNA genes with a high level of sequence diversity that are widely present in the human HMP gut database. Proteome analysis showed genes involved in butyrate production *via* the acetyl-CoA pathway to be highly expressed, with the second most dominant protein being butyryl-CoA dehydrogenase. In addition, the canonical proteins involved in a bacterial microcompartment were found to be present in high amounts, which is compatible with the experimental detection of vitamin B12 and several pathways with reactive metabolites where this cofactor plays a role. Comparative analysis of genomes and proteomes of closely related *Eubacterium* species will be presented as to identify unique features of the strain L2-7 and its relevance for human health.

CYANOBACTERIAL BIOACTIVE COMPOUNDS FROM BRAZILIAN UNDER-EXPLORED ENVIRONMENTS

T. Shishido Joutsen[1], J. Jokela[2], M. Wahlsten[3], D.P. Fewer[3], M.F. Fiore[4], L. Herfindal[5], P. Permi[6], K. Sivonen[3]
[1], Espoo, Finland
[2]University of Helsinki, Food and Environmental Sciences, Helsinki, Finland
[3]University of Helsinki, Department of Food and Environmental Sciences, Helsinki, Finland
[4]University of São Paulo, Center for Nuclear Energy in Agriculture, Piracicaba, Brazil
[5]University of Bergen, Department of Clinical Science and Centre for Pharmacy, Bergen, Norway
[6]University of Jyväskylä,
Department of Chemistry- Department of Biological and Environmental Science, Jyväskylä, Finland

Backgrounds

Brazil has a vast territory in South America which comprises different types of biomes, including Amazon, Caatinga, Pantanal and Cerrado. These diverse environments are characterized by high biodiversity. Cyanobacteria are photosynthetic prokaryotes found in diverse habitats.

Objectives

In this study, we analyzed cyanobacterial isolates from Brazilian under-explored environments to improve the knowledge of antimicrobial and anticancer compounds produced by these strains.

Methods

A total of 62 cyanobacterial isolates were tested against opportunistic fungi and bacteria (e.g. *Candida albicans*, *Staphylococcus aureus* and *Salmonella typhimurium*) and leukemia (MOLM-13) and normal (NRK) cell lines. Most of the cell extracts had anticancer activity (63%), followed by antibacterial (26%) and antifungal (11%) activities. Known bioactive compounds were detected using LC-MS and Q-TOF in 12 of the studied strains, including microcystins, hassallidins and puwainaphycins. Unknown bioactive compounds responsible for the observed activities are currently being isolated from crude methanol extract by HPLC. Preliminary results indicate that CENA513 and CENA514 produce a bacteriostatic compound and a bioactive compound with potent anticancer activity. CENA71, CENA72 and CENA302 produce hydrophobic antibacterial compound(s). CENA69 showed to produce a very potent cytotoxic compound. Further analysis will be performed to isolate and chemically characterize the bioactive compounds. We have sequenced the genomes of two strains and the genome mining is aiding in the discovery of the yet to known bioactive compounds.

Conclusions

This study will improve the knowledge about the genetic pathway involved in the compounds synthesis and the metabolites produced by cyanobacteria isolated from Brazilian environments.

Physiology / Biochemistry / Molecular Microbiology - Part III

THE PUTATIVE TYPE I SECRETION SYSTEM HGDB/HGDC IS ESSENTIAL FOR PROPER FUNCTIONALITY OF ANABAENA PCC7120 HETEROCYSTS

D. Shvarev[1], *C. Nishi*[1], *L. Wörmer*[2], *I. Maldener*[1]
[1]*Eberhard Karls University of Tübingen, IMIT Organismic Interactions, Tübingen, Germany*
[2]*University of Bremen,*
Organismic Geochemistry- MARUM – Center for Marine Environmental Sciences, Bremen, Germany

Backgrounds

The filamentous cyanobacterium *Anabaena* PCC7120 develops specific cells, called heterocysts, which arise in filaments during nitrogen starvation. The heterocysts fix atmospheric nitrogen and supply vegetative cells with nitrogen compounds. They create a micro-oxic environment to protect the nitrogenase complex from external oxygen by deposing a special cell envelope, which consists of two layers: the thick polysaccharide layer and the heterocyst specific glycolipid (HGL) layer. Previously we showed that *Anabaena* PCC7120 uses a specific type I secretion system (T1SS), for the export of HGLs into the cell envelope (Staron et al., 2011). This transporter comprises four different oligomeric proteins: the outer-membrane protein TolC/HgdD, the membrane fusion protein DevB, the inner membrane factor DevC and the ATPase DevA.

Objectives

To investigate a possible role of other T1SS in heterocyst differentiation we performed a mutational analysis in genes, which are homologous to genes of several subunits of the DevBCA complex. In this work we focused on functions of HgdB (*all5347*) and HgdC (*all5346*), which are homologues to DevB and DevC*,* respectively (see also Fan et al., 2005).

Methods

We mutated the *hgdB*- gene and re-investigated the phenotype using light and fluorescent microscopy, TEM and various analytical chromatographical methods.

Conclusions

The mutant in this T1SS is not able to form mature heterocysts and to grow on N_2 as a sole nitrogen source. We will present and discuss data on aberrant envelope formation, nitrogen fixation and the localization of the HgdC protein by GFP fusion and will show that HgdB/D is important for heterocyst HGL formation in *Anabaena*.

HOW DO BACTERIA MAKE PROTEINS? UNDERSTANDING THE BIOGENESIS OF C-TYPE CYTOCHROMES

A. Silva[1], A. Veríssimo[2], F. Daldal[3], R.O. Louro[1]
[1]Instituto de Tecnologia Química e Biológica António Xavier, Biochemestry, Oeiras, Portugal
[2]University of Texas, Biochemestry, El Paso, USA
[3]University of Pennsylvania, Biology, Philadelphia, USA

Backgrounds

Cytochromes-*c* are essential proteins for living organisms across all domains of life. These proteins are ubiquitous and play key roles in important biological processes, from electron transfer to apoptosis. These proteins are also involved in several bioenergetic processes, having crucial importance in bioremediation and biotechnological applications. *C*-type cytochromes are metalloproteins that contain heme(s) covalently bound to the polypeptide chain via 2 thioether bonds to cysteine side chains. Given the importance of this class of proteins, the process that leads to their formation in nature is equally important. The covalent attachment of heme and subsequent folding of the protein requires a dedicated maturation machinery. Despite the recognized biological importance and biotecnological applications of *c*-type cytochromes, this process is far from fully understood.

Several maturation systems have been described, including the Cytochrome-*c* maturation (Ccm) System I. This system is present in most Gram-negative bacteria, including the genus *Escherichia*, *Vibrio* and *Shewanella*. These are specially important as model organisms, pathogens and electroactive bacteria.

Objectives

The aim of this work is to characterize the cytochrome-*c* maturation system I (Ccm system).

Methods

Using isotopic labelling, NMR approaches and site directed mutagenesis, we aim to characterize protein interactions and recognition mechanisms between the substrates and components of System I to understand the functioning of this system.

Conclusions

This work will characterize how the apocytochrome *c* chaperone CcmI, recognizes different classes of substrates (apocytochromes *c*). This will provide unique insights on the nature of these interactions and structure of the interacting domains providing a full understanding on cytochrome biogenesis in bacteria.

MOLECULAR EPIDEMIOLOGY OF MDR ACINETOBACTER BAUMANNII FROM THREE TERTIARY CARE HOSPITALS FROM DIFFERENT REGIONS OF INDIA

L. Singhal[1], S. Kumar[2], U. Devi[3], V. Gautam[2], J. Chander[1], P. Ray[2]
[1]Government Medical College & Hospital, Microbiology, Chandigarh, India
[2]Post Graduate Institute of Medical Education & Research, Medical Microbiology, Chandigarh, India
[3]Regional Medical Research Centre, Microbiology, Dibrugarh, India

Backgrounds

Acinetobacter baumannii is a multidrug-resistant (MDR) nosocomial pathogen associated with healthcare-associated infections (HAIs). The organism's ability to survive in different environment for a prolonged period of time and its resistance to desiccation & disinfectants make it difficult to eradicate. Circulation among hospitalized patients through hospital settings is of particular concern in development of MDR *A. baumannii*.

Objectives

We studied the molecular epidemiology of clinical isolates of MDR *A. baumannii* from three major hospitals of India.

Methods

A total of 20 isolates of *A. baumannii* will be included in this study. 8 isolates each from two hospitals of North India, and 4 isolates from a North-East India will be subjected to MLST typing. *A. baumannii* species were identified with MALDI-TOF. Antimicrobial susceptibility for a set of antimicrobials was tested using disc diffusion method. MLST^{OX} was performed for isolates from North India and MLST of North-East India is being processed. From one Hospital (GMCH), out of 8 isolates, 3 isolates represented a dominating ST-231 belonging to International Clone-I (IC-I) and 4 were assigned new STs (1387, 1388, 1389 & 1390). Another hospital (PGIMER), showed 3 new STs (859, 1050 & 1051) and one isolate (ST 447) found belonging to IC-II.

Conclusions

In India, this is the first study of its kind, where we have reported 2 International Clones circulating in two North Indian hospitals. MLST results of third centre will have the better epidemiology of this bug. Another large-scale study would promisingly give a better picture of hospital-wide spread of different clones of *A. baumannii*.

Physiology / Biochemistry / Molecular Microbiology - Part III

IDENTIFICATION OF A NOVEL GENE INVOLVED IN BETA-LACTAM RESISTANCE IN STAPHYLOCOCCUS AUREUS

W. Sirisarn[1], *G. Xia*[1]
[1]*Division of Infection- Immunity and Respiratory Medicine,*
Faculty of Biology- Medicine and Health- The University of Manchester, Manchester, United Kingdom

Backgrounds

Methicillin-resistant *Staphylococcus aureus* (MRSA) remains a serious issue in clinical environments around the world. Beta-lactam resistance in MRSA depends on the transpeptidase activity of low-affinity penicillin binding protein, PBP2A, which is encoded by the *mecA* gene. In addition, resistance also requires certain 'auxiliary factors' such as *fmtA, tagO* and others.

Objectives

we aim to identify and characterise novel auxiliary factor genes, which help understand beta-lactam resistance mechanisms, and may provide new strategies to combat MRSA infections.

Methods

Using transposon mutagenesis, we identified a novel auxiliary factor, *auxB*. *auxB* mutants with different MRSA genetic backgrounds were constructed by phage transduction and allelic exchange. The beta-lactam susceptibility of these mutants were analysed by measuring the MIC of various beta-lactam antibiotics.

Conclusions

Transposon mutation or deletion of *auxB* causes a 2-32 fold reduction in the minimum inhibitory concentration (MIC) of cefoxitin, oxacililin, ceftazidime, cephradine and meropenem, and complementation restores these MICs back to the wild type level, suggesting auxB is required for beta-lactam resistance in MRSA.

Physiology / Biochemistry / Molecular Microbiology - Part III

MARINOBACTER HYDROCARBONOCLASTICUS SP17 BIOFILM FORMATION ON HYDROPHOBIC ORGANIC CARBON INVOLVES SIGMA 54-MEDIATED TRANSCRIPTIONAL REGULATION OF PUTATIVE EXPORTED PROTEINS

P. Sivadon[1], *I. Guefrachi*[1], *F. Hakil*[1], *L. Urios*[1], *R. Grimaud*[1]
[1]*IPREM UMR CNRS 5254, Microbial Ecology, Pau Cedex, France*

Backgrounds

Marinobacter hydrocarbonoclasticus SP17 (*Mh*SP17) degrades a wide range of hydrophobic organic carbon (HOC) through an oleolytic biofilm formed at hydrocarbon/lipid-water interfaces. The matrix of this oleolytic biofilm is mainly composed of proteins, some of which are being involved in the assimilation of hydrophobic substrates.

Objectives

To identify and characterize exported proteins that play in early steps of oleolytic biofilm formation and hydrocarbon/lipid assimilation.

Methods

Whole genome transcription analyses were conducted on early stages of biofilm formation on metabolizable HOCs (hexadecane or triolein) and on heptamethylnonane, a non metabolizable isomer of hexadecane. Although being able to adhere to the heptamethylnonane/water interface, *Mh*SP17 does not develop micro-colonies and subsequent biofilm, even in the presence of acetate as supplemental carbon source. Functional genomics was coupled to physiological studies in order to test the involvement of differentially expressed genes coding putative exported proteins on oleolytic biofilm formation.

Conclusions

Several genes expressing proteins with a common putative export signal showed similar overexpression patterns on metabolizable HOCs. Mutagenesis of the corresponding protein export system resulted in reduced oleolytic biofilm growth. These genes also carry a sigma 54-RpoN binding sequence in their promoter sequences and we could show that RpoN regulates their expression. Consistently, *rpoN* mutant exhibited severe reduction in cell adhesion to HOC/water interface and in oleolytic biofilm growth. Consequently, the capacity of *Marinobacter hydrocarbonoclasticus* SP17 to form oleolytic biofilms on hydrocarbons and lipids may involve the export of proteins of which expression is under the control of RpoN transcription factor.

FEMS7-1055
Physiology / Biochemistry / Molecular Microbiology - Part III

THE IDENTIFICATION OF A NOVEL REGULATORY NETWORK BETWEEN VIRULENCE REGULATOR YMOA AND QUORUM SENSING IN YERSINIA PSEUDOTUBERCULOSIS

A. Slater[1], J. Purves[2], P. Williams[1], S. Atkinson[1]
[1]The University of Nottingham, Centre for Biomolecular Sciences, Nottingham, United Kingdom
[2]The University of Nottingham, Department of Genetics, Leicester, United Kingdom

Backgrounds

Yersinia pseudotuberculosis is an enteropathogen colonising both the mammalian host and the food/water environment. To facilitate this biphasic lifestyle, thermo-dependent regulation, driven by key transcriptional regulators, governs the expression of genes on the 70 KB virulence plasmid (pYV), which is responsible for the production of a Type 3 Secretion system. One of these regulators is the histone-like protein YmoA that represses the expression of T3S-related genes on pYV below 37^{o}C.

Intercellular signaling, usually referred to as quorum sensing, is also known to play a role in the regulation of pYV, and in gram negatives, involves the production and sensing of N-acyl homoserine lactone (AHL) signal molecules through *luxRI* homologues: *ypsR/I* and *ytbR/I*.

Objectives

Considering the relationship between QS and T3S, we sought to investigate whether there is a relationship between the *Y. pseudotuberculosis* quorum sensing systems and YmoA.

Methods

To investigate this relationship at the transcriptional level, the *ymoA* promoter region was fused to the *luxCDABE* operon and introduced as a single copy into the *Y. pseudotuberculosis* chromosome. *ymoA* expression was then examined as a function of temperature and growth phase in four quorum sensing mutants by recording bioluminescence throughout growth at 22^{o}C and 37^{o}C.

Conclusions

The expression of *ymoA* was significantly reduced in the mutant background of all four quorum sensing genes at both 22^{o}C and 37^{o}C suggesting a role for quorum sensing as a positive regulator of *ymoA*, thus confirming a relationship between quorum sensing and as a key regulator of virulence.

LANTIBIOTICS AS AN ANTIBIOTIC ALTERNATIVE: CAN WE BYPASS THE NATURAL RESISTANCE SYSTEMS IN HUMAN PATHOGENS?

S. Smits[1]
[1]*Heinrich-Heine Universität Düsseldorf, Institue for biochemistry I, Duesseldorf, Germany*

Backgrounds

Antibiotic resistance is a major focus of medical research throughout the world. Lantibiotics are small antimicrobial peptides possessing high potency and specificity, and thus, are considered to be an excellent and novel candidate as an alternative to antibiotics. Their high activity is reflected by the observation that already 2-4 nM of the lantibiotic nisin is enough to kill a *L. lactis* culture. However, some human pathogenic strains are inherently resistant against these lantibiotics due to the up-regulation of a gene cluster (1). We focused on this gene cluster from the human pathogenic bacteria S*. agalactiae* that confers resistance against nisin. This gene cluster encodes for 4 functional proteins: the membrane-anchored nisin resistance protein *Sa*NSR, the ABC transporter *Sa*NsrFP and the two-component system comprising of *Sa*NsrR and *Sa*NsrK (2).

*Sa*NSR represents a belongs to the C-terminal specific protease superfamily, which cleaves the substrate nisin, thereby, lowering its antimicrobial activity. We solved the high-resolution 2.1 A X-ray structure of *Sa*NSR (3). Using mutagenesis *in vivo* assays and molecular modeling, we were able to identify that *Sa*NSR recognizes exclusively the C-terminus of nisin.
The ABC transporter *Sa*NsrFP belongs to the BceAB superfamily of ABC transporter and has a brought substrate specificity recognizing several different lantibiotics. It removes nisin from the membrane thereby inhibiting nisin mediated membrane pore formation.

Here, we will highlight our latest results towards understanding (I) the exact molecular mechanism of lantibiotic resistance as well (II) dissecting both the individual function of *Sa*NSR and *Sa*NsrFP.

Objectives

Human pathogens
Inhibition

Methods

X-ray crystallography
Growth inhibition
Molecular dynamics and modeling
Protein purification

Conclusions

*Sa*Nsr and *Sa*NsrFP contribute to lantibiotic resistance via two different but very distinct mechanisms. Only when both proteins are present full resistance in human pathogens.

INTRA- AND INTERSPECIES GENOMIC DIVERSITY OF CLINICAL ISOLATES OF PHYTOBACTER SPECIES FROM DIFFERENT GEOGRAPHICAL AND TEMPORAL ORIGIN

F. Rezzonico[1], L. Arend[2], H. D'Espindula[3], M. Mira[3], J. Blom[4], J. Pothier[1], M. Pillonetto[3], T. Smits[1]
[1]Research Group Environmental Genomics and Systems Biology- IUNR, Life Sciences and Facility Management, Wädenswil, Switzerland
[2]Molecular Bacteriology Division, Central Public Health Laboratory – State of Paraná, São José dos Pinhais, Brazil
[3]Core for Advanced Molecular Investigation- Graduate Program in Health Sciences, School of Medicine- Pontifícia Universidade Católica do Paraná, Curitiba, Brazil
[4]Bioinformatics and Systems Biology, Justus-Liebig-University, Giessen, Germany

Backgrounds

The genus *Phytobacter* has been found to harbour clinical isolates from a septicaemia outbreak occurring in Brazilian hospitals in 2013. Furthermore, strains previously included in Biotype XII (Brenner, 1984) of the former *Erwinia herbicola-Enterobacter agglomerans* complex (EEC) and isolated in United States during similar outbreaks in the 1970's could now also be assigned to this genus.

Objectives

Studying the intra- and interspecies genomic diversity of *Phytobacter* spp.

Methods

We have sequenced and assembled the genomes of multiple isolates of *P. diazotrophicus* and *P. ursingii*, the two species currently assigned to the genus, and compared them *in silico* using EDGAR 2.0. Genome sequences of two Enterobacteriaceae isolates retrieved in the NCBI database under erroneous species designation were also included in the comparison.

Conclusions

The genus is clearly distinct from other Enterobacteriaceae, with *Kosakonia* being the nearest neighbour. Comparative genomics identified several genus-specific features like the ability of nitrogen fixation from N_2, while at the species level the genetic differences underlying the differential substrate utilization between *P. diazotrophicus* and *P. ursingii* could be confirmed. Analysis of CRISPR arrays showed that Cas genes, only found in one isolate, must have been present in other isolates as well, as remnants of CRISPR arrays were found in their genomes. Presence of plasmids and phages indicate that the diversity may be influenced largely by horizontal gene transfer.

BACILLUS POLYFERMENTICUS B28 EXTRACT SUPPRESSES MELANOCYTE DIFFERENTIATION BY ATTENUATING THE WNT/ B-CATENIN PATHWAY

Y. Son[1], H.E. Jin[1], M.S. Kwak[1], M.H. Sung[1], S. Oh[1]
[1]Kookmin University, Bio and Fermentation Convergence Technology, Seoul, Republic of Korea

Backgrounds

The Wnt/b-catenin pathway regulates neural crest-derived melanocyte development and is thus a potential target for the development of whitening agents.
Bacillus polyfermenticus, known as a probiotic bacterium, has been used clinically for the treatment of various intestinal disorders. It also exhibits a number of physiological activities, such as antmicrobial activity, cholesterol-reducing activity, stimulation of IgG production, and an antiproliferative effect on Caco-2 colon cancer cells.

Objectives

The target of this study is to find the the extract of *Bacillus polyfermenticus* B28 capable of regulating Wnt/β-catenin signaling and how to inhibit melanocyte differentiation.

Methods

We used HEK293-FL reporter cells that were stably transfected with a human Frizzled-1 (*hFz-1*) expression plasmid and a synthetic b-catenin/Tcf-dependent luciferase reporter plasmid to screen a bacterial extract that inhibits Wnt/b-catenin signaling.
To prepare BPE, *B. polyfermenticus* B28 were grown in Luria Bertani (LB) broth medium for 18 h and then pelleted by centrifugation. The pellet was solubilized in 20 mM potassium phosphate buffer (pH 7.4) solution, sonicated, and homogenized by microfluidizer (Young Jin Corporation). BPE was prepared by centrifugation of the homogenate using a high speed centrifuge (Hanil Science Inc.) at 12,000 rpm.

Conclusions

B. polyfermenticus B28 extract (BPE) suppressed β-catenin response transcription (CRT), which was activated by Wnt3a-conditioned medium (Wnt3a-CM) by downregulating intracellular β-catenin in HEK293 reporter cells. In addition, BPE decreased the levels of intracellular β-catenin, microphthalmia-associated transcription factor (MITF), and tyrosinase in B16 melanoma cells, thereby reducing intracellular melanin production. Our findings indicate that BPE may have potential as a whitening agent for use in cosmetics and in the medical treatment of hyperpigmentation disorders.

Physiology / Biochemistry / Molecular Microbiology - Part III

ROLE OF MER IN THE TRANSPORT OF TOXIC METALS IN ESCHERICHIA COLI

Y. Sone[1], S. Uraguchi[1], R. Nakamura[1], Y. Takanezawa[1], M. Kiyono[1]
[1]Kitasato University, School of Pharmacy, Tokyo, Japan

Backgrounds

The characteristics of bacteria take up mercury into cells via Mer superfamily, i.e., MerC, MerE, MerF, and MerT, which transport mercuric ions into the cytoplasm, have been applied in engineering of bioreactor used for mercurial bioremediation. In all these proteins, one pair of cysteine residues is predicted to reside within the inner membrane. However there is no direct experimental evidence concerning bacterial transport of toxic metals until recently.

Objectives

Our objective was to clarify individual role of MerC, MerE, MerF, or MerT and potential in transport of toxic metals.

Methods

The toxic metals uptake capacities of *E. coli* cells that carried control vector or *mer* recombinants were examined. The cells were suspended in LB broth containing 5 μM $^{14}CH_3Hg^+$, 5 μM $C_6H_5Hg^+$, 10 μM Hg^{2+}, 300 μM Cd^{2+}, 10 μM AsO_2^-, 50 μM $HAsO_4^{2-}$, or 10 μM CrO_4^{2-} and incubated for various time at 37°C, respectively. The total metal of the harvested cells were measured using a liquid scintillation spectrometer ($^{14}CH_3Hg^+$), atomic absorption spectrometry analyzer ($C_6H_5Hg^+$ or Hg^{2+}) or inductively coupled plasma optical emission spectrometry analyzer (AsO_2^-, $HAsO_4^{2-}$ or CrO_4^{2-}), respectively.

Conclusions

The cells that expressed MerC, MerE, MerF, or MerT accumulated significantly more CH_3Hg^+, $C_6H_5Hg^+$, Hg^{2+}, AsO_2^-, or $HAsO_4^{2-}$ than control. MerC recombinants accumulated significantly more CrO_4^{2-} than control. Consequently, we demonstrated that MerC, MerE, MerF, and MerT are broad-spectrum toxic metals transporters. Our results suggested that all Mer transporters can be used for designing toxic metals bioremediation systems, moreover, MerC is the most efficient tool.

CHARACTERIZATION AND FUNCTIONAL ANALYSIS OF MITOGEN ACTIVATED PROTEIN KINASES IN THE DIMORPHIC FISSION YEAST SCHIZOSACCHAROMYCES JAPONICUS

T. Soto[1], P. Soluyanova[1], E. Gómez-Gil[1], B. Vázquez-Marín[1], M. Madrid[1], J. Vicente-Soler[1], M. Gacto[1], J. Cansado[1], A. Franco[1]
[1]Univesity of Murcia, Department of Genetics and Microbiology, MURCIA, Spain

Backgrounds

Mitogen-activated protein kinase (MAPK) cascades are universal signal transduction modules that play crucial roles in eukaryotic cells. In contrast to the well studied fission yeast *Schizosaccharomyces pombe*, a second species within the genus named *Schizosaccharomyces japonicus* shows a larger cell size and specific features including semi-open mitosis, light response and dimorphism.

Objectives

Like in other dimorphic fungi, this simple eukaryote may provide an attractive and suitable model to comparatively analyze MAP kinase signaling mechanisms and their role during the stress response and the transition from yeast to hyphal growth.

Methods

Here we show that Sty1^{Sj}, a p38-type MAPK, is involved in the adaptive cellular responses to stress and negatively regulates mycelial growth. Pmk1^{Sj}, an ERK-type MAPK, also responds to multiple stresses, but positively regulates cell branching and mycelial expansion. Remarkably, while Sty1 amino-acid sequence and structure is strongly conserved in both fission yeast species, Pmk1^{Sj} lacks a 24-amino acid motif within its N-terminal ATP-binding domain which is present and critical for activation in all eukaryotic MAP kinases studied so far. Moreover, Pmk1^{Sj} is totally functional in *S. pombe* cells, suggesting the existence of other modifications within Pmk1^{Sj} structure to bypass the need of a canonical ATP-binding domain domain for MAPK activation.

Conclusions

Our results suggest that in *S. japonicus* both Sty1^{Sj} and Pmk1^{Sj} positively regulate the cellular response to environmental changes, but play opposing roles during the regulation of the dimorphic transition.

Physiology / Biochemistry / Molecular Microbiology - Part III

PHYLOGROUP RECLASSIFICATION OF ESCHERICHIA COLI ISOLATES BY THE REVISED EXTENDED QUADRUPLEX PHYLOTYPING METHOD

M. Starčič Erjavec[1], *D. Žgur-Bertok*[1]
[1]*University of Ljubljana - Biotechnical Faculty, Department of Biology, Ljubljana, Slovenia*

Backgrounds

Clermont et al. in 2000 published a simple triplex PCR based phylotyping method. Based on newly available genome data Clermont et al. in 2013 proposed a new revised method of PCR phylotyping, the extended quadruplex PCR that was validated on two collections of human fecal isolates.

Objectives

The aim of our study was to broaden the validation of the study with additional *E. coli* isolates: human skin and soft-tissue infection *E. coli* isolates (SSTIEC), fecal *E. coli* isolates from healthy humans (hFEC), brown bear fecal *E. coli* (bFEC) and cattle fecal *E. coli* (cFEC).

Methods

The *E. coli* strains investigated in this study (102 SSTIEC, 90 hFEC, 86 bFEC and 89 cFEC) were gathered and partially characterized in our previous studies. In this study all the investigated strains were PCR phylotyped with the new extended quadruplex PCR method as published by Clermont et al. in 2013.

Conclusions

Our study showed that the most pronounced changes in the distribution of strains among phylogenetic groups were within the D group strains, as when employing the extended quadruplex method, the majority had to be re-placed into other phylogenetic groups. A considerable number of re-placements were also observed among A group strains, while less for the B1 and B2 groups. We conclude that the extended quadruplex PCR method is indeed a superior method for PCR phylotyping however, as some strains still (11% of strains in the case of cattle *E. coli*) remained unclassified, a revision of the revised method is needed.

IMPACT OF GLUTATHIONE METABOLISM ON ZINC HOMEOSTASIS IN SACCHAROMYCES CEREVISIAE

M.G. Steiger[1], A. Patzschke[1], C. Holz[2], C. Lang[2], T. Causon[3], S. Hann[3], D. Mattanovich[4], M. Sauer[4]
[1]Austrian Centre of Industrial Biotechnology, Systems Biology & Microbial Cell Engineering, Vienna, Austria
[2]Organobalance GmbH, Organobalance, Berlin, Germany
[3]University of Natural Resources and Life Sciences- Vienna BOKU, Department of Chemistry, Vienna, Austria
[4]University of Natural Resources and Life Sciences- Vienna BOKU, Department of Biotechnology, Vienna, Austria

Backgrounds

Zinc is a crucial mineral for all organisms as it is an essential cofactor for the proper function of a plethora of proteins and depletion of zinc causes oxidative stress. Therefore, it is highly important to understand how the cell can maintain and control metal homeostasis. Glutathione is the major redox buffering agent in the cell and therefore important to mitigate adverse effects of oxidative stress. In mammalian cells zinc deficiency is accompanied by a glutathione depletion. In the yeast *Saccharomyces cerevisiae* the opposite effect is observed: under low zinc conditions an elevated glutathione concentration is found. The main regulator to overcome zinc deficiency is Zap1.

Objectives

In this work, we set out to characterize the impact of glutathione and its derivatives on zinc homeostasis and if the transcriptional regulator Zap1 is involved in this cross talk.

Methods

Total zinc concentrations (ICP-MS) and free available zinc pools (fluorescence microscopy) were analysed in *S. cerevisiae* strains differing in their overall glutathione content. Furthermore, cellular phytochelatin levels were measured by LC-MS/MS. Deletion strains of Zap1 were generated and their glutathione content determined.

Conclusions

We show that Zap1p is not involved in a glutathione accumulation phenotype. Furthermore, we found that in glutathione accumulating strains also the metal ion binding phytochelatin-2, which is an oligomer of glutathione is accumulated. This increased phytochelatin concentration correlates with a lower free zinc level in the vacuole. Our results suggest that phytochelatin is important for zinc buffering in *S. cerevisiae* and thus explains how zinc homeostasis is connected with glutathione metabolism.

ADAPTING TO COMPETITIVE INHIBITION IN THE COMMUNITY CONTEXT: A TALE OF TWO SULFATE-REDUCING MICROBES

M. Stoeva[1], M. Mehta[1], R. Rushton-Green[2], L. Tran[1], J. Coates[1]
[1]UC Berkeley, Plant and Microbial Biology, Berkeley, USA
[2]University of Otago, Department of Microbiology and Immunology, Dunedin, New Zealand

Backgrounds

Inhibition of sulfate-reducing microorganisms (SRM) is of interest owing to the human-health and economic costs of sulfide, the byproduct of microbial sulfate-reduction. Perchlorate is a potent and specific inhibitor of SRM. For a complete understanding of the stability of inhibition, we are exploring mechanisms by which SRM evolve resistance to perchlorate. Previous work has shown that model SRM, *Desulfovibrio alaskensis g20* can adapt to 100mM perchlorate via a single nucleotide polymorphism (SNP) in the sulfate adenylyltransferase (*sat*).

Objectives

To further this research, we aim to understand adaptation to perchlorate across different SRM, as well as in a community context.

Methods

Sulfidogenic communities were transferred in increasing concentrations of perchlorate and compared to control communities in terms of community structure, frequency of the *sat* SNP and presence/frequency of novel mutations.

Conclusions

Results indicate that the *sat* is a target for adaptation in pure culture significantly more frequently than in a community, likely owing to the relatively higher cost of this mutation. In a community setting, a null mutation of a periplasmic histidine kinase (dde_0320) dominates. The phenotype of this mutation was confirmed using a transposon mutant of dde_0320. Currently, an RNAseq experiment is underway, to identify regulatory targets of dde_0320. *Desulfovibrio singaporenus MKS*, a SRM native to the sulfidogenic community, is also capable of adaptation to 100mM perchlorate, albeit by a different mechanism: *D. singaporenus* exhibits SNPs in transporter proteins. Efforts are currently underway to characterize these mutants. Thus, this works aims to describe ecologically-relevant adaptive mechanisms across diverse SRM against competitive inhibition.

Physiology / Biochemistry / Molecular Microbiology - Part III

CHARACTERIZATION OF B-D-MANNOSIDASE FROM BACILLUS SP

W. Sukhumsirichart[1], W. Seesom[1], T. Sakamoto[2]
[1]Srinakharinwirot University, Department of Biochemistry- Faculty of Medicine, Bangkok, Thailand
[2]Osaka Prefecture University, Department of Applied Life Sciences, Osaka, Japan

Backgrounds

β-D-mannosidase (EC 3.2.1.25) are glycoside hydrolase enzymes that cleave β-1,4-mannosidic-linked mannosides from the non-reducing end of various β-1,4-linked mannooligosaccharides. It is essential for the complete hydrolysis of mannan.

Objectives

To screen for β-D-mannosidase -producing microorganisms and to observe the characteristics of the extracted crude mannosidase enzyme.

Methods

A total of 299 microorganisms were screened on minimum medium containing locust bean gum at 37°C, and the species of the highest mannosidase producing microorganism was identified by 16S rDNA sequence analysis. Temperature and pH optimum and stability of the crude enzyme were examined.

Conclusions

Analysis of the 16S rDNA sequence revealed that the highest mannosidase producing microorganism was *Bacillus* sp. The activity of the crude enzyme was 0.8 unit/ml using 4-nitrophenyl β-D-monopyranoside as a substrate. The optimal pH and temperature for enzyme activity were observed to be 7.0 and 50°C, respectively. The enzyme was stable in pH ranges from 5 to 9, after 16 h of incubation at 4°C and stable up to 40°C for 1 h, and more than 80 % of initial activity remained. This exo-β-1,4-mannosidase can enzymatically release D-mannose from galactomannan, glucomannan and mannan that can be used for the production of bioethanol and other biochemical from biomass.

FEMS7-0790

COMPLETE GENOME SEQUENCE OF LACTOCOCCUS LACTIS G50 AND PILIN LOCUS STRUCTURE

C. Suzuki[1], K. Nakano[2], N. Moriya[1], M. Minami[2], M. Shinzato[2], M. Shimoji[2], N. Ashimine[2], A. Shiroma[2], S. Ohki[2], T. Nakanishi[2], H. Tamotsu[2], K. Teruya[2], K. Satou[2], H. Kimoto-Nira[1], M. Kobayashi[1], T. Hagi[1], M. Nomura[1], T. Hirano[2]
[1]National Agriculture and Food Research Organization, Institute of Livestock and Grassland Science, Tsukuba, Japan
[2]Okinawa Institute of Advanced Sciences, Research and Development Division, Uruma- Okinawa, Japan

Backgrounds

Lactococcus lactis subsp. *lactis* G50 isolated from Napiergrass has an ability to induce the production of cytokines (IL-12, IL-6, and TNF-α) in macrophage-like cell line J774.1. The stimulus required for TNF-α induction is heat sensitive, because heat-treated G50 loses the activity to induce TNF-α.

Objectives

To identify potential genetic determinants giving immunostimulatory activity to G50, complete genome sequence was obtained and analyzed by the single-molecule real-time (SMRT) technology.

Methods

The genomic DNA was purified at the early log phase, followed by 20-kb library construction for P6-C4 chemistry with shearing. Size selection was not performed. Two SMRT cells (each 240-min movies) were sequenced using the PacBio RS II platform (Pacific Biosciences, Menlo Park, CA). *De novo* assembly was performed using the hierarchical genome assembly process version 2. The G50 genome has been annotated with DDBJ MiGAP. Protein localization was predicted by PSORTb.

Conclusions

A single circular contig representing one chromosome (2,346,663 bp, G+C content of 35.03%, and 925× coverage) was obtained. No plasmids were detected either by assembly or gel electrophoresis. The genome of G50 was similar to that of *L. lactis* KF147 (query cover 89%, identity 99%). Using PSORTb, 57 proteins in 2621 ORF in the genome were deduced as either extracellular or attached to the cell wall, including a set of pilus proteins, YhgD, YhgE, and YhhB. The pilin tip protein YhgD is unique in that the C-terminal half of YhgD is strain specific. The pilin locu of lactococci were compared and discussed as a candidate of immunostimulating factor.

Physiology / Biochemistry / Molecular Microbiology - Part III

EPIGENETIC REGULATION OF GENE EXPRESSION DURING GIARDIA INTESTINALIS ENCYSTATION

E. Einarsson[1], U. Ribacke[2], L. Rojas[1], S. Svärd[1]
[1]Uppsala University, Department of Cell and Molecular Biology, Uppsala, Sweden
[2]Karolinska Institutet, Department of Microbiology- Tumour and Cell Biology, Stockholm, Sweden

Backgrounds

Infectious cysts of the intestinal protozoan parasite *Giardia intestinalis* are formed through the process of encystation, making this cellular differentiation crucial for transmission and survival. Other protozoan parasites like the malaria parasite *Plasmodium falciparum* have been shown to regulate differentiation between different life-cycle stages on the epigenetic level.

Objectives

To further study the molecular details of *Giardia* encystation, focusing on epigenetic regulation of gene expression.

Methods

We used our newly developed *in vitro* encystation protocol to generate differentiating cells from each 1.5 hrs of the 30 hrs encystation process. Transcriptional changes during the entire differentiation from trophozoites to cysts were studied using RNA sequencing (RNA-seq), genomic methylation detection and chromatin immunoprecipitation.

Conclusions

A high level of periodicity was observed for up- and down-regulated genes, both at the level of the entire transcriptome and putative regulators. The largest transcriptional changes were seen in the late phase of encystation with the majority of the highly up-regulated genes encoding hypothetical proteins and variant specific surface proteins (VSPs). The transcriptomic analyses were complemented by analyses of the methylation and histone modification status of selected encystation-regulated genes and these analyses suggest an important role of epigenetic regulation of gene expression during *G. intestinalis* encystation. Our results underline the importance of epigenetic regulation of gene expression during antigenic variation and differentiation in protozoan parasites.

Physiology / Biochemistry / Molecular Microbiology - Part III

QUANTITATIVE ANALYSES OF DNA AND RNA IN ENLARGED SPHEROPLASTS OF THE BACTERIUM LELLIOTTIA AMNIGENA.

S. Takahashi[1], *H. Nishida*[1]
[1]*Toyama Prefectural University, Biological Engineering, Imizu, Japan*

Backgrounds

Generally, bacterial spheroplasts do not divide, but they can grow and enlarge if placed in a broth containing a peptidoglycan synthesis inhibitor and high concentrations of salt. Spheroplasts of *Lelliottia amnigena*, from the family Enterobacteriaceae, enlarged up to >30 μm in diameter at the maximum (Takahashi & Nishida, 2016, Bull Toyama Pref Univ, 26, 27-30). Total DNA in spheroplasts increased during enlargement, suggesting that DNA replicates in spheroplasts (Takahashi & Nishida, 2015, J Gen Appl Microbiol, 61, 14-17). In addition, we compared RNA expression between early-growth spheroplasts and enlarged spheroplasts (Takahashi et al., 2016, AIMS Microbiol, 2, 152-189).

Objectives

In this study, we quantified DNA from a single spheroplast and RNA from normally-dividing cells, early-growth and enlarged spheroplasts, and filamentous cells generated from spheroplasts.

Methods

We selected spheroplasts with an inner membrane diameter of 9-15 μm and isolated a single cell using a micromanipulator at 24 h, 48 h, 72 h, and 96 h of growth. Concentrations of DNA were quantified using qPCR. RNA was isolated from normally-dividing cells, early-growth and enlarged spheroplasts, and filamentous cells. RT-qPCR was performed for the following 10 genes: cell division-related genes *ftsA* and *ftsZ*; DNA replication-related genes *hupA*, *topA*, and *recA*; stress response-related genes *clpB*, *pspA*, and *spy*; and cell surface-related genes *ompA* and *pbp1b*.

Conclusions

The amount of DNA in a single spheroplast did not increase after 24 h of growth. It suggests that the DNA replication ceased in enlarged spheroplasts after 24h of growth. Interestingly, the outer membrane continued to grow after 24h of growth. RNA expressions were different between enlarged spheroplasts and filamentous cells. For example, *clpB* and *ftsZ* were upregulated during enlargement, whereas these two genes were downregulated during filamentation. Conversely, *hupA* was downregulated during enlargement, but upregulated during filamentation.

Physiology / Biochemistry / Molecular Microbiology - Part III

LITR, A MERR-FAMILY TRANSCRIPTIONAL REGULATOR OF BACILLUS MEGATERIUM: ITS ROLE AND FUNCTION IN LIGHT-INDUCIBLE CAROTENOID PRODUCTION

H. Takano[1], K. Mise[1], K. Hagiwara[1], N. Hirata[1], S. Watanabe[1], H. Takano[1], K. Ueda[1]
[1]Nihon University, College of Bioresource Sciences, Fujisawa- Kanagawa, Japan

Backgrounds

Carotenoid production in certain non-phototropic bacteria protects cells from photo-oxidants and occurs in a light-dependent manner. The LitR/CarH family of transcriptional regulators acts as light-dependent, negative regulators of carotenoid genes in gram-negative bacteria such as *Thermus thermophilus* and *Myxococcus xanthus*. LitR repressor activity is controlled by adenosyl B12, a light-sensitive chromophore. However, biochemical characterization of the LitR/CarH family has been confined to gram-negative bacteria.

Objectives

We therefore investigated the function and role of the LitR homolog in the gram-positive, soil bacterium, *Bacillus megaterium* QM B1551.

Methods

B. megaterium wild type produced carotenoid in a light-dependent manner. However, the *litR* null mutant exhibited constitutive, light-independent carotenoid production, while the *litR*-complemented strain produced carotenoid in a light-dependent manner. Transcriptional analysis revealed that the expression of carotenoid biosynthesis genes is light-dependently regulated in the wild type strain; however, transcription of *litR* in the mutant was constitutive, indicating that LitR serves as a light-sensitive repressor that controls the expression of carotenoid genes. In concordance with these results, the LitR recombinant protein in complex with adenosyl B12 bound to the carotenoid promoter region in a specific and light-sensitive manner. *In vitro* transcriptional run-off assay demonstrated that the mixture of LitR and RNA polymerase light-dependently generates a transcript of the *crt* gene.

Conclusions

Overall, our results indicate that LitR of *B. megaterium* functions as an adenosyl B12-based, light-sensitive regulator.

Physiology / Biochemistry / Molecular Microbiology - Part III

REGULATION OF GRATA TOXIN-ANTITOXIN SYSTEM OF PSEUDOMONAS PUTIDA

H. Tamman[1], *A. Ainelo*[2], *R. Hõrak*[2]
[1]*Free University of Brussels ULB, Biologie Structurale et Biophysique, Gosselies, Belgium*
[2]*University of Tartu- The Institute of Molecular and Cell Biology, Chair of Genetics, Tartu, Estonia*

Backgrounds

Type II toxin-antitoxin (TA) systems consist of two proteins: a stable toxin that damages its host bacterium and an unstable antitoxin, able to inhibit the toxin. Many TA loci are regulated by conditional cooperativity, where the toxin, depending on its abundance, can act either as a co-repressor or de-repressor of transcription.
The toxin of GraTA system has been shown to decrease growth rate and influence stress tolerance of *Pseudomonas putida*. The quite stable antitoxin GraA inhibits the toxin GraT from causing cold-sensitive ribosome biogenesis defect by binding it into a complex.

Objectives

The current work set out to study the regulation of the GraTA system.

Methods

The transcriptional regulation of the *graTA* locus was studied by using a transcriptional fusion of *graTA* promoter and *lacZ* reporter gene both in *P. putida* and *E. coli*. The abundance of GraTA proteins was determined by Western blotting.

Conclusions

Differently from many other TA systems, *graTA* expression is not regulated by conditional cooperativity. We show that the *graTA* operon is autorepressed by antitoxin only, whereas the toxin is a de-repressor. Data also indicate that although the *graT* gene precedes *graA*, translation of the antitoxin is more efficient than the toxin's. This mechanism guarantees that GraA is produced in higher amounts than GraT and thus ensures the silencing of the toxin. Unequal translation of TA genes is likely to also play a role in the regulation of other TA operons with a similar gene order.

Physiology / Biochemistry / Molecular Microbiology - Part III

IDENTIFICATION OF UDP-GLUCOSE 4-EPIMERASE (GALE) GENE ISOLATING FROM THE ORAL METAGENOMIC DNA CONFERS RESISTANCE TO QUATERNARY AMMONIUM COMPOUNDS (QACS)

S. Tansirichaiya[1], L.J. Reynolds[1], G. Cristarella[1], A.P. Roberts[1]
[1]UCL Eastman Dental Institute, Microbial Disease, London, United Kingdom

Backgrounds

Overexposing and misusing of antimicrobial compounds results in bacteria developing resistance. The human oral cavity is one environment exposed to these compounds through foods and oral hygiene products.

Objectives

To identify and characterise antimicrobial resistance genes from the human oral metagenome.

Methods

We have adopted a metagenomic approach to screen for resistance genes from both culturable and unculturable bacteria in the human oral cavity. An oral metagenomic library, constructed in *Escherichia coli* using pCC1BAC vector, was screened against several antimicrobials.

Conclusions

Out of 12,277 clones screened, one clone was found to have resistance against two commonly used antiseptics, cetyltrimethylammonium bromide (CTAB) and cetylpyridinium chloride (CPC). Analysis of the plasmid from this clone showed that it contained a 17.1 kb insert, and the resistance was conferred by a UDP-4 glucose-epimerase (*galE*) gene homologous to one from *Veillonella parvula*. The product of *galE* is involved in LPS production. Analysis of the *E. coli* host showed the cell surface charge was more positive in the presence of *galE*, which could reduce the binding of these positively charges antiseptics, like CTAB and CPC, to the bacteria.

This is the first time that *galE* has been shown to be responsible for resistance against QACs.

Physiology / Biochemistry / Molecular Microbiology - Part III

A FAMILY OF SRNAS PLAYS A ROLE IN THE RESPONSE OF LISTERIA MONOCYTOGENES TO HEME TOXICITY

P. T. dos Santos[1], D. Sabharwal[1], P. Menendez-Gil[1], E.M. Sternkopf Lillebæk[1], B. H. Kallipolitis[1]
[1]University of Southern Denmark, Biochemistry and Molecular Biology, Odense M, Denmark

Backgrounds

At present, over 200 putative small non-coding regulatory RNAs (sRNAs) have been identified in *Listeria monocytogenes*. Interesting, several sRNAs have been identified as being induced in human blood. *L. monocytogene*s has the ability to lyse erythrocytes, remove heme from hemoglobin and liberate Fe^{2+} from heme. Even though iron is essential for life, it is highly toxic under aerobic conditions, as it reacts with oxygen species forming free radicals. Thus, *L. monocytogenes* needs to find a way to overpass the unfavorable conditions it encounters in the presence of excess heme.

Objectives

To understand why some sRNAs are highly induced in human blood, we hypothesized that this induction could be caused by high levels of heme in this environment. Therefore, the aim was to investigate the role of heme-induced sRNAs in response to excess heme and look for their putative targets in *L. monocytogenes.*

Methods

Wild-type cells were subjected to increasing concentrations of hemin and sRNAs levels were determined via Northen Blot analysis. To verify their role in the prevention of heme toxicity, growth of a strain lacking sRNAs was compared to the wild-type strain. Finally, a search was performed to identify possible targets of the sRNAs under hemin stress.

Conclusions

A family of sRNAs was greatly induced by hemin, and a strain lacking the sRNAs showed impaired growth in the presence of hemin, suggesting a fine-tuning role for these sRNAs in the prevention of heme toxicity. Putative target genes were identified and the mechanisms underlying the regulation by the sRNAs are under investigation.

WHOLE-GENOME SEQUENCING UNVEILS A POTENTIALLY NEW PSEUDOMONAS SPECIES ASSOCIATED WITH TN6372, A NOVEL BLAVIM-2-TRANSPOSABLE ELEMENT

J. Botelho[1], *F. Grosso*[1], *L. Peixe*[1]
[1]*UCIBIO/REQUIMTE- Laboratório de Microbiologia- Faculdade de Farmácia- Universidade do Porto- Porto- Portugal, Microbiology, Porto, Portugal*

Backgrounds

The *Pseudomonas putida* group represents a diverse cluster of opportunistic pathogens, such as *Pseudomonas putida*, *Pseudomonas monteilii* and *Pseudomonas mosselii*. Due to their resemblance, species identification is somehow challenging. Several studies reported the need to re-examine the differentiation of species within *P. putida* phylogenetic group.

Objectives

Here, we characterize the genetic environment of a carbapenemase gene in a clinical isolate belonging to a potentially new *Pseudomonas* species.

Methods

FFUP_PS_41 isolate, recovered from endotracheal tube secretions of a Neonatal/Pediatric Intensive Care unit patient with pneumonia, exhibited an extensively-drug resistant phenotype (only susceptible to colistin). Species identification was assessed by VITEK-2 system and confirmed by multi-locus sequence analysis (*rpoD*, *gyrB*, *rpoB* and 16S rRNA genes) and average nucleotide identity (ANI) analysis. The complete nucleotide sequence (6,523,850 bp; 62,2% GC content) was achieved by Illumina HiSeq sequencing platform and *de novo* assembly by SPAdes. Although FFUP_PS_41 isolate was identified as *P. putida* by VITEK-2, it displayed an ANI value <95% (cut-off for species identification) when compared with the complete genome of type strains belonging to the *P. putida* group. A strong correlation was observed with MLSA (<97% cut-off), suggesting that FFUP_PS_41 represents a new species, related to *P. putida* group. bla_{VIM-2} was associated with In103, a class 1 integron co-harboring aminoglycoside resistance genes (*aacA7* and *aacA4*). In103 was inserted in a novel putative transposon, hereby named Tn*6372*.

Conclusions

FFUP_PS_41 isolate most likely represents a new species, belonging to *P. putida* phylogeny group. The new transposable element highlights the ongoing process of bla_{VIM-2} dissemination throughout different species.

COMPLETE NUCLEOTIDE SEQUENCE OF PJB58, A BLAVIM-2-HARBORING PLASMID FROM PSEUDOMONAS AERUGINOSA

J. Botelho[1], F. Grosso[1], A. Mabrouk[2], L. Peixe[1]
[1]UCIBIO/REQUIMTE- Laboratório de Microbiologia- Faculdade de Farmácia- Universidade do Porto- Porto- Portugal, Microbiology, Porto, Portugal
[2]Laboratories UR12ES02-
The National Bone Marrow Transplant Centre- Tunis- Tunisia- University of Carthage- Faculty of Scie nces of Bizerte- Tunis- Tunisia, UR12ES02-The National Bone Marrow Transplant Centre, Tunis, Tunisia

Backgrounds

VIM-2 represents one of the most widespread carbapenemases among *Pseudomonas aeruginosa*. *bla*$_{VIM-2}$-carrying In58 integron has been mainly linked to a chromosomal location in different bacterial species, including *P. aeruginosa*.

Objectives

Here, we characterize the genetic environment of an In58-carrying plasmid.

Methods

Complete nucleotide sequence of plasmid pJB58, recovered from *P. aeruginosa* ST282 clinical isolate exhibiting a multidrug-resistant phenotype, was achieved by Illumina HiSeq and *de novo* assembly by SPAdes. Plasmid transferability was evaluated by conjugation. pJB58 (32,207 bp, 58,6% GC content) was related to *bla*$_{VIM-1}$-harboring plasmids pPC9, from *Pseudomonas putida* HB3267 strain from France (88% query cover and 99% identity) and pAMBL2, from *P. aeruginosa* in Spain (44% query cover and 99% identity), including the partitioning and stable inheritance system (*rep*, *kfrA* and *vapBC* toxin-antitoxin system). Replicase protein belongs to Rep-3 superfamily and shared 100% homology with the ones from pPC9 and pAMBL2. pJB58 lacked the complete machinery for self-conjugation, justifying the failure of conjugation. Yet, it might be mobilizable by a helper plasmid, since it carried a relaxase gene (*trwC*/*traI*), a putative *oriT* site and a type-IV coupling protein gene (*trwB*/*traJ*). Similar findings were observed for pPC9. A Tn*402*-like transposon comprising the In58 integron, harboring *bla*$_{VIM-2}$ and aminoglycoside resistance genes (*aacA7*, *aacC1* and *aacA4*), and IS*6100* was identified. A Tn*5393*c-like transposon harboring streptomycin resistance genes was also reported.

Conclusions

Complete nucleotide sequence of plasmid pJB58 from *P. aeruginosa* revealed the *bla*$_{VIM-2}$-harboring In58 integron in a putative mobilizable plasmid. These findings provide new insights on the mobile genetic elements associated with VIM-2 dissemination.

FIRST PHYSIOLOGICAL STUDY ON NOX EMISSIONS IN HALOARCHAEA: ARE THEY INVOLVED IN CLIMATE CHANGE?

J. Torregrosa-Crespo[1], L. L. Bergaust[2], C. Pire Galiana[1], L. R. Bakken[3], R.M. Martínez-Espinosa[1]
[1]Universidad de Alicante, Agrochemistry and Biochemistry, ALICANTE, Spain
[2]Faculty of Chemistry- Biotechnology and Food Science. Norwegian University of Life Sciences. Foug nerbakken 3 - 1430- Ås- Norway., Department of Chemistry- Biotechnology and Food Science., Ås, Norway
[3]Faculty of Environmental Sciences and Natural Resource Management. Norwegian University of Life Sciences. Fougnerbakken 3 - 1430- Ås- Norway., Department of Environmental Sciences., Ås, Norway

Backgrounds

Haloarchaea are extremophiles inhabiting saline and hypersaline media such as salt lagoons and salty ponds. Knowledge about denitrification in these microorganisms and in the Archaea domain in general is scarce. The few studies executed so far have dealt with biochemical aspects of the pathway[1], and to date there are no reports of physiological experiments addressing the release of gaseous nitrogen oxides (NO_x) by this group of microorganisms.

Objectives

This work is the first comprehensive study on NO_x emissions from Archaea. Three Haloarchaea strains, *Haloferax mediterranei, Haloferax denitrificans* and *Haloferax volcanii* were selected as model organisms and characterized with respect to denitrification phenotype.

Methods

A semi-automatic incubation system was used to monitor the kinetics of all relevant gases (CO_2, O_2, NO, N_2O, N_2)[2] during transitions from aerobic respiration to denitrification in batch cultures with low initial O_2 (1 vol% in headspace) and either nitrate or nitrite.

Conclusions

The results confirm that *Hfx. mediterranei* and *Hfx. denitrificans* are complete denitrifiers, producing N_2 as final product. All the available nitrate (5 mM) was recovered as N_2 with transient accumulation of nM concentrations of NO and N_2O. In contrast, *Haloferax volcanii* is a partial denitrifier, unable to reduce nitrate and N_2O, thus generating N_2O as final product in nitrite supplemented medium. Considering the large areas that haloarchaea inhabit on Earth, the results suggest that these extremophiles could represent a new group of microorganisms of relevance to NO_x emissions and climate change. However, complete denitrifiers could be used in wastewater treatments due to their ability to reduce NO_3^-, NO_2^- to N_2 (inert gas).

CONTROL ON THE COMPLEX PSEUDOMONAS AERUGINOSA RIBONUCLEOTIDE REDUCTION NETWORK BY THE ALGZR TWO-COMPONENT SYSTEM

E. Torrents[1], *L. Pedraz*[1], *A. Crespo*[1]
[1]*Insitute for Bioengineering of Catalonia IBEC, Bacterial Infections and antimicrobial therapies, Barcelona, Spain*

Backgrounds

DNA synthesis is one of the central processes of life, required for any living cell. The Ribonucleotide Reductase (RNR) family include the only enzymes able to catalyse the reduction of the ribonucleotides to deoxyribonucleotides, the building blocks of the DNA. RNRs comprises three classes of enzymes (class I, class II and class III); although eukaryotic cells codify only class I, bacteria can codify any combination of classes.

In the opportunistic pathogen *Pseudomonas aeruginosa,* we find all three classes codified in the same genome. It is believed that under the different situations this bacterium encounters, in planktonic growth and in biofilms, under free growth and under infections conditions, all three RNR classes are controlled by complicated regulation systems and play different roles.

Objectives

Understand the biological role of AlgR to fine regulate the transcription of the different ribonucleotide reductase genes in *Pseudomonas aeruginosa*.

Methods

In this work, we demonstrate the fine regulation of class I and class II RNR in *P. aeruginosa* by the AlgZR system by analysing their transcriptional regulation depending on different phosphorylation AlgR state as well as their specific interaction to the class Ia and II RNR promoter regions by EMSA.

Conclusions

We investigated how the AlgZR system helps to finely tune up the expression of class I and II RNR classes to adapt to different growing conditions and environmental situations, intertwining for the first time these two regulation networks.

BACILLUS SUBTILIS DISA AND RADA COOPERATE WITH HOLLIDAY JUNCTION PROCESSING PROTEINS IN THE RESCUE OF STALLED REPLICATION FORKS

R. Torres[1], *C. Gándara*[1], *E. Serrano*[1], *J.C. Alonso*[1]
[1]*Centro Nacional de Biotecnología CNB-CSIC, Biotecnología Microbiana, Madrid, Spain*

Backgrounds

Impediments to replication fork progression cause fork stalling. In *Bacillus subtilis* cells, the DisA protein coordinates the response to DNA replication stress and DNA repair by the poorly characterized DNA damage tolerance (DDT) pathways. DisA synthetizes c-di-AMP, a conserved essential second messenger. High or low levels of c-di-AMP delay cell proliferation until damage is circumvented. DisA and RadA are implicated in the processing or stabilization/destabilization of recombination intermediates.

Objectives

To gain insights into the role of DisA and RadA proteins during DDT in *B. subtilis.*

Methods

Survival assays were performed to test whether *disA* and *radA* in combination with *ruvAB*, *recG* or *recU* deletions render cells sensitive to methylmethane sulfonate or 4-nitroquinoline, agents that stall replication forks. The nucleoid phenotype of these mutants and the localization of fluorescent variants of DisA and RadA in different genetic backgrounds were analysed by fluorescence microscopy. Expression of the RecA protein in these mutants was analyzed by Western Blot. The c-di-AMP synthesis and ATP hydrolysis were analysed by thin-layer chromatography using purified DisA and RadA proteins.

Conclusions

The *disA* or *radA* deletion does not affect the expression of the RecA protein.
DisA and RadA genetically interact with RecG and RecU and in minor extent with RuvAB, proteins involved in the recovery of stalled replication forks.
DisA-YFP and RadA-CFP formed dynamic foci that become static in the absence of RecU or RecG.
DisA interaction with RadA or with a reversed fork (HJ) inhibits c-di-AMP synthesis. dsDNA interaction with DisA makes it insensitive to RadA-mediated inhibition of c-di-AMP synthesis.

AMPLIFICATION AND CLONING OF AN ALPHA-AMYLASE GENE FROM ANOXYBACILLUS FLAVITHERMUS K103 ISOLATED FROM AN ARMENIAN GEOTHERMAL SPRING

P. Hovhannisyan[1,2], H. Panosyan[1], A. Trchounian[1], N.K. Birkeland[2]
[1]Yerevan State University, Department of Biochemistry- Microbiology and Biotechnology, Yerevan, Armenia
[2]University of Bergen, Department of Biology and Centre for Geobiology, Bergen, Norway

Backgrounds

Thermozymes produced by thermophilic microorganism are stable and active at high temperatures. This feature makes them more advantageous compared to their mesophilic analogs for the usage in biotechnological processes. Amylases produced by thermophilic bacilli are the most widely used thermostable enzymes in starch industry and are in high demand

Objectives

The purpose of this work was to clone the alpha-amylase gene of the *Anoxybacillus flavithermus* K103 strain isolated from an Armenian geothermal spring.

Methods

Genomic DNA was isolated using GenElute Bacterial Genomic DNA Kit and sequenced using a HiSeq 400 Illumina genome sequencer. The DNA sequences coding for amylolytic enzymes were obtained and primers for an alpha-amylase were designed. The alpha-amylase gene was amplified and amplicons were ligated into a pET-21b(+) vector (Novagen) and transformed into chemically competent TOP10 *E. coli* cells.

Conclusions

Inserts were sequenced with designed primers, which confirmed that the gene sequence was correct and in the right reading frame and could be expressed in mesophilic *E.coli*. The alpha-amylase gene from *A. flavithermus* K103 shares 97% identity with the *Bacillus* sp. Alpha-amylases patented from different bacilli species are mostly comparable, suggesting that only limited natural variations in alpha-amylases may be discovered. Although the difference is not big at sequence level, it may have possible functional differences. Thus, it is important to express and purify the alpha-amylase from *A. flavithermus* K103 strain for further investigation.

The work was supported by the CPEA-2011/10081,CPEA-LT-2016/10095, ANSEF Microbio-3362 (HP), Thematic project of SCS RA 15T-1F399 (HP).

COMPENSATORY H2 PRODUCING ACTIVITY OF ESCHERICHIA COLI HYDROGENASES DURING MIXED CARBON SOURCES FERMENTATION

K. Trchounian[1], S. Mirzoyan[1], A. Vassilian[2], A. Trchounian[1]
[1]Yerevan State University, Biochemistry- Microbiology and Biotechnology, Yerevan, Armenia
[2]Yerevan State University, Ecology and Nature Protection, Yerevan, Armenia

Backgrounds

During mixed-acid fermentation *Escherichia coli* evolves H_2. H_2 is produced via reversible membrane bound [Ni-Fe]-hydrogenases (Hyd).

Objectives

H_2 generation was investigated when the cells were grown during the fermentation of mixture of glucose, glycerol and formate at pH 7.5.

Methods

H_2 production was measured by using pair of Ti-Si and Pt redox electrodes.

Conclusions

In glycerol supplemented assays wild type cells produced H_2 ~2.8 and ~2.3 fold less, compared to the assays supplemented with formate or glucose, respectively. Using single or double Hyd deficient mutants it was shown that H_2 production was the same, as in wild type. Only deletion of large subunits of Hyd-1 to 3 decreased H_2 production by ~5 fold. When glucose was supplemented the deletion of large subunits of Hyd-3 or Hyd-4 resulted in enhanced H_2 production by ~1.5 fold; moreover, each other Hyd enzyme worked towards H_2 oxidation. But the deletion of three large subunits of Hyd-1 to 3 decreased H_2 production by 40%. This might suggest that the rest 60% of H_2 came from Hyd-4. When formate was supplemented H_2 production was decreased by ~1.6 fold in Hyd-3 or Hyd-4 mutants, compared to wild type. In Hyd-1 and Hyd-2 double mutant H_2 production was enhanced by ~4.7 fold indicating that at these conditions they worked in H_2 oxidizing mode.

Taken together it might be concluded that different Hyd enzymes compensate each other for maintaining H_2 cycling and thus proton motive force generation. Moreover, new properties of Hyd enzymes especially Hyd-4 were identified at these conditions.

Physiology / Biochemistry / Molecular Microbiology - Part III

REGULATION OF ETHANOL DEGRADATION BY THE TEO-COMPONENT SYSTEM ABERDSR IN ACINETOBACTER BAUMANNII

P.Y. Tsai[1], K.S. Hsieh[1], H.Y. Shu[2], G.H. Lin[1]
[1]Master Program in Microbiology and Immunology, School of Medicine-Tzu Chi University, Hualien, Taiwan R.O.C.
[2]Bioscience Technology, Bioscience Technology-Chang Jung Christian University, Tainan, Taiwan R.O.C.

Backgrounds

Acinetobacter baumannii is an aerobic, rod-shape, no flagellum, gram negative opportunistic pathogen, and hospital disinfection agent, ethanol, can be used as its single carbon source. Biofilm and virulence factors were increased by low dose ethanol in *A. baumannii*.

Objectives

Low dose of ethanol may be an important growth factor in environment to *A. baumannii* for causing hospital-acquired infection. Environmental-sensing regulatory system which reported largely is two-component system (TCS). There are 16 TCSs in *A. baumannii*, but none was reported about regulation of ethanol metabolism.

Methods

Ethanol metabolism genes were screened from EZ-Tn5™<KAN-2> mutant library and confirmed by mark-less mutants. Physiological characteristics of mutants were cultured in M9 with 1% ethanol as single carbon source. Expressions of genes were detected by qRT-PCR and GFP reporter assay. Interaction of TCS, AbErdSR (*A. baumannii* ethanol regulated sensor/regulator), was used a TCS with reporter gene system (TCSG).

Conclusions

AberdSR single and double mutants loss ability of growth in M9 with 1% ethanol. Expression of *Abadh4* (*A. baumannii* alcohol dehydrogenase 4), *AberdS*, *AberdR*, and *actP* (acetate permease) were activated by ethanol in wild type, but did not shown in *AberdS* and *AberdR* single mutants. These results showed that AbErdSR is responsible for ethanol metabolism through the direct or indirectly regulation of alcohol dehydrogenase (ADH4) and *actP* for ethanol oxidation and acetate transport.

BIOSYNTHESIS OF THE TWO YJJM (LGOR) ISOFORMS IS SUBJECTED TO A COMPLEX PHASE-DEPENDENT REGULATION

M. Tutukina[1,2], I. Suvorova[3], U. Shvyreva[1], D. Gagarinskaya[1], J. Cole[4], F. Kondrashov[2], O. Ozoline[1]
[1]Institute of Cell Biophysics RAS, Functional genomics and cellular stress, Pushchino, Russia
[2]Centre for Genomic Regulation CRG and Universitat Pompeu Fabra UPF, Bioinformatics and genomics programme, Barcelona, Spain
[3]Institute for Information Transmission Problems RAS, ESC "Bioinformatics", Moscow, Russia
[4]University of Birmingham, School of Biosciences, Birmingham, United Kingdom

Backgrounds

YjjM transcription factor was predicted to be involved in control of L-galactonate metabolism thus contributing to alternative pathways important for bacterial colonization and motility. Based on structural similarity, YjjM belongs to the GntR family of transcription regulators. We discovered that *yjjM* has at least two ORFs resulting in synthesis of two proteins variable in their DNA-binding domain.

Objectives

The aim of this study was to unravel how synthesis of the two YjjM isoforms is regulated.

Methods

Promoters were mapped with PlatProm software, single-round, RNA-seq, and 5'-RACE. Mutants were obtained by site-directed mutagenesis and "gene doctoring". Transcription was measured by reporter assays and qRT-PCR. Proteins specifically bound to the *yjjM* promoters were detected using DNA sampling and LC/MS-spectrometry. YjjM products were identified by Western-blot.

Conclusions

YjjM is coded by a foreign gene that appeared in the *E. coli* MG1655 genome as a result of horizontal transfer, and has at least two protein isoforms, ~35 and ~25 kDa. Their translation is initiated from different mRNAs: transcription of the full-size mRNA requires upstream binding of the cAMP-CRP-alphaCTD complex and is inhibited by H-NS. During exponential growth, H-NS also strongly inhibits synthesis of a shorter isoform that performs a self-regulatory function. On stationary phase, H-NS repression is relieved, possibly due to self-regulation and other proteins such as Dps functioning upon transition to stat-phase when the cell switches to colonization. ChIP- and RNA-seq data suggested tight involvement of YjjM in control of cell colonization that, thus, could be also fine-tuned by H-NS, Dps and cAMP-CRP.

DISCOVERY AND CHARACTERIZATION OF THE NOVEL BACTERIAL ISOCYTOSINE DEAMINASES

J. Urbonavičius[1,2], *A. Aučynaitė*[2], *R. Rutkienė*[2], *D. Tauraitė*[2], *R. Meškys*[2]
[1]*Vilnius Gediminas Technical University, Department of Chemistry and Bioengineering, Vilnius, Lithuania*
[2]*Vilnius University, Department of Molecular Microbiology and Biotechnology- Life Sciences Center, Vilnius, Lithuania*

Backgrounds

Cytosine is one of four letters of a standard genetic code being part of both DNA and RNA. As part of the pyrimidine metabolism this heterocyclic base is converted into uracil by a hydrolase named cytosine deaminase. Isocytosine (2-aminouracil) is an isomer of cytosine.

Objectives

The aim of this study was to look for an enzyme converting isocytosine into uracil.

Methods

We used a uracil auxotroph-based selection strategy to search the metagenomic libraries for the genes encoding such enzymes. Three genes encoding potential bacterial deaminases were obtained. These genes were cloned into the expression vectors, expressed in *E. coli*, the recombinant proteins were purified, their enzymatic activities and substrate specificities were tested.

Conclusions

We found that isocytosine, but not cytosine is a substrate of the newly discovered isocytosine deaminases.

IDENTIFICATION OF GENES ENCODING FOR POLYKETIDE SYNTHASES AND NON-RIBOSOMAL PEPTIDE SYNTHETASES FROM THE ANTARCTIC MARINE FUNGUS PSEUDOGYMNOASCUS VERRUCOSUM

I. Vaca[1], *F. Vega*[1], *G. Vasquez*[1], *M. Henriquez*[1], *C. Gil-Duran*[2], *R. Chavez*[2]
[1]*Universidad de Chile, Departamento de Quimica, Santiago, Chile*
[2]*Universidad de Santiago de Chile, Departamento de Biologia, Santiago, Chile*

Backgrounds

The ability to produce secondary metabolites by filamentous fungi from extreme environments has been poorly studied. Recent evidences indicate that fungi inhabiting these environments are producers of novel secondary metabolites. However, in these fungi the specific function of many genes of secondary metabolism remains as unknown. In our laboratory, we isolated an Antarctic marine fungus belonging to the class Leotiomycetes whose extracts from fermentation broth, analyzed by 1H-RMN, showed an interesting chemical profile, suggesting the presence of novel secondary metabolites.

Objectives

In the present work, we perform the phylogenetic identification of this Antarctic fungus. In addition, we show the presence of genes encoding for polyketide synthases (PKSs) and non-ribosomal peptide synthetases (NRPSs) in its genome, and we describe the expression of these genes.

Methods

For the identification of the fungus, the phylogenetic position was determined by using four suitable molecular markers. On the other hand, partial sequences of five genes (four encoding for PKSs and one for NRPS) were isolated by PCR and analyzed by antiSMASH. Finally, the expression of these genes at different culture conditions was assessed by RT-PCR.

Conclusions

The results indicate that our isolate is closely related to the species *Pseudogymnoascus verrucosum*, whose presence had not yet been described in Antarctica. Analysis of the five sequences identified predicts that they would be part of clusters with unknown specific function. Only the PKS genes showed expression in the culture conditions tested, whereas the NRPS gene was silent. This work was supported by Fondecyt 1150894 and INACH RG_15-14.

IDENTIFICATION AND CHARACTERIZATION OF THE TRANSCRIPTIONAL REGULATOR RESPONSIBLE FOR REGULATION OF THE ESTABLISHMENT GENES PRESENT ON CONJUGATIVE PLASMID P576 OF BACILLUS PUMILUS

J. Val Calvo[1], *W. Meijer*[1]
[1]*Centro de Biología Molecular Severo Ochoa UAM-CSIC, Virology and Microbiology, MADRID, Spain*

Backgrounds

Aspects related with the DNA processing and transfer of conjugative elements from a donor to a recipient cell have been studied well. However, recipient cells contain systems to avoid the entry of foreign DNA. Successful transfer of a conjugative element requires therefore mechanisms to inactivate these defense mechanisms, and, -importantly-, these defense mechanisms must be inactivated only transiently during and shortly after transfer of the conjugative element to avoid that the cell becomes vulnerable to the entry of other foreign DNAs, for instance of phages. Conjugative plasmids contain genes, named establishment genes, which fulfill a role in establishment of the plasmid in the new host. Little is known how these genes are regulated.

Objectives

Unraveling the transcriptional regulation of establishment genes present on Bacillus pumilus conjugative plasmid p576.

Methods

In vivo and in vitro techniques were used to identify promoters located upstream of p576 establishment genes. Transcriptional fusions of these promoters were used to set up a system to identify the gene encoding the regulator of these promoters. EMSAs in combination with site directed mutants were used to demonstrate binding of the purified regulatory protein to these promoters.

Conclusions

We have identified the mechanism that is responsible for transient expression of establishment genes of plasmid p576 after being transferred into a recipient cell. Besides description of this transcriptional regulator, a new gene regulatory network for establishment genes is described for a Gram+ positive plasmid.

Physiology / Biochemistry / Molecular Microbiology - Part III

PROTEOME AND GENOMIC ANALYSIS OF CANDIDA ALBICANS EXOSOMES

V. Perez-donate[1], F. Perez-gimenez[2], L. Del Castillo-agudo[3], E. Valentin-gomez[3]
[1]HOSPITAL UNIVERSITARIO DE LA RIBERA, SERVICIO DE MICROBIOLOGÍA, ALZIRA, Spain
[2]Faculty of Pharmacy-University of Valencia, CHEMISTRY PHYSICAL, Burjassot Valencia, Spain
[3]Faculty of Pharmacy-University of Valencia, MICROBIOLOGY, Burjassot Valencia, Spain

Backgrounds

The morbility and mortality by *Candida albicans* has increased ostensibly in the last decades. In healthy individuals, *C. albicans* is a commensal but it can produce superficial injuries and systemic infections which can be harmless for the life of the patient. The knowledge of the molecular mechanisms of infections by *C. albicans* presents a great interest. The exosomes or extracellular vesicles (EV) are small membranous structures (40-200 nm) containing different kinds of macromolecules. However, the functional aspects of *C. albicans* EV remain unknown. Some authors attribute them a role in the communication between cells. These EV has been studied in various fungal pathogens as well as the model yeast *S. cerevisiae*.

Objectives

We have previously developed a protocol for EV purification from *Candida* species and analyzed its morphology and biochemical characteristics; in this work, we present a proteomic and a micro RNAs (miRNA) analysis.

Methods

EV were isolated as developed by our research group previously; analysis of proteins were carried out by MALDI-TOF, and miRNA identification by sequenciation; both analysis were carried out by the Servicio Central de Apoyo a la Investigación Experimental (SCSIE) at the University of Valencia (Burjassot, Valencia, Spain)

Conclusions

Proteome analysis showed the presence of 700 proteins, including cell wall proteins and sugar metabolism; however, a soft treatment of EV to detect surface proteins only showed 9 proteins mainly related to energy metabolism. The miRNA analysis identified 34 sequences most of them located in not transcribed regions but located in putative genetic regulation areas.

ENTEROCOCCAL ESP PROTEIN SELF-ASSEMBLE INTO AMYLOID AGGREGATES TO BUILD BIOFILMS

J. Valle[1], *I. Lasa*[1]
[1]*Centro de Investigación Biomédica Navarrabiomed/ UPNA, Patogénesis Microbiana, Pamplona, Spain*

Backgrounds

Recent insights into bacterial biofilms have induced a paradigm shift towards the recognition of functional amyloids as common building block structures of the biofilms. Amyloids are attractive extracellular building material because they generally resist to harsh denaturing conditions and proteases and their polymerization occurs in the absence of energy. Our group has demonstrated that the staphylococcal Bap protein, a member of the BAP family of proteins, is processed and fragments containing the N-terminus of the protein become aggregation-prone and self-assemble into amyloid-like structures.

Objectives

Based on our results obtained with the staphylococcal Bap protein, we propose to study the amyloidogenic properties of other members of the BAP proteins. Specifically, we have analyzed the capacity of the enterococcal Esp protein to self-assembly into amyloid fibers.

Methods

The N-terminal region of Esp (Esp_B domain) shares 33% homology with the N-terminal domain of Bap. Expression of a chimeric protein containing the Esp_B domain showed that this region is sufficient to confer multicellular behavior. Purified recombinant N-terminal region of Esp formed aggregates with amyloid like conformation at acidic pH and bind to amyloid diagnostic dyes. We used the curli-dependent amyloid generator C-DAG-system to test the amyloid-forming propensity of Esp. The presence of extracellular amyloid aggregates of Esp_B was confirmed by analyzing the capacity of the strains to bind Congo Red dye and by detecting the presence of fibrillar structures by electron microscopy.

Conclusions

These results suggested that the mechanism of amyloid-like aggregation showed for the BAP-like proteins might be a widespread mechanism to build the biofilm matrix.

SCH9P KINASE AND THE GCN4P TRANSCRIPTION FACTOR REGULATE GLYCEROL PRODUCTION DURING WINEMAKING

B. Vallejo[1], O. Helena[1], P. Cecilia[1], M. Emilia[1], A. Agustín[2]
[1]Universitat de Valencia, biochemistry and molecular biology, Valencia- Burjassot, Spain
[2]Instituto de Agroquímica y Tecnología de Alimentos IATA, Biotecnología, Valencia, Spain

Backgrounds

A basic understanding of the cellular mechanisms that allow cells to prevail in grape juice is essential to know how *Saccharomyces cerevisiae* adapts its metabolism in response to stressful winemaking conditions, mainly characterized by low nitrogen content. This feature is controlled by many nutrient-sensing pathways. The Tor/Sch9 pathway promotes growth and protein synthesis when nutrients are plenty and General Amino Acid Control, specifically transcription factor Gcn4p, is required for the activation of amino acid biosynthetic pathways.

Objectives

SCH9 impact on longevity depends on nitrogen/carbon ratio, as our previous results showed. When nitrogen is scarce, *SCH9* deletion shortens chronological life span under winemaking conditions and leads to increased glycerol accumulation, so we have investigated the molecular basis of this phenotype.

Methods

Transcriptomic and metabolomic approaches were carry out under winemaking conditions. *SCH9* deletion causes up-regulation of many amino acid biosynthetic pathways and *GCN4* overexpression produces short chronological longevity and increased glycerol. Therefore, both pathways are connected in terms of glycerol production and cause similar impact on yeast performance during winemaking. *SCH9* deletion down regulates peroxisomal genes, although localization of glycerol-3-P dehydrogenase Gpd1p, the limiting enzyme in glycerol biosynthesis, remains unchanged.

Conclusions

Despite both modificiations have different impact on the metabolome, *SCH9* deletion and *GCN4* overexpression cause down-regulation of glycolysis, and the common lower amount of the protective disaccharide trehalose may contribute to shorter longevity. *GCN4* overexpression increases the amount of most proteinogenic amino acids, while *SCH9* deletion down regulates most of them. *sch9*D increases the amount of lipids such phospholipids, ergosterol and sphingolipids.

MICROSCOPE: AN INTEGRATED PLATFORM FOR THE EXPLORATION AND CURATION OF MICROBIAL GENOMES

D. Vallenet[1], A. Calteau[1], S. Cruveiller[1], M. Gachet[1], G. Gautreau[1], A. Josso[1], A. Lajus[1], J. Langlois[1], J. Mercier[1], H. Pereira[1], R. Planel[1], J. Rollin[1], D. Roche[1], Z. Rouy[1], C. Médigue[1]
[1]CEA/Genoscope - Université d'Evry Val-d'Essonne - CNRS-UMR 8030 - Université Paris-Saclay, LABGeM, Evry, France

Backgrounds

The analysis of genomes from NGS platforms needs to be automated and fully integrated. However, maintaining consistency and accuracy in annotation is a challenging task because millions of proteins in databanks are not assigned reliable functions.

Objectives

The LABGeM team of the Genoscope sequencing center focuses its research activities on the development and application of new methods for genome analysis. These tools are then made available through MicroScope (http://www.genoscope.cns.fr/agc/microscope), an integrated platform dedicated to microbial genome annotation and comparative analysis, which is being developed in our group since 2004.

Methods

The resource provides data from complete and ongoing genome projects together with post-genomic experiments (i.e. transcriptomics, re-sequencing of evolved strains) allowing users to improve the understanding of gene functions. We will present an overview of the MicroScope analysis pipelines and illustrate the use of several new functionalities in the context of data discovery and expert annotation, which concern:

- comparative genomics with synteny computations and pan-genome analyses,
- the prediction of virulence and antimicrobial resistance genes,
- the detection and annotation of genomic regions of interest, like, secretion systems, integrons and secondary metabolite biosynthesis gene clusters,
- and metabolic network reconstruction assisted by the GROOLS expert system (https://github.com/grools).

Conclusions

To date, MicroScope contains data for about 7,000 microbial genomes, part of which are manually curated and maintained by microbiologists (>3,200 personal accounts in March 2017). The platform enables collaborative work in a rich comparative genomic context and improves community-based curation efforts.

RESPIRATORY COMPLEX I VARIANTS, SELECTED DURING EVOLUTION UNDER FREQUENT ANTIBIOTIC TREATMENT INDUCE BACTERIA PERSISTER CELL FORMATION THROUGH CYTOPLASMID ACIDIFICATION

B. Van den Bergh[1], J.E. Michiels[1], J. Schimpf[2], S. Bruschel[2], E. Vervisch[1], T. Friedrich[2], M. Fauvart[3], J. Michiels[1]
[1]KU Leuven, Microbial and Molecular Systems, Leuven, Belgium
[2]Freiburg University, Biochemistry, Freiburg, Germany
[3]imec, miLab team, Leuven, Belgium

Backgrounds

With rising antibiotic resistance and lacking new antibiotics targeting pristine targets, soon, mankind slips into an era where common infections will once again kill millions. Apart from resistance, bacteria can also resort to other means to evade antibiotics. Previously we showed evolution of extreme antibiotic tolerance in bacteria under frequent antibiotic exposure, not by antibiotic resistance but by acquiring mutations that increase the numbers of antibiotic-tolerant persister cells. One target is complex I, a membrane-embedded super enzyme of 535kDa and main entry point for electrons from NADH into the respiratory chain.

Objectives

We wanted to verify the importance and diversity of complex I variants in conferring extreme persistence levels and decipher their molecular mechanisms.

Methods

Whole genome sequencing on *Escherichia coli* evolved in the lab (both lab and pathogenic strains), identified a multitude of mutations in *nuo*. Surprisingly, all hit *nuoLMN* and none of the other 10 *nuo* genes. Genome engineering and antibiotic tolerance assays demonstrated their causality and ruled out overall knock-out effects. Biochemical analyses on purified complex I variants further confirmed stability and validity as entry point of electrons in the respiratory chain but instead indicated a diminished proton-translocating activity. Flow cytometry and pH-sensitive fluorophores pinpointed the effect specifically towards the pH component as membrane potentials remained unchanged, also explaining the unaffected antibiotic uptake of the mutants. Artificially changing cytoplasmic pH showed the causality of cytoplasmic acidification in the increased antibiotic tolerance.

Conclusions

Complex I variants, selected during frequent antibiotic exposure, influence bacterial persister cell formation through cytoplasmic acidification.

GROWING AKKERMANSIA MUCINIPHILA FOR THERAPEUTIC APPLICATIONS

K. van der Ark[1], S. Aalvink[1], C. Belzer[1], W. de Vos[1,2]
[1]Wageningen University and Research, Microbiology, Wageningen, The Netherlands
[2]University of Helsinki, RPU Immunobiology- Department of Bacteriology & Immunology, Helsinki, Finland

Backgrounds

The mucus degrading gut symbiont *Akkermansia muciniphila* is commonly associated with a healthy gut. Its relative abundance was found to be negatively correlated with metabolic disorders, obesity and chronic gut inflammations. We have previously shown that this anaerobic bacterium is capable to reduce mucosal levels of oxygen.

Objectives

To enable further physiological research, we aimed to develop a defined minimal medium to grow *A. muciniphila*, which is free of animal-derived compounds to allow application in clinical trials.

Methods

To support the design of a minimal medium we used predictions based on the genome-scale metabolic model (GEM). This suggested that *A. muciniphila* has a unique gap in the peptidoglycan synthesis pathway, since there is no gene annotated to code for GlmS, which mediates the conversion from fructose-6-phosphate (Fru6P) to glucosamine-6-phosphate (Glu6P) and is essential for peptidoglycan synthesis. We confirmed the absence of this conversion in *A. muciniphila* by overproducing the only alternative enzyme that could mediate this conversion, *A. muciniphila* NagB.

Conclusions

This enzyme was unable to efficiently convert Fru6P to Glu6P under physiological conditions. As a result, N-acetylglucosamine needs to be supplemented to the medium for *A. muciniphila* to synthesize peptidoglycan and grow efficiently. This and other knowledge obtained from the GEM was integrated to design and validate an animal component-free medium. The medium was used in preclinical trials in mice and to allow large scale production of *A. muciniphila* for human clinical trials. This study illustrates the use of GEMs to optimize growth and shows its applications for next generation therapeutic microbes.

ZINC-INDUCED TRANSPOSITION OF INSERTION SEQUENCE ELEMENTS CONTRIBUTES TO INCREASED ADAPTABILITY OF CUPRIAVIDUS METALLIDURANS

J. Vandecraen[1], P. Monsieurs[1], M. Mergeay[1], N. Leys[1], A. Aertsen[2], R. Van Houdt[1]
[1]SCK•CEN, Microbiology Unit, Mol, Belgium
[2]Katholieke Universiteit Leuven, Laboratory of Food Microbiology, Leuven, Belgium

Backgrounds

Mobile genetic elements play a significant role in bacterial evolution and Insertion Sequence (IS) elements are of specific interest as they constitute an importing driving force for genome plasticity. *Cupriavidus metallidurans* type strain CH34 is a well-studied metal-resistant β-proteobacterium and contains a very high number of genes involved in the resistance and processing of heavy metals as well as a high number of intact IS elements. It counteracts metal ion toxicity via a battery of resistance mechanisms, with an important role for its two megaplasmids pMOL28 and pMOL30. Interestingly, strain AE126, a derivative of CH34 cured of its megaplasmid pMOL30 harboring the main zinc resistance determinant, is still able to increase its zinc resistance.

Objectives

To determine the contribution of IS elements to the genetic adaptation of *Cupriavidus metallidurans* AE126 to toxic zinc concentrations.

Methods

Zinc resistant AE126 derivatives, which arose upon plating on medium supplemented with a toxic zinc concentration, were characterized in detail.

Conclusions

All resistant variants carried a compromised *cnrYX* regulatory locus, which resulted in derepression of CnrH sigma factor activity and concomitant induction of the corresponding RND-driven *cnrCBA* efflux system. Late-occurring zinc resistant variants likely arose in response to the selective conditions, as they were enriched in *cnrYX* disruptions caused by specific IS elements whose transposase expression was found to be zinc-responsive. Deletion of *cnrH*, and consequently the CnrH-dependent adaptation potential, still enabled adaptation by transposition of IS elements that provided outward-directed promoters driving *cnrCBAT* transcription. Thus, transposition of IS elements can be induced by stress conditions and play a multifaceted, pivotal role in the adaptation to zinc.

REGULATION OF CITRATE UTILISATION IN LACTOCOCCUS LACTIS

O. van Mastrigt[1], E. Mager[1], C. Jamin[1], T. Abee[1], S. Lillevang[2], E. Smid[1]
[1]Wageningen University & Research, Laboratory of Food Microbiology, Wageningen, The Netherlands
[2]Arla Foods, Arla Strategic Innovation Centre, Brabrand, Denmark

Backgrounds

Citrate is an important precursor for flavour formation in dairy fermentations. *Lactococcus lactis* subsp. *lactis* bv *diacetylactis* is one of the main species in dairy starter cultures that can utilise citrate. In this bacterium citrate utilisation is limited by transport of citrate via the plasmid-encoded citrate permease CitP.

Objectives

The aim of this study was to determine the mechanisms governing citrate utilisation in *L. lactis* to be able to select conditions which improve flavour formation.

Methods

L. lactis has been grown in chemostats at different pH values (5.5 and 7), types of nutrient limitation (lactose and amino acid) and in the presence and absence of citrate. Regulation of citrate utilisation was studied the level of (i) the plasmid copy number, (ii) *citP* transcription and (iii) citrate utilisation capacity.

Conclusions

We demonstrated that the plasmid copy number slightly increased in cells grown at low pH or under amino acid limitation. However, the main regulation mechanism for citrate utilisation is increased expression at low pH when citrate is present. The requirement of citrate has been overlooked in previous studies due to the presence of citrate in M17 growth medium. The increased transcription of *citP* correlated with a higher citrate utilisation capacity. Finally, acidic environments not only resulted in higher citrate utilisation rates, also acetoin formation significantly increased via induction of the acetoin pathway.

FEMS7-1166
Physiology / Biochemistry / Molecular Microbiology - Part III

MOLECULAR MECHANISM OF ACTION OF BACTERIAL GTP(GDP) PYROPHOSPHOKINASES

K. Van Nerom[1], *A. Garcia-Pino*[1]
[1]*Free University of Brussels ULB, BSBP, Gosselies, Belgium*

Backgrounds

Most bacteria can produce phenotypic variants of actively dividing cells, known as persisters, which are tolerant to most known antibiotics. Moreover, the pace of antibiotic discovery to combat resistant pathogens has slowed down. Discovering new targets, developing species-specific antibiotics and identifying prodrugs that have the potential to eradicate dormant persisters remains a challenge for modern molecular biology.

Objectives

The formation of persister cells is controlled by the bacterial signalling molecule ppGpp, which is synthesized by the almost ubiquitous enzyme RelA. Although this enzyme has been discovered several decades ago, the mechanism that leads to ppGpp synthesis and its regulation remain unknown. With this project, we aim to close that gap and study the regulation of RelA and the molecular mechanism of ppGpp-synthesis leading to persistence.

Methods

RelA from *Chlorobium tepidum* was incubated with six different Nanobodies prior to screening the ppGpp-producing activity of RelA by means of TLC. Nanobodies are antibody fragments from Camelid single chain antibodies that can bind specific epitopes of a target protein with high affinity. Nanobodies can act as inhibitors or activators of the target protein and can be used as a molecular tool to characterize their target.

Conclusions

We discovered two Nanobodies that activate ppGpp production by RelA from *Chlorobium tepidum*, while one Nanobody acts as an inhibitor of the enzyme. This research can lead to finding new ways to inhibit RelA *in vivo* and can provide a rational pathway to design new antibiotics with the potential to eradicate persistent bacterial infections.

Physiology / Biochemistry / Molecular Microbiology - Part III

SIRTUIN-DEPENDENT REVERSIBLE LYSINE ACETYLATION OF A TOXIN-ANTITOXIN SYSTEM MODULATES THE ACTIVITIES OF THIS SYSTEM, WHICH IS INVOLVED IN SALMONELLA PERSISTENCE.

C.M. VanDrisse[1], *A.R. Parks*[1], *J.C. Escalante-Semerena*[1]
[1]*UGA, Microbiology, Athens, USA*

Backgrounds

Bacterial toxin-antitoxin systems have been implicated in persistence of pathogens. Typically, toxin activity is neutralized through physical contact with its cognate antitoxin. Recently, others showed that the TacT toxin of *Salmonella enterica* acetylates aminoacyl-tRNAs leading to arrest of protein synthesis and persistence. We have further characterized the TacA (antitoxin) TacT (toxin) system of this bacterium, and show that TacT also acetylates TacA, a modification that is removed by the *Salmonella* CobB sirtuin deacetylase.

Objectives

To characterize the role of reversible lysine acetylation in *Salmonella* persistence.

Methods

Transfer of acetyl moieties by TacT (toxin) onto TacA (antitoxin) was detected by phosphor imaging. Removal of the label required incubation with the NAD^+-dependent CobB sirtuin deacetylase. The acetylation site in TacA was established by LC/MS/MS peptide fingerprinting. *In vitro* protein synthesis was used to quantify the effect of antitoxin acetylation on TacT aminoacyl-tRNA acetylating activity. Electrophoretic mobility shift assays were utilized to characterize DNA binding of wild-type and TacA acetylation-mimic variants.

Conclusions

While remaining in complex, TacT acetylated TacA, which caused an increase in TacT-dependent translation inhibition. Additionally, acetylated TacA altered TacAT binding to the *tacAT* promoter, which is currently being analyzed by RT-qPCR. *In vivo* analyses showed operons encoding TacAT variant complexes mimicking acetylated TacA had negative effects on growth, validating *in vitro* results. This is the first report of an acetyltransferase targeting a protein and non-protein substrate and the first report of reversible lysine acetylation of an antitoxin modulating the activity of the toxin, rather than physical separation of the toxin-antitoxin proteins.

Physiology / Biochemistry / Molecular Microbiology - Part III

THE SMALL PROTEIN TRPM MODULATES MORPHO-PHYSIOLOGICAL DIFFERENTIATION IN THE MODEL ACTINOMYCETE STREPTOMYCES COELICOLOR A3(2)

A. Vassallo[1], E. Palazzotto[1], M.V. Pravatà[1], L. Botta[2], G. Gallo[1], A.M. Puglia[1]
[1]University of Palermo, STEBICEF, Palermo, Italy
[2]University of Palermo, DICAM, Palermo, Italy

Backgrounds

TrpM, a small protein of 63 amino acids, modulates tryptophan (Trp) metabolism and morpho-physiological differentiation in the filamentous bacterium *Streptomyces coelicolor* A3(2), a model organism for antibiotic production and cell differentiation. Indeed, the *trpM* knock-out mutant strain is characterized by a delayed growth on minimal medium, smaller aerial hyphae, and reduction of both spore and antibiotic actinorhodin production in comparison with the wild-type strain. These observations were in agreement with proteomic analyses which highlighted a role for TrpM in controlling i) Trp production through Trp precursor availability and, thus ii) bacterial growth and morpho-physiological differentiation.

Objectives

Construction and morpho-physiological characterization of a *S. coelicolor* A3(2) *trpM* knock-in mutant.

Methods

- Construction of a *trpM* knock-in mutant by *E. coli-S. coelicolor* interspecific conjugation using the pIJ8600/trpM integrative plasmid.

- Scanning Electron Microscope (SEM) analysis.

- Spectrophotometric analysis and microbiological assays for evaluating antibiotic production.

Conclusions

A *trpM* knock-in mutant strain of *S. celicolor* A3(2) was constructed and showed an increased production of actinorhodin and spores: moreover, SEM analysis revealed an earlier formation of septa in aerial hyphae and confirmed that TrpM has a role in controlling the morpho-physiological differentiation of *S. coelicolor* A3(2).

MULTIPLE CROSSTALK BETWEEN TOR AND THE CELL INTEGRITY MAPK SIGNALING PATHWAY IN FISSION YEAST

B. Vázquez Marín[1], M. Madrid[1], A. Franco[1], T. Soto[1], E. Gómez-Gil[1], J. Vicente-Soler[1], M. Gacto[1], J. Cansado[1]
[1]University of Murcia, Genetics and Microbiology, Murcia, Spain

Backgrounds

In eukaryotic cells, the highly conserved Target of Rapamycin (TOR) and the Mitogen Activated Protein Kinase (MAPK) signaling pathways elicit adaptive responses to extra- and intracellular conditions by regulating essential cellular functions. In the fission yeast Schizosaccharomyces pombe the cell integrity MAPK pathway (CIP) regulates morphogenesis, cell wall structure and ionic homeostasis.

Objectives

To underscore the nature of the functional relationships between both TOR and CIP pathways in fission yeast.

Methods

We show that the Rab GTPase Ryh1, a TORC2 complex activator, cross-activates the CIP and its core member, the MAPK Pmk1, by two distinct mechanisms. The first one involves TORC2 and its downstream effector, Akt ortholog Gad8, which together with TORC1 target Psk1 increase protein levels of the PKC ortholog Pck2 during cell wall stress or glucose starvation. Also, Ryh1 activates Pmk1 in a TORC2-independent fashion by prompting plasma membrane trafficking and stabilization of upstream activators of the MAPK cascade, including PDK ortholog Ksg1 or Rho1 GEF Rgf1. Besides, stress-activated Pmk1 cross-inhibits Ryh1 signaling by decreasing the GTPase activation cycle, and this ensures cell growth during alterations in phosphoinositide metabolism.

Conclusions

Our results reveal a highly intricate cross-regulatory relationship between both pathways that warrants adequate cell adaptation and survival in response to environmental changes.

Physiology / Biochemistry / Molecular Microbiology - Part III

DISTINCT FUNCTIONAL RELEVANCE OF DYNAMIC GTPASE CYSTEINE METHYLATION IN FISSION YEAST

B. Vázquez Marín[1], T. Soto[1], R. Martín-García[2], P. Pérez[2], M. Madrid[1], E. Gómez-Gil[1], J. Vicente-Soler[1], M. Gacto[1], J. Cansado[1], A. Franco[1]
[1]University of Murcia, Genetics and Microbiology, Murcia, Spain
[2]Instituto de Biología Funcional y Genómica IBFG- Universidad de Salamanca, Morphogenesis and cell polarity, Salamanca, Spain

Backgrounds

The final step in post-traslational processing of Ras and Rho GTPases involves methylation of the prenylated cysteine by a isoprenylcysteine-O-carboxyl methyltransferase (ICMT). ICMT activity is essential for cell growth and development in higher eukaryotes, and inhibition of GTPase methylation has become an attractive target in cancer therapy to inactivate prenylated oncoproteins. However, the specificity and dynamics of the GTPase methylation process remain to be fully clarified. Notably, cells lacking Mam4, the ICMT ortholog in the fission yeast *Schizosaccharomyces pombe,* are viable.

Objectives

To analyze the role of methylation on GTPase localization and function in a simple eukaryotic model organism.

Methods

We show that methylation differentially affects GTPase membrane localization and signaling to MAPK cascades, being particularly relevant for plasma membrane tethering and downstream signaling of palmitoylated and farnesylated Ras and Rho GTPases lacking C-terminal polybasic motifs. Mam4 also negatively regulates TORC2 signaling by a cross-inhibitory mechanism relying on proper Rho GTPase methylation. Moreover, dynamic increase in cysteine methylation impairs cell growth, reduces Rho palmitoylation, and modulates its function *in vivo* either positively or negatively depending on the absence or presence of palmitoylation.

Conclusions

These results highlight the requirement for a strict control of GTPase methylation threshold *in vivo* to allow adequate GTPase function.

DIVERSITY OF MOBILE GENETIC ELEMENTS HARBOURED ON CHROMOSOME OF AVIBACTERIUM PARAGALLINARUM

C. Vazquez-Cruz[1], M.P.G. Sanchez-Alonso[1], Z. Guerrero-Gonzalez[1], N.E. Rojas-Ruiz[1], N. Negrete-Abascal[2], S. Vaca-Pacheco[2], V. Perez-Marquez[3]
[1]Instituto de Ciencias,
Centro de Investigaciones en Ciencias Microbiologicas- Benemerita Universidad Autonoma de Puebl a, Puebla, Mexico
[2]Universidad Nacional Autonoma de Mexico, Facultad de Estudios Superiores-Iztacala- Tlalnepantla, Estado de Mexico, Mexico
[3]Biotecnologia Veterinaria SA de CV, BIOVETSA, Tehuacan- Puebla, Mexico

Backgrounds

Four different *Avibacterium paragallinarum* genome sequences (AVP72, 221, JF4211 and CL) have been reported with a high number of contigs, except AVPG2015, that was grouped in 24 contigs. Those results could be due to: procedure to obtain the nucleotide sequence, the quality of sequences obtained, the procedure to assembly the information and the richness of repeated sequences in each genome.

Objectives

The aim of this work was to compare transposase, integrase and prophage sequences to understand the dynamics of them in the five reported *A. paragallinarum* genomes including one more recently sequenced by our laboratory (Avpg FES5 arranged in 46 contigs).

Methods

In silico analysis of three prophages was made in six genomes: CL, 221, JF4211, AVP72, AVPG2015 and FES5. Transposases and integrases analysis was made in CL and AVPG2015 genomes.

Conclusions

Lambdoid prophage sequences were found in all genomes. AvpmuC-2M and HP2-like sequences were found in CL, 221 and JF4211. CL genome is rich in transposase and integrase sequences (80 and 62, respectively) while AVPG2015 contains only 13 and 14 of each one; all of them grouped in five superfamilies of each group. Transposases and integrases sequences present in AVPG2015 genome just were classified into two families for each one. FES5 genome sequence is similar to AVPG2015 sequence and the low number of contigs among both, suggest that both strains are restrictive to mobile elements. A high number of movable elements into a genome sequence could be the main restriction to get a one molecule assembles in *A. paragallinarum* genomes.

Physiology / Biochemistry / Molecular Microbiology - Part III

ROLE OF AMINO ACID BIOSYNTHESIS IN SUPPRESSING THE THERMOSENSITIVE CELL DIVISION MUTANT ZIPA1 OF ESCHERICHIA COLI

D. Vega[1], W. Margolin[1]
[1]The University of Texas Health Science Center at Houston, Microbiology and Molecular Genetics, Houston, USA

Backgrounds

As reported by Pichof and Lutkenhaus in 2002, we observed that thermosensitive *zipA1* mutant was slightly elongated in LB at 30˚C and filamented at 42ºC. However, we also discovered that in minimal medium (either M9 or MOPS), *zipA1* cells grow poorly at 30ºC and form filaments and have other shape abnormalities. We confirmed that this cell division defect in minimal medium was exclusive to *zipA1*. Adding back casamino acids to M9 completely corrected the defects. Glycine or L-threonine greatly corrected the growth and division defect of *zipA1* in M9. Other amino acids can also correct the defects, but to a lesser degree.

Genes associated with L-threonine biosynthesis (*thrA*, *thrB* and *thrC*) were deleted in a *zipA1* background. Deletion of *thrB* or *thrC* but not *thrA,* partially suppressed thermosensitivity and cell defects. We considered L-homoserine (an intermediate in the biosynthesis of L-methionine, L-threonine and L-isoleucine) as the key player. Added L-homoserine did not suppress *zipA1* thermosensitivity in LB, but in M9 it partially suppressed division defects in *zipA1* despite inducing variations in cell width and length in *zipA*+ cells. L-homoserine is converted into S-adenosylmethionine (SAM), and the lack of SAM is known to inhibit cell division in *E. coli*. We confirmed that SAM was not involved in the *zipA1* phenotype.

The thermosensitivity of *zipA1*mutants lacking *glyA*, *ltaE* and *tdcB* was partially suppressed in LB, similar to the effect of *thrB* or *thrC* deletions. Therefore, blocking different branches of the threonine/glycine biosynthetic pathway can lead to partial suppression of the *zipA1* cell division defect.

Objectives

Characterization of the thermosensitive cell division mutant *zipA1* of *Escherichia coli*

Methods

Genetic Recombination-Transduction

Conclusions

Our data support a role of the L-threonine or glycine biosynthetic pathway in the function of ZipA and/or early stages of *E. coli* cell division, thus implicating amino acid homeostasis as a regulator of cytokinesis.

Physiology / Biochemistry / Molecular Microbiology - Part III

UNVEILING THE EVOLUTIONARY NEW ROLE OF CBIKP COBALTOCHELATASE FROM DESULFOVIBRIO VULGARIS

M. Videira[1], S. Lobo[1], I. Pacheco[1], M. Wass[2], M. Warren[3], M. Teixeira[1], P. Matias[1,4], C. Romão[1], L. Saraiva[1]
[1]Instituto de Tecnologia Química e Biológica António Xavier, Biological Chemistry, Oeiras, Portugal
[2]School of Biosciences- University of Kent, Biomolecular Medicine, Canterbury, United Kingdom
[3]School of Biosciences- University of Kent, Protein Science, Canterbury, United Kingdom
[4]Instituto de Biologia Experimental e Tecnológica, Structural Biology for Drug Discovery, Oeiras, Portugal

Backgrounds

Desulfovibrio vulgaris (*D. vulgaris*) are sulphate-reducing bacteria with numerous porphyrin containing enzymes. These organisms use sirohydrochlorin as substrate for metal insertion to synthesize sirohaem, cobalamin and haem *b*. Two homologs of CbiK sirohydrochlorin chelatase were previously identified in the genome of *Desulfovibrio vulgaris*, namely CbiK^{c} and Cbik^{p}, cytoplasmic and periplasmic forms, respectively. However, only Cbik^{p} is able to bind haem.

Objectives

This work aimed to study the structure/function relationship and the localization of *D. vulgaris* Cbik^{p} cobaltochelatase.

Methods

Site-directed mutagenesis was used to generate 11 specific Cbik^{p} mutants which were analysed regarding the chelatase activity and the oligomerization and haem binding properties. Furthermore, GFP fusions were made to Cbik^{p} to determine cellular localization.

Conclusions

We show that Cbik^{p} is a periplasmic protein. Two residues were identified as essential for the Cbik^{p} Co^{2+}/Fe^{2+} chelatase activity, namely His154 and His216. We also revealed that residues Arg54 and Glu76 are important for the oligomerization of Cbik^{p} as a tetramer. His96 was identified as the residue responsible for the binding of two haem molecules within the tetramer. We proved that two additional haem groups can be bound to the protein involving residue His103. Altogether, the absence of these two histidine residues from other bacterial CbiK cobaltochelatases, the periplasmic localization and the ability to bind more haem groups indicate that *D. vulgaris* Cbik^{p} may function as a haem transporter.

Physiology / Biochemistry / Molecular Microbiology - Part III

USTILAGO MAYDIS VACUOLAR ASPARTIC PROTEASE A, HOMOLOGUE OF THE HUMAN CATHEPSIN D PROTEIN IS INVOLVED IN DIMORPHISM AND PATHOGENESIS OF THE FUNGUS

L. Villa-Tanaca[1], V. Soberanes-Gutiérrez[1], P. Tesillo-Moreno[1], M. Juárez-Montiel[1], A. Ibarra-García[1], C. Hernández-Rodríguez[1], J. Ruiz-Herrera[2]
[1]Instituto Politecnico Nacional, Microbiología- ENCB, México- CDMX, Mexico
[2]Instituto Politecnico Nacional, Ingeniería Genética, Irapuato, Mexico

Backgrounds

Vacuole proteases have important functions in different physiological processes and during the autophagy phenomenon in fungi. As continuation of our studies of the proteolytic system of the *Ustilago maydis* a phytopathogenic Basidiomycota, we have analysed the role of the *pep4* gene encoding the vacuolar acid proteinase PrA in the pathogenesis and morphogenesis of the fungus.

Objectives

To analyze the role of the *pep4* gene encoding the vacuolar acid proteinase PrA in the pathogenesis and morphogenesis of the fungus and obtaining the recombinant *U. maydis* protease A by heterologous expression.

Methods

The location of the protease in the vacuole was performed by the use of fluorescent probes, we obtained deletion mutants of the gene in sexually compatible strains of *U. maydis* (FB1 and FB2). The *pep4um* gene was cloned and expressed in *Pichia pastoris*.

Conclusions

The yeast-to-mycelium dimorphic transition, was severely reduced in the Δ*pep4* mutants. Additionally, virulence of the mutants in maize seedlings was reduced, as revealed by the lower proportion of plants infected, and the reduction in these of the size in the tumours. A 54 kDa recombinant protein was observed and was confirmed to be an aspartic protease. It is important to note that the *in silico* analysis suggests that Pep4um is homologue of the human Cathepsin D protein, thus Pep4-um-rec protein may be used to test inhibitors of human Cathepsin D, an important breast cancer therapeutic target. These results are evidence of the importance of the *pep4* gene for the morphogenesis and virulence of *U. maydis*.

SIGNALING MEDIATED REGULATION OF METABOLISM IN BACILLUS ANTHRACIS

R. Virmani[1], Y. Hasija[2], Y. Singh[1]
[1]Prof. Y. Singh, Department of Zoology, Delhi, India
[2]Delhi Technological University, Biotechnology Department, Delhi, India

Backgrounds

Intracellular pathogens need to coordinate their metabolism with cell division process to survive and replicate inside the host cell. Thus, cell cycle machinery works to fine-tune the division process via multiple signaling pathways that critically monitor the environment.

Objectives

To understand the signaling mediated metabolic alteration of pathogenic bacteria, we aim to characterize the role of one of the key glycolytic enzyme, Enolase, which plays an important role in cellular events of *Bacillus anthracis*, the causative agent of Anthrax.

Methods

We studied the regulation of the enzyme by the signaling machinery of bacteria. Over expression strategies have been employed to check the effect of this glycolytic enzyme on spore revival process. Further, mass spectrometry was utilized to confirm the post-translational modifications.

Conclusions

Increase in the levels of Enolase, leads to disruption in the spore revival process; additionally, interaction of the enzyme with some key proteins involved in the cell cycle machinery was also confirmed. Our analysis revealed a novel mechanism by which cell division is linked to glycolysis. This study not only highlights the regulation of Enolase by the signal transduction cascade but also indicates a novel molecular circuit that controls cell growth and division. We propose, that the integration of metabolic and signaling cues allows the cells to modulate metabolism and assist in cell survival.

HOST FACTORS INVOLVED IN INTEGRON INTEGRASE-MEDIATED RECOMBINATION.

C. Vit[1], *C. Loot*[1], *G. Garriss*[1], *J. Matysiak*[2], *V. Parissi*[2], *D. Mazel*[1]
[1]*Institut Pasteur, Genomes and Genetic, paris, France*
[2]*Université de Bordeaux, Microbiologie fondamentale et pathogénicité, Bordeaux, France*

Backgrounds

Integrons are bacterial genetic elements that allow the capture of circular non-replicative gene cassettes and the expression of the ORF they carry. Integrons contain Y-recombinase, IntI, that recognizes and recombines a double-stranded *attI* site with a folded single-stranded *attC* site. This reaction is responsible for the formation of an atypical Holliday junction and its resolution has been shown to require a replication step unlike the classical pathway (Loot *et al.* 2012). Moreover, the integrase IntI1 (associated with Mobile Integrons) and IntI4 integrase (associated with the Sedentary Integron of *Vibrio cholerae*) have been shown to recombine with different efficiencies depending on the host (Biskri *et al.* 2005). These observations might reflect different requirements for host-encoded proteins, either for the recombination reaction itself, or for the resolution of the recombination intermediate.

Objectives

Here we aim at identifying host factors encoded in *V. cholerae* genome that may contribute to *attI x attC* recombination.

Methods

To identify these host factors we are using: 1) a biochemical approach in order to select proteins interacting with IntI1 or IntI4 (TAP-Tag and an *in vitro* purification of integrase partners (V. Parissi)) 2) a genetic screen to find out genes coding for proteins that are essential during *attC* x *attI* recombination with IntI4.

Conclusions

First results indicate that some proteins of the replication (DnaN or PriA) could interact with the IntI integrases, tests will be done to confirm these interactions.

DYNAMICS OF FUNCTIONAL MEMBRANE MICRODOMAINS IN BACTERIA

R. Wagner[1,2], *D. Lopez*[1,2]
[1]*Centro Nacional de Biotecnología CNB-CSIC, Microbial Biotechnology, Madrid, Spain*
[2]*Research Center for Infectious Diseases ZINF, Institute for Molecular Infection Biology IMIB, Würzburg, Germany*

Backgrounds

The cellular membrane fulfills an important function in protection and is the resource of communication with the surrounding. Especially for single cell organisms the integrity and functionality of membranes is crucial for the functionality of almost all cellular processes. The correct organization of membranes, including those from prokaryotes, relies on a heterogeneous distribution of constituent lipids and embedded proteins, which leads to the formation of membrane microdomains harboring proteins specialized in specific cellular processes. Functional membrane microdomains (FMMs) have been described to organize in the membrane of bacterial cells and their integrity has been shown to be important in cellular processes like signal transduction and membrane trafficking.

Objectives

Interestingly, FMMs are highly dynamic assemblies moving within the bacterial membrane. However, the biological significance and the underlying molecular mechanism that orchestrate FMM dynamics remain largely unknown.

Methods

Here, we use cutting-edge live-cell imaging techniques in combination with a number of biochemical and molecular approaches to investigate FMM dynamics in the bacterial models *Bacillus subtilis* and *Staphylococcus aureus*. Genetic and physiological targeting of cellular integrity led to unambiguous results showing that FMM dynamics is intimately associated with membrane integrity as well as the integrity of other membrane-related cellular structures.

Conclusions

Thus, alterations in membrane organization leads to severe interference in the FMM dynamics which in turn affects the functionality of FMM-associated cellular processes. Finding the biological significance of highly dynamic FMMs in the bacterial cell guides the design of antimicrobial agents for new yet unidentified target mechanisms.

FUNCTIONAL ANALYSIS OF TWO COMPONENT SYSTEM ABERASR IN ACINETOBACTER BAUMANNII

M.Y. Wen[1], *G.H. Lin*[1], *Y.H. Chiu*[1]
[1]*Tzu Chi University, Department of Microbiology, Hualien, Taiwan R.O.C.*

Backgrounds

Acinetobacter baumannii is a Gram-negative bacterium. In previous, *A. baumannii* could grow in low concentration of ethanol. Currently, no article published about two component system can regulate alcohol metabolism in *A. baumannii*. *In silico* analysis, AbEraSR in *Acinetobacter baumannii* share 26% and 33% amino acid sequence identity with EraSR in *P. aeruginosa*, respectively. EraSR is known as a two component system that can regulate alcohol metabolism.

Objectives

Whether AbEraSR plays a role in alcohol metabolism and finds out which gene will be regulated by AbEraSR.

Methods

Ethanol degradation of *A. baumannii* maker-less mutagenesis mutants were cultured in M9 medium with different concentration of ethanol as single carbon source. Regulation cascade of AbEraSR were confirmed by red fluorescence protein reporter gene system(TCSR) in *E. coli*. Electrophoretic mobility shift assay(EMSA) was demonstrated to determine the regulation of alcohol dehydrogenase which is a key enzyme in alcohol metabolism by AbEraR directly.

Conclusions

In single carbon source culture, the result showed that there were no significantly different between wild-type and Δ*AberaS* strain. However, this result indicated that there are another systems such as two component system or regulator protein can regulate AbEraSR or alcohol metabolism directly. In order to comprehensive understanding how AbEraSR regulates the downstream gene, we construct TCSR in *E. coli* and coordinate lab member construction of green fluorescence protein reporter gene system to comprehend regulation of these two component systems. If AbEraSR will regulate ADH the detector can detect red fluorescence.

ACUH FROM RUEGERIA LACUSCAERULENSIS IS A CROTONASE SUPERFAMILY ENZYME WITH ACTIVITY TOWARDS METHYLTHIOACRYLOYL-COA AND ACRYLOYL-COA

H. Bullock[1], Y. Zhu[1], C. Reisch[1], W.B. Whitman[1]
[1]University of Georgia, Microbiology, Athens, USA

Backgrounds

Dimethylsulfoniopropionate (DMSP) produced by marine phytoplankton is an important source of reduced carbon and sulfur for marine bacteria, and the DMSP demethylation pathway is a major mechanism for its assimilation. The final reaction in this pathway is catalyzed by DmdD, a crotonase superfamily enzyme that converts methylthioacryloyl-CoA (MTA-CoA) to acetaldehyde, CO_2, and methanethiol (MeSH). *Ruegeria lacuscaerulensis* metabolizes DMSP, however an ortholog to *dmdD* is missing from its genome.

Objectives

Does a paralog of DmdD provide the physiological activity for the demethylation pathway in roseobacteria lacking DmdD?

Methods

Results: RL_AcuH was isolated from *R. lacuscaerulensis* cell extracts based upon its activity toward MTA-CoA. Recombinant RL_AcuH possessed activity with MTA-CoA and crotonyl-CoA as well as high activity with acryloyl-CoA. For this reason, it was named acryloyl-CoA hydratase or AcuH. Due to its activity with acryloyl-CoA, AcuH was predicted to function in both the demethylation and cleavage pathways. Subsequent tests revealed that RL_AcuH required activation by ADP or NAD^+ for high catalytic efficiency towards MTA-CoA. RL_*acuH* was able to complement growth and MeSH production defects of a *Ruegeria pomeroyi dmdD* deletion mutation. While AcuH orthologs from *Dinoroseobacter shibae* DFL12, *Oceanibulbus indolifex* HEL45, *Pseudomonas putida* KT2440, and *Burkholderia thailandensis* E264 all had substantial activity towards crotonyl-CoA, their catalytic efficiency for MTA-CoA hydration was low, indicating that this is not likely to be a physiological function.

Conclusions

While AcuH is likely a physiological MTA-CoA hydratase in *R. lacuscaerulensis*, this activity is not uniform across all bacteria possessing AcuH-like enzymes.

DIMERIZATION OF THE POREFORMING TOXIN HOKB IS REQUIRED TO INDUCE PERSISTENCE IN ESCHERICHIA COLI

D. Wilmaerts[1], N. Verstraeten[1], M. Bayoumi[2], G. Maglia[3], J. Michiels[1]
[1]KU Leuven, Centre of Microbial and Plant Genetics, Heverlee, Belgium
[2]KU Leuven, Biochemistry- Molecular and Structural Biology Section, Heverlee, Belgium
[3]University of Groningen, Faculty of Mathematics and Natural Sciences, Groningen, The Netherlands

Backgrounds

When an isogenic bacterial population is treated with high doses of bactericidal antibiotics, a small fraction survives. These so-called persister cells are not genetic mutants but phenotypic variants. Toxin-antitoxin modules have been implicated in the induction of persistence. These systems inhibit essential cellular functions, leading to persistence.

Objectives

We have previously shown that the essential GTPase ObgE induces persistence in *E. coli* by upregulating the toxin HokB. After insertion in the membrane, HokB induces persistence by collapsing the membrane potential. We aim at further elucidating the mode of action of HokB.

Methods

We used conductance measurements on planar lipid bilayers to test *in vitro* pore formation by HokB. As we observed formation of covalently bound HokB dimers on a western blot, we tested whether disulfide bridges play a role in the persistence phenotype of HokB. For this, we used cysteine substitution mutants of HokB and knockout strains of periplasmic oxidoreductases.

Conclusions

Using a planar lipid bilayer, HokB was shown to form pores of 0.4-1.6 nm. In addition, we discovered that the formation of disulfide bridges in the periplasmic part of the peptide is mediated by periplasmic oxidoreductases and is essential for the persistence phenotype of HokB. Interestingly, the persister fraction was directly affected by chemically changing the ratio between monomers and dimers using dithiothreitol (DTT). Combined, our findings demonstrate the essential role of dimerization of HokB for persistence, offering the possibility to control persistence by changing the redox conditions.

DISTRIBUTION OF MAZEF/PEMIK LOCI AMONG STAPHYLOCOCCI AND THEIR GENETIC CONTEXTS

B. Wladyka[1], M. Bukowski[1], K. Hyz[1], M. Janczak[1], M. Hydzik[1]
[1]Jagiellonian University, Department of Analytical Biochemistry, Krakow, Poland

Backgrounds

Toxin-antitoxin (TA) systems are small genetic entities widespread among bacteria. Recently the importance of their role in various aspects of bacterial physiology has been growingly recognized. Generally, the systems are made of two components, with the antitoxin gene preceding the one for the toxin. The open reading frames are often overlapping and code for relatively small products. This, together with the knowledge of already described TA systems, allows for application of bioinformatics in search for undiscovered ones. Staphylococci are gram-positive bacteria associated with human and animals. Among them *S. aureus* is considered as a dangerous opportunistic pathogen with increasing drug-resistance.

Objectives

Recently, a significant amount of genetic data has been increasingly released due to the rapidly growing use of massive parallel sequencing methods. Nonetheless, the last comprehensive analysis of TA system distribution, which included 18 staphylococcal genomes, was undertaken seven years ago. Here we provide a distribution analysis of *mazEF/pemIK* loci among staphylococci based on over 6,000 genome sequences.

Methods

Five computational approaches based on BLAST+ tools were applied. Protein sequences of the well-characterized staphylococcal TA systems, MazEF-Sa and PemIK-Sa1, were used as prototypical ones.

Conclusions

Five computational approaches gave the same set of twelve *mazEF/pemIK* loci, with ten newly uncovered. Chromosomally encoded *mazEF-Sa* is present in virtually every staphylococcal genome. Despite greater diversity, the occurrence frequency of *pemIK* loci is generally low. Interestingly, the loci is often located on mobile genetic elements carrying drug resistance genes. Moreover, preference of *pemIK-Sa1*-carrying strains towards poultry *S. aureus* strains is noticeable.

PROTEIN-PROTEIN INTERACTION IN TYPE II-A CRISPR-CAS SYSTEM

S.P. Wong[1,2], F. Hille[1], H. Richter[1], K. Schmidt[1], C. Emmanuelle[1,2,3]
[1]Max Planck Institute For Infection Biology, Department of Regulation in Infection Biology, Berlin, Germany
[2]The Laboratory for Molecular Infection Sweden MIMS- Umeå Centre for Microbial Research UCMR-Umeå University, Department of Molecular Biology, Umeå, Sweden
[3]Humboldt University, Humboldt University, Berlin, Germany

Backgrounds

The RNA guided prokaryotic adaptive immune system CRISPR (clustered regularly interspaced short palindromic repeats)-Cas (CRISPR-associated) immunizes microorganisms against mobile genetic elements. The hallmark of the system is the genomic CRISPR array, which consists of repeat sequences interspaced with invader-derived spacer sequences. The immunity operates in three stages, *i.e.* (1) acquisition and integration of a short nucleic acid sequence from the invader into the CRISPR array (adaptation); (2) transcription and maturation of the transcripts into mature CRISPR RNAs (crRNAs) that contain a repeat and a spacer portion (biogenesis); (3) neutralization of the invaders by a crRNA-guided Cas nuclease that targets foreign nucleic acids through sequence complementarity between the cognate spacer of the crRNA and the invader's sequence (protospacer). Cas1, Cas2, Csn2 and Cas9 of the *Streptococcus thermophilus* type II-A CRISPR-Cas system are essential for adaptation, however, their interactions within a complex are still obscure.

Objectives

Analysis of the detailed Cas protein-protein interactions

Methods

First, *in vivo* acquisition studies verified the activity of the acquisition machinery (2 CRISPR-Cas systems, CRISPR1 and CRISPR3) of *S. thermophilus* LMD-9 after phage infection. We observed higher acquisition rates in the CRISPR3 locus compared to CRISPR1. An *in vitro* pull-down assay using recombinant Cas1 as bait protein demonstrated the Cas1-Cas9 protein-protein interaction. For further identification of the interacting residues, a SPOT membrane with an immobilized array of overlapping Cas1 peptides was used. The result demonstrated that the C-terminus of Cas1 interacts with Cas9.

Conclusions

In summary, we show the interaction between Cas1 and Cas9 and disclose involved residues.

OFF-PATHWAY ASSEMBLY OF FIMBRIA SUBUNITS IS PREVENTED BY CHAPERONE CFAA OF CFA/I FIMBRIAE FROM ENTEROTOXIGENIC E. COLI

D. Xia[1]
[1]*National Cancer Institute- NIH, Laboratory of Cell Biology, Bethesda, USA*

Backgrounds

The assembly of the class 5 CFA/I fimbriae of enterotoxigenic *E. coli* was proposed to proceed via the alternate chaperone-usher pathway.

Objectives

How different the alternate chaperone-usher pathway is from the classic chaperone-usher pathway is investigated.

Methods

Here, we show that in the absence of the chaperone CfaA, CfaB, the major pilin subunit of CFA/I fimbriae, is able to spontaneously refold and polymerize into cyclic trimers. CfaA kinetically traps CfaB to form a metastable complex that can be stabilized by mutations. Crystal structure of the stabilized complex reveals distinctive interactions provided by CfaA to trap CfaB in an assembly competent state through donor-strand complementation and cleft-mediated anchorage. Mutagenesis indicated that donor-strand complementation controls the stability of the chaperone-subunit complex and the cleft-mediated anchorage of the subunit C-terminus additionally assist in subunit refolding. Surprisingly, over-stabilization of the chaperone-subunit complex led to delayed fimbria assembly, whereas destabilizing the complex resulted in no fimbriation.

Conclusions

Thus, CfaA acts predominantly as a kinetic trap by stabilizing subunit to avoid its off-pathway self-polymerization that results in energetically favorable trimers and could serve as a driving force for CFA/I pilus assembly, representing an energetic landscape unique to class 5 fimbria assembly.

A GENETIC TOOL TO STUDY THE PHENOTYPE OF FOREIGN GENES

K. Yadav[1], *D. Hughes*[1]
[1]*Uppsala University, Department of Medical Biochemistry and Microbiology, Uppsala, Sweden*

Backgrounds

Horizontal gene transfer (HGT) is an important driver of evolution and is a major source of antibiotic resistance genes in bacterial pathogens. We developed a genetic tool using constitutive promoters of different strength to study the effect of expression level on the phenotypes of genes from distantly related bacteria expressed in *Escherichia coli*.

Objectives

We developed a genetic tool using constitutive promoters of different strength to study the potential of HGT to confer antibiotic-resistance in *E. coli* and how the level of resistance, and fitness, is affected by gene expression level.

Methods

Lambda-red recombineering was used to create a set of isogenic *E. coli* strains in which any HGT antibiotic resistance gene could be placed under the control of 8 different constitutive promoters. The relative strength of each promoter was quantified by measuring fluorescence intensity using a magnetic associated cell sorter (MACS).

Conclusions

The expression of sYFP in the set of constructed strains covered a wide range, from 2- to 500-fold above background level. We used the synthetic expression system to ask whether foreign ribosomal protection proteins (TetO, TetW, TetQ, TetB(P), OtrA) transferred by would be able to confer tetracycline resistance in *E. coli*. Using TetM as a positive control we showed that three of the foreign proteins, TetO, TetW and TetQ, conferred expression-dependent levels of resistance approximately equal to that conferred by TetM (>128 mg/mL at the highest level of expression). In contrast, TetB(P) conferred only a modest increase (8 mg/mL) and OtrA none at all even at the highest level of expression. Here we have developed and validated a genetic tool to study the influence of expression level on horizontally transferred foreign genes in *E. coli*. This system can be used to predict the potential of foreign genes to confer novel phenotypes such as antibiotic resistance on the recipient bacteria.

CHARACTERIZATION OF UNCHARACTERIZED TRANSCRIPTION FACTORS, YAGI, YBIH, AND YDCN, OF ESCHERICHIA COLI BY USING THE GENOMIC SELEX SYSTEM.

K. Yamamoto[1], *A. Ishihama*[2]
[1]*Hosei University, Department of Frontier Bioscience and Micro-Nano Technology Research Center-, Koganei- Tokyo, Japan*
[2]*Hosei University, Department of Frontier Bioscience and Micro-Nano Technology Research Center, Koganei- Tokyo, Japan*

Backgrounds

Escherichia coli contains a total of more than 4,400 protein-coding sequences on its genome. The selection of genes for expression and their expression level are determined by controlling the distribution of a limited number of transcription apparatus on the genome.

Objectives

A total of 7 species of sigma factor, the promoter recognition subunit of RNA polymerase (RNAP), and about 300 species of transcription factor (TF) are altogether involved in this gene selection process. At present, however, the regulatory functions are not known for about one fifth of the *E. coli* TFs.

Methods

For identification of the regulation targets by uncharacterized TFs, we have then developed an improved system of Genomic SELEX (systematic evolution of ligands by exponential enrichment). The Genomic SELEX screening system is particularly useful for identification of regulation targets of hitherto uncharacterized TFs. Although the majority of TFs regulates a number of target promoters and genes, but we have identified about 10 species of TFs that regulate only a single (or a few) target. Here we will describe three single-target TFs, YagI, YbiH, and YdcN. The targets predicted based on the SELEX screening were experimentally examined *in vitro* and *in vivo*.

Conclusions

Taken all these results together, we propose that: YagI is a repressor for the *yagA* and *yagE* operon; YbiH (remaned to CecR) is a bifunctional regulator, repressing the *ybiH* operon and activating the *rhlE* operon, both being involved in the sensitivity control to cefoperazone and chloramphenicol; and YdcN (remaned to StuR) is a regulator of sulfur utilization.

AN EXTRA REPABC LOCUS IN THE INCRH2 TI PLASMID PTIBO542 EXERTS INCOMPATIBILITY TOWARD AN INCRH1 PLASMID

S. Yamamoto[1], V. Agustina[1], A. Sakai[1], K. Moriguchi[1], K. Suzuki[1]
[1]Hiroshima University, Department of Biological Science- Graduate School of Science, Higashi-Hiroshima, Japan

Backgrounds

Ti/Ri plasmids in pathogenic *Agrobacterium* species are *repABC* replicons that are stably maintained by the function of *repABC* genes. Two Ti plasmids, pTiBo542 and pTiS4, belonging to incRh2 and incRh4 incompatibility groups, respectively, were reported to carry two *repABC* loci. However, the significance of the extra *repABC* genes remains unclear.

Objectives

The objective of this study is to reveal the roles of the two *repABC* loci in the two Ti plasmids, pTiBo542 and pTiS4.

Methods

We constructed mini replicons carrying any one or both of the *repABC* loci (referred to as *repABC1* and *repABC2* here) and examined their replication and incompatibility properties. The replication of the mini replicons was checked by transformation of Agrobacterial cells. The incompatibility between plasmids was evaluated by evicting the resident plasmid from the recipient cell by introducing the incoming plasmid in conjugation assay.

Conclusions

The *repABC2* loci of the two Ti plasmids lack an ability to replicate in *Agrobacterium* cells. However, a *repABC2* locus of pTiBo542 exerts incompatibility toward an incRh1 plasmid unilaterally and can thus displace the coexisting incRh1 plasmid efficiently. We suggest that the locus contributes to plasmid retention by eliminating the burden of co-existing competitive plasmids in host cells through its incompatibility.

Physiology / Biochemistry / Molecular Microbiology - Part III

CROSS-REGULATION BETWEEN TWO TYPE II TOXIN/ANTITOXIN SYSTEMS FROM DIFFERENT MOBILE GENETIC ELEMENTS IN SHEWANELLA ONEIDENSIS

J. Yao[1], *X. Wang*[1]
[1]*Chinese Academy of Sciences- South China Sea Institute of Oceanology, LMB, Guangzhou-, China*

Backgrounds

Toxin/antitoxin (TA) systems are prevalent in bacteria, archaea and bacteriophage. They can commonly found in mobile genetic elements (MGEs) such as plasmids, prophages and integrated conjugative elements. However, physiological functions of these TA systems and cross-regulation among these MGEs remain largely unexplored.

Objectives

Here we characterized a type II TA pair ParEso/CopGAso from cryptic prophage CP4So in *Shewanella oneidensis*.

Methods

We demonstrate that ParEso/CopGAso played an important role in the maintenance of CP4So circle after CP4So is excised from host genome. Toxin ParEso inhibited cell growth, resulting in filamentous growth and eventually cell death. The cognate antitoxin CopGAso neutralized the toxicity of ParEso through direct protein-protein interaction. Additionally, CopGAso autoregulated the TA operon through binding to the palindromic sequences (5'-GTATTACCTAGTAGTAC-3') in the promoter region. The N-terminal of CopGAso contains a typical Ribbon-Helix-Helix domain which exerts DNA-binding activity through binding to specific palindromic sequences. Additionally, antitoxin CopGAso also repressed the transcription of another type II TA system $PemIK_{SO}$ from the megaplasmid pMR-1 in *S. oneidensis* through binding to a similar palindrome in its promoter. We further demonstrated that CopGAso can also function as a positive regulator for the sigma factor RpoE2 and help mediate the oxidative stress response.

Conclusions

We thus provide evidences that type II TA systems from different mobile genetic elements can cross-talk through the DNA binding ability of the antitoxin component.

Physiology / Biochemistry / Molecular Microbiology - Part III

REMOVAL OF ACETYLATION OF SIALIC ACID BY ESTERASES POTENTIATES PNEUMOCOCCAL NEURAMINIDASE ACTIVITY FOR MUCIN UTILIZATION, COLONIZATION AND VIRULENCE

H. Yesilkaya[1]
[1]*University of Leicester, Infection- Immunity & Inflammation, Leicester, United Kingdom*

Backgrounds

Pneumococcal neuraminidase is a key enzyme for deglycosylation of host glycans, and plays an important role in host survival, colonisation, and pathogenesis of infections caused by *Streptococcus pneumoniae*. One of the factors that can affect the activity of neuraminidase is the acetylation present in its substrate sialic acid.

Objectives

The objective was to gather data to support hypotheses that pneumococcal esterases potentiate neuraminidase activity by removing acetylation from sialic acid, and this deacetylation will have a major effect on pneumococcal survival on mucin, colonisation, and virulence.

Methods

These hypotheses were tested using isogenic mutants and recombinant esterases in microbiological, biochemical and *in vivo* assays.

Conclusions

Pneumococcal esterase activity is encoded by at least four genes, SPD_0534 (EstA) was found to be responsible for the main esterase activity, and the pneumococcal esterases are specific for short acyl chains. Both the Axe and EstA esterases could use acetylated xylan and Bovine Sub-maxillary Mucin (BSM), a highly acetylated substrate, but only EstA was active against tributyrin (triglyceride). Incubation of BSM with either Axe or EstA led to the acetate release in a time and concentration dependent manner, and pre-treatment of BSM with either enzyme increased sialic acid release on subsequent exposure to neuraminidase. Mutation of *estA* alone or in combination with *nanA* (codes for neuraminidase A), or the replacement of its putative serine active site to alanine, reduced the pneumococcal ability to utilise BSM as a sole carbon source, sialic acid release, colonisation, and virulence in a mouse model of pneumococcal pneumonia.

Physiology / Biochemistry / Molecular Microbiology - Part III

COMPARISON OF PROTEOMIC EXPRESSION IN BRUCELLA ABORTUS MUTANTS WITH DIFFERENT CHARACTERISTICS BY TWO DIMENSIONAL ELECTCTROPHORESIS

P. Woo Bin[1], I. Young Bin[1], S. Soojin[1], H.S. Yoo[1]
[1]College of Veterinary Medicine - Seoul National Univer, Department of Infectious Diseases, Seoul, Republic of Korea

Backgrounds

Brucellosis caused by *Brucella abortus.* is debilitating and zoonotic disease. The bacterium is facultative intracellular organisms. Pathogenesis of the bacterial infection is very difficult. Therefore, underlying mechanism of the *B. abortus* infection is still remained to be resolved even though several researches have been done. As one of the steps, proteins showing different expression in the mutants showing different biological phenotypes were identified.

Objectives

Objective of this study was to identify the proteins showing the different expression level in *B. abrotus* mutants with different biological characteristics.

Methods

B. abortus mutants were generated by random insertion of transposon, EZ-Tn5^{TM}. Total proteins of 5 mutants and wild type of *B. abortus* were purified, analyzed by 2-DE and compared. Protein spots with a greater than 2-fold change were identified using LC-ESI-MS and Mascot.

Conclusions

Various spots showing increase or decrease in the expression were identified by 2-DE analysis of mutants and wild strains. Of the spots, commonly increased or decreased spots in the mutants were selected and identified. DnaK, ClpB, and Pgk were highly increased while SecA, EtfB, and RplK were highly decreased. In the proteins, heat shock proteins, ClpB and DnaK, may play an important role in the intracellular infection of *B. abortus* by protein aggregation suppression. Also, the changes in factor related to the growth, RplK, was related with phenotypic characteristics. These results may solve the clues related with virulence factors by observing the changes of various factors in the mutants. This work was supported by NRF (No. 2014R1A2A2A01007291) and BK21 PLUS.

Physiology / Biochemistry / Molecular Microbiology - Part III

CHARACTERIZATION OF THE FRUBKA OPERON REGULATOR FRUR IN VIBRIO CHOLERAE

C.K. Yoon[1], Y.H. Park[1], Y.R. Kim[1], Y.J. Seok[1]
[1]Department of Biological Sciences and Institute of Microbiology, Biological Science, Seoul, Republic of Korea

Backgrounds

Fructose repressor (FruR), which belongs to the GalR/LacI family of transcriptional regulators, regulates the expression of genes involved in the transport and utilization of fructose through direct binding to the cognate DNA sequence upstream of the *fruBKA* operon. In *Escherichia coli*, FruR has been elucidated as a global regulator responsible for controlling the carbon metabolic flux through repression or activation of mRNA expression of approximately 60 genes in 24 operons.

Objectives

Vibrio cholerae also has a FruR ortholog (vcFruR) that shares 47% amino acid sequence identity with *E. coli* FruR (ecFruR). vcFruR has unique features compared to the ecFruR.

Methods

In this study, we investigated the transcriptional regulation of FruR on the expression of the *fruBKA* operon. We were able to confirm the direct binding of FruR to three putative binding sites through DNase I footprinting and gel shift assays.

Conclusions

First, the oligomeric state of ecFruR is a homo-tetramer whereas vcFruR exists in a dimeric state *in vitro*. In addition, the gene encoding vcFruR is located adjacent to and divergently transcribed from the *fruBKA* operon. Lastly, only 3 sites are expected to be the target sites of FruR in the entire *V. cholerae* genome and these sites are located in the intergenic region between *fruR* and *fruBKA*. These findings indicate that vcFruR might have regulatory mechanism different from that of ecFruR. By binding to each target site in different combinations, vcFruR is considered to regulate the transcriptional level of the *fruBKA* operon and itself in *V. cholerae.*

FUNCTIONAL AND STRUCTURAL STUDIES OF THE NISIN RESISTANCE PROTEIN NSR OF STREPTOCOCCUS AGALACTIAE

J. Zaschke-Kriesche[1], B. Frieg[2], H. Gohlke[1], S.H.J. Smits[1]
[1]Heinrich-Heine-University- Duesseldorf, Institute of Biochemistry, Duesseldorf, Germany
[2]Heinrich-Heine-University- Duesseldorf, Institute of pharmaceutical and medical chemistry, Duesseldorf, Germany

Backgrounds

The antimicrobial peptide nisin contains 34 amino acids and is produced by some *Lactococcus lactis* strains. It is used in the food and dairy industry as a preservative since decades. It belongs to the lantibiotic subclass and displays high antimicrobial activity against mainly Gram-positive bacteria. The human pathogen *Streptococcus agalactiae*, however is resistant against nisin due to the presence of the *nsr*-operon (Khosa et. al 2013) encoding a two-component system NsrRK, an ABC-transporter NsrFP and the nisin resistance protein (NSR). Latter is a serine protease, which inactivates nisin by cleaving off the last six amino acids. We recently solved the X-ray structure of *Sa*NSR, which revealed that nisin is specifically recognized by NSR via the two last lanthionine-rings D and E (Khosa et. al 2016).

Objectives

The goal of this study is to overcome the lantibiotic-resistance in human pathogens using nisin as a model system. Thereby lantibiotics can be used as novel antibiotics and exploit there full potency.

Methods

We used molecular dynamics and simulations to screen over 3000 natural compounds to find inhibitors. The identified compounds were subjected to *in vivo* and *in vitro* assays to identify their ability to inhibit *Sa*NSR.

Conclusions

Here, we present the functional characterization of *Sa*NSR as well as the first subset of compounds, which can be used to bypass lantibiotic resistance in human pathogens allowing displaying the full potential of these peptides.

COMPARATIVE WHOLE-GENOME ANALYSIS REVEALS ARTIFICIAL SELECTION EFFECTS ON USTILAGO ESCULENTA GENOME

Y. Zhang[1], Z. Ye[1], Y. Pan[2], H. Cui[1], G. Jin[3], A. McHardy[2], L. Fan[3], X. Yu[1]
[1]China Jiliang University,
Zhejiang Provincial Key Laboratory of Biometrology and Inspection & Quarantine, Hangzhou, China
[2]Heinrich Heine University, Department of Algorithmic Bioinformatics, Düsseldorf, Germany
[3]Zhejiang University, Zhejiang Key Laboratory of Crop Germplasm Resources, Hangzhou, China

Backgrounds

Ustilago esculenta, infects *Zizania latifolia*, and induced host stem swollen to be a popular vegetable called *Jiaobai* in China. It is the long-standing artificial selection that maximizes the occurrence of favorable *Jiaobai*, and thus maintaining the plant-fungi interaction and modulating the fungus evolving from plant pathogen to entophyte.

Objectives

The aim of this study was to elucidation of the *U. esculenta* genomic information as well as expression profiles, to give more comprehensive insights into the molecular mechanism underlying artificial selection, and into smut fungi-host interactions.

Methods

Whole genome of *U. esculenta* was sequenced and transcriptomes of the fungi and its host were analyzed.

Conclusions

The 20.2 Mb *U. esculenta* draft genome of 6,650 predicted genes including mating, primary metabolism, secreted proteins, shared a high similarity to related Smut fungi. But *U. esculenta* prefers RNA silencing not RIP in defense and has more introns per gene, indicating relatively slow evolution rate. The fungus also lacks some genes in amino acid biosynthesis pathway which were filled by up-regulated host genes, and developed distinct amino acid response mechanism to balance the infection-resistance interaction. Besides, *U. esculenta* lost some surface sensors, important virulence factors and host range related effectors to maintain the economic endophytic life.

Physiology / Biochemistry / Molecular Microbiology - Part III

IDENTIFICATION OF THE TARGET OF THE TYPE II PARE2 TOXIN IN E. COLI

Z. Zhao[1]
[1]*Free University of Brussels ULB, Science, Gosselies, Belgium*

Backgrounds

TypeII Toxin-Antitoxin (TA) systems are protein pairs consisting of a stable toxin, and a labile antitoxin. In a former study, our group has identified a novel type II antitoxin family named *paaA*, which is associated with *parE* toxins. Together with a regulator named *paaR* in upstream, these ORFs constitute a three-component operon. Overexpression of ParE2 leads to cell death in a SOS-dependent manner. Using a ParE2-GFP fusion, it was shown that ParE2-GFP co-localized with the nucleoid, suggesting that ParE2-target complex is associated to DNA. The structure of ParE2 is similar to that of *C. crescentus* ParE but displays a distinct pattern of conserved surface residues, in agreement with its apparent inability to interact with GyrA

Objectives

The objective of this work is to identify the target of the ParE2 toxin.

Methods

The methods include (1) kill/rescue assay expressing subunits of DNA-gyrase (GyrA and GyrB) and of topoisomerase IV (ParC and ParE) with ParE2 toxin to test if there is compensation; (2) co-purification of ParE2-target complexes and (3) identification of target by mass spectrometry.

Conclusions

Preliminary data indicate that overexpression of subunits of topoisomerase IV ParC and ParE might lead to better protection against ParE2 activity than GyrA or GyrB overexpression. However, some refinements are needed since overexpression of these subunits also leads to some toxicity.

FEMS7-3162
Physiology / Biochemistry / Molecular Microbiology - Part III

EXPLORING BACTERIAL KILLING MECHANISMS ON THE APICAL SURFACE OF CULTURED PIG TRACHEAL EPITHELIA

S. Zhu[1]
[1]*the University of Hong Kong, School of Biomedical Sciences, Hong Kong, Hong Kong S.A.R.*

Backgrounds

Airway surface liquid on the apical side of epithelia contains antimicrobial substances for killing invaded bacteria.

Objectives

It is unclear how these antimicrobial substances are formed and regulated.

Methods

To address this question, we used the method of live and dead staining to measure killing of Gram-negative bacteria *Psedomonas (P.) aeruginosa*. Our data demonstrate that many *P. aeruginosa* either in a free form or attached to a gold EM grid were apparently killed after a short incubation period on the surface of cultured pig tracheal epithelia, and the bacterial killing rate was about 30% higher than that in PBS solutions as the control. Similar bacterial killing rates of *P. aeruginosa* were obtained when the bacteria were placed into washout fluid, collected from the apical side of epithelia using a small amount of the PBS solution. To explore possible candidates responsible for bacterial killing, we analyzed washout fluid and found the presence of several antimicrobial substances, such as lactoferrin, LPLUNC1 and lysozyme. Correlation analysis between the normalized protein level of each band in the silver-staining gel and corresponding bacterial killing rate by the same washout fluid indicates that the bacterial killing rate appeared to be positively correlated with the amount of protein at about 75 kD including lactoferrin, or at size slightly less than 10 kD possibly containing antimicrobial peptides.

Conclusions

These data suggest that cultured epithelia secrete several antimicrobial substances onto the apical surface of epithelia, in which lactoferrin and antimicrobial peptides might play an important role in enhancing bacterial killing in airway.

A NEW FAMILY OF STAPHYLOCOCCUS AUREUS PHAGES ISOLATED FROM PATIENTS WITH CYSTIC FIBROSIS

M. Ziemyte[1], M. Cervera-Alamar[1], K. Guzmán[1], M.Á. Tormo-Mas[1]
[1]HOSPITAL LA FE, Infección Grave, VALENCIA, Spain

Backgrounds

Mobile genetic elements (MGE) such as pathogenicity islands and bacteriophages are very common in clinical isolates of *Staphylococcus aureus*. Moreover, they are closely related with each other and its interaction leads to dissemination of various virulence factors. For example, bacteriophages are responsible for induction, packaging and transference of *Staphylococcus aureus* pathogenicity islands (SaPIs).

Objectives

As pulmonary infection with *S aureus* is a frequent problem in patients with cystic fibrosis we were interested in the role of MGE and its interaction in these strains.

Methods

During our study, we have tested 200 *S. aureus* isolates from 118 cystic fibrosis patients. Interestingly, 77% of these strains in its genome contained bacteriophage with integrase type III. After sequencing of 19 strains, we observed that 17 of them had conserved packaging module that was different from previously described phages. In all of the cases phages contained TerL, endonuclease HNH and a hypothetical protein that might be a new TerS. We determined that deletion of this protein doesn't affect phage DNA replication but completely eliminated phage packaging and infectivity. As obvious morphological changes in phage structure were observed in this mutant, we want to demonstrate cos-site cleavage by this HNH-TerS-TerL complex.

Conclusions

In future, we would like to characterize all proteins implicated in packaging machinery of these phages. Moreover, it is important know the implication of these phages in mobilization and transference of virulence factors, codified in other MGE like SaPIs. That might lead to better adaptation of these strains in patients with pulmonary infections in a worldwide.

REGULATION OF NITROGEN METABOLISM IN LACTOBACILLUS CASEI: THE SENSOR HISTIDINE KINASE PRCK IS A PHOSPHATASE

M. Zúñiga Cabrera[1], *B. Beamud Aranguren*[1], *A.B. García Lorenzo*[1], *C. Alcántara Baena*[1], *V. Monedero García*[1]
[1]*Instituto de Agroquímica y Tecnología de Alimentos, Biotecnología de Alimentos, Paterna, Spain*

Backgrounds

Lactic acid bacteria possess a limited amino acid biosynthetic capacity and need to obtain them from external sources. The response regulator PrcR plays a major role in the regulation of the proteolytic system in *Lactobacillus casei*. PrcR constitutes a signal transduction two-component system together with the sensor histidine kinase PrcK. PrcR regulates the expression of 353 genes in response to a complex source of amino acids. Gel mobility shift assays also showed that phosphorylation of PrcR enhanced its DNA binding activity.

Objectives

Characterization of the role of the PrcK in the regulation of the activity of PrcR.

Methods

A *L. casei* BL23 PrcK defective strain was obtained by a recombination strategy. Growth in media, acidification rate in milk and proteinase activity were determined. A comparative transcriptomic analysis was carried out by RNAseq. Phosphorylation of PrcR *in vivo* was monitored by PAGE with Phos-Tag and a specific anti-PrcR antibody.

Conclusions

Striking phenotypic differences were observed between the PrcR and the PrcK defective strains. In contrast to the PrcR mutant, the PrcK mutant did not display a growth defect in MRS, had low milk acidification rate and low proteinase activity. The transcriptomic analysis showed that 55 genes were differentially expressed compared to the parental strain and only 28 of them were also differentially expressed in the PrcR mutant strain. Analysis of the phosphorylation state of PrcR *in vivo* revealed that inactivation of PrcK resulted in the accumulation of phosphorylated PrcR indicating that PrcK acts as a phosphatase under our assay conditions.

BIOSYSTEMS TECHNOLOGY LTD: A NEW UNIVERSITY OF EXETER SPIN OUT COMPANY

O. Champion[1], *R. Titball*[2]
[1]*University of Exeter, BioSystems Technology, Exeter, United Kingdom*
[2]*University of Exeter, BioSciences, Exeter, United Kingdom*

Backgrounds

Insect larvae *Galleria mellonella* can be used as a model host in microbiological, microbiota and toxin research and also as an ecotoxicological model organism and for drug development programmes. Results in *G. mellonella* correlate well with results in mammalian models and in research projects using *G. mellonella* the number of experimental vertebrates used has been reduced by up to 80%. The use of *G. mellonella* for R&D therefore reduces reliance on mammalian research models, which is aligned with European and UK policy, saves money and allows high throughput screening of compounds at a level that would not be possible using mammalian models.

Objectives

Having used *G. mellonella* for our research at the University of Exeter and after discussion with many members of the research community about the model host *G. mellonella*, we have identified the lack of standardisation as one of the key limitations of the model.

Methods

To over come this we have developed TruLarv™, research grade *G. mellonella* that are age and weight defined and they are surface decontaminated. TruLarv™ come from an in bred colony for which a whole genome sequencing programme is currently underway. Unlike bait shop waxworms TruLarv™ are not bred using antimicrobials or hormones.

Conclusions

Participation in Innovate UK's Innovation and Commercialising University Research (ICURe) programme in 2015 accelerated the commercial translation of this research and the University spin out company BioSystems Technology Ltd was founded for which private angel investment has been secured and the first product, TruLarv™, was launched in 2016.

CARBOHYDRATE-MEDIATED DECONTAMINATION STRATEGIES AGAINST BIOTHREAT BACTERIA

M. Utratna[1], S. Deegan[1], K. Kubelková[2], J. Stulik[2], L. Joshi[3]
[1]Aquila Bioscience, Research and Innovation Building, Galway, Ireland
[2]Institute of Molecular Pathology, Faculty of Military Health Science- University of Defense, Hradec Kralove, Czech Republic
[3]Glycoscience Group,
National Centre for Biomedical Engineering Science- National University of Ireland Galway, Galway, Ireland

Backgrounds

Glycosylation is a key modification of proteins and lectin-carbohydrate interactions are essential in many host-microbial processes including adherence. The principle of using anti-adhesion strategies, based on glycobiology research, has already been shown to be effective in the prophylaxis and treatment, with examples for successful inhibition of bacteria, toxin and virus interactions.

Objectives

To study important carbohydrate-mediated microbial interactions, high-throughput lectin and glycan microarrays are increasingly utilised. We used custom made platforms covering a wide range of lectin specificities, carbohydrates presented on glycoproteins and neoglycoconjugates (NGCs) for profiling of biothreat agents (e.g. *Bacillus anthracis, Francisella tularensis, Clostridium botulinum*) and their low risk surrogate strains.

Methods

Initially, profiles of non-pathogenic surrogate microorganisms were used to nominate carbohydrate-based ligands for development and optimisation of decontamination technology against selected vegetative cells and spores. The technology was assembled and tested on non-pathogenic project models. Consequently, glycan/lectin binders were nominated by microarray technology for the selected biothreat bacteria. This novel technology, developed against BSL2 and BSL3 microorganisms, was tested in accredited labs for efficacy of decontamination and achieved high ability of capturing bacterial contaminants.

Conclusions

Overall, we describe a novel approach for studying lectin-carbohydrate interactions and the potential applications of glycomics microarrays in microbial research. Through a research-driven start-up company we present a prototype technology capable of capturing biothreat agents with high efficacy. Furthermore, this product captures viable bacteria which can be further analysed for diagnostic purposes. This innovative technology is portable, easy to use, non-toxic and environmentally friendly and will bring new insights for future decontamination strategies.

IMPROVED BIOPROSPECTING: DARWIN'S WAY

C. Vilanova[1]
[1]*Darwin Bioprospecting Excellence SL, Biotechnology, Paterna, Spain*

Backgrounds

Four billion years ago, life appeared on Earth in the shape of bacterial communities. Since then, microorganisms have evolved to make a habitable planet and to harbor a fabulous diversity of metabolic pathways and chemical abilities.

Objectives

Biotechnology and Synthetic Biology yield a full range of powerful industrial solutions, but they rely on the identification, modification and use of biological parts already present in the wild. Improved bioprospecting is the best choice to provide bioengineers with new consortia, strains, genes or any other biological part.

Methods

Successful bioprospecting includes sampling unreported environments, massive use and development of new culture media, combining culture and non-culture approaches, and using artificial selection pressures towards to promote the selection of the desired biological variants.

Conclusions

By combining natural and artificial selection in improved bioprospecting, it is possible to identify biological parts from the huge repository that is our planet. Culture screening, multi-omics and selection-based approaches are central for improved bioprospecting.

HIGH-QUALITY DRAFT GENOME SEQUENCE OF RAINEYA TEPIDIPHILA GEN. NOV., SP. NOV. A SLIGHTLY THERMOPHILIC BACTERIUM AND THE PROPOSAL OF RAINEYACEAE FAM. NOV.

L. Albuquerque[1], A.R. Polónia[2], H. Froufe[2], O. Lage[3], A. Lobo-da-Cunha[3], C. Egas[2], M. da Costa[1]
[1]Center for Neuroscience and Cell Biology- University of Coimbra, Laboratory of Microbiology, Coimbra, Portugal
[2]Biocant- Biotechnology Innovation Center, Next Generation Sequencing Unit, Cantanhede, Portugal
[3]Universidade do Porto,
CIMAR/CIIMAR – Centro Interdisciplinar de Investigação Marinha e Ambiental, Porto, Portugal

Backgrounds

One isolate designated, SPSPC-11^T, with an optimum growth temperature of about 45-50ºC and an optimum pH for growth between 7.5 and 8.0, was recovered from a reddish biofilm at the hot spring at São Pedro do Sul in Central Portugal (40° 46' N, 8° 4' W). Based on 16S rRNA gene sequence and phylogenetic analysis the new organism is most related to the species of the genus *Thermonema* with 16S rRNA gene pairwise sequence similarity of 82 to 83%.

Objectives

Growth, morphology, physiological and biochemical characteristics of the new isolate; determination of polar lipids, lipoquinones and fatty acid composition; determination of G+C content of DNA, 16S rRNA gene sequence and phylogenetic analyses; genome sequencing.

Methods

Cell morphology was examined by SEM and TEM. Phenotypic, chemotaxonomic and phylogenetic analysis were performed as described by Albuquerque *et al.*, 2014 (doi: 10.1016/j.syapm.2014.03.001). Genome was sequenced using paired-end sequencing and assembled with SPAdes (v 3.7.1).

Conclusions

Based on genotypic, phylogenetic, chemotaxonomic and phenotypic characteristics we describe a new species of a novel genus represented by strain SPSPC-11^T (=CECT 9012^T =LMG 29233^T) for which we propose the name *Raineya tepidiphila* gen. nov., sp. nov. We also propose the family *Raineyaceae* to accommodate this new genus.

TAXONOMIC STUDY OF PHOTOBACTERIUM STRAINS ISOLATED FROM DISEASED FARMED FISH IN SOUTH SPAIN

D.R. Arahal[1], T. Lucena[1], A.M. Labella[2], M. Manchado[3], D. Castro[2], J.J. Borrego[2]
[1]Universitat de València, Microbiology and Ecology & Spanish Type Culture Collection CECT, Burjassot, Spain
[2]Universidad de Málaga, Microbiology, Malaga, Spain
[3]IFAPA- Junta de Andalucía, Centro El Toruño, Puerto de Santa Maria, Spain

Backgrounds

Strains H01100409B, H01100413B, and H27100402H were isolated in 2004 from several internal organs of diseased redbanded seabream (*Pagrus auriga*) reared in Andalusia (IFAPA Centro El Toruño, Puerto de Santa María, Cádiz). Presumptive identification bases on partial 16S rRNA gene sequences clustered these three isolates within the genus *Photobacterium*.

Objectives

Phenotypic and phylogenetic characterization of strains H01100409B, H01100413B, and H27100402H in order to complete their identification and formal taxonomic proposals according to the Bacteriological Code.

Methods

Phenotypic determinations included standard morphological, physiological, biochemical and chemotaxonomic methods commonly used in the taxonomy of *Vibrionaceae*.

The phylogenetic analysis was performed including a multilocus scheme (MLSA) using six housekeeping genes: *gapA* (glyceraldehyde-3-phosphate dehydrogenase A), *topA* (DNA topoisomerase I), *mreB* (cell wall structural complex MreBCD), *ftsZ* (GTP-binding tubulin-like cell division protein), *gyrB* (DNA gyrase B subunit), and 16S rRNA.

WGS Illumina Miseq platform was used for genome sequencing. Read analysis, de novo assembly and annotation was done with software included in Galaxy Orione and RAST servers. Average Nuclotide Indexes (ANIb, ANIm) were calculated with JSpecies and OrthoANI software and estimated DNA-DNA hybridization (eDDH) using the Genome to Genome Distance Calculator.

Conclusions

Based on the polyphasic study performed, we have determined that strains H01100409B (= CECT 9192) and H27100402H (= CECT 9190), represent a novel species each, for which the names *Photobacterium andalusiensis* sp. nov. and *Photobacterium malacitana*, respectively, are proposed. Strain H01100413B (= CECT 9191) is identified as a member of *Photobacterium aquimaris*.

REAFFILIATION OF EDWARDSIELLA TARDA FISH ISOLATES TO THE NEW SPECIES EDWARDSIELLA PISCICIDA AND EDWARDSIELLA ANGUILLARUM

N. Buján[1], S. Balboa[1], J. L. Romalde[1], A. E. Estévez[1], B. Magariños[1]
[1]Fac. Bioloxía-CIBUS & Instituto de Acuicultura,
Microbioloxía e Parasitoloxía- Universidade de Santiago de Compostela, Santiago de Compostela, Spain

Backgrounds

Edwardsiella is a genus belonging to the family *Enterobacteriaceae*, described in 1965 by Ewing and MacWhorter. Until 2012, the genus consisted of 3 species: *E. hoshinae*, *E. ictaluri* and *E. tarda*. Based on genetic studies two novel species, *E. piscicida* and *E. anguillarum* were described in 2013 and 2015 respectively. *E. piscicida* compiled only pathogenic strains isolated from fish showing phenotypic characteristics identical to *E. tarda*. The capacity to ferment mannitol and arabinose is the unique characteristic distinguishable for *E. anguillarum*, but is not enough to a *bona fide* identification

Objectives

The description of the new *Edwardsiella* species made necessary a deeper study of the phylogeny of the genus to clarify the position of isolates previously classified as *E. tarda*.

Methods

A total of 57 strains and 4 genomes retrieved from the GenBank database of *Edwarsiella* were used in this work. All strains were previously identified by classical phenotypical tests.
Seven gene loci were selected, including 16S rRNA gene, *adk*, *atp*D, *dna*J, *gln*A, *hsp*60 and *tuf*, to perform the MultiLocus Sequence Analysis (MLSA).
The OrthoANI values among the genomes were calculated using OAT (v0.93). Moreover, estimated DNA-DNA hybridization was determined by the genome-to-genome distance calculator (GGDC2.1).

Conclusions

The results indicate that *Edwardsiella* isolates obtained from fish and previously identified as *E. tarda* should be reclassified as *E. piscicida* or *E. anguillarum*. The scarce phenotypic differences among *E. tarda*, *E. piscicida* and *E. anguillarum* made necessary the use of molecular techniques to a correct identification of these species.

Taxonomy / Systematics

THE NEW GENUS RODENTIBACTER INCLUDING RODENTIBACTER PNEUMOTROPICUS (PASTEURELLA PNEUMOTROPICA), RODENTIBACTER HEYLII AND SPECIES OF IMPORTANCE FOR IDENTIFICATION OF OPPORTUNISTIC PATHOGENS IN RODENT COLONIES

H. Christensen[1], *S. Adhikary*[1], *W. Nicklas*[2], *M. Bisgaard*[3], *R. Boot*[4], *T. Waberschek*[2], *B. Aalbæk*[1], *P. Kuhnert*[5], *B. Korczak*[5]
[1]*University of Copenhagen, Veterinary Animal Sciences, Frederiksberg C, Denmark*
[2]*Microbiological Diagnostics, German Cancer Research Centre, Heidelberg, Germany*
[3]*Bisgaard Consulting, Bisgaard Consulting, Viby Sj., Denmark*
[4]*Private, Private, Utrecht, The Netherlands*
[5]*Institute of Veterinary Bacteriology, University of Bern, Bern, Switzerland*

Backgrounds

It has been known for a long time that [*Pasteurella*] *pneumotropica* is not a member of *Pasteurella sensu stricto* and that biovars Jawetz and Heyl of [*Pasteurella*] *pneumotropica* should be classified as separate species.

Objectives

To investigate a collection of *Pasteurellaceae* mainly obtained from laboratory rodents, wild mice, and from mice and rats from petshops by extended pheno- and genotypic characterization and to classificy and name a new genus.

Methods

16S rRNA and partial *rpoB* gene sequencing were used to evaluate characters used for phenotypic identification and separation of taxa. Selected strains were further characterized based on whole genome comparison.

Conclusions

Whole genomic comparison of selected strains allowed the estimation of DNA-DNA renaturation and indicated the presence of 8 species within the genus. The type species is *R. pneumotropicus* including strains mainly from mice and including part of strains previously classified with [*Pasteurella*] *pneumotropica*. *Rodentibacter heylii* was proposed for a group that included the biovar Heyl of [*Pasteurella*] *pneumotropica*. *Rodentibacter ratti* which included the taxon 22 of Bisgaard was proposed for a new very large species mainly isolated from rats. *Rodentibacter heidelbergensis* and *Rodentibacter trehalosifermentans* also included strains only from rats. Strains from *Myodes glareolus* (bank vole) (taxon 41 of Bisgaard) were proposed as *Rodentibacter myodis*, two strains from rats including the reference strain of taxon 17 of Bisgaard as *Rodentibacter rarus* and another group with strains from *Apodemus* spp. were proposed as the new species *Rodentibacter mrazii*. The taxonomic changes will improve the identification of members of *Pasteurellaceae* isolated from rodents.

COMPARATIVE GENOMIC FEATURES OF BACILLUS VELEZENSIS, BACILLUS AMYLOLIQUEFACIENS AND BACILLUS SIAMENSIS

B.H. Chun[1], K.H. Kim[1], S.E. Jeon[1], C.O. Jeon[1]
[1]Chung-Ang University, Department of Life Science, Seoul, Republic of Korea

Backgrounds

Three *Bacillus* groups (*B*. *velezensis*, *B*. *amyloliquefaciens*, and *B*. *siamensis*) are not differentiated based on 16S rRNA gene sequences because they are very closely related each other. Therefore, using pan-genomes of the three *Bacillus* groups we investigated the phylogenetic relatedness and compared their genomic and metabolic features.

Objectives

The aim of this study is to investigate the comparative genomic and metabolic features of three *Bacillus* groups with high phylogenetic relatedness.

Methods

Genomes that were possibly affiliated to the three *Bacillus* groups were retrieved from GenBank based on >98% of 16S rRNA gene sequence similarities and >95% of average nucleotide identity values to their respective type strains. After removing low quality genomes using the CheckM program, the comparative genomic and metabolic features of three *Bacillus* groups were investigated using pan-genome.

Conclusions

The 64 high quality genomes of *B*. *velezensis* (54), *B*. *amyloliquefaciens* (6), and *B*. *siamensis* (4) were selected and A phylogenetic analysis based on 16S rRNA gene sequences showed that the three *Bacillus* groups were undifferentiated phylogenetically, while a phylogenetic analysis using 1,957 core genes showed that they were clearly differentiated into three different phylogenetic lineages. The three *Bacillus* groups had similar COG distribution patterns, but their molecular phenotype-based relatedness was differentiated into three groups. The comparative genome analysis of three *Bacillus* groups showed that all *B*. *velezensis* strains harbor a macrolactin gene cluster, while all *B*. *siamensis* strains have a xanthine metabolic gene cluster.

FEMS7-2527
Taxonomy / Systematics

COMPLETE GENOME SEQUENCE OF A NEW SPECIES OF THE GENUS SALINIVIBRIO

R.R. de la Haba[1], *C. López-Hermoso*[1], *C. Sánchez-Porro*[1], *A. Ventosa*[1]
[1]*Universidad de Sevilla, Microbiology and Parasitology, Sevilla, Spain*

Backgrounds

During an environmental survey in order to study the biodiversity of different hypersaline habitats 70 strains phylogenetically affiliated to the genus *Salinivibrio* were isolated and characterized. A total of 34 out of the 70 isolates strains grouped into a different lineage clearly separated from the *Salinivibrio* named species and may constitute a new species of this genus.

Objectives

The aim of this study was to obtain and to analyze the complete genome sequence of the strain AL184, a representative member of this putative new species of *Salinivibrio*.

Methods

A combined sequencing approach was accomplished by using the Illumina and PacBio technologies. Raw data were subjected to quality control and the resulting subset was assembled using SPAdes v. 3.9.1 with specific options for hybrid assembly, besides other additional assemblers for comparative purposes. The resulting genome was annotated and further analyzed.

Conclusions

Sequencing depths of 1000X and 350X using Illumina and PacBio technologies, respectively, was enough to completely reconstruct the 3.4 Mb genome of the strain AL184. SPAdes assembler produced the best results allowing to recover a single contig sequence. This complete genome can be used as a reference for future genome assemblies in the genus *Salinivibrio* as well as to study the synteny of other draft *Salinivibrio* genomes.

Taxonomy / Systematics

THE FAMILY ISOSPHAERACEAE: NEW INSIGHTS FROM COMPARATIVE GENOMICS

S. Dedysh[1], A. Ivanova[1], D. Naumoff[1], W. Liesack[2]
[1]Winogradsky Institute of Microbiology- Research Center of Biotechnology RAS, Microbiology of Wetlands, Moscow, Russia
[2]Max Planck Institute for Terrestrial Microbiology, Biogeochemistry, Marburg, Germany

Backgrounds

The family *Isosphaeraceae* accommodates stalk-free planctomycetes with spherical cells, which can be assembled in short chains, filaments or aggregates. These bacteria inhabit a wide variety of terrestrial and aquatic habitats. Their roles in nature, however, remain elusive due to difficulties of characterizing these bacteria by means of traditional cultivation approaches.

Objectives

This study was undertaken to determine the genome sequence of *Paludisphaera borealis* PX4^T and to compare it to those of other *Isosphaeraceae* members, for which complete genomes are presently available. *P. borealis* PX4^T is a newly described member of the *Isosphaeraceae* from boreal peatlands.

Methods

Genome sequencing was performed using the PacBio RSII platform. Annotation with *PROKKA* package was performed against the *UNIPROT* database and manually constructed database of annotated planctomycete genomes.

Conclusions

The finished genome of *Paludisphaera borealis* PX4^T consists of a 7.5 Mb chromosome and two plasmids, 112 and 43 kb in size. The genome size in other family members varies from 5.53 Mb in *Isosphaera pallida* IS1B^T to 9.74 Mb in *Singulisphaera acidiphila* DSM18658^T. All analyzed *Isosphaeraceae* planctomycetes have plasmids in numbers varying from one to four. The two plasmids from *P. borealis* display synteny to plasmids from other family members, suggesting their common evolutionary origin. Genomes of mesophilic *Isosphaeraceae* planctomycetes encode a large variety of carbohydrate-active enzymes, providing the potential to utilize a wide range of carbohydrates and glycoconjugates. In summary, our comparative genomic analysis revealed an extremely high glycolytic potential in *Isosphaeraceae* planctomycetes, which remains to be explored in future studies.

Taxonomy / Systematics

ENTOMOPATHOGEN ID: A MULTI-LOCUS SEQUENCE ALIGNMENT RESOURCE FOR ENTOMOPATHOGENIC FUNGI

C. Dunlap[1], *J. Ramirez*[1], *D. Labeda*[2]
[1]*NCAUR, Crop Bioprotection, Peoria, USA*
[2]*NCAUR, Mycotoxin Prevention and Applied Microbiology research unit, Peoria, USA*

Backgrounds

The ability to correctly identify entomopathogenic fungi is an important step in developing biopesticides and effectively communicating research results. Over the years, identifying entomopathogenic fungi has evolved from a system based on diagnostic morphological and physiological characters to molecular DNA based systems. Internal transcribed spacer (ITS) sequences have become the barcode of choice when identifying unknown fungi. While ITS sequencing is a great tool for identifying unknown fungi, it often lacks sufficient resolution to accurately identify common entomopathogenic fungi. The problem is further compounded by not having a curated database of reference sequences based on type material to compare sequences against.

Objectives

Develop a web-based Multi-Locus Sequence Alignment resource for common Hypocrealean entomopathogenic fungi.

Methods

The Entomopathogen ID Multi-Locus Sequence Alignment resource is a curated sequence database built on sequences from MLSA and other taxonomic studies of common Hypocrealean entomopathogenic fungi spanning the taxonomic families of Cordycipitaceae, Clavicipitaceae and Ophiocordycipitaceae.

Conclusions

The database provides a new resource to improve the taxonomic characterization of this group of fungi.

Taxonomy / Systematics

ASSESSING THE GLOBAL DIVERSITY OF A GENUS USING PHYLOGENOMICS

M. Garcia-Garcera[1], *M. Touchon*[1], *S. Brisse*[1], *E.P. Rocha*[1]
[1]*Institut Pasteur, Genomique Evolutive des Microbes, Paris, France*

Backgrounds

Most bacteria have poorly characterized environmental reservoirs and unknown closely-related species. This hampers the study of bacterial evolutionary ecology because both the environment and the genetic background of ancestral lineages are unknown.

Objectives

Our objectives are to assess the global diversity of a genus and its environmental distribution.

Methods

We combined metagenomics, comparative genomics, and phylogenomics to overcome this limitation, to identify known and novel taxa, and to propose environments where they can be isolated. We applied this method to characterize the ecological distribution of known and novel lineages of *Acinetobacter* spp.

Conclusions

We observed two major environmental transitions at deep phylogenetic levels, splitting the genus into three ecologically differentiated clades. One of these has rapidly shifted towards host-association by acquiring genes involved in bacteria-eukaryote interactions. We show that environmental perturbations affect species distribution in predictable ways*:* administration of antibiotics to bovines produces shifts from diverse to highly uniform, human-associated, communities of *Acinetobacter* spp. Our results uncover the diversity of bacterial lineages, overpassing the limitations of classical cultivation methods, and highlight the role of the environment in their evolutionary history

SPECIES STATUS OF THE PSEUDOMONAS STUTZERI GENOMOVARS

E. García-Valdés Pukkits[1], *G. Margarita*[2], *M. Magdalena*[2], *A. Busquets*[2], *J. Lalucat*[1]
[1]*University of the Balearic Islands, Biology- Microbiology and IMEDEA, Palma de Mallorca, Spain*
[2]*University of the Balearic Islands, Biology- Microbiology, Palma de Mallorca, Spain*

Backgrounds

Pseudomonas stutzeri was first described by Burri and Stutzer (1895) and van Niel and Allen (1952) precisely defined its phenotypic features and discussed its definitive designation as *P. stutzeri* by Lehmann and Neumann. *It* is an extremely ubiquitous species found in soils and marine and fresh waters, but it is also isolated as opportunistic pathogen in clinical specimens. In 1995 Ursing and collaborators coined for *P. stutzeri* the concept of genomovar as “genomic groups of strains delimitated by DNA-DNA pairing that are phenotypically so similar that they cannot be differentiated for the time being”. Nowadays 22 genomovars have been described within the species and a reference strain has been proposed for each genomovar.

Objectives

Comparative genomics of all the genomovar reference strains will confirm the experimental genomovar delineation and also clarify the genomic similarities and differences among *P. stutzeri* genomovars. Whole-cell MALDI-TOF MS clearly allows the differentiation of *P. stutzeri* genomovars. Combination of both techniques will sustain the proposal of a new bacterial species for each genomovar.

Methods

Whole genome sequences of 83 *P. stutzeri* strains, including all genomovar reference strains and distinct species belonging to the *P. stutzeri* group were analysed. ANI, GGDC, SpecI, as well as core and pangenome analyses were performed.

Conclusions

The genome molecular data obtained were in accordance with the MALDI-TOF MS results and clearly confirmed that at least 11 genomovars with more than one strain each, should be proposed as new species within the genus *Pseudomonas*.

TAXONOMIC CLARIFICATION OF THE PSEUDOMONAS SYRINGAE SPECIES GROUP STATUS BY PHYLOGENOMIC ANALYSIS

M. Gomila[1], *A. Busquets*[1], *M. Mulet*[1], *E. García-Valdés*[1], *J. Lalucat*[1]
[1]*University of the Balearic Islands, Biology, Palma de Mallorca, Spain*

Backgrounds

The genus *Pseudomonas* is taxonomically divided in two phylogenetic lineages (*P. aeruginosa* and *P. fluorescens*) based on the multilocus sequence analysis (MLSA) of four housekeeping genes. The *P. fluorescens* lineage contains six groups, one of them represented by *P. syringae*. Gardan and colleagues established in this species eight genomic groups, called genomospecies, based on DNA–DNA hybridization (DDH) analysis. Some of them later on were reclassified as different taxonomic species (*P. amygdali*, *P. avellanae, "P. coronafaciens"*, *P. ficuserectae*, *P. meliae, P. savastanoi*, *P. syringae*, *P. tremae*, and *P. viridiflava*). The taxonomic situation is more confuse when the pathovars are considered. Currently, the *P. syringae* species group is subdivided into over 60 pathovars defined by pathogenic characters, nine genomospecies defined by DDH and 13 phylogenetic groups (phylogroups) defined by MLSA.

Objectives

The main objective is to clarify the taxonomic delineation of *P. syringae* species group based on the phylogenomic analysis of more than 100 genomes sequenced and available in the database assigned to this group.

Methods

MLSA, Average nucleotide identity based on BLAST (ANIb) and Mummer (ANIm), Genome-to-Genome Distance Calculator (GGDC) as well as core and pangenome analyses have been performed to delineate the genomic species.

Conclusions

The analysis allowed to infer the taxonomic affiliation of all genomes analysed, some of them not correctly assigned. The pathovars did not follow the genomic clusters already defined. New genomic groups can be distinguished belonging to putative novel species. Genomic and phylogenetic approaches will provide the basis for a more reliable demarcation of *Pseudomonas* phytopathogenic species.

CITROBACTER LUSITANIAE SP. NOV. AND CITROBACTER VIEIRENSIS SP. NOV.: TWO NOVEL CITROBACTER SPECIES ISOLATED FROM AQUATIC SAMPLES

T. Gonçalves Ribeiro[1], B. Ribeiro Gonçalves[2], M. Silva[2], Â. Novais[1], E. Machado[1,3], L. Peixe[1]
[1]Faculty of Pharmacy- University of Porto, Microbiology, Porto, Portugal
[2]Institute of Molecular Medicine- Faculty of Medicine- University of Lisbon, Microbiology, Lisboa, Portugal
[3]Faculty of Health Sciences- University Fernando Pessoa, Microbiology, Porto, Portugal

Backgrounds

The relevance of *Citrobacter*, a genus comprising opportunist pathogens, is well known as it could act as a source of antibiotic resistance genes (*qnrB* and *bla*$_{CMY-2}$). Nevertheless, *Citrobacter* species differentiation based on conventional tests is problematic, preventing the recognition of species with greater clinical significance. Recently, we demonstrated that *recN* (DNA repair protein) based phylogenetic analysis provides an accurate discrimination among *Citrobacter* species, and unveiled isolates not affiliated to previously recognized species.

Objectives

The purpose of this work was to define the taxonomic position of two representative strains belonging to two potential novel *Citrobacter* species, using genotypic and phenotypic approaches.

Methods

Two strains, A60^T recovered from a water well and A316^T from a natural spring, both collected in Portugal, were characterized. These strains were sequenced using Illumina MiSeq. Draft genomes were obtained using SPADes, and annotated by Prokka software. The similarity of 16S rRNA gene sequence of strains A60^T and A316^T to those of other *Citrobacter* species type strains were <98.9% and <99.0%, respectively. Phylogenetic analysis based on *recN* sequences showed a clear distinction of A60^T or A316^T and the type strains of the closest related *Citrobacter* species, with A60^T clustering with clinical isolates deposited in public databases and A316^T in one branch. Genomic similarity assessed by Average Nucleotide Identity (ANI) between A60^T or A316^T and type strains of closely related *Citrobacter* species (*C. freundii, C. europaeus* and *C. braakii*) was in all cases lower than 94.5%. The ability to metabolize different compounds further discriminated A60^T or A316^T from other *Citrobacter* species. The G+C content of strain A60^T and A316^T is 52.0% and 51.5%, respectively.

Conclusions

The results obtained support the description of two novel species of the genus *Citrobacter*, for which the names *Citrobacter lusitaneae* sp. nov. (A60^T as type strain) and *Citrobacter vieirensis* sp. nov. (A316^T as type strain) are proposed.

POLYSACCHARIDE DECOMPOSERS AMONG HALOPHILIC ARCHAEA - A SYSTEMATIC GENOMIC AND PHENOTYPIC APPROACH

R.L. Hahnke[1], *J.P. Meier-Kolthoff*[1], *M. Göker*[1], *B.J. Tindall*[1]
[1]*DSMZ, Microorganisms, Braunschweig, Germany*

Backgrounds

Some *Bacteria* and *Archaea* taxa are known to thrive in carbohydrate-rich habitats as decomposers of particulate organic matter. In contrast, few polysaccharides have been tested and few taxa have been systematically investigated for polysaccharide degradation.

Objectives

With the aim of obtaining deeper insights into the evolution of carbohydrate metabolism in *Halobacteria*, we tested type strains in the family *Natrialbaceae* (*Archaea*) for their potential and ability to decompose polysaccharides.

Methods

Strains were incubated in media with NaCl concentrations of 10–32%, low nutrient concentrations and azurin-crosslinked polysaccharides in microtiter plates. Genome-scale phylogenies were inferred from whole proteomes using the Genome BLAST Distance Phylogeny (GBDP) approach. Genes encoding carbohydrate active enzymes were retrieved from the genome by matching the CAZy database.

Conclusions

Strains belonging to the genera *Halopiger* and *Halostagnicola* were rich in CAZymes, but strains belonging to the genera *Natronococcus*, *Natrinema*, *Natronorubrum*, *Natronolimnobius*, *Natronobacterium*, *Halobiforma* and *Halovivax* were not. Surprisingly, the diversity of polysaccharide decomposition differed significantly within the genera *Haloterrigena* and *Natrialba*. Galactomannan, pachyman, Barley-β-glucan and CM-cellulose were hydrolyzed only above 23% NaCl. Furthermore, the ability to grow on polysaccharides is directly correlated to the presence of genes of the semi-phosphorylated Entner-Doudoroff pathway in their genomes.

The results presented here demonstrate the advantage of a combined genomic and phenotypic approach to the systematic high-throughput screening of polysaccharide decomposition in prokaryotic taxonomy. Furthermore, the results provide additional information for the description and classification of microbial species and led to the discovery of so far hidden physiological features.

DIVERSITY OF HALOPHILIC ACTINOBACTERIA FROM ARID REGIONS OF SAUDI ARABIA FOR POTENTIAL APPLICATION IN THE PRODUCTION OF COMMERCIAL ENZYMES

W. Hozzein[1], S. Alharbi[2], A. Chinnathambi[2]
[1]King Saud University, College of Science, Riyadh, Saudi Arabia
[2]King Saud University, College of Science- Microbiology Department, Riyadh, Saudi Arabia

Backgrounds

Enzymes of halophilic microorganisms have many industrial advantages over their non-halophilic counterparts. The halophilic actinobacteria from the Saudi habitats have been largely unexplored and it is of great interest to study them for their potential biotechnological applications.

Objectives

The main objectives of the present study were to isolate halophilic actinobacteria from the arid regions of Saudi Arabia, study their diversity, screen them for their enzymatic potential and identify them to the species level by the polyphasic approach.

Methods

104 soil samples representing different desert and extreme arid habitats in four different regions in Saudi Arabia were collected. The elective isolation of 465 halophilic actinobacterial strains was carried out using different selective media. After de-replication of the isolates, 329 dissimilar halophilic strains were obtained. The diversity of the isolated organisms was estimated phylogenetically by analyzing the 16S rRNA gene sequences. The actinobacterial isolates were then screened for enzymatic activities, namely, amylase, cellulase, lipase and protease. The enzymatically-active strains and the interesting organisms from the biodiversity have been identified by studying their morphological and chemotaxonomical characteristics and confirmed by phylogenetic analysis.

Conclusions

The results revealed that the isolates belong to 17 families and 27 genera. The enzymatic activities rate was found to be 74%, 26%, 34% and 55% for amylase, cellulase, lipase and protease production, respectively, which may be promising commercially. The taxonomic results revealed that many strains will be described as new genera and species. The results are very encouraging and Saudi habitats could be considered as a good source for potentially useful actinobacteria.

IDENTIFICATION AND CHARACTERIZATION OF DERMABACTER JINJUENSIS SP. NOV. AS A CLINICAL PATHOGEN RESOURCE IN KOREA

K.J. Hwang[1], K.M. Lee[1], M.H. Kim[1], Y.K. Park[1]
[1]Koera National Institute of Health, Pathogen Resource TF, Cheongju-si, Republic of Korea

Backgrounds

Species-level identification is crucial to characterize unidentified bacterial pathogens for the efficient development and management of bacterial resources. Unidentified strains were collected from branch banks of the National Culture Collection for Pathogens (NCCP).

Objectives

A total of 437 unidentified pathogens based on the results of the VITEK 2 system were identified using 16S rRNA gene analysis and matrix-assisted laser desorption ionization-time of flight mass spectrometry (MALDI-TOF MS) for the development of national resources in NCCP. On the basis of phenotypic, biochemical, chemotaxonomic, and molecular studies, we reported that the 32T isolate from a clinical patient showed new species of *Dermabacter* in Korea.

Methods

Phylogenetic analysis based on 16S rRNA gene sequences revealed that 32T belonged to the genus *Dermabacter* and was closely related to *Dermabacter hominis* DSM 7083T (98.34%). And 32T was considered a potentially novel species because of its low score value (1.886); MALDI-TOF MS identification scores of ≥1.7 but <2.0 are accepted for identification to the genus level. The major cellular fatty acids were anteiso-C17:0 (28.33%), C16:0 (24.05%), anteiso-C15:0 (17.83%), and iso-C16:0 (11.54%). The DNA G+C content of strain 32T was 63.16 mol%, and the DNA-DNA hybridization value between 32T and *D. hominis* DSM 7083T was 49±1.6%.

Conclusions

We propose strain 32T as the representative of a novel taxon, *Dermabacter jinjuensis* sp. nov., with the type strain DSM 101003T. The strain has been deposited at the NCCP (=NCCP 16133T) and is expected to be used as a valuable pathogen resource.

CLASSIFICATION OF PSYCHROPHILIC GLIDING BACTERIA ISOLATED FROM ANTARCTICA

S. Králová[1], E. Staňková[1], I. Sedláček[1]
[1]Masaryk University, Department of Experimental Biology- Czech Collection of Microorganisms, Brno, Czech Republic

Backgrounds

Polar microbiology is a fast-growing field in the last years. As a part of polar systematics, the taxonomy of psychrophilic bacteria is focused on bacterial diversity in polar region, such as Antarctica.

Objectives

This study was focused on yellow pigmented and gliding Gram-stain negative bacteria isolated from the environment in Antarctica during years 2008-2014 (J. G. Mendel Station, James Ross Island). Aim of this study was to describe phylogenetic relationships of these psychrophilic bacteria against to already known species, as well as their physiology, biochemistry and other properties.

Methods

Isolated strains were firstly characterized with basic phenotyping including test for growth in different temperatures and in presence of NaCl, production of specific enzymes and ability to utilize different substrates. Secondly, all these strains were investigated by FAME (fatty acid methyl ester analysis), MALDI-TOF MS, repetitive PCR and their phylogenetic position was determined by partial 16S rDNA sequence analysis.

Conclusions

A group of 76 gliding psychrophilic bacteria was found among 587 pigmented strains in the present study. All strains were found to be Gram-stain negative, catalase positive rods with gliding motility enhanced by lower temperatures. All 76 strains were phylogenetically placed within the genus *Flavobacterium* forming at least 7 separated clusters. One strain was also Gram-stain negative and catalase positive psychrophilic bacterium with reduced gliding motility and expressing agarolytic activity. All these cold-adapted bacteria represent probably novel species within genus *Flavobacterium* and they might represent species with unique properties and/or producing cold-adaptive biomolecules applicable to biotechnology purposes.

Taxonomy / Systematics

ARCOBACTER LEKITHOCHROUS SP. NOV., A NEW SPECIES ISOLATED FROM A MOLLUSCAN HATCHERY IN NORWAY

A. L. Diéguez[1], *S. Balboa*[1], *J. L. Romalde*[1]
[1]*CIBUS- Facultad de Biología. Universidade de Santiago de Compostela, Microbiologiay Parasitologia, Santiago de Compostela, Spain*

Backgrounds

The genus *Arcobacter* belongs to the family *Campylobacteraceae* and the type species is *Arcobacter nitrofogilis*, initially described as *Campylobacter* and reclassiffied as a new genus. *Arcobacter* shows a global distribution and a high diversity of ecological niches: marine environments, waste and drink water, animal faeces, associated to plants or in oil field communities among others.

Objectives

To characterize four strains: LFT 1.7^T (=CECT 8942^T= DSM 100870^T), LT2C 2.5, LT4C 2.8 and TM 4.6 (= CECT 8943= DSM 100869) isolated from larvae and seawater obtained during a study on the microbiota associated to Great scallop (*Pecten maximus*) in a hatchery in Bergen (Norway).

Methods

These isolates were fully characterized using phenotypic, genomic and chemotaxonomic approaches.

Conclusions

Multilocus Sequence Analysis (MLSA) of five housekeeping genes and the 16S rRNA gene placed the strains within the genus *Arcobacter* in a well differentiated branch with regard to the rest of the species. *In silico* hybridization as well as the Average Nucleotide Identity (ANI) analysis showed a low percentage of similarity with known species of *Arcobacter*. All isolates were Gram-negative and motile rods, oxidase and catalase positive and required sea salts for growth. The DNA G+C content was of 28.7 mol%. Strain LFT 1.7^T contained MK-6 as the sole respiratory quinone. Based on all of these characteristics, the four Norwegian isolates represent a new species within the genus *Arcobacter* for which the name *Arcobacter lekithochrous* sp. nov. is proposed, with strain LFT 1.7^T (=CECT 8942^T= DSM 100870^T) as the type strain.

PHYLOGENOMIC ANALYSIS OF SPECIES IN THE PSEUDOMONAS PUTIDA PHYLOGENETIC GROUP

J. Lalucat[1], M. Gomila[2], A. Busquets[2], M. Mulet[2], E. García-Valdés[1]
[1]University of the Balearic Islands, Biology and IMEDEA CSIC-UIB, Palma de Mallorca, Spain
[2]University of the Balearic Islands, Biology, Palma de Mallorca, Spain

Backgrounds

Fifteen species have been recognized until December 2016 in the *Pseudomonas putida* phylogenetic group. Strains in the group are ecological relevant due to their metabolic versatility. However, also clinical strains of species in this group have been described. The whole genome sequence of all type strains in the group have been described and comparative genomics is for the moment the best approach to definitively identify the strains at the species level.

Objectives

Main objective is the taxonomic delineation of species in this phylogenetic group by using phylogenomic approaches. Hundred and thirty sequenced strains assigned to the genus *Pseudomonas*, or to species in the *P. putida* phylogenetic group, are analyzed to clarify their taxonomic position.

Methods

Four mainly accepted genomic tools in taxonomic analysis, namely Multilocus Sequence analysis (MLSA), Average Nucleotide Identity based on BLAST (ANIb), whole-genome based Average Nucleotide Identity (gANI) and Genome-to-Genome Distance Calculations (GGDC), are applied to 130 strains to delineate genomic species.

Conclusions

The 15 species type strains actually recognized within the group are clearly separated in the genomic analyses and at least 10 new genomic species can be delineated. Most of the putative new species are singletons, but others include several strains. A deep taxonomic analysis of each group is needed to propose formally the new species status.

FEMS7-1646
Taxonomy / Systematics

TAXONOMIC EVALUATION OF THE GENUS SALINIVIBRIO BASED ON MULTILOCUS SEQUENCE ANALYSIS AND OTHER MOLECULAR APPROACHES

C. Lopez-Hermoso[1], *R. Ruiz*[1], *T. Papke*[2], *C. Sanchez-Porro*[1], *A. Ventosa*[1]
[1]*Universidad de Sevilla, Microbiology and Parasitology, SEVILLA, Spain*
[2]*University of Connecticut, Molecular and Cell Biology, Stors, USA*

Backgrounds

The genus *Salinivibrio* includes halophilic bacteria and is commonly isolated from hypersaline habitats and salted food products. They grow optimally at ca. 7.5 % salts and are facultative anaerobic microorganisms. Currently, this genus comprises four species, one of them with three subspecies. Phylogenies based on the 16S rRNA gene sequence comparative analysis showed some incongruities, such as the clustering of the three subspecies as a polyphyletic group.

Objectives

The purpose of the present study was to refine the understanding of the phylogenetic relationships of the species and subspecies in the genus *Salinivibrio* and to clarify the current taxonomic status of the members of this genus by using Multilocus Sequence Analysis (MLSA) and DNA-DNA hybridization (DDH) approaches.

Methods

We have isolated and characterized 70 new strains from solar salterns located in different geographical locations. The MLSA study was based on the individual and concatenated sequence analysis of *gyrB*, *recA*, *rpoA* and *rpoD* housekeeping genes. The MLSA scheme was validated against DDH data by means of the Pearson's correlation coefficient.

Conclusions

These analyses permitted to include the isolated and type strains of *Salinivibrio* in four clearly different phylogroups, while one strain, represented by the type strain of the species *Salinivibrio sharmensis,* did not cluster with any of the other strains. Further the species level defined by a DDH value of 70 % was correlated with a 96 % cut-off for the concatenated MLSA gene sequence. Based on these criteria the phylogroup 1 could constitute a new separate species, while the strains included on the other three phylogroups are members of previously recognized *Salinivibrio* species.

FEMS7-1879
Taxonomy / Systematics

GENETIC DIFFERENTIATION OF BIOCONTROL RELATED TRICHODERMA STRAINS DEPOSITED AT THE SPANISH TYPE CULTURE COLLECTION (CECT) AS TRICHODERMA HARZIANUM

L. López-Ocaña[1], L. Moragues[2], A. Igual[1], P. Elizaquível[1], R. Aznar[1,2]
[1]University of Valencia, Spanish Type Culture Collection, Paterna Valencia, Spain
[2]University of Valencia, Microbiology and Ecology, Burjasot Valencia, Spain

Backgrounds

Trichoderma harzianum (Rifai, 1969) is a highly heterogeneous species that includes economically relevant strains effective in the control of soil-borne diseases. Due to the difficulty of separating the members of this genus most of the biocontrol strains were referred in the past to this species. Recently, a systematic revision on the *Trichoderma harzianum* complex revealed reorganization in the species composition, the description of new species and the re-identification of commercial biocontrol strains. Therefore, proper identification of strains at species -or even intra-species- level is advisable for commercial applications.

Objectives

To assess identification of strains deposited at the CECT as *T. harzianum* and to evaluate RAPD profiles and gene sequencing for intra-species differentiation.

Methods

A total of 35 *Trichoderma* reference strains, 31 *T. harzianum*, 2 *T. virens* and 2 *T. viride*, deposited at the CECT were examined through phylogenetic analyses with the nuc translation elongation factor 1-α (tef1 intron 4, TEF1), which proved efficient for species identification. RAPD profiles were determined with six different primers (OPA-2, 3, 10, 13 and 18 from Operon Technologic, and M13) for intra-species differentiation.

Conclusions

Analysis of TEF1 sequences revealed that strains deposited at the CECT as *T. harzianum* included members of other species in the *T. harzianum* complex, like *T. simmonsii*, *T. afroharzianum*, *T. guizhouense*, *T. atrobrunneum*, and other species like *T. citroviride*. Clustering analysis of combined RAPD profiles confirmed the species ascription of CECT *T. harzianum* strains obtained by TEF1 sequencing, and revealed slight differences within the species.

PHOTOBACTERIUM TORUGNENSIS SP. NOV., A NEW BACTERIUM ISOLATED FROM DISEASED FARMED FISH

T. Lucena[1], D.R. Arahal[1], A.M. Labella[2], D. Castro[2], J.J. Borrego[2], M. Manchado[3]
[1]Universidad de Valencia, Microbiology and Ecology & Spanish Type Culture Collection, Paterna, Spain
[2]Universidad de Málaga, Microbiology, Malaga, Spain
[3]IFAPA - Junta de Andalucía, Centro El Toruño, Puerto de Santa María- Cádiz, Spain

Backgrounds

Strains H01100410B, H20040403B, and H20040405H were isolated from liver and spleen of captived redbanded seabream (*Pagrus auriga*) in a mortality outbreak in autumn 2011 at the Southatlantic coast of Spain (IFAPA Centro El Toruño, Puerto de Santa María, Cádiz). Presumptive identification bases on partial 16S rRNA gene sequences clustered these three isolates within the clade Phosphoreum in the genus *Photobacterium*.

Objectives

Phenotypic and phylogenetic characterization of strains H01100410B, H20040403B, and H20040405H in order to complete their identification. Formal taxonomic proposal according to the Bacteriological Code.

Methods

Phenotypic determinations included standard morphological, physiological, biochemical and chemotaxonomic methods commonly used in the taxonomy of *Vibrionaceae*.

The phylogenetic analysis was performed including a multilocus scheme (MLSA) using six housekeeping genes: *gapA* (glyceraldehyde-3-phosphate dehydrogenase A), *topA* (DNA topoisomerase I), *mreB* (cell wall structural complex MreBCD), *ftsZ* (GTP-binding tubulin-like cell division protein), *gyrB* (DNA gyrase B subunit), and 16S rRNA.

WGS Illumina Miseq platform was used for genome sequencing. Read analysis, de novo assembly and annotation was done with software included in Galaxy Orione and RAST servers. Average Nuclotide Indexes (ANIb, ANIm) were calculated with JSpecies and OrthoANI software and estimated DNA-DNA hybridization (eDDH) using the Genome to Genome Distance Calculator.

Conclusions

Based on the polyphasic study performed, we have determined that strains H01100410B, H20040403B, and H20040405H to be a new species, and we propose *Photobacterium torugnensis* sp. nov., with strain H01100410B (= CECT 9189) as type strain.

FEMS7-0966
Taxonomy / Systematics

VIBRIO RADICULARIS SP. NOV. A NEW VIBRIO SPECIES ASSOCIATED TO RHIZOSPHERE OF ARTHROCNEMUM MACROSTACHYUM

M. Maciá[1], M.A. Ruvira[1], M.J. Piñar[1], S. Navarro-Torre[2], E. Pajuelo[2], I.D. Rodriguez-Llorente[2], D. Arahal[1], M.J. Pujalte[1]
[1]Universidad de Valencia, Microbiology and Ecology & Spanish Type Culture Collection, Paterna, Spain
[2]Universidad de Sevilla, Departament of Microbiology and Parasitology, Sevilla, Spain

Backgrounds

Strain RA1 was isolated in February 2014 from the rhizosphere of *Arthrocnemum macrostachyum* sampled in the estuary of the river Odiel (Huelva, Spain). This strain was related to the genus *Vibrio* by 16S rRNA sequence comparison, being *Vibrio kanaloae* and *Vibrio toranzoniae* the closest relatives with 95.8 and 95.7 % sequence similarity in BLAST, respectively.

Objectives

Phenotypic and phylogenetic characterization of strain RA1.

Methods

Physiological and biochemical methods, including fatty acid analysis and phylogenetic analysis of the almost complete 16S rRNA sequence of strain RA1.

Conclusions

Strain RA1 has less than 97.0% similar to any other *Vibrio* species and is phylogenetically related to the Splendidus clade.

Cells are Gram negative, motile rods, chemoorganotrophic and facultatively anaerobic, able to ferment sugars. It is mesophilic and slightly halophilic, unable to grow without salts. Oxidase and catalase positive, able to reduce nitrate to nitrite. Glucose is fermented without gas production. Negative for Voges Proskauer and indol production. Positive for ADH but negative for LDC and ODC. Hydrolyzes DNA, casein and gelatin but not Tween 80 and alginate. Positive in API ZYM for alkaline and acidic phosphatases leucine arylamidase and trypsin activities. Growth on synthetic medium (BMA) plus sole carbon and energy source occurs with monosaccharides, organic acids and aminoacids.

Main FAME are C16:1ω7c/ C16:1ω6c (SF3), C16:0 and C18:1ω7c, as other *Vibrio* species.

Phenotypic and phylogenetic data confirm that RA1 represents a new species in the genus *Vibrio*, for which we propose the name *V. radicularis* sp. nov. with strain RA1T (CECT 9082T, LMG 29974T) as the type strain.

ROSEOVARIUS SP. NOV. - A BACTERIUM ISOLATED FROM A SALINE SOIL BY DILUTION-TO-EXTINCTION CULTIVATION

D.J. Castro[1], I.M. Cerezo[1], M. Rodríguez[1], V. Béjar[1], F. Martínez-Checa[1]
[1]Facultad de Farmacia- Universidad de Granada, Microbiología, Granada, Spain

Backgrounds

The genus *Roseovarius* was first proposed with the description of *Roseovarius tolerans* as the type species of the genus within the family *Rhodobacteraceae.* This genus consists of 21 recognized species.

In this study we describe the strain D15^T, isolated from a sample of soil taken from Rambla Salada (Murcia) south-east Spain, a hypersaline rambla (a steep-sided river bed, normally dry but subject to flash flooding) using the dilution-to-extinction method.**Objectives**

The aim of this study was the characterization of the strain D15^T by a polyphasic approach, including phenotypic tests and genetic, chemotaxonomic and phylogenetic analyses.

Methods

Phenotypic characterization was carried out by morphological, physiological and biochemical test as API 20NE, API 50CH and API ZYM strips. Optimum growth conditions were determined by growing the strain in R2A medium at different NaCl concentration, pH and temperatures.

Conclusions

Cells were motile with a polar flagellum, rod-shaped, Gram-stain-negative, catalase- and oxidase-positive. They can grow optimally at 5% (w/v) NaCl, 30ºC and pH 7.0. The DNA G+C content of strain D15^T, estimated from the midpoint value (Tm) of their DNA was 59.2 mol%.

Phylogenetic analyses based on the 16S rRNA using the EzTaxon server showed that the most closely phylogenetically related species was *Roseovarius tolerans* with a similarity value of 96.12%.

The respiratory quinone (Q-10) and the fatty acid profiles of the strain D15^T were similar with those described for species of the genus *Roseovarius.*

Accordingly, on the basis of differences in phenotypic, chemotaxonomic characteristics and genetic distinctiveness, strain D15^T should be recognized as representing a novel species of the genus *Roseovarius.*

FEMS7-1330
Taxonomy / Systematics

MARINOBACTERIUM SP. NOV. - A BACTERIUM ISOLATED FROM A HYPERSALINE RAMBLA LOCATED IN MURCIA, SOUTH-EAST SPAIN

D.J. Castro[1], I.M. Cerezo[1], M. Rodríguez[1], V. Béjar[1], F. Martínez-Checa[1]
[1]Facultad de Farmacia- Universidad de Granada, Microbiología, Granada, Spain

Backgrounds

The genus *Marinobacterium*, belonging to the family *Alteromonadaceae,* within the class *Gammaproteobacteria,* was proposed by González *et al.* (1997). Currently, the genus comprises 16 strains with validly published names, isolated from different environments, such as a marine pulp mill, tidal flats, seawater, marine sediment, corals, roots and coastal seawater.

Objectives

In this study, we describe, by a polyphasic approach, a novel strain designated D7^T, isolated from a soil sample taken from a hypersaline rambla (a steep-sided river) located in Murcia, south-east Spain (Rambla Salada).

Methods

For the isolation of the strain D7^T we used the dilution-to-extinction method. Phenotypic characterization was carried out by morphological, physiological and biochemical test as API 20NE, API 50CH and API ZYM strips.

Conclusions

The cells were catalase- and oxidase-positive, Gram-stain-negative rods. Growth occurred at 15-40 °C (optimum 30-37°C), pH 5.5-9.5 (optimum pH 6.5-7.5) and with 0-7.5 % (w/v) NaCl (optimum 1-3 %).

Chemotaxonomic analysis showed that the respiratory quinone (ubiquinone-8) and fatty acid profiles were very similar to those described for species of genus *Marinobacterium*, including $C_{16:0}$ (28.7 %), summed feature 3 ($C_{16:1}\omega7c$ and/or $C_{16:1}\omega6c$, 26.6 %) and summed feature 8 ($C_{18:1}\omega7c$ and/or $C_{18:1}\omega6c$*, 25.2%*). Phylogenetic analysis based on 16S rRNA gene sequences revealed that strain D7^T was the most closely related to the genus *Marinobacterium*, sharing the highest 16S rRNA gene sequence similarity of 98% with *Marinobacterium zhoushanense* and 95.7% with *Marinobacterium lutimaris*. The genomic DNA G+C content of the strain D7^T was 60.3 mol%.

On the basis of the phenotypic, chemotaxonomic and genotypic characteristics, we suggest that strain D7^T represents a novel species of the genus *Marinobacterium*.

MULTILOCUS PHYLOGENETIC ANALYSIS OF THE GENUS LISTERIA: A PRAGMATIC TOOL FOR SPECIES IDENTIFICATION OF NEW ISOLATES

A. MARTINEZ-MURCIA[1], *A. Navarro*[2], *P. Elizaquivel*[3], *R. Aznar*[3]
[1]*Universidad Miguel Hernandez and Genetic PCR Solutions TM, Microbiologia, Orihuela, Spain*
[2]*Genetic PCR Solutions TM, Research, Elche, Spain*
[3]*Universitat de València, Microbiología y Ecología - Colección Española de Cultivos Tipo CECT, Valencia, Spain*

Backgrounds

According to the List of Prokaryotic names with Standing in Nomenclature (LPSN; www.bacterio.net/listeria.html), 19 species and 4 subspecies have been described for the genus *Listeria*. While *L. ivanovii* pathogenicity seems limited to ruminants, *L. monocytogenes* is the causative agent of listeriosis, a serious zoonotic disease with dramatic consequences in humans. Conventional microbiological standard methods are indispensable for the isolation of *Listeria*. Further, species identification by using biochemical tests may not give enough resolution due to their overlapping phenotypic diversity. Several phylogenies based on housekeeping gene sequencing have greatly improved the ability to discriminate *Listeria* species. To our knowledge, however, a comprehensive multi-gene phylogenetic approach is not available.

Objectives

To carry out a Multi-Locus Phylogenetic Analysis (MLPA) for all *Listeria* species described to date, using type strains and other “bona-fide” material acquired from public culture collections furtherly identified by 16S rDNA sequencing.

Methods

MLPA selected housekeeping gene-fragments were: *gyrB* (524bp), *rpoB* (592bp), *recA* (555bp), *gyrA* (783bp), *atpA* (611bp), *parE* (539bp), and *cpn60* (830bp).

Conclusions

Overall, single-gen phylogenetic relationships agreed to each other suggesting these genes evolve in concert and represent a reasonable phylogenetic hypothesis. Species clustering showed in the concatenated MLPA-tree (3.848 bp) was highly reproducible as indicated by bootstrap values (ca. 100%). The pictures showed a number of complex clades, some of them relatively distant to this referred as “*Listeria* sensu stricto”. High intra-species diversity in *L. monocytogenes* was ascertained. The MLPA approach performs as a robust frame to afford *Listeria* diversity for species identification.

THE WHOLE-GENOME ANALYSIS OF SOME EPIPHYTIC AND ASSOCIATIVE ISOLATES OF HETEROCYSTOUS CYANOBACTERIUM ANABAENA VARIABILIS

L. Mikheeva[1], *P. Meshcheryakova*[1], *E. Karbysheva*[1], *O. Zhenavchuk*[1]
[1]*Lomonosov Moscow State University, Biological faculty, Moscow, Russia*

Backgrounds

Filamentous heterocyst-forming cyanobacterium *Anabaena variabilis* ATCC 29413 is well investigated model organism with completely sequenced genome. Our experimental results and the data of other authors revealed the remarkable similarities of molecular-genetic properties between *A. variabilis* ATCC 29413, epiphytic strain *Anabaena* sp.182 and several strains of culturable minor cyanobionts from *Azolla* Lam. with genetic nature unresolved up to date.

Objectives

The aim of this work was the whole-genome sequencing of two *Anabaena* strains: rice plant epiphytic strain *Anabaena* sp.182 from Vietnam and the strain *Anabaena* sp.V5, culturable minor cyanobiont from leaf cavities of *Azolla pinnata*.

Methods

Pyrosequencing analysis of the entire *Anabaena* sp.182 and *Anabaena* sp.V5 genomes was performed using Genome Sequencer (GS) FLX with *A. variabilis* ATCC 29413 as a reference genome.

Conclusions

The obtained sequencing data have allowed us to establish the exact genetic nature of investigated strains, and to classify them as very closely related variants of model *A. variabilis.* Comparing to *A. variabilis* ATCC 29413 (originally isolated in 1964 in Missisippi) the *Anabaena* sp.V5 genome is characterized only by the loss of linear incision element (37 kb). In the genome of *Anabaena* sp.182 there is 1.4 kb insertion in gene *Ava_2562,* coding the hybrid response regulator protein that participates in Ca^{2+}-promoted regulation of phycobiline degradation, exopolysaccharide and gormogonia formation processes.

Such minimal genetic polymorphism of independent cyanobacterial isolates reveals the significant genome stability and adaptive capacity of *A. variabilis* that provide its wide spread occurrence and the ability to form stable associative complexes with plants due to mixotrophic metabolism.

QUICKLY GROUPING PROKARYOTIC GENOMES INTO PHYLOGENETICALLY COHERENT GROUPS: SAME-SPECIES RESOLUTION

G. Moreno-Hagelsieb[1], *S. Wu*[1]
[1]*Wilfrid Laurier University, Biology, Waterloo, Canada*

Backgrounds

Reported genomes do not always have a species names, and when they do, the phylogenetic "spread" of each species varies. Thus, there is a need for methods for grouping genomes into phylogenetically coherent groups. Available methods can be computationally intensive. DNA signatures are fast to compute and compare, and thus might be useful for species-level resolution of prokaryotic genomes.

Objectives

To test the similarity of clusters obtained using DNA signatures against those obtained using other phylogenomic distances, and 16S rRNA sequences.
To suggest thresholds using DNA signatures for species-level genome clustering equivalent to those obtained with more time-consuming thresholds.

Methods

We obtained the species names for each genome in the complete genomes dataset from NCBI. These species names were used to determine thresholds for species-level clustering using different phylogenomic-based, marker-gene-based, and compositional-based (DNA signatures calculated at the di, tri, and tetra-nucleotide levels) distances. We compared the clusters thus obtained by finding the corresponding clusters, defined as those containing the highest number of genomes in common. Their similarity was expressed as percent of genomes in common. Only cluster with ten genomes or more were used to calculate cluster similarity.

Conclusions

We found that the clusters obtained using DNA signatures are very similar to those obtained using other, more time-consuming distances. It is therefore adequate to save time in constructing these clusters using DNA signatures before attempting more complicated, computer-intensive, analyses.

PASTEURELLACEAE - BACTERIAL DIVERSITY AND ADAPTATION IN WILDLIFE HOSTS

K. Mühldorfer[1]
[1]*Leibniz Institute for Zoo and Wildlife Research, Department of Wildlife Diseases, Berlin, Germany*

Backgrounds

The family of the Pasteurellaceae includes phenotypically and genetically highly diverse bacterial species that play different roles in human and animal health and diseases. The biodiversity of the Pasteurellaceae causes significant difficulties in diagnostic laboratories, impacting not only the success of bacterial isolation or genetic detection but also accurate identification and taxonomic classification. In recent years, diagnostic challenges become more obvious in the field of zoo and wildlife diseases, where the number of variant or unknown bacteria belonging to the family of Pasteurellaceae is constantly increasing.

Objectives

This study aims for a better understanding of the diversity of Pasteurellaceae bacteria in a wide variety of captive and free-ranging wildlife hosts.

Methods

A total of 175 Pasteurellaceae isolates collected from diseased and clinically healthy mammals, birds and reptiles were identified based on their primary phenotypic characteristics. Combined 16S rRNA and *rpoB* gene analyses were used to investigate their genetic relatedness and phylogenetic relationship to known bacterial taxa.

Conclusions

Genetic results provide clear evidence of highly diverse, unclassified or unknown Pasteurellaceae-like species in wildlife hosts. For several isolates collected from small mammals, marsupials, ungulates, carnivores, birds and reptiles, the level of identification did not reach a specific bacterial genus or bacterial species. Furthermore, phylogenetic analyses revealed individual bacterial lineages and distinct clusters, which seem to correspond to a specific host or systematic group of animals and may indicate specific bacteria-host relationships.

A PROTEIN SEQUENCE SET FOR MULTILOCUS SEQUENCE ANALYSIS (MLSA) AND PHYLOGENOMIC AFFILIATION IN THE MARINE ROSEOBACTER LINEAGE

B. Nogales[1], *M. Mas-Lladó*[2], *R. Bosch*[1]
[1]*University of the Balearic Islands UIB and IMEDEA UIB-CSIC, Microbiology, Palma de Mallorca, Spain*
[2]*University of the Balearic Islands, Microbiology, Palma de Mallorca, Spain*

Backgrounds

The Roseobacter lineage (*Rhodobacteraceae*, *Alphaproteobacteria*) is an important group of marine bacteria. Robust phylogenetic reconstructions using concatenates of a variable number (i.e. 52-78) of single-copy, conserved protein sequences have been done. This provides a backbone for the affiliation of new isolates. However, the pace of genome sequencing in this lineage requires continuous reevaluation of a *core* protein set useful for phylogeny.

Objectives

In this study we propose a set of fourteen protein sequences for MLSA in the Roseobacter lineage that reproduces correctly the phylogeny of the lineage and can be used for the affiliation of new isolates.

Methods

To define the MLSA protein set we calculated a *core* proteome using 96 Roseobacter genome sequences (114 proteins). We retrieved the conserved residues, concatenated them and calculated a phylogenetic tree by maximum parsimony. After calculating individual trees for each protein we selected fourteen of them (4,462 amino acid positions) whose concatenated sequences reproduced better the topology of the *core* proteome tree. To check the usefulness of this MLSA protein set we included 69 additional genome sequences and calculated a new tree (4,412 aligned positions).

Conclusions

We observed differences only in the grouping of two isolates belonging to the two most deeply-branching genomic groups and in the intra-group branching order of a third genomic group. Therefore, most of the isolates were placed in the expected genomic group and genus, confirming the usefulness of this approach for the rapid and robust affiliation of new isolates of the Roseobacter lineage.

ARCOBACTER LACUS SP. NOV. AND ARCOBACTER CAENI SP. NOV., TWO NEW SPECIES ISOLATED FROM RECLAIMED WATER

A. Pérez-Cataluña[1], *M.J. Figueras*[1], *N. Salas-Massó*[1]
[1]*Universitat Rovira i Virgili- IISPV,*
Unidad de Microbiología - Departamento de Ciencias Médicas Básicas - Facultad de Medicina y Cien cias de la Salud, Reus, Spain

Backgrounds

The genus *Arcobacter* belongs to the family *Campylobacteraceae* and differs from *Campylobacter* on the basis of the capacity of the species to growth at low temperatures. Since its description in 1991, 24 species had been added to the genus.

Objectives

In the present study we performed a taxonomic study using a polyphasic approach including genome information of two strains (RW43-9 and RW17-10) recovered from secondary treated wastewater.

Methods

The first identification with the *rpoB* gene sequencing, revealed on the basis of the phylogenetic analysis that those strains formed two potentially new linages. A phylogenetic analysis of the 16S rRNA gene and of the concatenated sequences of 5 housekeeping genes (*atpA*, *gyrA*, *gyrB*, *hsp60* and *rpoB*) i.e. MLPA was performed. In addition, genomic DNA was sequenced and used for genomic comparison. The Average Nucleotide Identity (ANI) and the *in silico* DNA-DNA hybridization (*is*DDH) was calculated between the genomes of the two new taxa and their nearest species. Phenotypic characterization of these two strains was also performed.

Conclusions

The differential phenotypic characteristic between the strains RW 43-9 and RW17-10 and its nearest species are the ability to growth in TSA supplemented with 5% sheep blood at 37ºC and 42ºC in anaerobiosis and the inability to growth in minimal medium, respectively. These findings together the MLPA analysis and the values of ANI (<96%) and isDDH (<75%), demonstrate that these strains represent two new species, for which the names *Arcobacter lacus* (type strain RW43-9^T=CECT 8994^T=LMG 29062^T) and *Arcobacter caeni* (type strain RW17-10^T =CECT 9140^T=LMG 29151^T) are proposed.

CREMEIBACTER MARIS GEN. NOV., SP. NOV., FROM COASTAL MEDITERRANEAN SEAWATER

M.J. Pujalte[1], L. Rodrígo-Torres[2], T. Lucena[2], D.R. Arahal[1]
[1]Universitat de Valencia, Microbiología y Ecología, Valencia- Burjassot, Spain
[2]Universitat de Valencia, CECT, Valencia, Spain

Backgrounds

The *Rhodobacteraceae* family, on the *Alphaproteobacteria,* includes more than a hundred genera, most of them isolated from marine environments. Strain CECT 7735^T, isolated from beach seawater (Valencia, Spain) on marine R2A medium, was related by 16S rRNA gene sequence phylogeny to the *Roseobacter* clade of the family. *Phaeobacter gallaeciensis* DSM 26640^T, *Thalassobius abyssi* JAMH043^T and *P. inhibens* DSM 16374^T were the closer relatives, with 97.5 to 97.1% 16S similarity.

Objectives

Phylogenetic, phenotypic, chemotaxonomic and genomic characterization of CECT 7735^T.

Methods

Phenotypic and chemotaxonomic determinations were performed by techniques widely used in taxonomic studies. 16S rRNA gene sequence was compared to those of species with validly published against EzBioCloud database. Illumina Miseq platform was used for genome sequencing. Read analysis, assembly and annotation was done with software included in Galaxy Orione Server and RAST server. Average Nuclotide Indexes (ANI) were calculated with applications in http://jspecies.ribohost.com and OrthoANI software and estimated DNA-DNA hybridization (eDDH) using Genome to Genome Distance Calculator (http://ggdc.dsmz.de).

Conclusions

CECT 7735^T is Gram-negative, chemoorganotrophic, strictly aerobic and slightly halophilic. It requires Na, Mg and Ca ions for growth. Preferred carbon sources are aminoacids. It exhibits 70.3-70.5 ANI and 20.1 to 21.5% eDDH to other *Phaeobacter* species. Phylogenetic analysis with 16S RNA gene sequences does not show a close relationship to *Phaeobacter* or *Pseudophaeobacter* species. Thus, it is considered to represent a novel genus and species, for which the name *Cremeibacter maris* gen. nov., sp. nov. is proposed. The type strain is CECT 7735^T (=LMG 29909^T).

MOLECULAR SYSTEMATICS OF THE GENUS ACIDITHIOBACILLUS: INSIGHTS INTO THE PHYLOGENETIC STRUCTURE AND DIVERSIFICATION OF THE TAXON

R. Quatrini[1], A. Moya-Beltrán[1,2], H. Nuñez[1], P.C. Covarrubias[1], F. Issotta[1], J.P. Cardenas[3], M. Gonzalez[1], J. Atavales[1], L.G. Acuña[1], D.B. Johnson[4]
[1]Fundación Ciencia para la Vida, Microbial Ecophysiology Laboratory, Santiago, Chile
[2]Universidad Andres Bello, Facultad de Ciencias Biologicas, Santiago, Chile
[3]uBiome, San Francisco, USA
[4]Bangor University, College of Natural Sciences, Bangor, United Kingdom

Backgrounds

The acidithiobacilli are sulfur-oxidizing bacteria that thrive in both natural and anthropogenic acidic environments. They contribute to the generation of acid rock drainage in several different geoclimatic contexts, and their properties have long been harnessed for the biotechnological processing of minerals. Presently, the genus is composed of seven validated species, described between 1922 and 2015: *Acidithiobacillus thiooxidans*, *A. ferrooxidans, A. albertensis*, *A. caldus*, *A. ferrivorans*, *A. ferridurans* and *A. ferriphilus*. However, a large number of strains and sequence clones have been obtained over the years, many of which remain unclassified or are miss-assigned, muddling the picture from an evolutionary standpoint.

Objectives

Our goals were to investigate the phylogenetic relationships within this species complex and revise the phylogenetic species boundaries.

Methods

For that purpose we collected sequences affiliated to *Acidithiobacillus* spp. from public and private databases and used three different typing approaches with varying degrees of resolution: 16S rRNA gene-based ribotyping, oligotyping, and multi-locus sequencing analysis.

Conclusions

Results obtained indicate that there is still considerable unexplored diversity within this genus. At least six new lineages, supported by the different methods used herein, were identified. Although the diagnostic characteristics of these subgroups of strains are as yet unresolved, correlations to specific metadata hint to the mechanisms behind econiche-driven divergence of some of the species/phylotypes identified. The emerging phylogenetic structure for the genus outlined in this study will guide isolate selection for future population genomics and evolutionary studies in this important acidophile model.

DEFINING THE SPECIES MICROMONOSPORA SAELICESENSIS UNDER THE FRAMEWORK OF GENOMICS

R. Riesco[1], *C. Prieto*[2], *V. Formamid*[1], *M.E. Trujillo*[1]
[1]*Edificio Departamental- Universidad de Salamanca, Microbiología y Genetica, Salamanca, Spain*
[2]*NUCLEUS- Edificio I+D+i, Servicio de Bioinformática, Salamanca, Spain*

Backgrounds

Current prokaryotic taxonomy uses a polyphasic approach, considering multiple aspects of the microorganism, including phenotypic, genotypic and chemotaxonomic characteristics. However, this approach has serious shortcomings, particularly in the reproducibility of some phenotypic methods. The introduction and improvement of cost-effective whole-genome sequencing methods has provided a new working framework. Unlike DNA-DNA hybridization, the “gold standard” for defining genomic species, genomic data can be stored and made available to the scientific community for subsequent comparisons. In turn, genomic data can also be used to predict phenotypic traits reliably.

Objectives

The aim of the present study was to analyse general overall genome relatedness indices (OGRI) to define the species *Micromonospora saelicesensis* as compared to the polyphasic approach. Genome sequences were also used as a mining source for the prediction of the expected phenotype**.**

Methods

Whole-genome sequences were obtained for sixteen strains identified as *Micromonospora saelicesensis* using 16S rRNA gene, multilocus sequence analyses, DNA-DNA hybridization and metabolic profiles. The data was analyzed using the OGRI methods and compared to previous results. In addition, a series of *in-vitro* phenotypic assays performed at different times were confronted with *in-silico* predictions.

Conclusions

Comparative genomic results showed high variability among the strains studied, indicating that some of them may represent new species. *In-vitro* phenotypic test showed discrepancies among the independent studies, confirming the lack of reproducibility even within the same laboratory. Finally, the use of *in-silico* predictions proved useful for defining a specific phenotype among the strains analyzed.

Taxonomy / Systematics

THALASSOBIUS AUTUMNALIS SP. NOV., A NEW ROSEOBACTER ISOLATED FROM SEAWATER SURROUNDING CULTIVATED OYSTERS

L. Rodrigo Torres[1], *M.J. Pujalte*[1], *T. Lucena*[1], *D. Ruiz*[1]
[1]*Universitat de Valencia, Microbiology and Ecology, Valencia- Burjassot, Spain*

Backgrounds

The genus *Thalassobius* was described by Arahal et al. in 2005 and currently comprises 7 species. This genus belongs to the *Rhodobacteraceae* family, of the *Alpha-proteobacteria,* which includes 128 genera and more than 400 species, most of them from marine environments.

Strains XSM11 and 11SM11 were isolated in November 1989 from seawater (Vinaroz, Spain). The 16S rRNA gene sequence phylogeny placed these isolates within the genus *Thalassobius*, with *T. mediterraneus* CECT 5383^T (99.6% similarity), *T. gelatinovorus* CECT 4357^T (97.6%), and *T. aestuarii* DSM 15283^T (97.4%) as the closest relatives.

Objectives

Phylogenetic, phenotypic, chemotaxonomic and genomic characterization of strains XSM11 and 11SM11.

Methods

Phenotypic and chemotaxonomic determinations were performed by techniques widely used in taxonomic studies. 16S rRNA gene sequence was compared to those of species with validly published against EzBioCloud database. Illumina Miseq platform was used for genome sequencing. Read analysis, assembly and annotation was done with software included in Galaxy Orione Server and RAST server. Average Nuclotide Indexes (ANI) were calculated with applications in http://jspecies.ribohost.com and OrthoANI software and estimated DNA-DNA hybridization (eDDH) using Genome to Genome Distance Calculator (http://ggdc.dsmz.de).

Conclusions

The strains were Gram-negative, non-motile, chemoorganotrophic, aerobic and slightly halophilic, with complex ionic requirements. They exhibited less than 80 % ANIb and less than 25 % eDDH to the types of any other *Thalassobius* species, but 99.9 % and 98.5 %, respectively on these indexes, to each other. On the basis of the results, strains XSM11 and 11SM11 are considered to represent a novel species of the genus *Thalassobius*, for which *Thalassobius autumnalis* sp. nov. is proposed. The type strain is XSM11^T (=CECT 5118^T =LMG 29904^T).

[3]Aigües de Barcelona, Empresa Metropolitana de Gestió del Cicle Integral de l'Aigua- SA, Barcelona, Spain
[4]Cetaqua, Water Technology Center, Barcelona, Spain

Backgrounds

This work is part of an ongoing project, which aims at developing a database of the culturable fraction of bacteria present in drinking water (Drinking Water Library) to be used by drinking water laboratories to improve the efficiency in the management of this resource.

Objectives

To improve the accuracy and robustness of MALDI-TOF MS identification technique of drinking water associated bacteria by widening the available MALDI-TOF MS profiles coverage of reference strains.

Methods

A total of 203 reference strains deposited in CECT were selected according to: source of sample (related to drinking water), culture medium (R2A agar), optimum growth temperature (20-30ºC) and strains belonging to genera that were reported as related to drinking water.

Sample preparation for MALDI-TOF MS was carried out using the ethanol/formic acid extraction protocol recommended by Bruker Daltonics. The spectra measurements were recorded with UltraFleXtrem (Bruker Daltonics) mass spectrometer. The Flexanalysis and Biotyper 3.1 software (Bruker Daltonics) was used for the analysis of the spectra.

A total of 568 (out of 1014) water isolates (bottled mineral water, mineral source water and drinking water utility). remained unidentified after comparison with the current commercial database. After profiles clustering, representative isolates were selected and compared to the enlarged database.

Conclusions

Despite of the 203 new profiles included in the Drinking Water Library only one of the representative isolates could be identified at genus level. Therefore this database still needs to be completed. Further work is ongoing to disclose the identity of the remaining representative isolates that might even represent new species.

PAENIBACILLUS SP. LPB0068T, A NOVEL SPECIES ISOLATED FROM PACIFIC OYSTER

S.K. Shin[1], S. Choi[1], H. Yi[2,3]
[1]Korea University, BK21PLUS Program in Embodiment: Health-Society Interaction. Department of Public Health Sciences. Graduate School, Seoul, Republic of Korea
[2]Korea University, BK21PLUS Program in Embodiment: Health-Society Interaction. Department of Public Health Sciences. Graduate School-, Seoul, Republic of Korea
[3]Korea University, School of Biosystem and Biomedical Science, Seoul, Republic of Korea

Backgrounds

A novel endospore-forming, rod-shaped, Gram-stain-positive bacterial strain, designated LPB0068^T, was isolated from Pacific oyster in Korea.

Objectives

The aim of this study was to investigate the taxonomic position of the new isolate by a polyphasic approach and genome sequence analysis.

Methods

Morphological, cultural, biochemical, physiological, chemotaxonomic tests and phylogenic analysis were performed. Major cellular fatty acids, polar lipids, and menaquinone were determined. The whole genome sequences of strain LPB0068^T and their closely related strains were determined. The genomic relatedness of strain LPB0068^T to other *Paenibacillus* species was calculated by the BLAST-based average nucleotide identity (ANI) score and digital DNA-DNA hybridization (dDDH).

Conclusions

Gene sequence analysis of the 16S rRNA indicated that this isolate is closely related to *Paenibacillus macquariensis* subsp. *macquariensis* DSM 2^T (98.1 %), and *Paenibacillus macquariensis* subsp. *defensor* JCM14954^T (98.0 %). The genome of strain LPB0068^T consists of a circular chromosome with a total length of 4.6 Mb and three circular plasmids of 20, 21, and 87 Kb. The G+C content was 40.0 mol%. ANI and dDDH revealed that strain LPB0068^T is independent from other *Paenibacillus* species. Phenotypic features also distinguished the isolate from related species. On the basis of phenotypic and genotypic results, strain LPB0068^T merits a novel species status of the genus *Paenibacillus*. This study was funded by the Survey of Korean Indigenous Species Program through the National Institute of Biological Resources funded by the Korean Ministry of Environment.

GENOME-BASED INFERENCE OF LATE ACQUISITION OF OXYGENIC PHOTOSYNTHESIS AND AEROBIC RESPIRATION IN THE CYANOBACTERIA

R. Soo[1], J. Hemp[2], D. Parks[1], W. Fischer[2], P. Hugenholtz[1]
[1]Australian Centre for Ecogenomics, School of Chemistry and Molecular Biosciences, Brisbane, Australia
[2]Division of Geological and Planetary Sciences, California Institute of Technology, Pasadena, USA

Backgrounds

Cyanobacteria are one of the most important microbial groups on Earth with the origin of oxygenic photosynthesis in this phylum leading to the rise of oxygen ~2.3 billion years ago. This event altered the course of evolution by facilitating the development of aerobic respiration and complex multicellular life. However much remains to be learned about cyanobacterial diversity and evolution. For example, the *Melainabacteria,* a non-photosynthetic lineage sister to the photosynthetic Cyanobacteria, was recently described based on genome recovery from metagenomic datasets. Environmental 16S rRNA gene surveys suggest that there are at least three extant classes of Cyanobacteria: *Oxyphotobacteria* (comprising all recognised photosynthetic Cyanobacteria), *Melainabacteria*, and a basal branching group *ML635J-21*, for which genome sequences have yet to be reported.

Objectives

To obtain the first genomic representation of *ML635J-21* and additional *Melainabacteria* genomes, in order to provide insights into the evolution of oxygenic photosynthesis and aerobic respiration in the Cyanobacteria.

Methods

We assembled and binned three draft genomes belonging to class *ML635J-21* from public metagenomic datasets, for which we propose the name *Sericytochromatia.* In addition, we obtained 28 *Melainabacteria* genomes from environmental metagenomes and discovered 10 previously misclassified *Melainabacteria* genomes in public databases. Genomes were assessed for the presence of marker genes of oxygenic photosynthesis and aerobic respiration, and phylogenetic trees were inferred from identified Complex III and IV genes.

Conclusions

All members of the *Melainabacteria* and *Sericytochromatia* lack photosynthetic machinery indicating that phototrophy was not an ancestral feature of the Cyanobacteria, and that *Oxyphotobacteria* acquired the genes for photosynthesis relatively late in cyanobacterial evolution. Independent acquisition of aerobic respiratory complexes in the three classes supports the inference of late acquisition of oxygenic photosynthesis.

Taxonomy / Systematics

INTRODUCING THE SPOROBIOME: AN UNEXPLORED NEXUS OF RESISTOME AND NOVEL HUMAN PATHOGENS

G. Tetz[1]
[1]*Human Microbiology Institute, Human Microbiology, New York, USA*

Backgrounds

Microbiomes can be categorized based on common features, allowing the performance of deeper analyses. For example subdivisions—virome, fungal biome, resistome—are based on the totality of all genes of a specific microbial population. Spore-forming bacteria, the diversity of which is considered to be underestimated, possess unique features that differentiate them from other microorganisms. Bacterial endospores render the resistance to unfavorable environmental conditions. This provides challenges in treating such infections: higher rates of transmission; persistence ; high rates of relapses ; presence of sporulation-related virulence factors; protection from the immune response and antibacterials. Here, we suggest that studying the totality of genes of spore-forming bacteria, which we propose to name sporobiome, will facilitate our understanding of their role in health and diseases.

Objectives

Pure cultures of 30 different species of spore-forming bacteria including 12 previously unknown species, were isolated. The complete genome sequences of the previously unknown species were deposited in GenBank. Analyzing the sporobiome of these bacteria revealed multiple genes encoding virulence factors and antibiotic resistance, including virulence factors associated solely with spore-forming bacteria. Expression of antibiotic-resistance genes was studied.

Methods

Previously unculturable, aerobic, spore-forming bacteria were isolated from the microbiota of patients with lung infections and cancer. We identified bacteria by using by using a novel workflow that is combination of microbiological, biochemical (Vitek 2, MALDI-TOF), and genetic (Illumina HiSeq 2500) analyses. De novo assembly was performed using SPAdes genome assembler software. Antibiotic susceptibility was determined via the disc diffusion method and Vitek2.

Conclusions

Our approach allows to evaluate previously unknown spore-forming bacteria within human microbiome. We suggest that further study of the sporobiome will facilitate understanding its unique role in disease, the spread of genetic information among different ecological niches, and the maintenance and spread of antibiotic-resistance genes.

PLEOMORPHOCHAETA CAUDATA GEN. NOV., SP. NOV. AND PLEOMORPHOCHAETA OLEARIA SP. NOV., TWO BIOSURFACTANT-PRODUCING STRAINS FROM AN OFFSHORE OIL FIELD

B. Arroua[1], L. Urios[1], M. Ranchou-Peyruse[1], M. Magot[1], P. Bouriat[2], A. Ranchou-Peyruse[1], R. Grimaud[1]
[1]IPREM UMR CNRS 5254 - Université de Pau et des Pays de l'Adour, Equipe Environnement et Microbiologie, 64013 Pau Cedex, France
[2]IPRA - FR 2952 - Université de Pau et des Pays de l'Adour, LFC-R, 64013 Pau Cedex, France

Backgrounds

Petroleum reservoirs harbour microbial communities with a wide range of activities. These microorganisms can impact oil quality and recovery through detrimental effects such as corrosion of pipeline and hydrocarbon biodegradation and/or beneficial effects like microbial enhanced oil recovery (MEOR). MEOR consists in injecting allochthonous or stimulating indigenous bacteria that increase oil recovery by altering oil/water/rock interface properties or rock permeability.

Objectives

Activities linked to MEOR were explored for two strains, named SEBR 4223 and SEBR 4209, that were isolated from produced water of an offshore oil field.

Methods

Biosurfactant production was tested by measurement of interfacial activity of the culture supernatant with cyclohexane using a pendant drop tensiometer. The taxonomic characterization of strains SEBR 4223 and SEBR 4209 has been achieved by following a polyphasic approach.

Conclusions

Both strains were able to lower the interfacial tension, suggesting the production of a biosurfactant. Results obtained in this study suggested that these strains represent two novel species of a new genus belonging to the *Spirochaetaceae*. Considering the important pleomorphism of the cells, the names *Pleomorphochaeta*, for this new genus, *Pleomorphochaeta caudata* and *Pleomorphochaeta olearia*, for strains SEBR 4223 and SEBR 4209 respectively, are proposed.

CULTURE-DEPENDENT STUDY OF ARCHAEA AND BACTERIA FROM SALTERNS AND SALINE SOILS WITH DIFFERENT SALINITY RANGES

A. Durán-Viseras[1], M.J. León[1], C. Sánchez-Porro[1], A. Ventosa[1]
[1]University of Seville, Dept Microbiology and Parasitology, Sevilla, Spain

Backgrounds

Recent metagenomic studies on ponds of salterns with different salinities (from ca. 10 % to salt saturation) have shown that the microbial diversity is strongly influenced by the salinity and permitted to determine the major microbial groups that inhabit ponds with increasing salinities as well as their activities. Most studies have been focused on the higher salinity ponds (designated as crystallizers), with haloarchaea, nanohaloarchaea and some Bacteroidetes as dominating populations. However, the intermediate salinity saltern ponds have not been studied in detail

Objectives

Metagenomic data indicate that a large percentage of the prokaryotes in intermediate to high salinity ponds have not yet been isolated in pure culture. The aim of this study is the isolation and characterization of the archaea and bacteria which may be the dominant population on these saline habitats.

Methods

Clasical and new methodologies have been used for the isolation of halophilic archaea and bacteria under different growth conditions. They have been preliminary identified by partial 16S rRNA gene sequencing analyses.

Conclusions

We have isolated a large collection of strains which belong to the haloarchaea and halophilic bacteria (moderately and extremely). Most of these strains belong to previously reported taxa, as inhabitants of hypersaline environments even though they a large proportion are members of genera that are most frequently isolated in laboratory media but are not constituting a large percentage of the microbial population, as reported by molecular approaches. On the other hand, we have isolated some new strains which may represent new taxa and their features are under investigation.

[8]DOE Joint Genome Institute, DOE Joint Genome Institute, Walnut Creek, USA
[9]The City University of New York,
Department of Biology and School of Earth and Environmental Sciences, New York, USA

Backgrounds

The *Epsilonproteobacteria* is the fifth validly described class of the phylum Proteobacteria, known primarily for clinical relevance and chemolithoautotrophy in various terrestrial and marine environments, including deep-sea hydrothermal vents. However, the phylogenetic placement of this class has become less certain as 16S rRNA gene repositories expand and additional molecular markers are considered. For example, many concatenated marker gene analyses have failed to recover the *Epsilonproteobacteria* as monophyletic with other classes of Proteobacteria.

Objectives

We sought to evaluate the placement of *Epsilonproteobacteria* within the bacterial tree of life, and to assess the suitability of their continued inclusion within the Proteobacteria using comparative genomics.

Methods

A data set of 22,773 bacterial genomes (including 653 *Epsilonproteobacteria*) was obtained and analysed using both ribosomal RNA and 120 single copy protein markers. Evidence for the inclusion of *Epsilonproteobacteria* within the phylum Proteobacteria was assessed based on single- and concatenated-gene trees using a variety of tree building methods. Sequential jackknifing of outgroup phyla from the data set was performed to test the robustness of phylogenetic affiliations under differing combinations of bacterial genomes.

Conclusions

Based on the assessment of almost 300 phylogenetic tree topologies, we conclude that the continued inclusion of *Epsilonproteobacteria* within the Proteobacteria is not warranted, and that this group should be reassigned to the novel phylum Epsilonbacteraeota (*phyl. nov.*). We further recommend the reclassification of the order *Desulfurellales* (*Deltaproteobacteria*) to a novel class within this phylum. We also recommend a number of subordinate changes at the family level, to ensure consistency with the genome-based phylogeny.

GENOME CHARACTERIZATION OF STRAIN KB1, A NOVEL MEMBER OF THE GENUS BLAUTIA ISOLATED FROM A HUMAN FECAL SAMPLE

S.J. Yang[1], N.R. Shin[2], W. Kang[2], B. Jin-Woo[2], K. Byung-Yong[1]
[1]ChunLab- Inc., Bioinformatics Reserach Institute, Seoul, Republic of Korea
[2]Kyung Hee University,
Department of Life and Nanopharmaceutical Sciences and Department of Biology, Seoul, Republic of Korea

Backgrounds

The genus of *Blautia* is a member of the family *Lachnospiraceae* and now contains eleven validly published species. Most of species in this genus are Gram positive, coccoid, and strictly anaerobic bacteria found in human fecal samples. According to recent studies, *Blautia* is a one of most abundant group in gastrointestinal(GI) and found that level of this group was a strong indicator of a gut health.

Objectives

In this study, we present the genome characters of strain KB1, a novel bacterium of the *Blautia* genus.

Methods

The strain KB1, belonged to the *Blautia* genus was isolated from a human fecal sample in an anaerobic condition using brain-heart infusion(BHI) agar. The genome was sequenced on the MiSeq platform of Illumina using a paired-end library.

Conclusions

Phylogenetic analysis based on 16S rRNA gene and whole genome sequences by average nucleotide identity (ANI) showed that strain KB1 is closely related to *Blautia* species. The genome was assembled to 49 contigs and total length of the contigs was 6,044,239 nucleotides with a G+C content of 46.3%. The genome harbors 14 rRNA genes, 64 tRNA genes, 5,152 CDS. The genome was predicted to have complete gene sets for glycolysis, citric acid cycle, pentose phosphate pathway and PRPP biosynthesis. Based on genome characteristics presented in this study, we propose to the strain KB1 as represents a novel species within the genus of *Blautia*.

PROTEOMIC APPROACH FOR THE IDENTIFICATION OF BACILLUS SPECIES USING MATRIX-ASSISTED LASER DESORPTION/IONIZATION-TIME OF FLIGHT MASS SPECTROMETRY

W.S. Yu[1], H.M. Chenong[1], H.N. Do[1], K.J. Hwang[1]
[1]Korea National Institute of Health,
Pathogen Resource TF- Center for Infectious Diseases- Korea National Institute of Health- Korea Center for Disease Control and Prevention, Cheongju, Republic of Korea

Backgrounds

The genus *Bacillus*, consisting of phylogenetically and phenotypically diverse species, represents rod-shaped, endospore-forming bacteria, including species of medical importance. The application of matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS) has greatly facilitated bacterial identification.

Objectives

In this study, we compared various methods of taxonomic identification of *Bacillus* strains:the VITEK 2 (bio-Mérieux, France), 16S rRNA gene sequencing and MALDI-TOF MS. We also supplemented the main spectrum profiles (MSPs) of the reference strains and clinical isolates with MALDI Database (Bruker Daltoniks, Germany), thus increasing rates of identification when using MALDI-TOF MS.

Methods

Thirty *Bacillus* strains were obtained from the National Culture Collection for Pathogens in Korea and were identified using the VITEK 2, 16S rRNA gene sequencing and MALDI-TOF MS. The pathogenicity of the *Bacillus* strains was confirmed through the identification of virulence genes by multiplex PCR. The dendogram of MSPs was compared with the phylogenetic tree constructed based on the 16S rRNA gene sequences and rep-PCR fingerprinting.
The rates of species-level identification were 40%, 80%, and 76.3% using the VITEK 2, 16S rRNA gene sequencing and MALDI-TOF MS, respectively. Thirty new entries of MSPs were manually entered into our MALDI database, which included the entire Bruker MALDI database. The results of phylogenetic analysis showed that MALDI-TOF MS is an effective tool for identification of *Bacillus* strains.

Conclusions

Bacillus strains were more efficiently identified using MALDI-TOF MS and 16S rRNA gene sequencing than the VITEK 2. Continual addition of MSPs to a proteome-based database can result in increased rates of identification using MALDI-TOF MS.

MOLECULAR DETECTION OF BIODIVERSITY OF TOMATO VIRUSES IN EGYPT AND PHYLOGENY ANALYSES OF SOME DETECTED ISOLATES

E. Abdel Aleem[1], C. Ratti[2], M. Rabie[1], F.A. Fattouh[1]
[1]Botany and MicrobiologyDepartment, Faculty of Science, Alexandria University, Alexandria, Egypt
[2]DipSA – Patologia Vegetale, Università di Bologna, Viale G. Fanin, 40 - 40127 Bologna, Italy

Backgrounds

Lycopersicon esculentum (tomato) is recognized as the second significant vegetable crop in the world. Egypt is the fifth largest producer of tomatoes in the world while over 9 million tons of tomatoes are produced annually. Tomatoes, a major export crop, contribute significantly to Egyptian economy.

Objectives

Tomato is subject to infection by a number of plant viruses that affect its yield and quality.

Methods

Recent surveys for the detection of tomato viruses by RT-PCR using synthetic specific oligonucleotide primers have allowed the identification of three major viruses infecting tomato. *Tomato yellow leaf curl virus* (TYLCV), *Cucumber mosaic virus* (CMV) and *Tomato mosaic virus* (ToMV) were detected in major tomato growing areas surveyed. Several isolates of TYLCV, CMV and ToMV were selected for further molecular characterization through sequencing of key genome parts of each. Full length sequencing was performed for one isolate of each of the three viruses. Phylogenetic analyses were performed which allowed the identification of closely related isolates in other parts of the world.

Conclusions

To our knowledge, this is the first characterization of CMV isolates from subgroup IB and the first report of ToMV in Egypt. Our results give a direct indication of the necessity to focus efforts on viral disease surveillance and to face the challenges of international trade in agriculture products for the proper management of those diseases.

HEALING THE YEAST FROM L-A VIRUS(ES)

L. Aitmanaitė[1], A. Konovalovas[1], E. Servienė[2,3], S. Serva[1,3]
[1]Vilnius University, Department of Biochemistry and Molecular Biology, Vilnius, Lithuania
[2]Nature Research Centre, Laboratory of Genetics, Vilnius, Lithuania
[3]Vilnius Gediminas Technical University, Department of Chemistry and Bioengineering, Vilnius, Lithuania

Backgrounds

Yeast L-A virus is a member of Totiviridae family, representing the group of viruses widespread among fungi and protozoa. Its single segment dsRNA genome encodes a major coat protein Gag and a Gag-Pol fusion protein, which functions as RNA-dependent RNA polymerase. Some wild yeast strains in addition to widespread L-A carry a satellite called M dsRNA. Satellite dsRNA genome solely encodes a secreted protein toxin, thus providing coding cell with survival advantage. L-A spreads by direct cytoplasm contacts occurring during cell division and cell-cell mating, while extracellular stage of these viruses remains unknown.

Objectives

Global gene expression analysis of yeasts focusing on the impact of L-A dsRNA should reveal molecular mechanisms involved in the maintenance of virus. In order to obtain relevant RNA-seq results, an efficient procedure for eliminating of L-A virus from yeast is required. Until now, three main approaches were used: treatment by heat, cycloheximide, and 5-fluorouracil. All listed treatments are cytotoxic for yeast and therefore could result in false positive hits in -omics experiments.

Methods

Our group constructed expression vectors of different L-A virus Gag proteins. The impact of Gag protein expression on native L-A virus was examined by nucleic acid electrophoresis, RT-PCR and killer phenotype assay.

Conclusions

Overexpression of L-A capsid protein Gag results in complete L-A virus elimination from yeast. L-A elimination occurs not only in case of overexpression of genuine capsid protein; capsid proteins from some of the different type L-A viruses are competent for exclusion, also. The obtained data highlight the evolutionary relationship between various types of L-A viruses, sharing molecular mechanisms for virus maintenance in yeast.

BIOINFORMATIC ANALYSIS OF L1, E6 AND E7 SEQUENCES FROM HUMAN PAPILOMA VIRUSES OF HIGHEST AND LOW RISK MOST FREQUENTLY IN LATIN AMERICA

A. Angulo[1], M.C. Yépez[1], M. Guerrero[1]
[1]University of Nariño, Centro de Estudios en Salud - CESUN, Pasto, Colombia

Backgrounds

Intratype HPV diversity in virus molecular variants leading alterations to changes in the residues of its functional domains related to the persistence of infection and the progression of cervical cancer precursor lesions (CCU) has been revealed. Variations in virus nucleotide sequences can be used as a tool in epidemiological studies to identify biomarkers, and clarify the virulence, expression and transformation of host cells, as well as taxonomic and evolutionary HPV studies.

Objectives

To analyze nucleotide sequences of the L1, E6 and E7 genes, to recognize the phylogenetic relationships, variants of genotypes and geographic distribution of the most frequent high and low risk HPV from Latin America.

Methods

Phylogenetic approximations from L1 gene sequences under the maximum likelihood criterion using the MEGA v.6.0.5 program were made. Variability analysis of E6 and E7 genes was performed with software BioEdit V. 7.2.5, which allowed the identification of punctual mutations for specific variants of each genotype of HPV, which we later projected on maps to establish their distribution with ArcGis v. 10.2.

Conclusions

770 sequences from 13 countries, mainly Costa Rica, Mexico and Brazil, were obtained for HPV types 6, 11, 16, 18, 31, 33, 35, 45, 52, 58 and 97. 24 new mutations for specific HPV types, except to HPV 6, 16, 31 and 35. This results allowed to identify point mutations that positively could correlated with the persistence of the virus and the NIC grade II and III, and give to these genotypes evolutionary advantages and adaptive mechanisms.

DRAFT GENOME SEQUENCE OF BACTERIOPHAGE BK30P, LYTIC PHAGE THAT INFECTS MACROMONAS

K. Baek[1], *A. Choi*[1]
[1]*Nakdonggang National Institute of Biological Resources, Freshwater Bioresources Research, Sangju-si, Republic of Korea*

Backgrounds

Bacteriophages lyse specific bacterial hosts, controlling bacterial abundance and diversity and influencing biogeochemical cycles, which makes the study of viruses ecologically important.

Objectives

we present the first draft genome sequence of this strain.

Methods

Genomic DNA was extracted from strain BK30P using a DNeasy blood and tissue kit. Genome sequencing was performed using the Illumina sequencing technology with library constructed. The bacterial genome was assembled *de novo* into one contig. The data was then submitted to the Rapid Annotation using Subsystem Technology (RAST) server and the National Center for Biotechnology Information genome sequence database. Potential coding sequences were searched for using the Basic Local Alignment Search Tool (BLAST) against the Pfam and COG databases.

Conclusions

Bacteriophage BK30P is a lytic bacteriophage that infects the geuns macromonas strain BK30, a Freshwater bacterium affiliated with Burkholderiales. Both the bacteriophage and the host bacterial strain were isolated from surface freshawater samples collected off the Nakdong river of Korea. The phage particle has an icosahedral capsid with a diameter of ~60 nm and a long tail of ~82 nm in length; these characteristics constitute the distinctive morphology of the myoviridae family. The complete genome sequence of phage BK30P is 43,064 bp long with 58.6% G+C content. This complete genome sequence is the first report of a lytic phage that infects macromonasa, for which the name “macromonasphage” is proposed.

ISOLATION AND CHARACTERIZATION OF A NEW TEMPERATE BACTERIOPHAGE OF VIBRIO ANGUILLARUM

O. Flores[1], K. Paez[1], D. Castillo[2], M. León[1], R. Bastías[1]
[1]Pontificia Universidad Católica de Valparaíso, Instituto de Biología, Valparaíso, Chile
[2]University of Copenhagen, Marine Biological Section, Copenhagen, Denmark

Backgrounds

Vibrio anguillarum is a recurrent pathogen in Aquaculture industry. In marine environments its abundance, diversity and evolution can be influenced by lytic and temperate bacteriophages.

Objectives

The aim of this work was to characterize the new temperate bacteriophage Valp1 of *V. anguillarum* that was isolated from coastal waters in Valparaíso, Chile.

Methods

The phage was characterized by TEM, genome analysis and biological properties, while the lysogenized strain was compared with the *wt* strain in their growth and biochemical profile using the BIOLOG system.

Conclusions

The bacteriophage Valp1 presents an icosahedral head of 60 nm and a tail of 90 nm. A preliminary analysis of its 43 kb genome revealed the presence of 36 ORF and confirmed its temperate nature. The phage was not detected in other *V. anguillarum* strains genomes, but 72% of the ORF presented partial identity with prophage proteins found in *V. cyclitrophicus*. The growth of the *wt* host strain decreases in presence of the bacteriophage (MOI=1), while the growth of the lysogenized strain is slightly lower comparing to the *wt*, but was not affected by the addition of Valp1. The lysogenic strain did not show any alterations in biofilm formation or motility; however presents alterations in 11.7% of the biochemical tests comparing to the *wt* strain. These results suggest that the bacteriophage Valp1 can affect the metabolism of its host. This work is the first step to understand how the phage Valp1 can be influencing the fitness, evolution or even the virulence of *V. anguillarum* in the environment.

Virology

SAT, A NOVEL PARVOVIRAL PROTEIN INDUCING CELL LYSIS

C. Bretscher[1], *J. Nüesch*[1]
[1]*German Cancer Research Center, Tumor Virology, Heidelberg, Germany*

Backgrounds

MVMp and H1 are rodent parvoviruses – small, non-enveloped icosahedral particles with a 5.1 kb single-stranded DNA as a genome. Due to their striking oncotropism and oncolytic activities some of these agents are considered as excellent candidates for a virotherapy of cancer. This, together with a strong safety profile led to first phase I/IIa clinical trials targeting glioblastoma multiforma and pancreatic ductal adeno carcinoma.

Objectives

The main parvoviral oncotoxic protein is thought to be the large non-structural protein NS1. However, additional viral factors appear to be required to efficiently permeabilize the plasma membrane and to induce cell lysis. Recently, a short conserved hydrophobic polypeptide termed SAT of presently unknown function was identified in the related porcine parvovirus. SAT contains a transmembrane domain and is found to localize to membranous compartments such as the endoplasmatic reticulum, the Golgi and the plasma membrane. These findings led us to hypothesize that SAT might act as a viroporin, a family of viral proteins that are capable of permeabilizing membranous structures through multimerization within the target compartment.

Methods

In fact, after transfection we could show in an immunoprecipitation, in a proximity ligation assay and in a cell-lysis assay that SAT homo-oligomerizes and in consequence permeabilizes the plasma membrane. Current investigations are focused to determine the oligomeric state of SAT and to determine the impact of distinct motifs in the polypeptide being involved in the lytic process.

Conclusions

Our recent findings strongly support our hypothesis of SAT being involved in pore-formations and release of progeny particles from infected cells.

VIRUCIDAL ACTIVITY OF GAMMA RADIATION ON ENTERIC VIRUSES

A. Pimenta[1], D. Guerreiro[1], J. Madureira[1], F. Margaça[1], S. Cabo Verde[1]
[1]Instituto Superior Técnico, Centro de Ciências e Tecnologias Nucleares - C2TN, Bobadela LRS, Portugal

Backgrounds

Enteric viruses, such as norovirus (NoV) and adenovirus (AdV), are a major cause of water and foodborne diseases. These viruses are environmentally stable and resistant to conventional treatments and common disinfectants. Among non-thermal treatment methods, ionizing radiation is recognized as a useful and effective means of disinfection.

Objectives

The goal of this study was to investigate the inactivation by gamma irradiation of murine norovirus type 1 (MNV-1), as a NoV surrogate, and human adenovirus type 5 (AdV-5) in six different aqueous substrates and two types of fresh berry fruits.

Methods

Phosphate Buffer Saline, demineralized water, tap water, Fetal Bovine Serum solutions as well as fresh strawberries and raspberries, were inoculated either individually with MNV-1 and AdV-5 or with a viral pool of both viruses. The spiked samples were irradiated in a Co-60 chamber at doses of 1 kGy up to 11 kGy. The infectivity of viral particles of MNV-1 and AdV-5 was tested by plaque assay using Raw 264.7 and A549 cells, respectively. D_{10} values and virucidal efficiency of gamma irradiation were estimated for each virus and substrate.

Conclusions

On wastewater suspensions it was achieved a reduction on MNV and AdV titers of 3 log PFU/ml after irradiation at 5 kGy. For spiked fresh berries irradiated at 4 kGy it was obtained a reduction on virus titers of 2 log PFU/g. But, non-linear inactivation survival curves were obtained for MNV and AdV in fresh fruits, leading to the detection of infective viral particles at a dose of 11 kGy.
The irradiation treatment indicated virucidal activity for the enteric viruses, although the viral inactivation by gamma radiation was found to be dependant on the substrate where the viruses are present. The irradiation technology can be an effective virus mitigation tool to treat polluted waters, which are a major vehicle of contamination for fresh produce.

IDENTIFICATION OF VIRUSES INFECTING SWEET POTATOES IN KOREA USING NEXT-GENERATION SEQUENCING

Y. Jo[1], H. Choi[1], W.K. Cho[1]
[1]Seoul National University, Department of Agricultural Biotechnology, Seoul, Republic of Korea

Backgrounds

Sweet potato [*Ipomoea batatas* (L.) Lam] is one of the most important food crops and is cultivated worldwide. Although sweet potatoes grow from seeds, most are vegetatively propagated by planting rooted sprouts or slips. Therefore, many sweet potatoes are infected by various viruses, reducing production.

Objectives

In June 2016, we collected several sweet potato samples from six different regions in Korea for the identification of viruses infecting sweet potatoes.

Methods

Pooled samples were subjected to total RNA extraction followed by library preparation. Six different libraries were paired-end sequenced by HiSeq 2000. Sequenced raw data were used for *de novo* transcriptome assembly using Trinity. Assembled contigs were subjected to BLAST search against a viral reference database.

Conclusions

We identified seven known viruses infecting sweet potatoes. Of the six regions, only in the library from Yeongam were none of viruses identified, while the libraries from Iksan and Yeoju each contained a large number of viral reads associated with at least five viruses. Of identified viruses, *Sweet potato virus C* and *Sweet potato feathery mottle virus* were abundantly present in five regions. In many cases, sweet potatoes were co-infected by several viruses. The virus infection rates and the kinds of viruses infecting sweet potatoes were varied by region. This is the first report of viruses infecting sweet potatoes in Korea using next-generation sequencing. Our results will be useful for virus diagnosis and the generation of virus-free sweet potato plants.

FEMS7-0730

IDENTIFICATION OF VIRUSES INFECTING BARLEY IN KOREA USING NEXT-GENERATION SEQUENCING

H. Choi[1], Y. Cho[1], W.K. Cho[1]
[1]Seoul National Univesity, Department of Agricultural Biotechnology, SEOUL, Republic of Korea

Backgrounds

Barley (*Hordeum vulgare*) is an annual cereal grain belonging to the family *Poaceae* that has been cultivated for more than 7000 years. Although barley is tolerant to abiotic stresses such as cold, drought, and salinity, many kinds of pathogens, including viruses, cause reduction of barley production.

Objectives

In order to examine viruses infecting barley in Korea, we harvested 110 barley plants showing viral disease symptoms from 17 different regions in Korea.

Methods

We pooled samples according to six geographical regions and generated six different libraries for RNA sequencing using next-generation sequencing. Raw data sequenced by HiSeq 2000 were *de novo* assembled using Trinity. The assembled contigs were subjected to BLAST search against a viral genome database.

Conclusions

We identified eight different viruses infecting barley. Of these, *Barley yellow mosaic virus* (BaYMV in the genus *Bymovirus*) was dominant, followed by *Barley mild mosaic virus* (BaMMV in the genus *Bymovirus*) and *Barley yellow dwarf virus* (BYDV in the genus *Luteovirus*). Furthermore, the barley viromes derived from different regions showed region-specific viral communities. In addition, we obtained five nearly complete genomes for BaYMV and two for BaMMV. Moreover, we calculated viral copy number and single nucleotide variations (SNVs) for assembled viral genomes. The number of identified SNVs for each virus was dependent on the cultivated regions. Taken together, this is the first comprehensive study of barley viromes in Korea.

SINGLE VIRUS GENOMICS, A PROMISING METHODOLOGY TO STUDY THE UNCULTURED HUMAN VIROME.

M.J. de la Cruz Peña[1], F. Martínez Hernández[1], M. Lluesma Gomez[1], M. Garcia[1], O. Fornás[2], L. Díaz[3], M.A. Muñoz Fernández[3], F. Marco[4]
[1]Universidad de Alicante, Department of Physiology- Genetics and Microbiology, Alicante, Spain
[2]Barcelona Biomedical Research Park-Centre for Genomic Regulation, Flow Citometry Unit, Barcelona, Spain
[3]Hospital General Universitario Gregorio Marañón, Department of Immunology, Madrid, Spain
[4]Hospital General Universitario de Alicante, Department of Immunology, Alicante, Spain

Backgrounds

Viruses play significant and different roles in the biosphere and are very abundant in all environments. Our research focused on the uncultured human salivary viruses. Although several surveys have studied the natural viral assemblages in human saliva (Willner et al., 2011; Abeles et al., 2014; Pride et al., 2012), very little is known about differences in viral composition between healthy and immunoglobulin A (IgA), M (IgM) and G (IgG) immunodeficiency people. For instance, IgA acts as an important first line of defense against microbes in the mucous membranes.

Objectives

In the present study we combine Metaviromics and Single Virus Genomics to unveil the genetic information of ecologically predominant viruses present in these contrasting biological conditions of the human mucus.

Methods

Single Virus Genomics allows to obtain the genetic information directly from one virus at a time without the need of culturing the host. First, single viral particles are directly separated by flow cytometry from the saliva by fluorescence activated viral sorting. Then, the genetic material of single sorted viruses was whole genome amplified by multiple displacement amplification and finally sequenced. In parallel, metaviromes from same sample were sequenced and used for a cross genomic comparison with single virus genome datasets

Conclusions

Albeit we are at the beginning of our research, so far, we unveiled the genome of three highly abundant uncultured *Streptococcus* and *Moraxella* phages. This suggests that this promising methodology will open new ways to contrast hypothesis in the human microbiome.

IMPACT OF GLOSSINA PALLIDIPES SALIVARY GLAND HYPERTROPHY VIRUS ON A HETEROLOGOUS HOST, G. F. FUSCIPES

G. Demirbas Uzel[1,2], A.G. Parker[1], M.J.B. Vreysen[1], R.L. Mach[2], A.M.M. Abd-Alla[1]
[1]International Atomic Energy Agency,
Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, Vienna, Austria
[2]Vienna University of Technology,
Institute of Chemical- Environmental and Biological Engineering- Research Area Biochemical Technol ogy, Vienna, Austria

Backgrounds

Tsetse flies (Diptera: Glossinidae) are the vector of African trypanosomosis, the cause of sleeping sickness in humans and nagana in animals. The development of resistance by trypanosomes to the available drugs makes vector control the most effective approach for sustainable management of nagana. The sterile insect technique (SIT) is an effective method to suppress or eradicate tsetse flies in the frame of an area-wide pest management programme. SIT includes the mass production of the target insect and release of sterile males in the targeted area to compete with wild males in mating with wild females.

Objectives

Tsetse mass rearing is a challenge for SIT application and an understanding of the reproductive biology and associated pathogens is essential to improve mass rearing. *Glossina fuscipes fuscipes* is one of the most important vectors of sleeping sickness in central Africa. GpSGHV affects the fecundity, productivity and therefore performance and sustainability of *G. pallidipes* colonies.

Methods

In this study, we evaluated the impact of GpSGHV on the performance of a *G. f. fuscipes* colony including productivity, mortality, survival, flight ability and insemination rates.

Conclusions

The results indicate that GpSGHV infection has a significant impact on mortality, productivity, survival and mating ability but not on adult flight ability or insemination rates in *G. f. fuscipes*. These results explore the important role of GpSGHV in the sustainability of *G. f. fuscipes* colonies and the need to implement measures to avoid virus infection to ensure the successful establishment of mass rearing of this species for SIT programmes.

VIRAL TAGGING: IDENTIFYING BACTERIA PREFERENTIALLY INFECTED BY BACTERIOPHAGES

M. Dzunkova[1], *C. Rinke*[1], *J. Daly*[1], *L. Deng*[2], *P. Hugenholtz*[1]
[1]*University of Queensland, Australian Centre for Ecogenomics, Brisbane, Australia*
[2]*Helmholtz Zentrum München, Institute of Virology, Neuherberg, Germany*

Backgrounds

The recently developed viral tagging method allows the host range of viruses to be determined without the need for plaque formation tests. Fluorescently stained bacteriophages from an environmental sample are mixed with a non-stained bacterial host. Bacterial cells infected by phages are collected by the fluorescence activated cell sorting (FACS). The DNA of the infecting phages is then sequenced and analyzed.

Objectives

To date, the viral tagging method has only been applied to bacterial isolates. Our goal was to extend the method to uncultured bacterial species of the human gut microbiome, and to determine the network of bacterial-viral interactions in that ecosystem.

Methods

Viral particles isolated from feces of a healthy volunteer were fluorescently stained and mixed with bacterial cells recovered from the same sample. FACS was used for collection of 100,000 bacterial cells tagged with stained viruses in three replicate sorts, along with the non-tagged cells as controls. The attachment of bacteriophages to the bacterial cell surface was confirmed by electron microscopy. DNA from the collected cells was shotgun sequenced and the bacterial species identified using marker genes.

Conclusions

A subset of the bacterial species in the volunteer's gut microbiome were found to be enriched in the viral-tagged populations. Specifically, *Streptococcus, Clostridium, Blautia, Dorea* and *Ruminococcus* were more abundant in the viral-tagged fraction, while *Bacteroides, Roseburia* and *Sutterella* were under-represented relative to non-tagged controls. Our results suggest that some gut species are more prone to the attack by native bacteriophages. Future investigations will resolve the host-viral interaction network in this ecosystem.

INACTIVATED NERVOUS NECROSIS VIRUS (NNV) VACCINE ELICITS ANTIVIRAL ACTIVITY AND PROTECTION IN THE TELEOST EUROPEAN SEA BASS (DICENTRARCHUS LABRAX)

E. Chaves-Pozo[1], Y. Valero[1], M. Djamal[2], D. Ceballos-Francisco[3], M.A. Esteban[3], A. Cuesta[3]
[1]Insituto Español de Oceanografía, Mazarrón, Mazarrón, Spain
[2]Université de Blida, 2Institut des Sciences Vétérinaires, Blida, Algeria
[3]University of Murcia, Cell Biology & Histology, Murcia, Spain

Backgrounds

Nodavirus (NNV; *Nodaviridae* family, *Betanodavirus*genus), is one of the most threatening virus for teleost fish and causes the viral encephalopathy and retinopathy (VER) diseasethat alters brain and retina structure and function. Amongmarine fish, the European sea bass (*Dicentrarchus labrax*), a very relevantspecies in Mediterranean aquaculture, is one of the mostsusceptible species, being larvae and juvenile stages those sufferinghighest mortalities. To date, no effective vaccines are available.

Objectives

Our aim was to generate an inactivated NNV vaccine for sea bass and evaluate the immunity and protection.

Methods

Sea bass specimens of 10 g were intraperitoneally injected with UV-inactivated NNV and after 1 month infected with a lethal dose of NNV. Antiviral activity and specific antibody levels were determined in serum samples as well as the fish protection.

Conclusions

The vaccine elicited antiviral activity and antibody levels in sea bass specimens as well as increased the relative protection survival up to 57.9%. This is one of the few NNV vaccines tested in sea bass and the protection conferred was very similar to other NNV vaccine types and other fish species.

Acknowledgements. Financial support by grants AGL2013-43588-P and AGL2014-51839-C5-1-R (MINECO and FEDER) and 19883/GERM/15 (*Fundación Séneca de la Región de Murcia*, Spain) is gratefully acknowledged.

HUMAN SAPOVIRUS IN STOOL SAMPLES OF SPAIN. A ONE YEAR STUDY

M. F. Varela[1], E. Rivadulla[1], J. L. Romalde[1]
[1]Universidade de Santiago de Compostela, Department of Microbiology and Parasitology, Santiago de Compostela, Spain

Backgrounds

Human Sapovirus is an emerging pathogen causing gastroenteritis in people of all ages worldwide. It has nonenveloped icosahedral morphology, small size (30-38 nm) and cup-shaped depressions on its surface. Sapovirus genome is a single-stranded positive-sense RNA molecule of 7.3-7.5 kb, with two or three open reading frames, depending on the genogroup. Its transmission occurs via the faecal-oral route. Symptoms are similar to those caused by others enteric viruses such as Norovirus, therefore laboratory diagnosis is needed to study its emergence.

Objectives

The main objective of the study was to determine the prevalence of human Sapovirus among the population of the Galician region (NW of Spain) through the analysis of samples from symptomatic outpatients with different ages and during different seasons of the year.

Methods

A total of 2,372 stool samples were collected weekly over one year, starting July 2010, from the Clinical University Hospital of the city of A Coruña, Galicia. Detection and quantification was carried out by RT-qPCR using specific primers and probes for human genogroups I, II and IV.

Conclusions

Overall detection rate was 14.3%, being slightly higher in ages 0-2 and 3-5 years old (15.6 and 15.2%, respectively). Positive samples were located along all months of the year, with peaks of detection on September, October and February. Mean value for quantified samples was 8.9×10^5 RNAc/g of feces, with the age group between 0-2 years old presenting the highest quantification and elders than 60 years old the lowest (5.6×10^6 and 1.3×10^5 RNAc/g of feces, respectively).

THE SPREAD OF PICI-LIKE ELEMENTS IN GRAM-NEGATIVE BACTERIA

A. Fillol-Salom[1], R. Martínez-Rubio[2], R. Abdulrahman[1], R. P Novick[3], R. Davies[1], J. R Penades[1]
[1]Infection- Immunity and Inflammation, Bacteriology, Glasgow, United Kingdom
[2]Universidad CEU Cardenal Herrera, Departamento de Ciencias Biomédicas, Moncada, Spain
[3]Skirball Institute, Departments of Microbiology and Medicine, New York University Medical Center, USA

Backgrounds

Staphylococcus aureus pathogenicity islands (SaPIs) are mobile genetic elements (MGEs) with extreme importance in virulence intimately related to certain temperate (helper) bacteriophages, whose life cycles they parasitise. We have recently discovered and extensively characterized a family of pathogenicity islands in Gram-positive cocci, the phage-inducible chromosomal islands (PICIs), which contribute substantively to horizontal gene transfer, host adaptation and virulence.

Objectives

We now report that similar elements also occur widely in Gram-negative bacteria. Their uniqueness is defined by a constellation of features: unique and specific attachment sites, exclusive PICI genes, a phage-dependent mechanism of induction, unique replication origin organisation, convergent mechanisms of phage interference and specific packaging of PICI DNA into phage-like infectious particles, resulting in very high transfer frequencies.

Methods

By an *in silico* analysis we have identified a considerable collection of putative PICI-like elements in different Gram-negative bacteria.
Afterwards, we have performed *in vitro* and *in vivo* characterisation of the different modules. And finally to characterise the regulatory system we have used an enzymatic assays.

Conclusions

Overall, based on these findings we propose that all these elements along with the elements found in Gram-positive bacteria represent the discovery of a new and unique class of mobile genetic elements, the phage-inducible chromosomal islands, which have had a broad impact on lateral gene transfer in the bacterial world. Also, we suggest that the PICIs represent two or more distinct lineages, have spread widely throughout the bacterial world, and have diverged much more slowly than their host organisms or their prophage cousins.

NATURAL VARIATION IN THE STABILITY OF SULFOLOBUS ISLANDICUS ROD-SHAPED VIRUSES ISOLATED FROM YELLOWSTONE NATIONAL PARK

K. Gazi[1], *D. Grogan*[1]
[1]*University of Cincinnati, Department of Biological Sciences, Cincinnati, USA*

Backgrounds

Among the three domains of cellular life, archaea are the least understood, and functional information about archaeal viruses is very limited. For example, it is not known whether many of the viruses that infect hyperthermophilic archaea retain infectivity for long periods of time under the extreme conditions of geothermal environments.

Objectives

To investigate these viruses' capability of Infecting under the extreme conditions of geothermal environments.

Methods

A number of plaque-forming viruses related to SIRVs, isolated from Yellowstone National Park in a previous study, were evaluated for stability under different stress conditions, including high temperature, drying, and extremes of pH.

Conclusions

Screening of 34 isolates revealed a 95-fold range of survival with respect to boiling for two hours and 94-fold range with respect to drying for 24 hours. Comparison of 10 viral strains chosen to represent the extremes of this range showed little correlation of stability with respect to different stresses. For example, three viral strains survived boiling but not drying. On the other hand, five strains that survived the drying stress did not survive the boiling temperature, whereas one strain survived both treatments and the last strain showed low survival of both. The basis for these differences has not been identified, but the extent of the variation suggests that multiple properties of each viral isolate combine to determine the biological stability of the virions.

EXPRESSION ANALYSIS OF MIRNA IN PLASMA DURING AN INFECTIOUS SALMON ANAEMIA VIRUS INFECTION

C. Salazar[1,2], S.H. Marshall[1,2], F. Gómez[3]
[1]Pontificia Universidad Católica de Valparaíso, Biology Department, Valparaiso, Chile
[2]Fraunhofer Chile Research, Valparaíso, Chile
[3]Laboratorio de Genética e Inmunología molecular, Instituto de Biología,
Pontificia Universidad Católica de Valparaíso

Backgrounds

Infectious salmon anemia virus (ISAV) belongs to the *Orthomyxovirus* family and possesses a single stranded RNA genome of negative polarity divided into 8 segments. ISAV is the causative agent of the infectious salmon anemia disease which affects *Salmo salar,* causing a big outbreak in 2007 in Chile; since then the production recovered but the presence of the virus remains a problem.

miRNAs are small non-coding RNA which regulate mRNA expression at post-transcriptional level. They have been found in different body fluids, like plasma and serum, and their expression pattern can be altered in a variety of pathophysiological conditions.

Objectives

Given the importance of the salmon industry in Chile, a deep understanding of the interaction between ISAV and the target cell is a must. In the present work, we studied the expression pattern of miRNA on plasma samples during an ISAV infection on *S. salar* fishes.

Methods

Briefly, fishes were intraperitoneally infected with ISAV, and at 5 and 10 days post infection plasma samples were obtained from infected fishes and controls and small-RNA Seq was performed. The obtained data was analyzed using bioinformatic tools aiming to identify different expression of miRNA in plasma between control versus infected samples.

Conclusions

An *in silico* analysis of expression was performed and showed that three miRNA: miR-122, miR-29c and miR-145 are differentially expressed on infected plasma samples. As conclusion *S. salar* present miRNA on plasma and their pattern of expression changes during ISAV infection.

COMPARATIVE ANALYSIS OF VARIATION AND SELECTION IN THE HCV GENOME

J.Á. Patiño-Galindo[1], F. González-Candelas[1]
[1]FISABIO-CSISP / University of Valencia, Joint Research Unit Infection and Public Health, Valencia, Spain

Backgrounds

Genotype 1 of the hepatitis C virus (HCV) is the most prevalent of the variants of this virus. Its two main subtypes, HCV-1a and HCV-1b, are associated to differences in epidemic features and risk groups, despite sharing similar features in most biological properties. Analyzing the selective pressures acting on these subtypes is interesting for antiviral research.

Objectives

To analyze the impact of positive selection and structural constraints on the evolution of HCV-1a and HCV-1b genomes and to compare the selective pressures in the different proteins of these two subtypes.

Methods

393 HCV-1a and 179 HCV-1b sequences were subjected to diversifying positive selection analyses with FEL and MEME. By means of logistic regression analyses, the distributions of positively selected and conserved sites were compared, in each subtype, considering different factors such as RNA secondary structure, the presence of different epitopes (antibody, CD4 and CD8), and secondary protein structure.

Conclusions

Less than 10% of the genome was found to be under positive selection, and purifying selection was the main evolutionary process acting in both subtypes. Logistic regression analyses revealed that similar selective forces act at the genome level in both subtypes: RNA secondary structure and CD4 T-cell epitopes are associated with conserved sites, while CD8 T-cell epitopes are associated with positive selection in both subtypes.
Similar selective constraints are acting along HCV-1a and HCV-1 b genomes. The results obtained give information about the effect of some interactions between HCV and its host on HCV variability, which may be useful for antiviral research against this virus.

CHARACTERISATION OF NOVEL STAPHYLOCOCCUS AUREUS-INFECTING PHAGE

B. Grygorcewicz[1], A. Augustyniak[1], A. Wasak[1], X. Stachurska[1], J. Laskowska[1], P. Nawrotek[1]
[1]West Pomeranian University of Technology-
Szczecin- Faculty of Biotechnology and Animal Husbandry,
Department of Immunology- Microbiology and Physiological Chemistry, Szczecin, Poland

Backgrounds

Staphylococcus aureus is a hazardous etiological agent of skin and wound infections. Additionally, health problems caused by methicillin-resistant *Staphylococcus aureus* (MRSA) became a great challenge in terms of eradication of the pathogen. Bacteriophage-based therapy can be an effective method for treatment of the MRSA infections. Additionally, phage therapy can significantly reduce the cost of standard treatment based on antibiotics.

Objectives

The aim of this study was to isolate a novel *Staphylococcus aureus*-infecting bacteriophage and to evaluate its lytic activity.

Methods

Bacteriophage was isolated from bovine milk with *S. aureus* ATCC 6538 used as a host. The morphology of the bacteriophage was observed using transmission electron microscopy. The host range together with the efficiency of plaquing, adsorption rate, multiplication parameters, pH and thermal stability were evaluated by plaque assay based on the double agar layer method. The lytic activity of bacteriophage as well as the degradation of biofilm formed by *S. aureus* were assessed by spectrophotometric methods.

Conclusions

The isolated bacteriophage can effectively lyse planktonic cells and the degrade biofilm biomass of numerous *S. aureus* strains (n=87). This suggests that isolated bacteriophage could be applied as a therapeutic/biocontrol agent against *S. aureus* strains of human and animal origin.

ISOLATION OF VIRUSES INFECTING HALOARCHAEA FROM URMIA LAKE

H. Hashemi Motahar[1], *E. Arefian*[1], *M.A. Amoozegar*[1]
[1]*Faculty of Biology - College of Science - University of Tehran -, Microbiology, Tehran, Iran*

Backgrounds

Viruses play an important role as a controller of the prokaryotic population as they are the only known predators in hypersaline environments. Moreover, they provide applicable genes and proteins to industries. All known archaeoviruses which are increasingly studied in the last decades, infecting two phyla *Euryarchaeota* and *Crenarchaeota*.

Objectives

Urmia Lake (located in the northwest of Iran) is one of the largest hypersaline lakes in the world and has faced with drought problem in recent years. The goal of this study was to identify the viral resources and protect them against destruction danger.

Methods

hypersaline water samples were collected from Urmia Lake and centrifuged. The sedimented phase was inoculated to MGM 23% media for isolating the archaea. The Antibiotic test was performed to approve the archaeal identity. To finding the culture logarithmic phase, the growth curves of the isolates were drawn using spectrophotometric experiment. The supernatant was passed through 0.45 and 0.22 µm syringe filters and was mixed to archaeal hosts and MGM soft agar and then poured to solid media for plaque assay. The plaques were isolated and viruses re-cultured several times to obtain purified plaques. The morphological features of the viruses were studied by Trans Electron Microscope (TEM).

Conclusions

TEM analysis revealed spherical morphology with an inner membrane surrounded by an icosahedral capsid.

TRANSCRIPTOMICS AND PROTEOMICS OF THREE PHAGE INFECTIONS WITH VARYING EFFICIENCY

C. Howard-Varona[1], K.R. Hargreaves[1], N.E. Solonenko[1], L.M. Markillie[2], R.A. White III[2], C. Ansong[2], G. Orr[2], J.A. Adkins[2], M.B. Sullivan[1]
[1]The Ohio State University, Microbiology, Columbus, USA
[2]Pacific Northwest National Laboratory PNNL, Environmental Molecular Sciences Laboratory EMSL, Richland, USA

Backgrounds

Bacterial viruses (phages) are central to applied and environmental microbiology given their benefits in phage therapy and their impacts to cell mortality, gene transfer and biogeochemical cycles, respectively. Driving these are the strategies and outcomes of phage-host interactions, including host-range (generalist/specialist) and infection efficiency (efficient/inefficient), which are especially poorly understood in nature.

Objectives

Here we seek to understand infection strategies of a generalist and a specialist phage infecting one environmental *Bacteroidetes* host with opposite infection efficiency.

Methods

Genome-wide transcriptomics and proteomics, coupled with phage-host physiology experiments and genomics

Conclusions

Overall, phages had similar transcriptional dynamics, but their proteomes and different host response to each phage revealed mechanisms driving infection efficiency. Namely, controlling host transcriptome and proteome enabled the specialist phage to induce early activation of host translation and have an efficient infection by: *i*) expressing anti-restriction genes early and overcoming host restriction/modification defenses; and *ii*) synchronizing transcription and translation. The generalist's inefficient infection lacked such cellular take-over and failed to *i*) overcome host restriction/modification and protease defenses, and *ii*) synchronize transcription and translation, which resulted in delayed protein production. However, when infecting its original host, a genetically-related strain, the generalist phage displayed transcriptional-translational synchronization and the infection was efficient. Together, these data provide insight into generalist/specialist and efficient/inefficient infection strategies, and a foundation for investigating any phage-host interaction in nature.

MULTIEPITOPE PROTEINS BASED ON THE ENVELOPMENT PROTEIN E2 OF CHIKUNGUNYA VIRUS AND THE NON-STRUCTURAL PROTEIN NS1 OF DENGUE VIRUS AS ANTIGENS TO DETECT VIRUS INFECTIONS

L.M.S. López[1], A. Rojas[1], M.E. Acosta[1], L. Aria[1], Y. De Guillén[1], B. Infanzón[1]
[1]Instituto de Investigaciones en Ciencias de la Salud- Universidad Nacional de Asunción, Production Department, Asunción, Paraguay

Backgrounds

Chikingunya virus (CHIKV), an emergent alphavirus during the last years, and dengue virus (DENV) an endemic flavivirus, are cause of many cases of fever in Paraguay. For this reason, it becomes necessary to develop a fast and accurate serological diagnosis of these infections.

Objectives

We aimed to produce two multiepitope recombinant functional proteins as antigens for antibody detection.

Methods

A synthetic gen was designed to express the mE2 based on the synthetic protein reported before. The gene was composed of four epitopes of the envelopment E2 of CHIKV. A second synthetic gene coding for a protein mNS1, derived from specific epitopes of the non-structural protein NS1 of the four DENV types, was designed after the study of isolated sequences reported in the country and the border countries. It is important to point that the DENV vaccine, commercialized since 2016, is based on the envelopment protein of the virus, therefore, the development of a test based on another antigenic protein, is crucial for the control of new cases after vaccination.

The two chimeric proteins, mE2 and mNS1, were expressed in *Escherichia coli* and were purified from crude extract by affinity chromatography. The antigenic role of the protein has been assayed by western blot with positives and negatives serum samples.

Conclusions

The production of the two proteins, mE2 and NS1, may allow the development of a local, low cost, and more sensitive test to improve the diagnosis during epidemic episodes

GENETIC DIVERSITY OF HUMAN METAPNEUMOVIRUS IN HOSPITALIZED CHILDREN WITH ACUTE RESPIRATORY INFECTIONS IN CROATIA

M. Jagušić[1], A. Slovic[1], S. Ljubin Sternak[2], G. Milinarić-Galinović[3], D. Forčić[1]
[1]University of Zagreb, Centre for Research and Knowledge Transfer, Zagreb, Croatia
[2]University Medical School of Zagreb and Teaching Institute of Public Health "Dr. Andrija Štampar", Molecular Microbiology Department, Zagreb, Croatia
[3]Croatian National Institute of Public Health, Department of Virology, Zagreb, Croatia

Backgrounds

Human metapneumovirus (HMPV) is recognized as an important etiological agent of acute lower respiratory tract infections in infants.

Objectives

The objectives of this study were molecular epidemiology and evolutionary analysis of HMPV strains which produced moderate and severe acute respiratory tract infections in children in Croatia during four consecutive seasons (2011–2014).

Methods

A total of 117 HMPV samples collected from hospitalized paediatric patients presenting with acute respiratory tract infections and tested by direct immunofluorescence assay were analysed by amplifying a part of the F gene. Sixteen samples were further phylogenetically analysed based on sequences of all three virus transmembrane glycoproteins: F, G and SH gene.

Conclusions

HMPV genome was identified in 92 of 117 samples (78%); the circulation of multiple lineages of HMPV was confirmed. In 2011, 2012, and 2014, subgroups A2 and B2 co-circulated, while B1 gained prevalence in 2013 and 2014. Importantly, the presence of a unique subcluster A2c in Croatia was established. This study provides new insights into epidemiology and genetic diversity of HMPV in this part of Europe.

TWO FATAL CRIMEAN-CONGO HEMORRHAGIC FEVER FOLLOWING INFECTION WITH AN AP92 LIKE STRAIN OF CRIMEAN-CONGO HEMORRHAGIC FEVER VIRUS IN IRAN

T. Jalali[1], M. Fazlalipour[1], V. Baniasadi[1], S. Azad-Manjiri[1], T. Mohammadi[1], Y. Jamshidi[1], S. Khakifirouz[1], M. Salehi-Vaziri[1]
[1]pasteur Institute of Iran, Arboviruses and Viral Hemorrhagic Fevers National Ref Lab, Tehran, Iran

Backgrounds

Crimean-Congo Hemorrhagic Fever (CCHF) is an important tick-borne viral zoonotic disease which can cause up to 50% mortality in infected patients. The main routes of transmission of CCHFV are by infected tick bites or through exposure to blood or tissues of patients or viremic animal. The disease is known to be endemic in Africa, South East Europe, Asia and the Middle East. Previously it has been proposed that the AP92 strain of CCHF virus is not virulent and could be used as a vaccine candidate; however, in recent years there have been reports of mild clinical diseases following infection with AP92 like strains.

Objectives

Here, we report two fatal cases of CCHF following AP92 like strains of CCHFV in north of Iran.

Methods

In summer of 2015, sera of two CCHF probable cases were sent to the Department of Arboviruses and Viral Hemorrhagic Fevers (National Ref Lab), Pasteur institute of Iran for CCHF laboratory diagnosis.

Molecular analysis of serum indicated CCHFV infection for both cases and serological analysis could not detect IgM or IgG in their samples. Sequence analysis revealed high similarity of these isolates to the AP92 strain. The isolates were designated as Iran-4465 and Iran-4675 with accession numbers KT588640 and KT899991 respectively.

Although both cases were subjected to ribavirin and supportive therapy, they died due to server hemorrhage.

Conclusions

Although AP92 strain of CCHF is not considered virulent in Greece and Turkey, interestingly we report fatal CCHF cases due to AP92 like strains. The AP92 like strains are genetically distinct from other strains reported so far in Iran.

NOSOCOMIAL AND LOCAL OUTBREAK OF CRIMEAN CONGO HEMORRHAGIC FEVER IN IRAN

M. Salehi-Vaziri[1], V. Baniasadi[2], M. Fazlalipour[2], S. Khakifirouz[2], S. Azadmanjiri[2], T. Mohammadi[2], Y. Jamshidi[2], S. Azizizadeh-Haghighi[2], M.H. Pouriayevali[2], T. Jalali[3]
[1]Pasteur Institute of Iran, Arboviruses and Viral Hemorrhagic Fevers National Ref Lab, Tehran, Iran
[2]Pasteur Institute of Iran, Arboviruses and Viral Hemorrhagic Fevers National Reference Laboratory, Tehran, Iran
[3]Pasteur Institute of Iran, Arboviruses and Viral Hemorrhagic Fevers National Reference Laboratory, Tehrani, Iran

Backgrounds

Crimean-Congo hemorrhagic Fever (CCHF) is considered the main viral hemorrhagic fever (VHF) and arboviral disease in Iran. It is a vector-borne zoonotic disease transmited through infected tick-bites, nosocomially or contact with blood and tissues of viremic livestock.

Objectives

The objective of this work is to report nosocomial and local outbreaks of CCHF in Iran in recent years and to determine the risk factors.

Methods

According to guidline of National Expert Committee on VHFs in Iran (NEC), serum sample of CCHF probable cases are refered to Department of Arboviruses and VHFs (National Ref Lab), Pasteur Institute of Iran for molecular and serological analysis by RT-PCR and IgM ELISA.
From October 2000 to January 2017, 4586 probable cases had been analyzed in which 1179 were IgM and/or RT-PCR positive and among them 160 were fatal cases, during this period more than eight outbreaks of CCHF have occurred in Khorasan-e-Razavi, Khorasan-e-Shomali, Khuzestan, Fars, Sistan-va-Baloochestan and Yazd provinces with 30 confirmed cases. 21 cases (70%) were infected due to direct exposure to blood/tissues of viremic livestock and the remaining 9 cases (30%) became infected through direct contact with CCHF patients. In these outbreaks, 5 (17%) confirmed cases were fatal in which 2 were healthcare workers.

Conclusions

The analysis of CCHF outbreaks in Iran reviled that most important route of transmission is direct contact with infected blood/tissues of viremic livestock as well as nosocomial infections in Iran; Therefore, decrease in traditional slaughtering, development of standard abattoir and education of the healthcare workers for standard case management may play important role in prevention and control of the disease in Iran.

NEXT GENERATION SEQUENCING (NGS) ANALYSIS REVEALS ATTENUATING MUTATIONS IN VARICELLA-ZOSTER VIRUS FOLLOWING EXTENSIVE IN VITRO PASSAGING

J.S. Jeon[1], Y.H. Won[1], S.C. Kim[1], J.H. Ahn[2], M.J. Song[3], O.S. Shin[4], C.H. Lee[1]
[1]Chungbuk National University, Microbiology, Cheongju, Republic of Korea
[2]Sungkyunkwan University School of Medicine, Molecular Cell Biology, Suwon, Republic of Korea
[3]Korea University, Biosystems and Biotechnology, Seoul, Republic of Korea
[4]Korea University, Biomedical Sciences, Seoul, Republic of Korea

Backgrounds

Varicella-zoster virus (VZV) is a causative agent for chickenpox in primary infection and shingles after reactivation from latency. Comparative genomic sequence analysis of clinical and vaccine strains suggested potential sites responsible for attenuation.

Objectives

In this study, we attempted to understand attenuating mutations in highly passaged VZV strains.

Methods

Three clinical VZV strains were passaged *in vitro* cell culture up to 110 times. Different passages of YC01 (p14, p61, p110), YC02 (p14, p61, p110) and YC03 (p6, p61, p110) were subjected to next-generation sequencing and their full genome sequences were compared with each other.

Conclusions

Mutations were detected at 300, 256, and 126 sites in the strains YC01, YC02 and YC03, respectively. Most of the mutations were A to G and T to C transitional mutations. Approximately 70~80% of mutations were found in open reading frames (ORF), and ORF 62 exhibited highest frequency of mutations. Codon adaptation index (CAI) values decreased while %GC values increased as VZV strains were passaged *in vitro* cell culture. Vaccine-type mutations were found at 7 positions, T to C substitution at 5 positions (560, 105705, 106262, 107252, 108111) and A to G substitution at 2 positions (105169, 111650). Direct PCR sequencing of these positions at various passages of VZV strains identified the passage numbers when the attenuating mutations occurred. Thus, our study provides new insight into the extent of the attenuating mutations associated with *in vitro* passaging of multiple VZV strains.

[4]Kobe University Graduate School of Medicine, Center for Infectious Diseases, Kobe, Japan
[5]Airlangga University, Institute of Tropical Disease, Surabaya, Indonesia
[6]Udayana University, Department of Microbiology- School of Medicine, Denpasar, Indonesia
[7]Airlangga University, Department of Biochemistry- School of Medicine, Surabaya, Indonesia
[8]Airlangga University,
Department of Microbiology- School of Medicine and Insitute of Tropical Disease, Surabaya, Indonesia

Backgrounds

The used standard-of-care treatment for chronic hepatitis C is Pegylated-Interferon/Ribavirin (PEG-IFN/RBV), however, many patients do not achieve a sustained virological response (SVR). It has been known that the success of this treatment is affected by viral and host factors. Recent studies revealed a strong association between Interleukin-28B (IL-28B) single-nucleotide polymorphisms (SNPs) and the response, which varied among ethnic groups.

Objectives

This study aimed to investigate the IL-28B SNPs associated with the HCV treatment response among HCV genotypes in Indonesians.

Methods

IL-28B SNPs were analyzed by PCR-direct sequencing in PBMC of 34 treated patients in Malang and Denpasar, Indonesia. HCV genotype and viral load were also examined.

Conclusions

Most patients were ethnic Java people (82.4%) and the rest were Bali, Batak-Lampung, Java-Madura, Gorontalo, Japan-Toraja people. They were mostly infected with HCV genotype 1 (70.6%), followed by genotypes 2 and 3. However, they mostly achieved EVR (Early Virological Response)/SVR (75.8%). Analysis of IL-28B SNPs revealed that most patients (94%) carried major genotypes of rs12979860 (CC), rs11881222 (TT), rs8103142 (AA), rs8099917 (TT), except one patient with heterozygous genotypes of the four SNPs and another patient with the major genotypes of rs12979860, rs11881222, rs8099917, but heterozygous genotype of rs8103142. Most patients with the major genotypes (75.0%-75.8%) and one patient with the major genotypes of the three SNPs achieved EVR/SVR, whereas the other patient with heterozygous genotypes of the four SNPs had NVR (Non-Virological Response).
In conclusion, the IL28B SNPs in Indonesian patients (mostly Javanese) were mainly the major genotypes, which is considered to be advantageous for PEG-IFN/RBV.

ISOLATION OF HALOPHILIC AND HALOTOLERANT BACTERIA INFECTING BACTERIOPHAGE IN SOILS AND SEDIMENTS OF URMIA SALT LAKE

R. Kamyab[1], E. Arefian[1], M.A. Amoozegar[1]
[1]Faculty of Biology - College of Science - University of Tehran -, Microbiology, Tehran, Iran

Backgrounds

soil microorganisms are essential for nutrient cycle and life of ecosystems. Many studies show they are playing an important role in evolution of their bacteria. The Urmia Lake is third largest saline lake in Iran. These years due to drought and loss of many biological species in this lake, identification and conservation of lake genetics resources is critical.

In this study soil and sediment from southern part of lake were collected and transferred to the laboratory and according to culture-dependent approaches, bacteria and phages were isolated. Bacterial hosts were identified R and plaque isolated bacteriophages were characterized by transmission electron microscopy.

Objectives

The aim of this study was isolation and characterization of phages from Urmia Lake halophilic and halotolerant bacteria for preservation of lake genetic resources.

Methods

serial dilutions of soil and sediments samples were cultured on SWN medium and incubated at 34° C for 24 hours. Bacteria colonies were isolated and purified. Molecular identification of bacterial microorganisms was performed by 16srRNA sequencing. Then fifty grams of soils and sediments inoculated in SWN broth medium and incubated for 24 h at 34 °C on a shaking platform. The supernatant was separated by centrifugation and passed through 0/45µm and 0/22µm filters respectively. To perform a plaque assay, the filtrated lysate was inoculated onto hosts. After plaques isolation, phages were purified with spot assay and morphological analysis was performed by negative staining and TEM.

Conclusions

TEM figures showed Purified bacteriophage**s** are belong to head-tail viruses. The morphological analysis propose that virus is related to *Myoviridae* family.

IDENTIFICATION OF VACCINIA VIRUS REPLISOME PROTEINS BY IPOND COUPLED WITH MASS SPECTROMETRY

T. Senkevich[1], *B. Moss*[1]
[1]*National Institute of Allergy and Infectious Diseases, Laboratory of Viral Diseases, Bethesda, USA*

Backgrounds

Vaccinia virus (VACV) replicates in the cell cytoplasm and encodes most of the proteins needed for its autonomous life cycle.

Objectives

The major requirements for DNA replication are fulfilled by 9 virus proteins but uncertainty remains as to whether this set is complete and whether host proteins might supply some missing functions.

Methods

To address this question, we applied the recently developed iPOND (Isolation of Proteins on Nascent DNA) method that has been proven a valuable tool for the identification of protein composition of eukaryotic replisomes.

Conclusions

We adjusted iPOND for the analysis of the cytoplasmic VACV replisome and confirmed the association with pulse-labeled DNA of all 9 VACV proteins shown to be required for DNA replication. In addition, the telomere-binding protein I1 that was not previously implicated in DNA replication was identified as a replisome component. Among host proteins, both subunits of topoisomerase II were confidently identified in the replisome from wild-type infected cells but not from cells infected with a knockout in VACV DNA ligase gene, in agreement with the previously reported interaction of viral ligase with topoisomerase II. Other host proteins involved in DNA replication or repair were virtually absent from VACV replisomes, with a possible exception of PCNA. Additionally, 16 VACV proteins involved in intermediate and late but not early transcription were also detected in association with pulse-labeled DNA. These findings suggest coupling of DNA replication with intermediate and late transcription as was recently shown for herpes simplex virus.

STRUCTURAL BIOLOGY OF THE GENETIC SWITCH FROM BACTERIOPHAGE TP901-1

K.K. Rasmussen[1], K.E.H. Frandsen[1], E.B. Erba[2], M. Pedersen[3], A.K. Varming[1], M. Kilstrup[4], K. Hammer[4], P.W. Thulstrup[1], M.R. Jensen[2], L. Lo Leggio[1]
[1]University of Copenhagen, Department of Chemistry, Copenhagen, Denmark
[2]University Grenoble Alpes, Institut de Biologie Structurale, Grenoble, France
[3]Technical University of Denmark, Novo Nordisk Foundation Center for Biosustainability, Lyngby, Denmark
[4]Technical University of Denmark, Metabolic signalling and regulation- Department of Bioengineering, Lyngby, Denmark

Backgrounds

Virus particles infecting bacteria, bacteriophages, can be classified into two categories namely lytic or temperate bacteriophages. TP901-1 is a temperate bacteriophage, and infects *Lactococcus lactis*. TP901-1 either produce new progeny (lytic life cycle), or survive as prophage in the infected bacterium (lysogenic life cycle). A genetic switch consisting of two promoters, three operator sites (O_R, O_L and O_D), and two proteins CI and MOR, controls the lysis-lysogeny decision. The hexameric repressor CI, binds to O_R, O_L and O_D, resulting in the lysogenic life cycle, whereas MOR modulates the repression in a so far unknown way, leading to the lytic life cycle.

Objectives

We are investigating the structural biology of this genetic switch by complementary biochemical and biophysical techniques.

Methods

Includes X-ray crystallography and solution scattering, mass spectrometry, CD and NMR spectroscopy.

Conclusions

We have determined the crystal structure of the DNA binding domain (NTD) of CI in complex with the O_L half site and characterized a dimeric, truncated variant of CI (CIΔ58) showing cooperativity of DNA binding for the dimer and identifying a helical dimerization region linked to the NTD by a flexible linker. Recently we have modelled the CIΔ58:O_L complex based on SAXS data. Our current focus now are determination of the structure of the C-terminal multimerization region of CI by crystallography, and the interaction of CIΔ58:MOR by native mass spectrometry, NMR spectroscopy and SAXS. Initial results suggest that CIΔ58:MOR and CIΔ58:O_L complexes are mutually exclusive supporting the hypothesis of a competition between CI and MOR as determinant of the cell fate.

SEVEN AMINO ACID DIFFERENCES IN 126 KDA AND MOVEMENT PROTEIN (MP) BETWEEN TWO PMMOV ISOLATES AFFECTS QUALITY OF SEEDS AND SYMPTOM SEVERITY IN CAPSICUM ANNUUM

H. Lim[1], J.K. Kim[1], E.Y. Seo[1], S.H. Yu[1], J. Hammond[2]
[1]Chungnam National University, Applied Biology, Daejeon, Republic of Korea
[2]United States Department of Agriculture – Agricultural Research Service US National Arboretum, FNPRU, Beltsville, USA

Backgrounds

Two isolates of *Pepper mild mottle virus* (PMMoV) were selected from a nationwide survey of pepper fields in Korea from 2014 to 2015, in which *Cucumber mosaic virus* was also detected; the two PMMoV isolates, S-47 (KX399390) and J-76 (KX399389), share ~99% amino acid identity and are closely related to PMMoV-CN (AY859497), PMMoV-BJ (HQ699080) and PMMoV-J (HQ699080). Amino acid sequence comparisons revealed 99.75%, 99.82%, 98.51%, and 100% identity in the ORF1 (126 kDa), ORF22 (180 kDa), MP, and CP respectively in two isolates; there are three amino acid differences (R(142)K, D(583)K, V(931)I) in the 126 kDa protein and four (K(134)R, V(192)A, N(226)D, L(250)S) in MP.

Objectives

In order to compare seed quality and symptom severity of two isolates we generated infectious clones of S-47 and J-76, and T7 promoter driven transcripts.

Methods

Nicotiana benthamiana infected with the two isolates produced very severe symptoms, whereas only mild symptoms developed in *Capsicum annuum*. Differences in seed production and seed transmission between the two isolates were detected in *Capsicum annuum*, which might be the result of about thirteen times higher viral replication of J-76 than S-47. Gene silencing suppressor function of 126 kDa and cytoskeleton-connected plasmodesmata localization of MP of S-47 and J-76 showed no difference between isolates, whereas 126 kDa of S-47 clearly formed intranuclear aggregates not observed with J-76 126 kDa.

Conclusions

Differences between these isolates in RdRp-related functions such as replication and subcellular localization suggest that variation in replication efficiency or differential interactions with host proteins may affect seed production and seed transmission in *C. annuum*.

FEMS7-1492

SSRA-ASSOCIATED PROPHAGES IN SHEWANELLA

X. Liu[1]
[1]*South China Sea Institute of Oceanology, Key Laboratory of Tropical Marine Bio-resources and Ecology, Guangzhou, China*

Backgrounds

Gene *ssrA* (tmRNA) is a hot spot for the integration of horizontally transferred genetic elements in bacteria.

Objectives

Through comparative genomic analysis, we found that 17 out of 54 *Shewanella* strains harbor prophages at *ssrA*.

Methods

Further analysis showed that these *ssrA*-associated prophages in *Shewanella* can be divided into two major groups, the P4-family group and the P2-family group. All of the P4-family prophages contain at least one copy of the *alpA* gene which is known to cause the P4-like prophage excision in *S. oneidensis* and in *E. coli*. To study whether P2-family prophages in *Shewanella* excite proficiently like P4-family group prophage, the gene contents of P2-family prophages were analyzed. Result showed that gene contents of the P2-family prophages are conserved in structural region and regulatory region. The regulatory region contains three adjacent regulatory proteins (CI, CII, and Cox). Though Cox protein in P2-like prophages in *Shewanella* (66 amino acids) lacks the C-terminus compared to the Cox of phage P2 (91 amino acids), expression of Cox protein in *Shewanella putrefaciens* W3-18-1 caused the excision frequency of *P2-like ssrA*-associated prophage increased 10^5-fold. Excision of *ssrA*-associated prophage in W3-18-1 abolish the SsrA function by destroy the G•U wobble base pair of *ssrA*, similar as the excision of P4-like prophage inserted in SsrA.

Conclusions

We found two major groups of prophage integrate at *ssrA* in *Shewanella*, P4-family group and P2-family group. Like AlpA induces P4-family prophage excision, Cox promotes excision of the P2-family prophage. Excision of P2-family prophage in W3-18-1 also abolish the *ssrA* gene function.

NEW INSIGHTS INTO SPATIO-TEMPORAL DYNAMICS OF EUROPEAN BAT LYSSAVIRUS TYPE-1 IN EPTESICUS SP BATS

P. Mingo-Casas[1], V. Sandonís[1], E. Obón[2], J.M. Berciano[1,3], S. Vázquez-Morón[1], J. Juste[4], J.E. Echevarría[1,3]
[1]Centro Nacional de Microbiología - Instituto de Salud Carlos, Virology, Majadahonda, Spain
[2]Centro de Fauna Salvaje de Torreferrussa, Generalitat de Catalunya, Torreferrussa- Santa Perpètua de Mogoda, Spain
[3]CIBER, Epidemiology and Public Health CIBERESP, Madrid, Spain
[4]Doñana Biological Station CSIC, Evolutionary Ecology, Seville, Spain

Backgrounds

Rabies is an ancient zoonosis caused by several lyssaviruses throughout the world. One of them is the European Bat Lyssavirus type-1 (EBLV-1), which is endemic in great part of Europe and comprises two different subtypes (EBLV-1a and EBLV-1b). This virus is mainly associated to *Eptesicus serotinus*, which accounts for more than the 95% of the infected bats detected in Europe, including the northern half of the Iberian Peninsula (recently discovered). However, other sibling species, *Eptesicus isabellinus* accounts for all the cases detected in the south.

Objectives

Here, the spatio-temporal dynamics of EBLV-1 on this two species is studied in the general European context with the latest discovered strains.

Methods

A total of 185 EBLV-1 400 bp nucleoprotein sequences from all across Europe were analysed by Bayesian phylogenetic inference using the BEAST software package. Temporal dynamics were reconstructed by using a relaxed uncorrelated molecular clock, either with constant and exponential growth priors on population size to generate maximum clade credibility (MCC) trees.

Conclusions

Most recent common ancestor (tMRCA) estimation for EBLV-1 is considerably recent (175 years, 95% HPD: 47-260 years), quite higher to the tMRCA previously shown by Hughes, G.J 2008, but with lower 95% HPD interval. tMRCA estimates for viral lineages EBLV1a and EBLV1b were 70 and 55 years respectively, showing 15 years of difference between their ancient slice point in Europe. Thereby, we suggest a bottleneck pressure during XIX century to have extinct ancient EBLV-1 strains and influenced their *E. serotinus* hosts.

CHARACTERIZATION OF PORCINE PICORNAVIRUSES (TESCHOVIRUS, SAPELOVIRUS, ENTEROVIRUS G) IN THE CZECH REPUBLIC

R. Moutelikova[1], *J. Prodelalova*[1], *M. Toman*[2]
[1]*Veterinary Research Institute, Virology, Brno, Czech Republic*
[2]*Veterinary Research Institute, Immunology, Brno, Czech Republic*

Backgrounds

Members of the family *Picornaviridae* are important viruses responsible for a variety of human and animal diseases. Porcine picornaviruses (namely Teschovirus A - PTV, Sapelovirus A - PSV and Enterovirus G – EV-G) are often found in apparently healthy pigs but they are capable of causing variety of disorders from mild diarrhoea to fatal encephalomyelitis (strain PTV-1). However, the pathogenicity and the ensuing importance of porcine picornaviruses in pig farming was not yet clearly defined.

Objectives

In our project an epizootiological study was carried out during which both healthy and diseased pigs of all age categories were sampled. First, the prevalence of monitored picornaviruses was determined. Second, the suitable tools for genotyping of PTV-, PSV-, and EV-G-positive samples were tested.

Methods

During the first year a collection of 122 faecal samples and 141 oral and nasal swabs were screened for the presence of picornaviruses with the reverse transcription-nested-PCR (RT-nPCR) with the use of primers detecting the conserved 5‘-NTR region of genome. For the purpose of genotyping of positive samples, partial nucleotide sequence of VP1 gene coding capsid protein was sequenced and compared to data in GenBank.

Conclusions

So far, in the collection of faecal samples there were 18 samples (14.8%) positive for PTV, 10 samples (8.2%) positive for PSV and 52 samples (42.6%) positive for EV-G. In 19.7% of samples more than one pathogen was found. In the set of oral and nasal swabs 16 samples (11.3%) were positive for PTV and 1 sample (0.7%) was positive for PSV.

TARGETED DELIVERY OF PHAGES INDUCED ANTI-CANCER EFFECT IN MICE MODELS

H. Myung[1], M. Kim[1], H. YoonJung[1]
[1]Hankuk University of Foreign Studies, Bioscience and Biotechnology, Yongin, Republic of Korea

Backgrounds

Oncolytic animal viruses are well documented and proven to be effective against cancer. Their anticancer effect was generally based on two ways; one is their ability to infect and lyse host cells while the other is enhancement of host immune responses.

Objectives

Phages are viruses and can be engineered to dsiplay peptides targeting specific cancer cells. We wanted to see whether phages can act as oncolytic virues.

Methods

In this experiment, bacteriophage T7 was engineered to display target specific peptides against mouse tumor cell lines. Two different cell lines used were CT-26 (colorectal cancer) and B16-F10 (melanoma). Two peptides targeting each cell lines were TCP1 and pep42, respectively. Mice were grafted intraperitoneally with each cell line, and tumor mass was allowed to grow for 6 days. Then phage T7 displaying targeting peptides were injected into tumor mass and mice were further observed until day 17.

Conclusions

Mice grafted with CT-26 showed 85% reduction in tumor mass when treated with phages. Mice grafted with B16-F10 showed 76% reduction in tumor mass when treated with phages. Cytokines IL1-a and TNF-a increased significantly in mice treated with phages. Macrophage infiltration into tumor mass was observed from immunohistochemistry. Thus phage treatment could be another option as oncolytic viruses for cancer.

INHIBITION OF HEPATITIS C VIRUS RNA BY SMALL RNAS DERIVED FROM TRNAS

H. Cho[1], W. Lee[1], G.W. Kim[1], S.H. Lee[1], J.S. Moon[1], M. Kim[1], J.W. Oh[1]
[1]Yonsei University, Biotechnology, Seoul, Republic of Korea

Backgrounds

Hepatitis C virus (HCV) propagation is dynamically regulated during the course of chronic infection that leads to liver diseases such as hepatocellular carcinoma (HCC) because cellular transcriptomes, including mRNAs and non-protein coding RNAs, which modulate proviral or antiviral host factors are subjected to reprogramming. Recent deep sequencing of small RNA libraries from various human cancer tissues and cell lines has identified diverse types of tRNA-derived RNA fragments (tRFs). Like microRNAs (miRNAs), tRFs may have diverse physiological roles in gene expression regulation, oncogenesis, and development.

Objectives

Despite accumulating evidence strengthening the notion of the presence of tRFs in cells, potential roles of tRNA-derived smRNA in host cells and during the course of pathogen infection remain elusive. Recently, tRFs, which were previously regarded as merely degradation intermediates, have emerged as potential effectors participating in gene expression regulation.

Methods

We analyzed small RNA profile in the human HCC cell line Huh7, which supports the propagation of HCV, and identified a 19-nt long structured, single-stranded RNA, with a 5′-monophosphate, as the most abundant tRF among single gene-mapped tRFs.

Conclusions

We provide evidence for a negative regulatory role of tRF_U3_1 on HCV, establishing a new paradigm for understanding pathophysiological roles of tRFs during the course of HCV infection.

DESIGN AND DEVELOPMENT OF CHIKUNGUNYA VIRUS E2 RECOMBINANT ANTIGEN FOR CHIKV DIAGNOSTICS BASED ON GENETIC DIVERSITY ANALYSIS

C. Park[1], S.Y. Cho[2], S.H. Kim[2], S.H. Park[2], S.M. Choi[2], J.H. Choi[2], J.H. Yoo[2], D.G. Lee[2]
[1]The Catholic University of Korea - College of Medicine, Vaccine Bio Research Institute, Seoul, Republic of Korea
[2]The Catholic University of Korea - College of Medicine, Internal Medicine, Seoul, Republic of Korea

Backgrounds

The spread of mosquito-borne viral disease is increasing public concerns due to climate change and viremic travelers, even if not epidemic country. Chikungunya virus (CHIKV) is an alphavirus causing mosquito-borne viral disease characterized by high fever and sudden onset of polyarthralgia. Although there have been few report excepts for overseas travelers infected by CHIKV in South Korea, the development of diagnostics is an urgent need for the surveillance of these infectious disease.

Objectives

Based on the genetic analysis, we tried to design and develop E2 recombinant proteins which cover antigen variation for CHIKV diagnostics by using global gene database.

Methods

Two hundred fifty eight of E2 were analyzed by position-specific iterated BLAST. Ranged from 100 to 93.6%, ninety three of genetic variant were extracted, and their antigenic epitopes were analyzed by Kolaskar & Tongaonkar methods and Bepipred epitope prediction at IEDB. Among twenty epitopes in E2, 13 of variable region were found. Their codons were optimized for expression of *E. coli* Lemo (DE3) strains.

Conclusions

Phylogenetic analysis exhibited 4 major groups representative for geographic clonal lineage in E2 genes. Especially three of genetic variant were found in STKDNF (E2EP3 epitope) relevant to early neutralizing response to CHIKV. These candidates for diagnostics were purified in *E. coli* system by SDS denaturing method (1.887mg/L, 1.296mg/L, and 1.531mg/L respectively), and their antigenicity was confirmed by Western-blot. This study showed a trial of genetic design based on global database and an approach for coping with variations in viral diagnostics.

Virology

THE NS3/NS4B REGION OF DENGUE VIRUS IS A DETERMINANT FOR EFFICIENT REPLICATION

S. Phanthanawiboon[1]
[1]*Faculty of Medicine/Khon Kaen University, Microbiology, Khon Kaen, Thailand*

Backgrounds

Varieties of dengue replication have been occurred from high to low due to genetic variation of RNA viruses. Replication capacity determines viral characters which contribute to viral virulence, host susceptibility and virus evolution. Both structural and non-structural proteins of dengue have been found to involve in replication process but theirs role in replication efficiency is not clear.

Objectives

This study aims to identify the protein of dengue serotype 4 which is essential for viral replication efficacy by using chimeric viruses.

Methods

Total 5 chimeric viruses (C-NS1, NS3-NS5, NS3-NS4B, NS4B-NS5, NS5) were constructed based on the restriction enzyme sites from high replicative (Dengue 4, H241) and low replicative (Dengue 4, R05-167) infectious plasmids. Replication ability of each chimeric viruses was determined in Vero and C6/36 mosquito cell line using focus and plaque forming assay. Essential amino acid of the high replicative NS3-NS4B chimeric was determined by single and double amino acid reverse-substitution.

Conclusions

We found the important role of NS3, NS4A and NS4B proteins of DENV4 in replication efficiency. Substitution of these proteins ameliorated replication ability and the size of virus. Only double amino acid reverse substitution affected viral replication of NS3-NS4B chimeric viruses revealed the important of amino acid combination in viral replication efficacy. These data provides useful information for further understanding of viral fitness and viral protection.

PHAGE-INDUCIBLE CHROMOSOMAL ISLANDS IN THE GRAM-POSITIVE COCCI

N. Quiles-Puchalt[1], R. Martínez-Rubio[2], M. Martí[3], S. Humphrey[1], G. Ram[4], D. Smyth[4], J. Chen[4], R. Novick[4], J.R. Penadés[1]
[1]Infection- Immunity and Inflammation. University of Glasgow, Bacteriology, Glasgow, United Kingdom
[2]Universidad Cardenal Herrera, Departamento de Ciencias Biomédicas, Valencia, Spain
[3]Instituto valenciano de Investigaciones Agrarias CITA-IVIA, Centro de Investigación y Tecnología Animal, Castellón, Spain
[4]Skirball Institute. New York University Medical Center, Departments of Microbiology and Medicine, New York, USA

Backgrounds

The *Staphylococcus aureus* pathogenicity islands (SaPIs) are a cohesive subfamily of extremely common phage-inducible chromosomal islands (PICIs) that generally encode for genes involved in virulence and factors involved in the host adaptation process. They reside quiescently at specific attachment sites in the staphylococcal chromosome and are induced by helper phages to excise and replicate. They are usually packaged in small capsids composed of phage virion proteins, giving rise to very high transfer frequencies, which they enhance by interfering with helper phage reproduction.

Objectives

As the SaPIs represent a highly successful biological strategy, being widely distributed with many natural *Staphylococcus aureus* strains containing two or more, we search for similar elements in the Gram-positive cocci.

Methods

To identify and characterize similar elements in other Gram-positive cocci we have made use of BLAST searches and ortholog analysis along with different molecular techniques such as enzymatic assays, Southern blotting, and allelic mutant replacement.

Conclusions

Based on resemblance to the paradigmatic SaPI genome, we have identified large cohesive families of similar elements in the lactococci and pneumococci/streptococci plus a few such elements in *Enterococcus faecalis*. We have characterized in depth the enterococcal element, EfCIV583, and have shown that it very closely resembles the SaPIs in functionality as well as in genome organization. Furthermore, based on extensive ortholog analyses, we found that the PICI elements represent distinct but parallel lineages, suggesting that they represent convergent evolution towards a highly successful lifestyle. In summary, our findings greatly broaden the PICI family to include elements from three genera of cocci.

FEMS7-0629
Virology

ROLE OF AICHI VIRUS IN ACUTE GASTROENTERITIS IN GALICIA (NW SPAIN)

E. Rivadulla Veira[1], *M. Fernández Varela*[1], *J. López Romalde*[1]
[1]*University of Santiago de Compostela, Microbiology and Parasitology, SANTIAGO DE COMPOSTELA, Spain*

Backgrounds

Enteric viruses are the cause of the majority cases of acute gastroenteritis worldwide. They multiply in the intestines, are excreted in faeces and be dispersed through fecal-oral route. In recent years Aichi virus (AiV) has emerged as responsible for food-borne outbreaks associated with diarrheal disease.

Objectives

The aim of this study was the detection and quantification of AiV in clinical samples collected during a 1-year period (July 2010–June 2011) from Complejo Hospitalario Universitario de A Coruña (CHUAC).

Methods

A total of 1751 from outpatient specimens of all ages affected with gastroenteritis were examined using a reverse transcription-quantitative PCR (RT-qPCR) procedure.

Conclusions

AiV was detected in 47 samples (.3%). Positives percentage of the six different age-groups, that have been established for subsequent data analysis were: 0.87% from 0–2 years , 0.17% from 3–5 years, 0.29% from 6–12 years, 0.06% from 13– 18 years, 0.69% from 19–59 years , 0.58% from >60 years and 0.06% from seven samples of unknown age that were also included. These samples were negative for the principal agents of acute gastroenteritis worldwide as Rotavirus (RV), Norovirus (NoV) and Sapovirus (SaV), except one sample in which coinfection with NoV was found.

Evidences obtained indicate that the prevalence of this enteric virus is considerably lower than those of RV, NoV and SaV, but is still present at some extent in the populations. Further studies are needed in order to determine the actual role of AiV as a causative agent of acute gastroenteritis in Galicia.

PHYLOGENETIC ANALYSIS OF BOVINE VIRAL DIARRHEA VIRUSES ISOLATED FROM CLINICAL INFECTED DAIRY COWS

N. Rudan[1], E. Marković[2], L. Barbić[1], Z. Hajek[3]
[1]Faculty of Veterinary Medicine University of Zagreb,
Department of Microbiology and Infections Diseases with Clinic, Zagreb, Croatia
[2]Ministry of Agriculture, Board of Veterinary Managers, Zagreb, Croatia
[3]Nexe group, Farm of dairy cows, Feričanci, Croatia

Backgrounds

In this research a BVDV infection was studied in the herd of dairy cattle, on the farm with 1500 Holstein-Friesian cattle, on which clinical symptoms characteristic for BVD were previously recorded. Animals in the herd were not vaccinated against BVDV, but were vaccinated against coronavirus, adenovirus and all bovine common respiratory infections.

Objectives

The aim of research was to detected the presence of BVD specific antibodies and also BVD viral antigens, with reference to viral nucleic acids in searched sera samples, because of evidence the persistent infections in the herd.

Methods

Prevalence of specific antibodies was proven using virus-neutralisation test (VNT) and Ab-ELISA test. Presence of antigens were tested by Ag-ELISA test, and viral nucleic acids with qRT-PCR method.

Conclusions

Presence of BVD antibodies was found in 194 out of 233 tested sera (83.26%) by VNT. With Ab-ELISA presence of BVD antibodies was found in 203 sera of tested cows (87.12%). Presence of antigens were proven in 2 of 233 sera samples (0.86%), and also confirmed by quantatitive PCR test. Phylogenetic analysis of BVD virus isolates, based on a comparative analysis of nucleotide sequences of 5'NTR segment, refer their affiliation to *genotype 1*, *subtype 1d* in phylogenetic tree.

NEW HIGHLY IMMUNOGENIC VARIANTS OF ATTENUATED VACCINIA VIRUS

S. Shchelkunov[1], S. Yakubitskiy[1], I. Kolosova[1], R. Maksyutov[1]
[1]State Research Center of Virology and Biotechnology VECTOR, Genomic research, Koltsovo, Russia

Backgrounds

Since 1980, in the post-smallpox vaccination era, the human population has become increasingly susceptible to not only variola (smallpox) virus, but also other zoonotic orthopoxviruses. The need for new safe vaccines against orthopoxviruses is great now.

Objectives

The aim of this work was to introduce targeted deletions into the genome of vaccinia virus (VACV) as well as to study the reproductive properties of the resulting VACV strains in cell cultures and the level of induced virus neutralizing antibodies in vaccinated mice and the effectiveness of their protection against ectromelia virus (ECTV) infection at a lethal doses.

Methods

The Lister vaccine strain LIVP of VACV was used as a parental virus for generating a recombinant LIVPdelta5 clone defective in five virulence genes *A56R*, *B8R*, *J2R*, *C3L*, and *N1L* and LIVPdelta6 clone with an additional deletion in the *A35R* gene. Targeted disruption of these loci did not affect virus replication in mammalian cell cultures. Recombinant VACVs exhibited a reduced inflammatory response and attenuated neurovirulence relative to LIVP. In a subcutaneous mouse model, the level of virus neutralizing antibodies in the case of immunization with LIVP or LIVPdelta5 strains reached approximately the same level, which provided similar values of protection against ECTV. Strain LIVPdelta6 induced a significantly higher level of virus neutralizing antibodies and protection against ECTV infection compared to other VACV strains studied.

Conclusions

The LIVPdelta5 and LIVPdelta6 recombinant strains hold promise as a safe live vaccine strains for preventing smallpox and other orthopoxvirus infections.

EFFICIENT INDUCTION OF IMMUNE RESPONSES BY DNA VACINE AGAINST ZIKA VIRUS

S. Shin[1], N.Y. Kim[2], H.B. Ahn[3], Y.K. Shin[3]
[1]Seoul National University, Bio-MAX/N-Bio, Seoul, Republic of Korea
[2]ABION Inc., Drug Development, Seoul, Republic of Korea
[3]Seoul National University, College of Pharmacy, Seoul, Republic of Korea

Backgrounds

Zika virus is an arbovirus of the Flavivirus genus within the Flaviviridae family. Recently, Zika virus infection has become public health concern following a large outbreak in South America in 2015. Due to the potential burden of illness from microcephaly and Guillian-Barre syndrome, WHO declares a global health emergency over Zika virus on February 1, 2016. Currently, no vaccine or antiviral therapy is available for Zika virus infection.

Objectives

In this study, we have developed Zika plasmid DNA vaccine that expressed codon-optimized 75 kDa of premembrane and envelope genes containing IgM signal sequence.

Methods

This constructed plasmid was transfected into mammalian cells and transgene expression was verified with western blot and fluorescence microscopy. Transfection studies revealed that recombinant protein was expressed and was actively secreted into cell supernatants. The immunogenicity of this DNA vaccine was also confirmed. Following vaccination of Balb/c mice via intradermal route by electroporation, all vaccinated animals developed premembrane and envelope-specific binding antibodies.

Conclusions

Our study indicates that DNA vaccine encoding codon-optimized premembrane and envelope with IgM signal sequence can induce immune responses, thus providing a useful approach to protect against Zika virus infection.

NEW VARIANT OF RABBIT HAEMORRHAGIC DISEASE VIRUS (RHDVB) IN YOUNG RABBITS: CLINICAL AND PATHOLOGICAL CHARACTERIZATION

S. Pacho-jimenez[1], E. Dahdouh[1], A. Fernandez-manzano[2], A. Rodriguez-bertos[2], M. Suarez-rodriguez[1]
[1]Universidad Complutense De Madrid, Facultad De Veterinaria-sanidad Animal, Madrid, Spain
[2]Universidad Complutense De Madrid, Visavet, Madrid, Spain

Backgrounds

Rabbit Haemorrhagic Disease (RHD) is caused by infection with a rabbit calicivirus. It was first reported to affect adult rabbits and to result in very high morbidity and mortality rates. Symptoms of RHD include liver necrosis, pulmonary oedema and Disseminated Intravascular Coagulation (DIC), and leads to death within 24-48 hours. In 2010, a new distinct variant of the virus (RHDVb) was reported and was found to also infect young rabbits and to show symptoms similar to the classical variant.

Objectives

Since RHDVb has the potential of causing devastating outbreaks among young rabbits, our objective is to characterize the gross and histopathological alterations of two RHDVb isolates recovered from infected young rabbits in Spain.

Methods

Forty rabbits were infected with two different RHDVb isolates and necropsies were performed after death. Samples from the liver, lungs, spleen, kidneys, heart, lymph nodes, trachea, and brain were obtained for histological study.

Conclusions

Results and Discussion

Clinical and pathological findings revealed that one of the RHDVb strains induced a faster and more fatal disease in comparison with the second. Moreover, the lesions produced by this isolate were more extensive and intense. These preliminary outcomes showed marked differences among isolates of the same RHDVb where one displayed higher pathogenicity that the other.

Conclusions

In this study, we showed that two different isolates of RHDVb produced different clinical and pathological manifestation of RHD among young rabbits. Further investigations into the genetic differences between these isolates are necessary before determining the mechanisms that could explain this difference.

ECTROMELIA VIRUS INDUCES TUBULIN CYTOSKELETON REARRANGEMENT IN MYELOID DENDRITIC CELLS, ACCOMPANIED BY LOSS OF MICROTUBULE ORGANIZING CENTER AND INCREASED A-TUBULIN ACETYLATION

L. Szulc-Dabrowska[1], M. Palusinski[1], J. Struzik[1], F.N. Toka[1,2]
[1]Warsaw University of Life Sciences,
Faculty of Veterinary Medicine- Department of Preclinical Sciences, Warsaw, Poland
[2]Ross University School of Veterinary Medicine, Department of Biomedical Sciences, Basseterre, St Kitts & Nevis

Backgrounds

Ectromelia virus (ECTV) belongs to the *Orthopoxvirus* genus of the *Poxviridae* family. It is a natural pathogen of mice that causes mousepox, a lethal disease of certain strains of mice. ECTV is a suitable model to study immunobiology of variola virus (VARV) and other orthopoxviruses, as well as pathogenesis of generalized viral infections. Orthopoxviruses exploit the host cell cytoskeleton for penetration, transport and release of progeny viral particles. So far, it is not known how orthopoxviruses influence the cytoskeleton of immune cells, especially dendritic cells (DCs), in which those viruses (with the exception of ECTV) undergo an abortive replication cycle.

Objectives

The aim was to investigate the effect of ECTV infection on the morphology of the tubulin cytoskeleton in myeloid DCs (mDCs).

Methods

mDCs were generated from murine bone marrow (BM) precursors using recombinant mouse granulocyte-macrophage colony stimulating factor (GM-CSF). BMDCs were infected with Moscow strain of ECTV and after 24 hours immunofluorescent staining and fluorescence microscopy analysis were performed.

Conclusions

The α-tubulin cytoskeleton in mDCs underwent dramatic rearrangement during ECTV infection. The microtubule network was disorganized, less intertwined and more “relaxed”. Decreased γ-tubulin staining indicated disappearance of the microtubule organizing centre (MTOC). Moreover, in infected cells increased acetylation of α-tubulin was observed. The elevated acetylation level of α-tubulin may lead to stabilization of microtubules, which are exploited by progeny ECTV virions for intracellular transport.

MYELOID DENDRITIC CELLS PRODUCTIVELY INFECTED WITH ECTROMELIA VIRUS HAVE IMPAIRED INNATE AND ADAPTIVE IMMUNE FUNCTIONS

L. Szulc-Dabrowska[1], J. Struzik[1], F.N. Toka[1,2], M. Bossowska-Nowicka[1], A. Ostrowska[3], Z. Nowak[4], M. Gierynska[1]
[1]Warsaw University of Life Sciences,
Faculty of Veterinary Medicine- Department of Preclinical Sciences, Warsaw, Poland

[3]Warsaw University of Life Sciences, Analytical Center, Warsaw, Poland
[4]Warsaw University of Life Sciences,
Faculty of Animal Sciences- Department of Genetics and Animal Breeding, Warsaw, Poland

Backgrounds

Myeloid dendritic cells (mDCs) are key antigen presenting cells responsible for initiation of adaptive antiviral immune response. Some viruses employ sophisticated and host-specific strategies to control the immune cells that are important for induction of antiviral immune response. In particular, this can be observed in viruses that exhibit a narrow host range and have co-evolved with their natural host. A good example is the ectromelia virus (ECTV) of mice – an orthopoxvirus closely related to variola virus.

Objectives

The aim of this study was to investigate the impact of ECTV infection on immune functions of mDCs.

Methods

Bone marrow DCs (BMDCs) were prepared from BALB/c mice and infected with ECTV and additionally treated with LPS, with appropriate controls. After 24 h cells were used in experiments to determine cell phenotype, cytokine production, gene expression and signal transduction.

Conclusions

Infected mDCs showed inability to uptake and process antigen. mDCs did not reach a mature phenotype and were unable to secrete proinflammatory cytokines or induce T cell responses. Decreased cytokine/chemokine response resulted from impaired ligand-induced nuclear accumulation of NF-κB, IRF3 and IRF7 transcription factors and down-regulation of many genes involved in TLR, RLR and NLR signaling pathways. Moreover, ECTV-infected mDCs failed to stimulate proliferation of allogeneic $CD4^+$ T cells in mixed lymphocyte reaction. Overall, our results demonstrate a massive disruption of innate and adaptive immune functions in ECTV-infected mDCs, which compromises their ability to initiate downstream T-cell activation events.

ANALYZING THE INTERACTIONS BETWEEN THE HIV-1 GENOMIC RNA AND HOST PROTEINS THROUGH PROXIMITY LIGATION ASSAY

D. Toro Ascuy[1], B. Rojas-araya[1], A. Leyva[1], A. Dellarossa[1], F. Valiente-echeverria[1], R. Soto-rifo[1]
[1]Universidad de Chile, Virología, Santiago de Chile, Chile

Backgrounds

Human Immunodeficiency Virus type-1 (HIV-1) gene expression is highly complex and tightly regulated. Once the host RNA polymerase II recognizes the viral promoter it drives the synthesis of one single messenger RNA molecule, the 9-kb genomic RNA (gRNA), which first undergoes alternative splicing early during replication. Later on, the gRNA in its unspliced form is used as an mRNA for the synthesis of structural proteins and enzymes but also as the packaged genome. The molecular events that allow the interaction between the gRNA and the cellular machineries for nuclear export, translation or packaging have not yet been fully elucidated. The viral protein Rev has been identified as key viral component involved in nuclear export, translation and encapsidation of the unspliced transcript suggesting that Rev is an active component of different HIV-1 gRNA ribonucleoprotein complexes throughout viral replication.

Objectives

The aim of this study was to analyze the interactions between the HIV-1 genomic RNA and host proteins through proximity ligation assay (PLA).

Methods

We adapted the PLA, which is usually used to analyze protein/protein interactions, and characterized interactions between the HIV-1 gRNA and host proteins involved in nuclear export and translation initiation.

Conclusions

Our results validate the PLA as a simple and useful tool to study HIV-1 gRNA/protein interactions within cells. This protocol also serves to determine the subcellular locations where gRNA/protein interactions occur

GENETIC AND LIFE-HISTORY TRAITS ASSOCIATED WITH THE DISTRIBUTION OF PROPHAGES IN BACTERIA

M. Touchon[1], *A. Bernheim*[1], *E. Rocha*[1]
[1]*Institut Pasteur - UMR3525, Microbial Evolutionary Genomics, Paris, France*

Backgrounds

Nearly half of the sequenced bacteria are lysogens and many of their prophages encode adaptive traits. Yet, the variables driving prophage distribution remain undetermined

Objectives

We identified 2246 prophages in complete bacterial genomes, using comparative genomic approaches, to study the genetic and life-history traits associated with lysogeny.

Methods

While optimal growth temperatures and average cell volumes were not associated with lysogeny, prophages were more frequent in pathogens and in bacteria with small minimal doubling times. Their frequency also increased with genome size, but only for genomes smaller than 6 Mb. The number of spacers in CRISPR-Cas systems and the frequency of type III systems were anticorrelated with prophage frequency, but lysogens were more likely to encode type I and type II systems. The minimal doubling time was the trait most correlated with lysogeny, followed by genome size and pathogenicity.

Conclusions

We propose that bacteria with highly variable growth rates often encounter lower opportunity costs for lysogeny relative to lysis. These results contribute to explain the paucity of temperate phages in certain bacterial clades and of bacterial lysogens in certain environments. They suggest that genetic and life-history traits affect the contributions of temperate phages to bacterial genomes.

CRISPR-CAS PROVIDES PARTIAL IMMUNITY AGAINST A PHAGE THAT ENCODES AN ANTI-CRISPR PROTEIN

S. van Houte[1]
[1]*environment and sustainability institute, biosciences, Penryn, United Kingdom*

Backgrounds

The CRISPR-Cas adaptive immune system is widespread in bacteria and can provide effective protection against phage infections. In response, phages evolved anti-CRISPR genes that inhibit bacterial adaptive immunity. Phage DMS3vir+*acrF1* encodes AcrF1, which binds the Csy3 subunit of the Csy complex of *Pseudomonas aeruginosa* strain PA14 and causes loss of DNA binding activity of the complex.

Objectives

Here we aim to examine the evolutionary consequences of *acrF1* on CRISPR immunity.

Methods

Using experimental evolution and infection assays,

Conclusions

we show that CRISPR-Cas still provides partial immunity against anti-CRISPR phage. If infected at low MOI, CRISPR drives phage to lower frequencies, but at high MOI, the phage can increase in frequency. The results are consistent with a model that AcrF1 expression may be “too little, too late” during a first infection, but upon secondary infection phage faces a weakened immune response that can be successfully blocked by AcrF1.

DYNAMIC BIOFILM ARCHITECTURE CONFERS INDIVIDUAL AND COLLECTIVE MECHANISMS OF PHAGE PROTECTION

L. Vidakovic[1], P.K. Singh[1], R. Hartmann[1], C.D. Nadell[1], K. Drescher[1,2]
[1]Max Planck Institute for Terrestrial Microbiology, Max Planck Research Group Bacterial Biofilms, Marburg, Germany
[2]Philipps University Marburg, Department of Physics, Marburg, Germany

Backgrounds

Bacteria often live in surface-attached communities, termed biofilms. Within these communities bacteria secrete an extracellular matrix that can protect cells from exogenous stress. In their natural environments, biofilms regularly encounter the presence of viral pathogens, termed bacteriophages.

Objectives

Our aim was to understand the mechanisms that determine phage-biofilm interactions and the infection dynamics.

Methods

In order to study phage-biofilm interactions we developed a method to visualize phage spread inside living *E. coli* biofilms. By insertion of *sfgfp* into the T7 phage genome, the conversion of susceptible to infected cells can be tracked spatiotemporally at the single-cell level using a recently-developed custom confocal microscope. Using a combination of bacterial genetics, molecular biology, and fluorescent reporters, we were able to understand key elements of phage-biofilm interactions.

Conclusions

Biofilm susceptibility to phage infection is dependent on the stage of biofilm development and the production of biofilm matrix. The removal of curli, a major component of the *E. coli* matrix, generated biofilms that were rapidly infected by phages, regardless of the age of the biofilms. Visualization of curli fibers within biofilms further demonstrated a dynamic matrix composition. The development of phage tolerance in biofilms was synchronous with the production of curli fibers. We further discovered that curli-dependent biofilm protection is achieved by two mechanisms: (1) curli fibers prevent phages from diffusing inside biofilms, and (2) curli fibers protect individual cells from phage infection. Our results show that a single component of the biofilm matrix can provide individual as well as collective protection against phage infection.

CHARACTERIZATION OF ASFV A238L PROTEIN INTERACTION SITES WITH NF-KB

G. Vigara Astillero[1], *D. Pérez-Núñez*[1], *Y. Revilla*[1]
[1]*Centro de biología molecular Severo Ochoa, Virology and Microbiology, Madrid, Spain*

Backgrounds

African Swine Fever virus (ASFV), is a large DNA virus infecting monocytes and macrophages of domestic pigs and wild board, causing an acute and mortal disease. Within its encoded proteins, the protein A238L, previously defined in our lab, has a special interest as it's capable of causing immune suppression on the host by interacting with several cellular immunomodulators such as NF-kB and NF-AT, among others, putatively acting as substitute of cellular proteins like IkB during infection.

Objectives

The immunomodulatory capabilities exhibited by viral A238L protein are of interest for a biotechnological use, by finding new compounds which mimicry the function of the viral protein, as potential anti- inflammatory drugs. Thus, the main objective of our project is to characterize the interaction sites of the viral protein A238L with NF-kB immunomodulator, allowing us to design pharmacophores.

Methods

For this means, we have generated a model comparing IkB structure with A238L protein, identifying several common structures on both proteins. Based on these results, we have identified several residues putatively implicated on the interaction of A238L with NF-kB, based on its homology with IkB. Currently, we are generating several mutants based on this information using directed-mutagenic assays, on a pcDNA-A238L vector. Our plan is to use these mutant proteins on luciferase-reporter assays to assess the NF-kB promoter activation, together with interaction studies in vitro.

Conclusions

With these studies, in addition to designing new drugs for inflammatory diseases, we will contribute to the thorough knowledge about ASFV, against which there are no known therapies or vaccines.

Centre de recherche de l'Institut universitaire de cardiologie et de pneumologie de Québec, Quebec, Canada
[3]Université Laval, Institut de biologie intégrative et des systèmes, Quebec, Canada
[4]Université Laval, Groupe de Recherche en Écologie Buccale GREB, Quebec, Canada

Backgrounds

Antibiotic resistance is a global concern that negatively impacts the aquaculture industry. The Gram-negative waterborne bacterium *Aeromonas salmonicida* subsp. *salmonicida* is the etiological agent of furunculosis, one major fish disease in farms raising salmonids, leading to significant economic losses. Studies reported that many strains of *A. salmonicida* are now resistant to antibiotics, making it difficult to treat infections. Recent reports suggest that virulent phages could be used in a context where antibiotherapy is less effective.

Objectives

The present study investigated the potential of lytic phages as biocontrol agents against *A. salmonicida*. To do this, phages infecting *A. salmonicida* were collected and investigated at both genomic and microbiological levels.

Methods

The genome (double-stranded DNA) of 12 phages specific to *A. salmonicida* was sequenced by Illumina MiSeq and *de novo* assembled. The genomes were then analyzed using bioinformatics to find the pangenome of the data set, allowing a clustering of the phages. Finally, the host range of the phages was tested against a panel of 65 *A. salmonicida* isolates from various geographical origins.

Conclusions

Our results indicate that at least 6 genomic groups of phages can infect *A. salmonicida* and that some of them have a broad host range. In fact, the 65 strains could be infected by at least one phage and a cocktail of phages could be designed to cover the set of *A. salmonicida* strains tested. The next step will be to test *in vivo* the capacity of infected fish to recover from furunculosis after a phage treatment.

Bacterial lifestyles associated with olive trees and other woody plants

WHAT DO GENOME SEQUENCES OF XYLELLA FASTIDIOSA TELL US ON HOST ADAPTATION AND LIFESTYLE OF XYLELLA

M.A. Jacques[1], *N. Denancé*[1], *M. Briand*[1]
[1]*INRA, IRHS, Beaucouzé, France*

The extension of international trading and global changes affect the distribution of diseases posing new threats to food production and the preservation of some plant species in the environment. Thus an in-depth knowledge on how pathogens adapt to their environment is a prerequisite for further control and surveillance strategies. *Xylella fastidiosa* is one of the most dangerous plant-pathogenic bacterium that recently emerged in Europe. More than 350 plant species are listed as hosts of this bacterium. While *X. fastidiosa* is responsible for economically important diseases in some crops, ornamentals, and trees, in most host plant it does not cause any symptoms; these plants serving as unseen inoculum reservoir. However, some plant species fail to support *X. fastidiosa* growth in environmental conditions favorable to this bacterium. Moreover, *X. fastidiosa* is a genetically heterogeneous species with six subspecies and a number of clusters of strains that more or less group strains according to host plants and/or diseases. Finally, *X. fastidiosa* is prone to recombination and in several cases recombination was associated to host shift in field. These characteristics make *X. fastidiosa* a good model to look for genetic determinants responsible for host adaptation and lifestyle. We use typing methods, comparative genomics, and develop tools to identify sequences associated with specific traits. Analyses of core and accessory genomes of sets of strains differing by their taxonomic assignation to a subspecies, host and places of isolation highlighted key elements involved in host specificity that could also be used to develop novel identification tests.

[3]Instituto de Agricultura Sostenible (IAS-CSIC). Avda. Menéndez Pidal, 14004, Córdoba, Spain

Xylella fastidiosa is a fastidious plant pathogenic bacterium, xylem localised and vector transmitted, considered a quarantine organism in the European Union (EU). There are several subspecies described and their scientific and economic importance is due to unique characteristics: it has more than 350 plant hosts, different behaviors in them, causes severe symptoms and economic losses, has a long list of vectors and very difficult control. Originally discovered in America, X. fastidiosa subsp. pauca was reported on olive trees in southern Italy in 2013, where it is now responsible of the most severe disease never described in this crop. Comparative genomics suggests that it could have been introduced with plants from Costa Rica. After intensive surveys in the EU countries and analyses following the EPPO standard protocol, this pathogen was reported in France (Corsica and mainland) in 2015, in a greenhouse in Germany in 2016 and was also detected as widespread in Spain (Balearic islands) since 2016. Subspecies multiplex, fastidiosa and pauca, were found in these outbreaks. The detections of different subspecies of X. fastidiosa in few years in several EU countries, underline the presence of different genotypes and the risk of introducing additional genetic diversity. Recent information about X. fastidiosa biology and epidemiology suggests that the pathogen could have been present at least in Italy, France and Spain (and probably in other countries) for several years. This bacterium represents a threat not only for agricultural crops, but also for landscape trees and ornamentals, especially in Mediterranean countries.

[2]ETS Ingenieros Agrónomos- Universidad Pública de Navarra, Laboratorio de Patología Vegetal, Pamplona, Spain
[3]Centro de Biotecnología y Genómica de Plantas CBGP. Universidad Politécnica de Madrid UPM-Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria INIA, Biotecnología, Pozuelo de Alarcón- Madrid, Spain

Bacteria belonging to the *Pseudomonas syringae* species complex, which includes *Pseudomonas savastanoi*, cause diseases in a broad variety of both woody and herbaceous plants. Although most research on the interactions established by this group of bacteria has focused on herbaceous plant pathogens, considerable efforts have been made during the last years to establish suitable models to study their interaction with woody plants. *P. savastanoi* produces aerial tumours on the host, causing one of the most important diseases of olive, but also infecting a plethora of plant species, including oleander, ash and broom plants. Moreover, *P. savastanoi* has recently been pointed out as an emergent pathogen of the ornamental species *Mandevilla sanderi* in several countries, including Spain (Caballo-Ponce *et al*., 2016). After the genome sequencing of the olive pathogen *P. savastanoi* pv. savastanoi NCPPB 3335 and the identification of novel virulence factors in this bacterium, our work has focused in the functional analysis of several of these virulence determinants, with special emphasis on specific factors associated with woody hosts. We have shown the translocation of eleven NCPPB 3335 type III secretion system effectors (T3E) into plant cells, some of which are associated to woody hosts (Castañeda-Ojeda *et al*., 2017). Other characterized virulence determinants include two enzymes involved in the metabolism of the bacterial second messenger c-di-GMP (Aragón *et al*., 2015a, 2015b) and several operons encoded in a genomic region of the NCPPB 3335 chromosome, named WHOP (from woody host and *Pseudomonas*), that is absent in *P. syringae* strains infecting herbaceous plants (Caballo-Ponce *et al*., 2017). Currently, we are studying the evolution of host specificity in *P. savastanoi* using the genome sequences of several strains isolated from different hosts.

Bacterial lifestyles associated with olive trees and other woody plants

BACTERIAL MULTISPECIES INTERACTIONS IN THE OLIVE-KNOT

V. Venturi[1], E. Caballo Ponce[2], M. Xianfa[1], G. Uzleac[1], C. Ramos[2]
[1]ICGEB, Bacteriology, Trieste, Italy
[2]Universidad de Malaga, Facultad de Ciencias, Malaga, Spain

It is believed that most bacteria live in constant association or in the vicinity of many different bacterial species. In addition, most bacteria are now believed to produce and respond to chemical signals in a cell-density dependent manner in a process known as quorum sensing (QS). QS results in a synchronous response of bacterial populations which confers them a form of multicellularity and enables them to adapt and survive to challenging environments. Most bacterial QS studies thus far have involved mono-species (in fact mono-strain) set up which are rather distant from what occurs in nature. It is our major interest to investigate chemical signaling in interspecies bacterial communities and the possible role of chemical signals in plant-bacteria interactions.

We are using beneficial bacterial endophytes which enter the plant via the rhizosphere to study interspecies interactions and dynamics of endophytic life style and multispecies community formation. This could lead to the use of endophytes as microbial products to improve plant health and sustainability in agriculture. In parallel we are studying bacterial interspecies signaling using a plant disease as a model. The olive knot disease caused by *Pseudomonas savastanoi* results in tumors/galls in olive trees; we have established that inside the tumors, together with the pathogen, other bacterial species interact and communicate with the pathogen resulting in mutual benefit and in a more aggressive disease.

CRISPR as it is

CRISPR TECHNOLOGIES FOR BACTERIA

D. Bikard[1]
[1]*Institut Pasteur, Microbiology, Paris, France*

Over the past few years CRISPR systems have been derived into powerful tools to edit genomes, control gene expression, visualize nucleic acids in vivo, modify epigenetic marks, kill cells and more. Most of these tools rely on the RNA-guided nuclease known as Cas9 which can be easily reprogrammed to bind and cut almost any position in a genome. We focus on the application of these technologies to bacteria. We have recently investigated the properties of Cas9 as well as the catalytic dead variant known as dCas9 in *E. coli*. The introduction of double strand breaks by Cas9 at a specific genomic position leads to cell death as such beaks cannot be repaired through homologous recombination, the main DNA repair pathway in bacteria. We used this property as a selection tool in both *E. coli* and *S. pneumoniae*, and to develop sequence-specific antimicrobials against *S. aureus*. Work on the dCas9 protein has revealed how it can be used to precisely tune the expression level of several target genes independently and with low noise levels. Finally, the ability to knockdown gene expression with dCas9 can also be used in high-throughput screens to unravel gene function and interaction. All in all, CRISPR provide a fantastic toolkit to study and fight pathogenic bacteria.

CRISPR as it is

MILESTONES IN CRISPR RESEARCH

F.J. Martinez Mojica[1], C. Almendros[1], N.M. Guzmán[1], B. Gómez-Tavira[1], J. García-Martínez[1], R. Maldonado[1]
[1]Univerisity of Alicante, Fisiología- Genética y Microbiología, San Vicente del Raspeig, Spain

Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) were first seen in the bacterium *Escherichia coli* in 1987. In early 1990's, CRISPR arrays were also found in archaea where they appeared to be playing a relevant, yet enigmatic role. After verifying the widespread occurrence of CRISPR among prokaryotes, disparate *cas* (CRISPR-associated) genes could be identified and the diversity of CRISPR-Cas systems became evident. While diverse functions had been proposed for these systems since the discovery of the repeats, it was not until the origin of spacers (i.e., repeat-intervening sequences) was disclosed that the first hint in the right direction was provided: CRISPR are involved in interference against transmissible genetic elements targeted by the spacers. This observation led to the seminal demonstration that CRISPR-Cas enable prokaryotes to defend themselves against invading DNA. The mechanism responsible for achieving such adaptive immunity was conceived soon after the specific contribution of the main components of this system, repeats, spacers and certain Cas proteins, began to be understood. It was shown that CRISPR arrays are dynamic regions able to gain new spacers upon infection and generate single-spacer RNAs that through the repeat sequence guide Cas endonucleases against spacer-complementary sequences, resulting in target degradation. However, some CRISPR-Cas systems and stand-alone CRISPR regions or Cas proteins play roles not-related to immunity, relaying on regulation of gene expression or DNA repair activities among others, targeting DNA and/or RNA depending on the particular system. Thirty years after their discovery, many questions remain yet about these versatile, highly evolved repeat-based systems.

EVOLUTIONARY ECOLOGY OF CRISPR-CAS

E.R. Westra[1]
[1], *United Kingdom*

Bacteria have a range of sophisticated immune mechanisms to protect against virus infections, but it is unclear why all these different mechanisms evolved in the first place. Under laboratory conditions, bacteria typically evolve de novo virus resistance using either surface modification or CRISPR-Cas adaptive immune systems. In this talk I will discuss ecological factors that can tip the balance in the evolution of these two immune mechanisms and examine their distinct co-evolutionary implications.

FEMS7-1091
Epigenetics of bacterial infections

BACTERIAL INDIVIDUALITY AND COOPERATIVE VIRULENCE

M. Ackermann[1]
[1]*IBP, ETH Zurich and Eawag, Zurich, Switzerland*

A number of recent experiments has established that bacterial cells can act as individuals: genetically identical cells that reside in a homogeneous environment often vary in gene expression, activity and behaviour. This variation, which is known as phenotypic heterogeneity, can be biologically relevant: it can lead to the division of labor in clonal groups and also help these groups to survive external perturbations. I will focus on the biological significance of phenotypic heterogeneity in bacterial infections, using Salmonella Typhimurium as a model system. Clonal populations of S. Typhimurium differentiate into two subpopulations that differ in the expression of virulence genes. We find that this heterogeneity in virulence gene expression has important consequences: it leads to cooperative virulence that is required for effective infection of the host, and allows Salmonella to survive treatment with antibiotics. Intriguingly, there is an interplay between these two consequences, so that treatment with antibiotics can alter the infection dynamics and prolong the period of transmission. I will discuss whether some of these findings could represent general principles that apply to other pathogens and infections. Understanding how bacterial individuality impacts the dynamics of pathogen populations and the course of infections can potentially lead to new ways to control infections.

FEMS7-3306
Epigenetics of bacterial infections

NON MUTATIONAL RESISTANCE TO ANTIBACTERIAL AGENTS

J. Casadesus[1]
[1]*Facultad de Biología, Departamento de Genética, Sevilla, Spain*

Non mutational preadaptation to lethal selection

Josep Casadesús

Departamento de Genética, Universidad de Sevilla, Sevilla, Spain

When a bacterial population is subjected to lethal selection (e. g., encounter with a phage or exposure to an antibacterial agent), preexisting mutant cells survive. In certain cases, however, wild type cells can also survive. Non mutational preadaptation is made possible by the existence of phenotypic heterogeneity in isogenic populations of bacteria. If a physiological state that permits survival is propagated by a feedback loop, a progeny of adapted cells is formed. In certain cases, the feedback loop is a heritable DNA methylation pattern. In other cases, however, feedback loops can be formed without the involvement of DNA epigenetic marks. Three examples are as follows:

(i) Exposure of *Salmonella* to bile triggers the RpoS-dependent general stress response, which increases bile resistance. Because the *rpoS* promoter is noisy, certain *Salmonella* cells activate the general stress response in the absence of bile. High RpoS expression permits survival of certain cells in the presence of bile, and a positive feedback loop sustains or even amplifies the RpoS response, giving rise to a bile-resistant population.

(ii) Random variations in the expression or the activity of critical cell functions can confer adaptive resistance to certain antibiotics. In *Salmonella*, for instance, expression of porin genes is noisy, and reduced porin synthesis confers kanamycin resistance. Because transcription of porin decreases in the presence of kanamycin, a negative feedback loop propagates kanamycin resistance.

(iii) Nalidixic acid resistance requires mutation (e. g., in the QRDR region of *gyrA*). However, the level of nalidixic resistance conferred by a QRDR mutation can be further increased by active efflux mediated by the AcrAB-TolC pump. Cell-to-cell differences in efflux occur, and cells with high efflux show increased nalidixic acid resistance. Because nalidixic acid activates efflux, the response is propagated by a positive feedback loop.

Epigenetics of bacterial infections

PHASE VARIATION IN BACTERIAL PATHOGENS

M. Van der Woude[1]
[1]*University of York, Centre of Immunology and Infection- HYMS and Biology, York, United Kingdom*

Phase variation is a common virulence strategy among bacterial pathogens. This heritable but reversible regulation frequently affects the cell surface and leads to single cell heterogeneity in a clonal population. One molecular mechanism is the result of epigenetic regulation that is dependent on changes in the DNA methylation pattern at specific Dam target sequences. Key features of this regulatory mechanism will be presented, which also illustrates why occurrence of this specific type of phase variation can remain undetected based on genome sequence analyses.

The O-antigen of the LPS is one of the defining features for a Salmonella serovar, and is used in diagnostics. We have identified families of O-antigen modifying genes in salmonella genomes and using our identified “phase variation signature sequence” show that the majority will be controlled by epigenetic phase variation. This alters the antigenicity, and thus likely is an immune evasion mechanism. However, our work shows that modifying the O-antigen composition has other important effects on the population. This work will be presented and illustrate how this epigenetic regulation in salmonella may impact on diagnostics, serovar evolution, and host-pathogen interactions. Our findings will be placed into the broader context of Dam and salmonella virulence, and on DNA methylation in bacterial pathogens in general.

IMPACT OF NUTRITIONAL AND TEMPARATURE STRESSES ON YEAST FERMENTATIONS

E. García-Rios[1], Y. Su[1], S. Muñiz[1], A. Querol[1], J.M. Guillamón[1]
[1]Institute of Agrochemistry and Food Technology IATA-CSIC, Food Biotechnology, Paterna, Spain

Our group is interested in understanding the mechanisms involved in adaptation that have shaped the yeast genome conferring properties of biotechnological interest. Different –omics techniques as well as evolutionary analysis are used to understand adaptation of yeasts of industrial interest to stresses. In this presentation, our insights gained in two of the most important environmental and nutritional stresses (low temperature and nitrogen availability) during wine fermentation will be shown. Low temperature alcoholic fermentations (10-15ºC) are becoming more frequent due to the winemaker's tendency to produce wines with more pronounced aromatic profile. However, this temperature is far from the optimum range for the main fermentative yeast *S. cerevisiae*, affecting both the yeast growth and fermentation rates. Nitrogen is an essential nutrient for yeast during wine fermentation. The deficiency of nitrogen is one of the major reasons of sluggish or stuck fermentation. Therefore, it is of great interest to characterize the nitrogen requirement of *S. cerevisiae* industrial strains. Curiously, our data reinforce the connection between both stresses. Low temperature firstly impacts on plasma membrane fluidity, affecting primarily to cellular nutrient uptake. Thus, low temperature and nutritional stress share many adaptative mechanisms in yeasts during industrial fermentations. Our approach has been to identify key physiological, metabolic and molecular mechanisms involved in the overcome of both stresses, and use this information for the design of rational genetic improvement strategies to obtain more robust and adapted yeast strains to grow during stressful industrial conditions.

MOTIVES AND MAPS TO ENJOY SPANISH FERMENTED FOODS AND BEVERAGES

Humberto Martín

Dpto. Microbiología II. Facultad de Farmacia. Universidad Complutense de Madrid and IRYCIS (Instituto Ramón y Cajal de Investigación Sanitaria)

Traditional fermented foods and beverages have been produced and consumed since the first civilizations. Their increased storage life, safety, pleasant flavors and effects on the well-being of the consumers were highly appreciated properties, becoming essential components of the human diet. Today, although the industrialization has reduced their number, there are still hundreds of fermented foods and beverages, and many of them represent a great cultural heritage in many countries. Microorganisms involved in fermentative processes transform meat, vegetables, dairy, legumes, cereals and fruits, often into stable microbial ecosystems. During this process, the involved microbes increase the bio-availability of nutrients, degrade toxic components and produce antimicrobial, antioxidant and bioactive compounds. All these abilities transform therefore the raw materials into potential functional foods.

A special category of the fermented products are represented by the alcoholic fermented beverages. Whereas the intake of high amounts of alcohol is well known to be harm for health, scientific reports consistently suggest that its moderate consumption by healthy adults seems to have beneficial effects, especially when considered as a part of the Mediterranean diet. A J-shaped relationship between alcohol consumption and mortality, with lower risk for moderate alcohol consumers than for abstainers or heavy drinkers is drawn by most epidemiological studies. In fact, a consensus scientific document on the effects on health of moderate beer consumption was published last year, showing evidence for no harm of moderate beer consumption for major chronic conditions and some benefit against cardiovascular disease.

Spain is a fascinating country for fermented products lovers, not only chesses, sausages or pickles, but especially for soft alcoholic beverages, including cider, wine or beer, with inexpensive and very high quality products. Some essential “maps” for enjoying them will be presented.

Fermented beverages: An interesting side of microbial abilities

YEAST TO STUDY XANTHOHUMOL EFFECTS ON EUKARYOTIC CELLS

V. Mascaraque[1], J.M. Rodríguez-Peña[1], J. Arroyo[1], C. Nombela[1]
[1]Facultad de Farmacia. Universidad Complutense de Madrid UCM and Instituto Ramón y Cajal de Investigación Sanitaria IRYCIS,
Departamento de Microbiología II. Cátedra Extraordinaria de Bebidas Fermentadas, Madrid, Spain

Biomedical research carried out over the last years has reported xanthohumol (XN), the main prenylated flavonoid synthesized in hop cones, to be one of the polyphenols in beer responsible for many of the health benefits associated with its moderate consumption. Since XN is present only in those drinks and foods that contain hops, beer is almost the only dietary source of this flavonoid. XN possesses a wide range of pharmacological properties, including chemopreventive, anti-inflammatory, hypolipidemic, anti-infective and anti-oxidative bioactivities, giving this flavonoid promising potential in the prevention or treatment of different types of cancer, specific microbiological infections and several lifestyle-related diseases. Even though many health beneficial effects have been assigned to XN by studies in different mammalian cell lines, it is still unknown how XN mediates many of these effects and there is a lack of data about the regulatory network involved in those processes.

Saccharomyces cerevisiae is one of the most important yeast used for humans throughout history and not only in the food industry but also as a eukaryotic model microorganism with an invaluable role for the progress of biomedical sciences. For those reasons, the goal of the present work is to study how XN modulates cell physiology and the gene expression profile of *S. cerevisiae* cells in an effort to shed light on the mechanisms involved in XN response.

Our studies have revealed an association between the effect of XN and the metabolic stage of yeast cells. Cells in a high metabolic and energetic stage are more sensitive to XN than cells with a slower growth rate or in a non-proliferating stage. The analysis of the transcriptional profile and the transcription factors involved in XN response has disclosed a connection between some differently expressed genes and the physiological effects of XN observed on mammalian cells. Furthermore, an in depth study of the transcriptional response to XN has revealed the possibility that this flavonoid could hold some new potential anti-cancer activities.

DOMESTICATION OF BEER AND WINE YEASTS

J.P. Sampaio[1]
[1]*Universidade Nova Lisboa, Life Sciences, Caparica, Portugal*

Yeasts of the genus *Saccharomyces* are used since the dawn of civilization to ferment a myriad of foods and beverages that range from more familiar and globally dispersed products such as wine, beer and bread to less well-known and more locally-consumed beverages. Although it is usually assumed that *Saccharomyces* yeasts have underwent a domestication process equivalent to those already known for plant crops and livestock, the genomic underpinnings of yeast domestication remain unknown. Moreover, the natural history, ecology and distribution of *Saccharomyces* in truly natural habitats is poorly known, which hinders the study of the emergence of domesticated genotypes that likely derive from wild ancestors. Complete genome sequences made available by Next Generation Sequencing techniques, and phylogenetic and population analyses, allow an unprecedented fine scale resolution of population dynamics and organismic evolution. The combination of these approaches with detailed field ecology studies provides a powerful tool to study the evolutionary ecology, natural phylogeography and domestication history of *Saccharomyces*. Here, the most recent findings concerning the domestication trajectories of wine and beer yeasts will be discussed. The yeasts responsible for the fermentation of these two products, although belonging to the same species, appear to be quite distinct. For example, the nucleotide diversity of the main group of ale beer yeasts more than doubled that of wine yeasts, which might be a consequence of fundamental differences in the modes of beer and wine domestication.

POLARIBACTER BLOOMS IN THE ARCTIC OCEAN: IS THERE A ROLE FOR PROTEORHODOPSIN?

C. Pedrós-Alió[1]
[1]*Centro Nacional de Biotecnologia ESQ2818002, Systems Biology, Cantoblanco. Madrid, Spain*

Backgrounds

The Arctic Ocean experiences major changes along the winter to summer transition. In previous studies we found that the planktonic microbial community changed composition around the time of ice breakup. Moreover, one Bacteroidetes genus, *Polaribacter*, usually dominated de Bacteroidetes assemblage. We analyzed the changes in abundance of this bacterium with time, reconstructed its gene content, and followed gene expression. In particular, we had seen a peak in expression of proteorhodopsin (PR) at ice breakup.

Objectives

We wanted to determine the potential importance of PR for the bloom.

Methods

We sampled surface water off Cambridge Bay (Canada) from early March to late June and obtained metagenomes and metatranscriptomes of three size fractions.

Conclusions

Bacteroidetes increased from 10% in March to 50% of the 16S rDNA reads in June, while chlorophyll a increased from 1 to 14 mg m^{-3}. *Polaribacter* became the dominant Bacteroidetes population making up 60% of the 16S rDNA reads. *Polaribacter* contigs assembled from the metagenomes had clusters of genes involved in extracellular polysaccharide degradation including groups of SusD-TonB genes (used for polymer degradation and transport of the monomers to the inside of the cell). These clusters showed synteny with those of *Polaribacter irgensii* (isolated from Antarctica) or from *Polaribacter* Hel-I-88 (isolated from Helgoland with relatively cold waters), but not with SAG MS024-2A or *Polaribacter* MED152 (isolated from warmer waters). This suggests that *Polaribacter* in cold waters prefer polysaccharides while those in temperate waters prefer proteins. Analysis of PRs is currently underway

METAGENOMIC AND METATRANSCRIPTOMIC STUDIES OF THE MICROBIAL COMMUNITIES ASSOCIATED TO CULTURED CLAMS

J.L. Romalde[1]
[1]*CIBUS-Faculty of Biology. Universidade de Santiago de Compostela, Microbiology and Parasitology, Santiago de Compostela, Spain*

The bivalve culture sector, in particular the clam culture, is of great importance in Galicia (NW Spain). The overexploitation of the natural beds, together with other factors, have led to the import of seed and adult clams, with the subsequent risk of introduction of new pathologies (i.e. the appearance of the brown ring disease). During the last decade, different projects developed by our research group focused on the study of the culturable microbiota associated to clam populations allowed not only the identification of new bacterial genera and/or species, determining their possible effects on the clam growth, either negative (pathogenic potential) or beneficial (probiotic activity), but also to check the sanitary condition of the clam populations. The use of culture-independent techniques, namely next-generation sequencing, was addressed to get a comprehensive understanding of the bacterial assemblages within clam tissues, avoiding the limitations the culture-based procedures.
The studies included clam populations of two species, Manila clam (Ruditapes philippinarum) and carpet-shell clam (Ruditapes decussatus) from two localities in the Galician coast. Samplings were carried out in summer and winter to analyze any possible seasonal variation. Different organs, including mantle, gills, gonads, and hepatopancreas were analyzed also separately in order to determine differential tropisms of bacteria, as well as the ecological and functional role or the pathobiological key factors for the appearance of disease.
Overall, this metagenomic analysis revealed the presence of more than 15 bacterial phyla within the clam microbiome along with a significant number of unclassified bacteria, suggesting that these filter-feeding organisms are likely a rich source of bacterial repository that continues to be under examined.

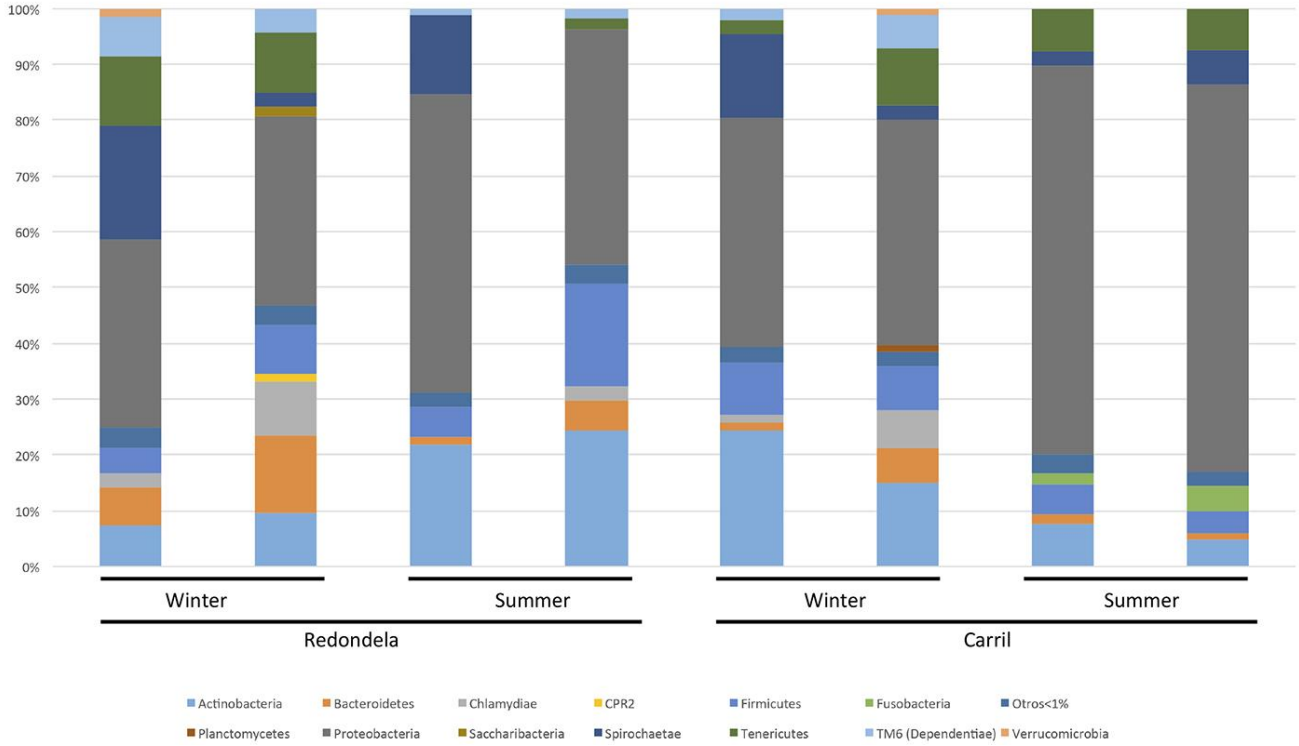

Figure 1.- Distribution of detected bacterial phyla in the clam samples obtained from two different locations in Galicia.

The highest number of Operational Taxonomic Units (OTUs) were observed in gonad and hepatopancreas tissues, which also rendered the highes species richness as calculated by Chao-1 index.

Although with relative differences associated to clam species or season, the most abundant taxa corresponded with Proteobacteria, Actinobacteria and Bacteriodetes (Fig. 1). It is noteworthy that most recovered bacterial groups by conventional culture-based techniques, namely Vibrio, Aliivibrio or Pseudoalteromonas among others, represented minor groups or were even not detected by metagenomic analysis. Conversely, some major groups in the 16S rRNA amplicons analysis were not detected with culture-based techniques. However, some of these organisms could be recovered using a dilution-to-extinction protocol, such as representatives of the genus Janthinobacterium.

The samples were also used for metatranscriptomic profiling aiming to reveal active metabolic pathways in the different clam organs and tissues. To obtain an overall profile of the gene functions throughout the different clam species, locations and seasons, coding sequences (CDSs) obtained from the samples were classified using COGs (Cluster of Orthologous Groups). An impressive variety of metabolic functions were found to be active in clam tissues, and their putative roles will be discussed.

This research was supported by grant AGL2013-42628R from the Ministerio de Economía y Competitividad (Spain).

SPACE-TIME FRONTIERS OF MARINE VIRAL ECOLOGY

J.S. Weitz[1]
[1], *USA*

Viruses influence the fate of microbial cells and populations. Yet, there remain many obstacles to understand how virus-host interactions at the microscopic scale constrain and control macroscopic ecological patterns and ecosystem function. In this talk I highlight what theory and models can contribute to linking processes and patterns across scales. In doing so, I describe recent and ongoing efforts to characterize fluctuations in the relative abundances of marine viruses and their microbial hosts, infer virus-microbe infection networks in situ, and characterize the role and relevance of multiple infections.

Role of microorganisms in the degradation of materials

FUNGAL DEGRADATION OF THERMAL-MODIFIED WOOD; ULTRASTRUCTURAL AND CHEMICAL ASPECTS

G. Daniel[1], J.S. Kim[1], J. Gao[1], M. Jebrane[1], N. Terziev[1]
[1]Swedish University of Agricultural Sciences, Forest Products, Uppsala, Sweden

Over the last decade the increasing awareness of environmental issues and legislation against the use of toxic wood protective chemicals has spurred the development of cost effective wood modification processes with an aim of not only reducing toxicity, but also retain and even increase the service life of wood. One of these processes termed “thermal modification (TM)” employs heat at elevated temperatures (160-220 ^{o}C) which causes changes in the wood structure whereby the dimensional stability can be increased and the durability and service life against fungal decay improved. One recent variation of the TM process known as thermo-vacuum (TV) employs a thermal wood process in which oxygen is removed by vacuum and heat transfer to the wood provided by convection in a so called “dry process”. Aspects on the physical and mechanical properties of TM wood as well as other macroscopical changes (e.g. density, color, swelling, mass loss, cracking) are quite well-known for a wide range of different TM treated wood species including both temperate and tropical soft- and hardwoods. However, despite the wide interest and great possibilities for using TM wood in-service, very little is known concerning modifications induced in the native wood material at ultra- and microstructural levels after treatments and how this effects decay by major fungal groups including white-, brown- and soft rot fungi.
Since all changes at macroscopic levels are derived from ultra/microstructural changes, it is likely that such knowledge can help to further understand and develop TM processes. In the present work we have studied the durability of a number of temperate soft- (fir, spruce) and hardwoods (beech, ash) treated by the TV process at temperatures ranging between 160-220 ^{o}C using a variety of white- (*Trametes versicolor*, *Pycnoporus sanguineus*, *Phlebia radiata*), brown- (*Postia placenta*, *Gloeophyllum trabeum*) and soft (*Phialophora mutabilis*, *P. malorum*, *Chaetomium globosum*) rot fungi using EN 113 or AWPA E10-08 durability tests. Aspects of wood modification at ultra- and microstructural levels were studied using a number of histo/cytochemical staining, immuno-antibody approaches using light-, fluorescence- and transmission electron microscopy (TEM).
Studies showed that improvement in decay resistance (i.e. according to EN-350-1) of TV wood which was optimal in the range 200-220 ^{o}C for the different rot types and fungal species used can be traced to modifications (e.g. polymer loss/redistribution) at the wood cell wall level in pectins (homogalacturonans, rhamnogalacturonan), hemicelluloses (xylan, glucomannan) and lignin (guaiacyl, syringyl). The much greater variability in cellular composition and chemistry (i.e. high cell wall hemicellulose composition) and range of different cell types with different chemistry in hardwoods compared with softwoods provides for the much greater difficulties for developing protection. In the softwoods and at high temperatures (i.e. > 200 ^{o}C), increased protection against decay was provided at the molecular level in the S2 layer by densification and lignin aggregation. TV modification only produced marked changes in decay morphology for soft rot in both hard- and softwoods which likely reflect modification of the non-cellulosic polymers and lignin. In the present talk, an overview will be given of the effects TM treatments have on the ultrastructure of wood cell walls and the implications this has for protection against major wood decay fungi.

FEMS7-1136
Role of microorganisms in the degradation of materials

MINERAL-MICROBIAL INTERACTIONS: GEOMICROBIOLOGY AND BIODEGRADATION

A. De los Ríos[1], *C. Ascaso*[1]
[1]*Museo Nacional de Ciencias Naturales-CSIC, Biogeoquímica y ecología microbiana, Madrid, Spain*

The biological and mineral components of terrestrial microbial ecosystems cannot be separately analyzed because of intimate mineral-microorganism relationships. Microorganisms colonizing rocks actively interact with the minerals of the colonized substrate but microorganisms within soil crusts and polar cryptogamic covers are also frequently associated with minerals. These relationships give rise to complex mineral-microorganism interactions, which result in physical and chemical alteration of the minerals and rocks. Such interactions are essential for initial pedogenesis processes and ecosystem functioning. Most microorganism-mineral interactions occur within an organo-mineral matrix composed mainly of a mixture of EPS and different autochthonous and allochthonous mineral constituents. The interactions established likely dependent on the three-dimensional organization of biotic and abiotic factors, and evolve over the time.

Microorganisms are the main form of terrestrial life in extreme environments, such as those of desert areas, and pioneers in the colonization of new habitats. Geomicrobiological interactions play an important role in this colonization because they help form protective microenvironments and microhabitats in which microorganisms survive and may even thrive.

Built stone is also colonized by microorganisms, but this time, the impacts of mineral-microorganisms interactions are non-beneficial because they induce non-desirable changes in the colonized lithic substrate (biodeterioration). Such detrimental microbial activity is conditioned by the physicochemical properties of the stone used in different constructions and the environmental conditions. Mechanical actions are the main force behind these alterations but, in most cases, chemical actions also play a role.

Solar Panels: Accessible, Ubiquitous and Highly Standardised Collectors of Sub-aerial Biofilms

Morphologically simple microbial biofilms have prevailed since life began on Earth. Biofilms form at the interfaces of solids with gases or liquids and have multiple effects on substrate and element cycles. In geobiological terms, the most interesting microbial communities are those that form on solids exposed to air (sub-aerial). Microbial colonisers of the atmosphere-lithosphere interface include algae, cyanobacteria, fungi as well as heterotrophic bacteria and they have colonised virtually every rock surface throughout the entire geological history of the Earth. In addition to sequestering carbon, sub-aerial biofilms (SABs) actively participate in rock weathering. Rock-inhabiting SABs are the primary settlers on lava following volcanic eruptions and on rocks following the retreat of glaciers. SABs especially dominate hostile environments in which growth of higher vegetation is restricted especially in deserts, polar- and alpine-regions. SABs are the primary colonisers of lithospheric (e.g. rocks) and anthropogenic substrates (buildings, monuments, solar panels, etc.). Life at the solid material/atmosphere interface influences and is affected by both the underlying substrate and the microclimate surrounding it. Although sub-aerial life is ubiquitous, how SABs develop and importantly degrade underlying substrates can only be clarified in well-controlled experiments that often involve simplified model systems. So far, biofilm development on solar panels has been studied using; (i) metagenomics; (ii) *in situ* microscopy; and (ii) classical microbiological methods that are both qualitative and quantitative. Here we suggest that solar panel biofilms are accessible and highly relevant objects to study microbial ecology, geobiology and biodeterioration.

FEMS7-0416
Role of microorganisms in the degradation of materials

MICROORGANISMS IN DETERIORATION OF HISTORICAL BUILDING MATERIALS

B. Gutarowska[1]
[1], *Poland*

Microbial colonization of historical building materials can lead to severe deterioration. Historical building materials are exposed to changing atmospheric condition, varying humidity, temperature, pH, light, chemical pollution, what stimulate microorganisms to growth and metabolic activity. Macroscopic symptoms of biodeterioration include visible surface defects, fiber splitting, pitting, microbial biofilms, discoloration, bulging plaster, peeling paint, moreover mechanical properties are changed, what is important for structural elements. Direction of biodeterioration is determined by chemical composition of materials, their porosity, water permeability and availability of nutrients. Mechanism of deterioration of inorganic building materials (brick, mortar, stone) caused by moulds, bacteria including cyanobacteria, algae, lichens, bryophytes involves the reaction between microbial metabolites e.g. organic and inorganic acids with components in building materials, what leads to increase solubility of components or formation of salts, which may be washed out from the surface resulting in reduced compressive strength. Organic materials (wood) are biodegradated by the action of extracellular enzymes of colonizing insects, filamentous and decay fungi, bacteria, what leads to the decomposition of cellulose and other components. Studies demonstrate that a combination of many new generation methods is suitable solution for analysis of historical building' biodeterioration including: molecular methods (construction of clone libraries, high-throughput sequencing) to assess VBNC microorganisms; metabolomics analysis of chemical compounds profiles what indicates mechanisms of biodeterioration (QTOF-HPLC-MS, MALDI), electron microscopy imaging technics what shows degradation of building materials (FESEM-EDX). Lecture will present examples of biodeterioration of famous historical buildings in Poland, Italy, Austria and other countries.

SEM-SEIMC: Antimicrobial stewardship: from the lab to the patients

ROLE OF MICROBIOLOGY LABORATORY IN ANTIMICROBIAL STEWARDSHIP PROGRAMS

R. Canton Moreno[1]
[1], *Madrid, Spain*

Clinical microbiology laboratories and clinical microbiologist play a pivotal role in antimicrobial stewardship programs. IDSA (*Infectious Diseases Society of America*) and SEIMC (Sociedad Española de Enfermedades Infecciosas y Microbiología Clínica) have established in their respective guidelines of antimicrobial stewardship programs that clinical microbiologist must be included as core members of stewardship teams. More recently this role has been recognized by the ECDC (European Center for Disease Prevention and Control). Main activities of clinical microbiology laboratory include (rapid) identification of pathogens, antimicrobial susceptibility testing, phenotypic detection and molecular characterization of antimicrobial resistance microorganisms and their corresponding resistance mechanisms, detection and characterization of outbreaks, surveillance cultures and timeline reporting of microbiological findings. Moreover, clinical laboratories should incorporate typing techniques (rep-PCR, PFGE, MLST or in the future whole genome sequencing) and offer statistical reports. Relevance of these activities have been reinforced with the increasing worldwide frequency of multi-drug resistant (MDR) organisms, particularly with carbapenemase producing organisms and new resistance threats such as colistin resistance due to *mcr-1* transferable gene. The implementation of surveillance programs (either with culture or with molecular methods) for the detection of colonized patient with MDR organisms as part of antimicrobial stewardship programs has demonstrated clear benefits to reduce antimicrobial use and infections due to MDR organisms. Moreover, the introduction of new techniques that also decrease reporting time of clinical microbiology laboratories, such as molecular or proteomic (MALDI TOF MS) ones, has also impact in antimicrobial use and antimicrobial resistance rates. Both World Health Organization and United Nations have recognized the antimicrobial resistance as a public health problem and encourage nations to implement actions to reduce it. These actions include access to (rapid) microbiological diagnosis and better antimicrobial use.

SEM-SEV: Viral pathogenesis mediated by small RNAs and RNA silencing supressors

ROLE OF SMALL-RNAS IN VIROID PATHOGENESIS

F. Di Serio[1]
[1]*Institute for Sustainable Plant Protection CNR, National Research Council of Italy, Bari, Italy*

Viroids are tiny, circular, naked and infectious RNAs that replicate in the nuclei (family *Pospiviroidae*) or chloroplasts (family *Avsunviroidae*) and then invade systemically their host plants, which may react developing severe diseases. Viroid RNAs are targeted by Dicer-like (DCL) ribonucleases generating viroid-derived small RNAs (vd-sRNAs) of 21-24 nt that are loaded into Argonaute (AGO) proteins, the major effectors of RNA silencing. The biological roles of vd-sRNAs have been at least partially unveiled, with data supporting their involvement in anti-viroid defense and pathogenesis. In this respect, it has been shown that symptoms induced by a chloroplast-replicating viroid may be elicited by vd-sRNAs that, resembling structurally and functionally microRNAs, down-regulate the expression of a host gene and trigger pathogenesis via a post-transcriptional RNA silencing-based mechanism. A similar pathogenic mechanism has been proposed for several nuclear-replicating viroids, but the evidence seems less solid. Multidisciplinary approaches, mainly based on genome-wide approaches (degradome sequencing, deep sequencing of vd-sRNAs and transcriptome analyses) should help to clarify whether vd-sRNAs are actually involved in the pathogenesis elicited by nuclear-replicating viroids or alternative molecular mechanisms must be considered.

Severe outcome in influenza virus infected patients is associated with reduced accumulation of defective viral genomes

Influenza A virus (IAV) infection can be severe or even lethal in toddlers, the elderly and patients with certain medical conditions. Infection of apparently healthy individuals nonetheless accounts for many severe disease cases and deaths, suggesting that viruses with increased pathogenicity co-circulate with pandemic or epidemic viruses. Looking for potential virulence factors, we have identified a viral genetic determinant that contributes to infection outcome. A polymerase mutation identified in a fatal IAV case, when introduced into two different recombinant virus backbones, led to reduced defective viral genomes (DGs) production and increased pathogenesis in mice. These data provide genetic support for the association of pathogenicity and low DGs accumulation induced by mutations present in pathogenic viruses circulating in humans. Testing this association, we performed a genomic analysis of viruses isolated from a cohort of previously healthy individuals who suffered highly severe IAV infection requiring admission to Intensive Care Unit, and patients with fatal outcome who additionally showed underlying medical conditions. These viruses were compared with those isolated from a cohort of mild IAV patients. Viruses from highly severe/fatal outcome patients showed significantly fewer DGs accumulation than control viruses, suggesting that low DGs abundance constitutes a new virulence viral pathogenic marker in humans, regardless of the mutations responsible.

Program of Plant Responses to Stress, Barcelona, Spain

FUNCTIONAL DIVERSITY AND PARTIAL REDUNDANCY OF POTYVIRAL RNA SILENCING SUPPRESSORS

The concept of RNA silencing refers to a complex ensemble of regulatory mechanisms controlling gene expression in most eukaryotic organisms. Plants use this system as a major antiviral defense, forcing plant viruses to counteract it by developing RNA silencing suppressors (RSSs). Viral RSSs are very diverse and usually assume additional functions. That is the case of HCPro, the well-characterized RSS from members of the genus *Potyviru*s (family *Potyviridae*), which is also required for aphid transmission. However, members of other genera of this family express divergent HCPros lacking RNA silencing suppression, and surrogate this activity to other proteins also encoded by sequences at the 5'-terminal region of the viral genome. We have demonstrated that the transframe product P1N-PISPO from the potyvirus *Sweet potato feathery mottle virus* (SPFMV) shows weak silencing suppression activity in an agroinfiltration system. In agreement with this fact, P1N-PISPO was able to replace HCPro, although with very low efficiency, in the infection of the potyvirus *Plum pox virus*. In contrast, SPFMV HCPro did not appreciably suppressed RNA silencing in the agroinfiltration system, but supported the infection of a PPV variant lacking its native HCPro. Recently, we reported that a novel RSS-unrelated activity of PPV HCPro prevents CP degradation by forming stable virus particles. We have now demonstrated that this activity depends on virus replication and can be provided, at least partially, by SPFMV HCPro. Together, our results highlight the functional diversity and partial redundancy of RSSs supporting potyviral infections.

DEFECTIVE VIRAL GENOMES AS DETERMINANTS OF PARAMYXOVIRUS PATHOGENESIS

C. Lopez[1]
[1], *Philadelphia, USA*

The innate immune response controls viral replication or kill infected cells through the production of effector molecules, such as type I IFNs and TNF. Yet, viruses have evolved strategies to avoid elimination that allow them to persist in circulation. Defective viral genomes (DVGs) generated during the replication of most viruses have long been considered a viral product with evolutionary advantages in facilitating virus persistence. However, recent evidence demonstrates a contrasting critical role for DVGs in promoting strong induction of anti-viral immunity during infections with a number of RNA viruses. Why and how DVGs and host interact to achieve these two divergent and critical functions is poorly understood. Using RNA-FISH to probe DVGs and full-length (FL) viral genome at a single cell level during paramyxovirus infections, we identified a subset of infected cells that is dominated by DVGs (DVG-high) and is less prone to viral induced apoptosis than cell dominated by FL genomes. Transcriptional profiling revealed that DVG-high cells actively engage a strong TNF pro-survival program. Remarkably, TNF secreted in response to MAVS signaling during viral infection dictates the apoptosis of FL-high cells while supporting the survival of DVG-high cells. The MAVS/TNF axis leads to up-regulation of TRAF1/ TNFRII signaling in DVG-high cells extending their life span enough to promote the generation of persistent infections. Thus, our data suggest that DVGs are a pivotal component of the paramyxovirus-host interaction that determines the subsistence of virus and host by limiting acute virus replication while protecting a subset of infected cells from apoptosis thereby facilitating virus persistence.

Structural nanomicrobiology

NANOSCALE APPROACHES TO A SYNTHETIC BACTERIAL AMYLOIDOSIS

R. Giraldo[1]
[1], *Spain*

Backgrounds

Protein amyloids arise from the conformational conversion and assembly of a soluble protein into fibrils with a crossed β-sheet backbone, leading to devastating proteinopathies. The WH1 domain of the bacterial protein RepA assembles into amyloid fibres *in vitro*.

Objectives

We aim to unravel amyloid structure, assembly and toxicity at the interface across Microbiology and Nanoscience.

Methods

Electron and atomic force microscopies, surface-enhanced Raman spectroscopy, microfluidics, bacterial genetics, protein engineering.

Conclusions

RepA-WH1 fibres are bundles of intertwined tubular protofilaments made of distorted protein monomers. Fibres can be nucleated by gold nanorods functionalized with the protein and assembly monitored as an increase in β-sheet. RepA-WH1 causes in *E. coli* a *vertically* transmissible amyloid proteinopathy. Bacterial lineages maintain two strains of RepA-WH1 amyloids and the DnaK chaperone modulates phase transitions between both. Oligomeric amyloidogenic precursors form at the bacterial nucleoid. RepA-WH1 builds pores through model membranes. RepA-WH1 is a minimal, synthetic bacterial model of an amyloid disease (reviewed in: *Prion* 10:41-9, 2016).

[5]Newcastle University, Institute of Cell and Molecular Biosciences, Newcastle upon Tyne, United Kingdom

Encapsulin nanocompartments are intracellular protein cages that are structurally related to the capsids of the HK97 bacteriophage and are distributed across many bacterial and archaeal species. Encapsulins sequester a number of different enzymes within their lumen through specific interactions with short localisation peptides on their cargo proteins. These cargoes include the well-characterised dye-dependent peroxidases, a new class of decameric ferritin, and a number of recently identified proteins with unknown functions. In the case of the dye-dependent peroxidases, the encapsulin cage protects the cell from oxidative damage resulting from the peroxide-radical mechanism these proteins employ to cleave carbon-carbon bonds in their substrates. Using X-ray crystallography in concert with structural Mass spectrometry, we have determined the structure of the decameric ferritin from *Rhodospirillum rubrum* and show that it possesses the ferroxidase activity found in other members of the ferritin family, but due to its open annular structure it is unable to directly sequester iron. We show that the encapsulin shell associated with these ferritins acts as a cage to store the ferric iron as ferrihydrite minerals. The encapsulin cages are between 25 and 35 nm in diameter, and have more interior space than the 8 nm ferritin nanocages; they are consequently able to store an order of magnitude more iron than classical ferritins. Our recent results on these decameric ferritins have identified the key residues responsible for both their multimerisation and ferroxidase activity.

CRYSTALLOGRAPHIC STRUCTURES, RECEPTOR-BINDING AND APPLICATIONS OF VIRUS FIBRE PROTEINS

M.J. Van Raaij[1]
[1]*Centro Nacional de Biotecnología CNB-CSIC, Department of Macromolecular Structure, Madrid, Spain*

Both adenoviruses and bacteriophages use fibre proteins to recognize their host cells.Bacteriophages are complicated onetime nanomachines that transfer their genomic material into susceptible host bacteria. They have specialized proteins for initial, reversible, host cell wall recognition. Once a suitable host is found, the phage commits to infection by irreversible attachment via a secondary receptor interaction.
We have solved the detailed structures of several phage receptorbinding proteins and have shown them to be mainly betastructured, but structurally highly diverse and containing several new protein folds. Structures of the receptor-binding proteins of the coliphages T4, T5 and T7, of the Salmonella phage epsilon15 and of the Staphylococcus phages S241 and K will be shown.
Adenoviruses fibre proteins also serve as primary host cell recognition proteins and we have recently determined structures of the first atadenovirus and siadenovirus fibre head domains. We also discovered that the atadenovirus LH3 capsid protein contains a bacteriophage tailspike fold.
Ongoing structural, mutational and binding analysis of virus receptor-binding proteins with receptors and receptor analogues will be discussed. Bacteriophage receptor-recognizing proteins may be used for bacterial detection, while modification by natural or experimental mutation of bacteriophage receptorbinding domains may allow retargeting of phages to alternative host bacteria. Their shape and stability may also allow their use in nanotechnological applications.

IN-PATIENT EVOLUTION OF PSEUDOMONAS AERUGINOSA POPULATIONS IN HUMAN LUNGS

H.K. Johansen[1], J. Haagensen[2], R. Marvig[3], S. Molin[2]
[1]Rigshospitalet, Department of Clinical Microbiology, Copenhagen Ø, Denmark
[2]Technical University of Denmark, The Novo Nordisk Foundation Center for Biosustainability, Lyngby, Denmark
[3]Rigshospitalet, Center for Genomic Medicine, Copenhagen Ø, Denmark

IN-PATIENT EVOLUTION OF *PSEUDOMONAS AERUGINOSA* POPULATIONS IN HUMAN LUNGS

Objective: Persistent airway infections with *Pseudomonas aeruginosa* are responsible for the gradually decreasing lung function in cystic fibrosis (CF) patients. The aim of our research is to identify which properties are involved in persistence of *P. aeruginosa* (PA) in the lungs of young CF patients.

Methods: Clinical isolates of PA have been collected for 10 years to cover the earliest infection stages. We have whole genome sequenced more than 600 PA isolates from 41 CF patients. From these sequences clone types were identified, and selected phenotypes, eg. antibiotic susceptibility, adhesion (biofilm) and growth rates were determined.

Results: Almost 75% of all CF patients were infected with the same clone-type during the entire collection period, despite intensive antibiotic therapy. Persistence was not associated with antibiotic resistance. We detected 23 tobramycin resistant isolates out of 379 (6%) isolates and 17 piperacillin + tazobactam resistant isolates out of 403 (4%) isolates. More than 20% of all isolates displayed reduced growth rates, and significantly more isolates had lower adherence compared to increased adherence (biofilm) ($p<0.0003$).

Conclusions: Most CF patients acquire persistent infections from their first colonization by PA, suggesting that current clinical definitions of colonization and chronic infection need to be revised. Persistence of PA cannot be explained phenotypically and genetically because antibiotic resistance is only observed in scattered early PA isolates, and the increased generation time is not associated with any clear pattern of antibiotic resistance. The reduced or unaffected biofilm formation over time suggests that persistence is not derived from biofilm development.

FEMS7-0070
The pangenome of prokaryotic populations

PROKARYOTIC VIRUSES, PANGENOMES AND EVOLUTIONARY SELECTION UNITS
F. Rodriguez-Valera[1]
[1], *Spain*

The genomic diversity present in concurrent individuals in a given bacterial population is enormous. Cells (or clonal lineages) contain different alleles of the genes in the core genome that vary typically ca. 5% in nucleotide identity but can have much higher local diversity. However, where these concurrent lineages display more divergence is in the flexible genome. Part of it is dispersed throughout the core in small synteny breaks, but about 50% of the flexible genome is concentrated in flexible genomic islands (fGIs). They can be classified in (at least) two different kinds. Additive fGIs like integrons vary by accretion of gene cassettes that code for biotic and abiotic niche interaction such as antibiotic resistance and production, metabolism and transport of specific substrates or cell regulation and chemotaxis. Additive fGIs vary very rapidly in evolutionary time scales through site directed recombination. Replacement fGIs code for outermost exposed polysaccharides (glycotypes) such as the O-chain or exopolysaccharides, they vary more parsimoniously by doble cross-over homologous recombination . This mechanism leads to complete exchange of the island by another present in a separate lineage. We propose that the presence of several glycotypes coexisting in the population is the key to the long range survival and stability of complex clone consortia by a negative density-dependent selection mechanism based on bacteriophages that recognise only some specific glycotypes. Furthermore, we would like to propose that a complex population made up of multiple clonal lineages and their cognate phages represent a single group selection unit.

Yeast as eukaryotic models and cell factories

THE YEAST CHRONOLOGICAL AGING MODEL: PROTEOTOXIC STRESS AND AGE-RELATED DYSFUNCTIONS

P. Ludovico[1]
[1]*School of Medicine, Life and Health Sciences Research Institute ICVS, Braga, Portugal*

Background

Aging is a complex and multi-factorial process that results in the progressive accumulation of molecular alterations and disruption of different cellular functions. Genome instability, nutrient sensing, mitochondria dysfunction and loss of proteostasis are some of the proposed aging hallmarks, nevertheless the relationships between these phenomena have been largely unexplored. Yeast provides a simple and powerful model for cellular aging research particularly for the understanding of the relationships between aging hallmarks.

Objectives

In this presentation, the yeast chronological aging model will be explored and several examples of new insights produced in this cellular eukaryotic model will be discussed.

Methods

Studies on the yeast chronological aging model have shown that elevated levels of hydrogen peroxide, generated during caloric restriction, a manipulation that extends life span and retards age-related phenotypes in a variety of species, reduces the accumulation of superoxide anions. On the other hand, the use of yeast aged cells expressing the Parkinson's disease related protein, alpha-synuclein, provided new findings on loss of proteostasis during aging. Alpha-synuclein is a naturally prone to misfold protein impacting on protein quality control system such as autophagy. We found that increased autophagy and mitophagy observed in yeast cells expressing alpha-synuclein accelerates chronological aging. The regulation of autophagy and its crosstalk with genomic instability will be discussed.

Conclusions

Overall, the data to be presented gives new insights on cellular mechanisms of aging. "*All the models are wrong but some are useful*" and this is the case of the yeast aging model.

FEMS7-2221
Yeast as eukaryotic models and cell factories

YEAST AS A MODEL FOR UNDERSTANDING CELL SIGNALING-ASSOCIATED PATHOLOGIES

I. Rodríguez-Escudero[1], T. Fernández-Acero[1], M.D. Oliver[1], I. Bravo[1], R. Pulido[2], V.J. Cid[1], M. Molina[1]
[1]Universidad Complutense, Dpt. Microbiología II. Facultad de Farmacia, Madrid, Spain
[2]BioCruces Health Research Institute, Cancer Research, Barakaldo, Spain

Given the conservation of signaling mechanisms and cellular processes along the evolutionary scale, the yeast *Saccharomyces cerevisiae*, a readily manageable unicellular eukaryotic organism, represents an excellent tool for the functional study of proteins of complex organisms that, upon heterologous expression, are able to couple or interfere with yeast signaling or growth. This approach, often referred as 'humanizing yeast', also allows the development of yeast-based bioassays adaptable to high throughput screening (HTS), for identifying specific inhibitors of human proteins involved in disease. One successful example carried out by our group is the reconstitution in yeast of the oncogenic pathway involving PI3K (phosphatidylinositol 3-kinase), PTEN (phosphatidylinositol 3-phosphatase) and protein kinase Akt.

The aim of this talk is to analyse the scope as well as the pros and cons of using yeast as a model for studying cell signaling- associated diseases and drug discovery, exemplified by the PI3K pathway. Functional analyses on yeast cells expressing human proteins involved in PI3K signaling have been performed by using growth assays, directed and random mutagenesis, cell and molecular biology techniques and functional genomics (transcriptomics, genomic mutant collections, etc). By this means, the PI3K humanized model yeast allowed us to identify oncogenic mutations in catalytic and regulatory PI3K subunits, PTEN and Akt, as well as PI3K inhibitors to be developed for anticancer therapy. Functional studies on the putatively therapeutic long version of PTEN have been also feasible in this model. At the same time, the system has proven to be useful to further understanding yeast physiology, particularly lipid signaling.

Yeast as eukaryotic models and cell factories

UNDERSTANDING THE MECHANISM OF SACCHAROMYCES SPECIES ADAPTATION TO WINE FERMENTATIONS

A. Querol[1], E. Navarro-Tapia[2], R. Pérez-Torrado[3]
[1], Spain
[2]Institute of Agrochemistry and Food Technology IATA-CSIC, Food Biotechnology, Paterna, Spain
[3]Institute of Agrochemistry and Food Technology IATA-CSIC, Food Biotechnology, 46980, Spain

In wine fermentation, high ethanol concentrations is one of the main metabolites responsible of problematic fermentations. The adaptation to high ethanol is also very important in the cases of sparkling and Sherry wines. Although many efforts have been made, mechanisms of ethanol tolerance are not fully understood in *Saccharomyces cerevisiae*. This work studied two *S. cerevisiae* strains, CECT10094 and Temohaya-MI26, isolated from flor wine and agave fermentation (a traditional fermentation from Mexico) respectively, which differ in ethanol tolerance, in order to understand the molecular mechanisms underlying the ethanol stress response and the reasons for different ethanol tolerance.

The transcriptome was analyzed after ethanol stress and, among others, an increased activation of genes related with the unfolded protein response (UPR) and its transcription factor, Hac1p, was observed in the tolerant strain CECT10094.

Although our data and others authors ensure that the UPR is triggered by the unfolded proteins generated by ethanol in the cell, the mechanism of activation not being known. In this study we have investigated the activation of the UPR response in yeast *S. cerevisiae* by ethanol stress and we want to know if really the ethanol produces unfolded proteins and if this is the mechanism of activation of UPR after an ethanol stress. According these data, we can conclude that, although UPR activation was observed, unfolded proteins do not accumulate in the ER under 8% (v/v) ethanol stress. We also ruled out inositol depletion as an alternative mechanism to activate the UPR under ethanol stress.

Yeast as eukaryotic models and cell factories

YEAST PHYSIOLOGICAL TOXICOGENOMICS: INSTRUMENTAL TO GUIDE THE DEVELOPMENT OF ROBUST CELL FACTORIES

I. Sa-Correia[1]
[1]*iBB-Institute for Bioengineering and Biosciences- Instituto Superior Técnico, Bioengineering, Lisbon, Portugal*

Background: The improvement of the capacity of industrially relevant yeasts to tolerate toxic substrates or products, combined with operating conditions that do not allow maximum stress tolerance, is an important challenge of modern Biotechnology. Yeast physiological toxicogenomics provides a holistic assessment of the complex adaptive responses to chemical stresses and the identification of tolerance or susceptibility determinants, at a genome-wide scale. [1] This knowledge is instrumental to guide synthetic pathway engineering and other practices for increased cell robustness manipulation either for the sustainable production of fuels and chemicals or for the control of food and beverage spoilage yeasts.

Objectives: This talk will focus on our current knowledge on the physiological genomics of the adaptive response and tolerance to relevant stresses in the cell factory *Saccharomyces cerevisiae* and the food spoilage yeast *Zygosaccharomyces bailii,* remarkably tolerant to weak acid food preservatives. [2]

Methods: Chemogenomic, transcriptomic, (quantitative- and phospho-) proteomic,lipidomic analyses and genome sequencing and analysis coupled with bioinformatics tools and molecular and cellular biology studies are explored to unveil genome-wide adaptive response programs and tolerance/susceptibility determinants to single and multiple relevant stresses.

Conclusions: The involvement of genes, proteins and signaling pathways in yeast adaptation and tolerance to relevant stresses is being elucidated based on genome-wide strategies. Those are candidate molecular targets for genetic manipulations to endure yeast cells against multiple stresses expected to occur during biotechnological and food industry processes.

ROLE OF BIOFILM FORMATION ON ANTIBIOTIC RESISTANCE IN PSEUDOMONAS AERUGINOSA

J. Ayala[1], C. Aguilera[2], A. Ropy[3]
[1]Centro de Biología Molecular "Severo Ochoa", CSIC-UAM, Madrid, Spain
[2]Universidad de la Frontera,
Facultad de Medicina- Departamento de Ciencias Preclínicas- Unidad de Microbiología, Temuco, Chile

Community and nosocomial infections by *Pseudomonas aeruginosa* still create a major therapeutic challenge. The resistance of this opportunist pathogen to β-lactam antibiotics is determined mainly by production of the inactivating enzyme AmpC, a class C cephalosporinase with a regulation system more complex than those found in members of the Enterobacteriaceae family. This regulatory system also participates directly in peptidoglycan turnover and recycling. One of the regulatory mechanisms for AmpC expression, recently identified in clinical isolates, is the inactivation of LMM-PBP4 (Low-Molecular-Mass Penicillin-Binding Protein 4), a protein whose catalytic activity on natural substrates has remained uncharacterized until now. We carried out in vivo activity trials for LMM-PBP4 of Pseudomonas aeruginosa on macromolecular peptidoglycan of *Escherichia coli* and *Pseudomonas aeruginosa*. The results showed a decrease in the relative quantity of dimeric, trimeric and anhydrous units, and a smaller reduction in monomer disaccharide pentapeptide (M5) levels, validating the occurrence of D,D-carboxypeptidase and D,D-endopeptidase activities. Under conditions of induction for this protein and cefoxitin treatment, the reduction in M5 is not fully efficient, implying that LMM-PBP4 of *Pseudomonas aeruginosa* presents better behavior as a D,D-endopeptidase. Kinetic evaluation of the direct D,D-peptidase activity of this protein on natural muropeptides M5 and D45 confirmed this bi-functionality and the greater affinity of LMM-PBP4 for its dimeric substrate. A three-dimensional model for the monomeric unit of LMM-PBP4 provided structural information which supports its catalytic performance. So, LMM-PBP4 of *Pseudomonas aeruginosa* is a bi-functional enzyme presenting both D,D-carboxypeptidase and D,D-endopeptidase activities; the D,D-endopeptidase function is predominant. Our study provides unprecedented functional and structural information which supports the proposal of this protein as a potential hydrolase-autolysin associated with peptidoglycan maturation and recycling. The fact that mutant PBP4 induces AmpC, may indicate that a putative muropeptide-subunit product of the DD-endopeptidase activity of LMM-PBP4 could be a negative regulator of the pathway. Role of this muropeptide on *ampR*-dependent biofilm induction will be discussed. Incubation of *Pseudomonas aeruginosa* with 5x MIC of imipenem caused the development of spherical shaped cells, which are able to recover after drug elimination We traced the effect of imipenem on activities of Penicillin Binding Proteins (PBPs), DD-endopeptidases, DD-carboxypeptidases, LD-carboxypeptidases, and peptidoglycan composition in spheroplast and rod-shaped *Pseudomonas aeruginosa*. We found that the rod-shaped mutant PAOΔ*dacB*Δ*dacC*Δ*pbpG*Δ*ampC* displayed the same behavior as the wild type PAO1 in spheroplast generation and rod shape recovery beyond imipenem treatment and elimination, respectively. Also, spheroplasts from both strains had similar changes in their PG composition like increase in levels of M3 and anhydromuropeptides. Additionally, spheroplast PG had a decrease in levels of M5, D44, D45 and D-D muropeptides. These changes in PG composition can be explained by imipenem inhibition of DD-endopeptidase and DD-carboxypeptidase activities. This proposal was confirmed by quantification of PBPs by Bocillin-FL test and qRT-PCR which revealed disappearance of many PBPs bands from samples of spheroplast membranes. Our data suggests that the large increase in M3 muropeptides was due to the uncompensated activity of LD-carboxypeptidases. Also, these results demonstrate that activities of LMM-PBP4, LMM-PBP5 and LMM-PBP7 are not essential for recovery of rod shape in imipenem-induced spheroplasts in *Pseudomonas aeruginosa*. These data contributes to

understanding of the regulatory aspects of resistance to β-lactam antibiotics in this bacterial model, and provide a link with other biological processes.

SYNERGISTIC EFFECTS AND INHIBITION OF BIOFILM FORMATION OF OCELLATIN PEPTIDES IN PSEUDOMONAS AERUGINOSA

L.J. Bessa[1], J.R.S.A. Leite[1,2], P. Eaton[1], P. Gameiro[1]
[1]Requimte, LAQV, Departamento de Química e Bioquímica,
Faculdade de Ciências da Universidade do Porto, Porto, Portugal
[2]Área de Morfologia, Faculdade de Medicina, Universidade de Brasília, UnB, Brasília, Brasil

Backgrounds

Antimicrobial resistance is putting at stake the effective treatment of many infections. It is therefore pertinent to search for new antimicrobials, inhibitors of biofilms and agents able to restore or potentiate the activity of existing antibiotics. Five peptides (Ocellatins-PT2 to –PT6) isolated from the skin secretion of the frog *Leptodactylus pustulatus* and previously characterized [1], were used in this study.

[1] Marani MM *et al.* J. Nat. Prod. 2015;78(7):1495-504. doi: 10.1021/np500907t.

Objectives

Assess potential synergies between peptides and antibiotics against multidrug-resistant isolates. Study the ability of peptides in inhibiting the biofilm proliferation of *Pseudomonas aeruginosa* isolates.

Methods

The combination of peptides and clinically important antimicrobial drugs was assayed through the disc diffusion method on agar, against multidrug-resistant isolates of *Escherichia coli*, *Staphylococcus aureus* and *P. aeruginosa*. Potential synergy between Ocellatins and ciprofloxacin or ceftazidime against *P. aeruginosa* were further confirmed using a broth microdilution checkerboard method. The inhibition of *P. aeruginosa* biofilm formation by Ocellatin-PT3 was evaluated through 1) the crystal violet assay and 2) microscopic visualization by atomic force microscopy (AFM). The minimum biofilm inhibitory concentration (MBIC) was also determined.

Conclusions

Ocellatin-PT3 showed synergy with ciprofloxacin and ceftazidime against multidrug-resistant isolates of *P. aeruginosa*. The mechanisms behind these synergies must be further explored, however, hypothetically, we can suppose these peptides can increase the membrane permeability, allowing an easier entrance of the antibiotics into the cell. Equally, Ocellatin-PT3 was shown to be very promising in preventing the proliferation of a 24-h mature *P. aeruginosa* biofilm, the MBIC being 8× the MIC.

FEMS-ALAM-SEM workshop: Crosstalk between biofilm formation and applied microbiology

ANTIBIOTIC SUSCEPTIBILITY AND BIOFILM FORMATION OF URINARY ISOLATES OF ENTEROCOCCUS FAECALIS FROM PATIENTS IN CONSULTATION AT THE CHARLES NICOLLE HOSPITAL, TUNIS

R. Chettaoui[1], *G. Mayot*[1], *I. Boutiba*[2], *P. Di Martino*[1]
[1]*Université de Cergy-Pontoise, Laboratoire ERRMECe, Cergy-Pontoise, France*
[2]*Université de Tunis, Laboratoire de Bactériologie de l'hôpital Charles Nicolle de Tunis, Tunis, Tunisia*

Backgrounds

Enterococcus faecalis is a major nosocomial uropathogen.

Objectives

We report here the epidemiological investigation of drug resistance and *in vitro* biofilm formation among *E. faecalis* strains isolated from patients in consultation for presumptive urinary tract infection in the Charles Nicolle Tunisian hospital from October 2015 to March 2016.

Methods

The microbial isolates obtained after urine cultivation on CLED agar were identified by Gram staining, oxidase or catalase reaction, and conventional biochemical tests. The susceptibility to antibiotics was determined by the disk diffusion method according to recommended French standard. Biofilm formation was quantified using the microtiter plate assay and crystal violet staining.

Conclusions

Of the 120 samples analysed, 39% were positive for *Esherichia coli*, 23% for *Enterococcus faecalis*, 10% for *Proteus mirabilis*, 9% for *Candida albicans*, 8% for *Staphylococcus aureus*, 7% for *Enterococcus faecium*, and 5% for *Klebsiella pneumoniae*. The 28 corresponding *E. faecalis* isolates showed systematic resistance to oxacillin, cefalotin, and clindamycin; moderate rates of resistance to pristinamycin, ciprofloxacin, streptomycin, tetracycline and erythromycin; and low resistance frequencies to chloramphenicol, ampicillin and linezolide. All isolates showed susceptibility or intermediate susceptibility to imipenem, rifampicin, teicoplanin and vancomycin. Multi-resistance to at least three different classes of antibiotics was detected in 14 isolates. The patients infected by *E. faecalis* were predominantly men with a mean age of 46.8 years, with an underlying disease. All the 28 *E. faecalis* isolates effectively formed biofilms to varying degrees. The correlation between biofilm formation, multi-resistance to antibiotics, and underlying diseases is discussed.

FEMS-ALAM-SEM workshop: Crosstalk between biofilm formation and applied microbiology

PEL EXOPOLYSACCHARIDE MACHINERY IS INVOLVED IN BIOFILM ARCHITECTURE DEVELOPMENT BY ACIDITHIOBACILLUS THIOOXIDANS

M. Diaz[1], N. Guiliani[1]
[1]University of Chile, Faculty of Sciences - Department of Biology, Santiago, Chile

Backgrounds

Acidophilic bacterial communities from natural environments frequently occur as biofilms, slimes and other macroscopic growth formations on mineral surfaces, streams and water bodies. Several reports emphasized the taxa of *Acidithiobacillus* as a predominant structural and active player in acidophile communities. In addition, the molecular understanding of biofilm formation by *Acidithiobacillus* spp. has been pointed out to design biological strategies to improve the efficiency of bioleaching process. We have previously described the second messenger cyclic diguanylate (c-di-GMP) as a key player for biofilm formation by several *Acidithiobacillus* species.

Objectives

In the course for the characterization of c-di-GMP effectors, we have recently identified a complete *pel*-like operon in *Acidithiobacillus* species only capable to oxidize reduced inorganic sulfur compounds such as *At. caldus* and *At. thiooxidans*. Thus the main goal of this work was to characterize the structural role of Pel exopolysaccharide in biofilm formation by *At. thiooxidans*.

Methods

Here results obtained from biochemical, genetic, microscopy and proteomic analysis will be reported. By using total RNA obtained from planktonic and adhered sulfur-grown cells, transcriptomic analysis revealed that genes belonging to *pel*-like operon are overexpressed in adhered cells. Mutagenesis experiments indicated that c-di-GMP effector PelD is involved in the regulation of biofilm architecture in this microorganism. Proteomic experiments are actually running to characterize long filamentous structures overexpressed in *pelD*- null-mutant strain.

Conclusions

Our current results point out a pivotal role for Pel exopolysaccharide machinery in the attachment to solid energy substrates by *Acidithiobacillus* sulfur-oxidizing species.

This work was supported by Fondecyt 1120295 and 1160702.

DEVELOPMENT OF NOVEL ANTIMICROBIAL AND ANTIBIOFILM PEPTIDES FOR FOOD APPLICATIONS

V. Ghate[1], T. Stern[1], Z. Hayouka[1]
[1]The Hebrew University of Jerusalem - The Faculty of Agriculture, Institute of Biochemistry- Food Science and Nutrition, Rehovot, Israel

Backgrounds

Food-borne diseases have a major health, social, economic and industrial impact. As food production becomes increasingly automated, the number of surfaces which food come into contact with and the potential for cross-contamination increases. Food contamination leads to spoilage and growth of pathogenic microorganisms. Biofim is defined as structured aggregation of surface-attached bacteria encased in an extracellular matrix that leads to bacterial resistance to antibiotics. The difficulty of successfully treating biofilm and the increasing resistance of microbes to traditional treatments demands for the discovery of compounds with novel mode of action to tackle this threat. Host-Defense Peptides (HDPs) are produced by eukaryotes as part of the innate immune response to bacterial infection. These agents represent a potential source of inspiration for development of new antibacterial agents but less is known about their ability to prevent biofilm formation.

Objectives

Designing new approaches to inhibit microbial food contamination and bacterial biofilm formation while maintaining quality, freshness, and safety are required.

Methods

The broad molecular diversity among HDPs suggests that their activity is not tightly coupled to specific features of amino acid sequence or peptide conformation. This situation has inspired us to develop sequence-random hydrophobic-cationic peptides that display antibacterial behavior. We employed solid-phase synthesis in an unconventional way to generate peptide mixtures that contain one type of hydrophobic residue and one type of cationic residue. So far we have demonstrated their broad antimicrobial activity and selectivity towards several pathogenic bacteria. In the current talk we will present our findings on the ability of our compounds to prevent biofilm formation either by inhibiting the initial bacterial adhesion to the surface or by the removal of the established biofilm.

Conclusions

According to our findings the random peptide mixtures are able to control and manage biofilm and might be use as a lead biofilm inhibitor to prevent food contamination.

ELICITING ELECTRON TRANSFER IN ACIDOGENIC BIOCATHODES FROM CHANGES IN THE BIOFILM MICROBIOME

E. Perona-Vico[1,2], R. Blasco-Gómez[2], S. Puig[2], J. Colprim[2], L. Bañeras[1]
[1]Universitat de Girona, Institut d'Ecologia Aquàtica, Girona, Spain
[2]LEQUIA, Institute of the Environment. Universitat de Girona, Girona, Spain

Backgrounds

Microbial electrosynthesis (MES) is acquiring importance as an environment-friendly platform for the production of commodity chemicals from CO_2. In MES, direct and a mediated electron transfer events have been proposed as initial electron harvesting mechanisms. In this sense, a better understanding of the cathode microbiome will help to elucidate which microbial species are likely participating in electron capture.

Objectives

This study aimed to determine the composition of the bacterial community present in electrotrophic biofilms with increasing operation times. Our idea was to test the bacterial populations that remained firmly attached on the electrode, being at the forefront of electron harvesting in electrode-driven acidogenesis.

Methods

Biocathodes basically consisted of a carbon cloth electrode poised at -0.8 V (vs. standard hydrogen electrode, SHE), operated in a two-chambered bioelectrochemical system. Microbial diversity of the biofilms and the bulk liquid was analysed using barcoded amplicon massive sequencing (Illumina®), after two and six months of operation.

Conclusions

Microbial diversity was low in newly developed biofilms (H'=2.8) and significantly increased in older ones (H'=3.5). Despite this change, putative electrotrophic bacteria, such as *Clostridium* and *Sporomusa*, occurred at a high relative abundance (33.83% and 18.18% of sequences, respectively), and appeared from the very beginning of MES operation. The relative abundance of these species **i**ndicates a major involvement of direct electron transfer mechanisms. Electrotrophic bacteria were partially substituted by non-electroactive bacteria (*Cellulomonas* and *Rhodocyclaceae*) probably growing at the expenses of electrically generated acetate. The presented results indicate that preventing growth of heterotrophic bacteria is mandatory to up-scaling MES towards application.

Backgrounds

Campylobacter jejuni is a commensal in poultry but also a human bacterial pathogen that is a predominant cause of enteritis worldwide. Its capsule is an external polysaccharide layer important for colonization and virulence. In most strains, the capsule comprises a modified heptose.

Objectives

To investigate the biological roles and biosynthetic pathways of capsular heptoses.

Methods

This work uses knockout mutagenesis, phenotypic analyses and many types of biochemical assays for carbohydrate analyses and enzymology.

Conclusions

We deciphered the biosynthesis pathways for 6-deoxy-D-*altro*-heptose of strain 81-176 and 3,6-OMe-L-*gluco*-heptose of strain NCTC 11168. This allowed a direct comparison of novel C3/C5 epimerases and C4 reductases involved in these pathways. We determined the activity of 7 enzymes, revealing unexpected functions and specificities and complex regulatory loops. Knockout mutagenesis studies of heptose modifying genes in strain NCTC 11168 showed that heptose modification is not necessary for capsule synthesis but affects bacterial resistance to serum and bile salts, biofilm formation, adhesion to intestinal epithelial cells and their invasion. The mutants also showed slightly decreased phagocytosis by macrophages but no defect for survival inside macrophages. We also demonstrate that heptose modifying genes are important for colonization and persistence of *C. jejuni* in chicken. These findings suggest that fine tuning the capsule composition via heptose modification contributes to host pathogen interactions.

This work provides grounds for the elucidation of similar pathways of other pathogens. It provides new molecular tools to synthesize carbohydrate antigens useful for vaccination and to screen for enzymatic inhibitors with antibacterial effects that could be used to decrease Campylobacteriosis.

RESISTANCE TO THE BACTERIOCIN LCN972 AS DECIPHERED BY GENOME SEQUENCING

S. Escobedo[1], Ö.C.O. Umu[2], A. Rodríguez[1], D.B. Diep[2], B. Martinez[1]
[1]IPLA-CSIC, Technology and Biotechnology of Dairy Products, Villaviciosa-Asturias, Spain
[2]Norwegian University of Life Sciences, Faculty of Chemistry- Biotechnology and Food Science, Ås, Norway

Backgrounds

In view of the current threat of antibiotic resistance, new antimicrobials with low risk of resistance development are demanded. Lcn972 is a lactococcal bacteriocin that inhibits septum formation in dividing target cells by binding to the cell wall precursor lipid II. Moreover, it has a species-specific spectrum of activity, making Lcn972 an attractive template to develop or improve existing antibiotics.

Objectives

Our aim was to identify mutations underlying resistance to Lcn972.

Methods

Whole-genome sequencing (WGS) of the sensitive *Lactococcus lactis* MG1614 (MIC=10 AU/ml) and two Lcn972-resistant (Lcn972R) derivatives D1 and D1-20 with MICs of > 320 AU/ml and 80 AU/ml, respectively, was performed using the Illumina MiSeq platform and Rapid Annotation Subsystem Technology (RAST) server. Sequence reads were assembled with SPAdes 3.1.0. CONTIGuator and Mauve software tools were used for contigs mapping and comparison over the reference genome.

Conclusions

Two previously identified mutations in *L. lactis* D1 and D1-20 were mapped and confirmed by WGS: 1) a 22.6-kbp deletion enclosing genes involved in maltose metabolism, the two component system (TCS) F and the phage infection protein (Pip), and 2) insertion of IS*981* that activates the promoter of *llmg_2447* coding for a putative anti-ECF sigma factor. Additionally, a new mutation was identified, entailing insertion of IS*905* in the promoter of the operon *llmg_0186_celB* that specifies the IIC component of the cellobiose phosphotransferase PTS system. The insertion took place between the putative -35 and -10 promoter regions and the consequences, in terms of promoter activity, are currently under investigation.

DOES THE FOOD PRODUCTION HAS A KEY ROLE IN THE ANTIBIOTIC RESISTANCE BURDEN?

L. Peixe[1], *P. Antunes*[2], *C. Novais*[3]
[1]*Faculdade de Farmácia da Univ. do Porto, Faculdade de Farmácia da Univ. do Porto, Porto, Portugal*
[2]*Faculdade das Ciências da Nutrição da Univ. do Porto, Faculdade das Ciências da Nutrição da Univ. do Porto, Porto, Portugal*
[3]*Faculdade de Farmacia da Univ. do Porto, Faculdade de Farmacia da Univ. do Porto, Porto, Portugal*

Increased antibiotic resistance in nearly all bacteria causing infections challenges the eradication of human infections raising morbidity and mortality. Human exposition to antibiotic-resistant bacteria could occur through a number of routes such as human-to-human spread, environment, direct contact with animals, and also through the food chain. Foods from many different animal sources and in all stages of processing contain abundant quantities of resistant bacteria and resistance genes.

Supported on different studies it has been possible to elucidate the link to animal production of different antibiotic-resistant species, namely of *E. coli* and *Salmonella* resistant to extended-spectrum β-lactams. More recently, the global spread of microorganism with MCR-1 (a protein conferring resistance to colistin, a last resort antibiotic) and the presence of such organisms in livestock raise concerns about the possibility of their dissemination throughout food. Consequently, there is a need for interventions to reduce the use of antibiotics in the animal production and of quick methods for tracking antibiotic-resistant clones in order to assist in the formulation of measures to prevent their potential spread.

ANTIMICROBIAL PEPTIDES AND THE EVOLUTION OF RESISTANCE

D. Ramon[1]
[1], *Paterna, Spain*

During the last five years an increasing amount of information about the composition of the human gut microbiome has been generated. Most of this information has been obtained from healthy volunteers but also description of gut microbiomes from people suffering different pathologies, mainly related with gastrointestinal disorders, has been established.

In our company we have studied the gut microbiome of patients suffering several disorders (celiac disease, atopic dermatitis and psoriasis, unfertility). Changes in the profiles of microbial communities have been detected in all the cases. Taking into account this information we have generated different cocktails of probiotic strains that have been used in clinical trials. The results of these clinical trials are very promising opening the way for the creation of nutritional supplements or functional foods containing these probiotics.

This strategy based on microbiome analysis is actually used for the study of other pathologies in our company. All these results will be presented in the congress.

BIFIDOBACTERIUM LONGUM IPLA20022 IS ABLE TO COUNTERACT THE CYTOTOXIC EFFECT OF CLOSTRIDIUM DIFFICILE UPON HT29 COLONOCYTES

L. Valdés-Varela[1], M. Gueimonde[1], B. Sánchez[1], P. Ruas-Madiedo[1]
[1]IPLA-CSIC, Microbiology and Biochemistry of Dairy Products, Villaviciosa-Asturias, Spain

Backgrounds

Infections caused by *Clostridium difficile* are increasing and constitute a problem due to the high morbidity and mortality rates in groups of risk, being the main aetiological agent of antibiotic-associated diarrhoea. This opportunistic pathogen is a common inhabitant of the intestinal microbiota but starts to proliferate after a microbiota dysbiosis caused by antibiotic treatment. The major virulence factor is the production of different toxins, mainly A and B. In previous works we have selected the strain *Bifidobacterium longum* IPLA20022 as a probiotic candidate being able to *in vitro* reduce the toxicity of *C. difficile* LMG21717 producing both types of toxins.

Objectives

Our aim is to gain insight into the potential mechanisms involved in the ability of IPLA20022 strain to reduce the cytotoxic effect of *C. difficile* upon an intestinal epithelial monolayer obtained from HT29 cells.

Methods

Different cellular fractions were obtained from *B. longum* IPLA20022 and were incubated with *C. difficile*. Afterwards, the cell-free supernatants were tested for their anti-clostridial capability upon HT29 cells using the RTCA (real time cell analyser) technology following the integrity of the intestinal monolayer; the remaining toxins were analyzed by means of ELISA tests. Those bifidobacterial fractions showing capability to reduce the toxicity of *C. difficile* were analyzed by means of proteomic techniques.

Conclusions

Preliminary results show that extracellular factors from *B. longum* IPLA20022 are involved in the reduction of clostridial cytotoxicity. This opens new opportunities for the therapeutically application of the strain, or their metabolites, for attenuating symptoms of *C. difficile* infection.

SURVEY OF THE METABOLICALLY ACTIVE BACTERIAL MICROBIOME OF LYMPH NODES IN SLAUGHTER PIGS, CONFIRMED BY CULTIVATION OF VIABLE BACTERIA AND AMPLICON PYROSEQUENCING

S.U. Wetzels[1,2], *M. Dzieciol*[1], *M. Wagner*[1,2], *S. Schmitz-Esser*[2,3], *E. Mann*[1,2]
[1]*Institute for Milk Hygiene- Milk Technology and Food Science,*
Department for Farm Animals and Veterinary Public Health- University of Veterinary Medicine Vienna, Vienna, Austria
[2]*Research Cluster 'Animal Gut Health', University of Veterinary Medicine Vienna, Vienna, Austria*
[3]*Department of Animal Science, Iowa State University, Ames, USA*

Backgrounds

The exploration of microbiota in lymphatic organs is relevant for tracing of microbial translocations and cross-contamination during slaughter.

Objectives

This study aimed (1) to characterize the bacterial diversity of unreactive ileocecal lymph nodes (ICLNs) of slaughter pigs and to investigate microbiome shifts in enlarged, purulent or granulomatous ICLNs, (2) to characterize viable, cultivable bacteria, and (3) to define the metabolically active bacterial microbiota in lymph nodes.

Methods

Three approaches were used: (1) 16S rRNA gene pyrosequencing from 32 lymph nodes, (2) collection of 209 isolates with aerobic and anaerobic cultivation and near full-length 16S rRNA gene sequencing, and (3) cDNA pyrosequencing, to investigate the lymph node's bacterial metabolically active fraction, including non-cultivable bacteria.

Conclusions

(1) Pyrosequencing yielded 175,313 sequences, clustering into 650 operational taxonomic units (OTUs). OTUs were assigned to 239 genera and 11 phyla. Beside of a highly diverse bacterial community we observed significant shifts in pathologically altered ICLNs. (2) *Proteobacteria* and *Firmicutes* were the most abundant phyla. Purulent and granulomatous ICLNs tended to contain more *Proteobacteria* than asymptomatic and enlarged ICLNs. Isolates could be assigned to 25 species belonging to 17 genera. (3) The number of detected OTUs per lymph node varied highly (23-171 OTUs). *Serratia proteamaculans* (best type strain hits) were most abundant (41.8%). We conclude that (i) lymphatic organs harbor a high diversity of metabolically active bacteria, (ii) the occurrence of viable bacteria in lymph nodes is not restricted to pathological processes and (iii) lymphatic tissues may serve as contamination source in pig slaughterhouses.

Vaccines

NEW TUBERCULOSIS VACCINES: FROM THE DISCOVERY TO CLINICAL EVALUATION IN HIGH-BURDEN COUNTRIES

M. Carlos[1]
[1]*Universidad de Zaragoza, Microbiologia, Zaragoza, Spain*

The only vaccine in use against TB in humans today is BCG, a live attenuated vaccine derived from the bovine pathogen *Mycobacterium bovis*. BCG presents variable protection against pulmonary forms of TB. Genomic comparative studies have shown loss of a number of major mycobacterial antigens and about 23% of *M. tuberculosis*-specific human T-cell epitopes in BCG relative to the human pathogen *Mycobacterium tuberculosis*. MTBVAC is a new live tuberculosis vaccine based on a genetically attenuated *phoP-fadD26*-deletion mutant of *M. tuberculosis*. The presence of stable deletion mutations in two independent virulence genes abrogates the risk of reversion to virulence. MTBVAC has shown a comparable or superior safety and immunogenicity profile to BCG in different preclinical animal models including new-born mice model (Arbues *et al* Vaccine 2013 and Broset *el al* mBio 2015, Aguilo et al JID 2016).

A first-in-human MTBVAC clinical trial was recently completed successfully in healthy adults in Lausanne, Switzerland sponsored by Biofabri (NCT02013245) (Spertini *et al* LRM 2015). In this trial, when MTBVAC was given at the same dose as BCG ($5x10^5$ CFU), there were more responders in the MTBVAC group than in the BCG group, with a greater frequency of polyfunctional $CD4^+$ central memory T cells. MTBVAC is the first live-attenuated *M. tuberculosis* vaccine to enter clinical trials and to date has shown a comparable safety profile to BCG. A notable finding in the first trial was the absence of ESAT-6 and CFP-10-specific T cell responses at the end of the study, suggesting that interferon-g release assays (IGRAs) could be utilized as study endpoints in future efficacy trials to test efficacy against *M. tuberculosis* infection. The immunogenicity data show that MTBVAC is at least as immunogenic as BCG. Altogether these data supported the advanced clinical development in high-burden countries where TB is endemic. A Dose-escalation safety and Immunogenicity study to compare MTBVAC to BCG in newborns with a safety arm in adults is currently ongoing in South Africa sponsored by Biofabri (NCT02729571). MTBVAC is developed with the goal to provide improved efficacy over BCG for use in new-borns, adolescents and adults as a preventive strategy against tuberculosis in high-burden countries (Arregui *et al* PeerJ 2016).

Funding: Biofabri, TuBerculosis Vaccine Initiative (TBVI). BIO2014 5258P and TBVAC2020 643381 Spanish and European grants.

Vaccines

MULTIVALENT COMBINATION OF MTBVAC-BASED VACCINES CONSTRUCTED IN THREE WIDESPREAD LINEAGES OF MYCOBACTERIUM TUBERCULOSIS

I. Perez[1], *C. Martin*[1], *J. Gonzalo-Asensio*[1]
[1]*Universidad de Zaragoza, Microbiología- Medicina Preventiva y Salud Pública, Zaragoza, Spain*

Backgrounds

Despite the existence of a vaccine against TB (BCG), this disease still causes 1.8 millions of deaths per year *(WHO, 2016)*. BCG is based on the cow pathogen *Mycobacterium bovis* and its protection against pulmonary TB in adults is variable. For this reason it has been constructed a new live attenuated candidate vaccine, MTBVAC, based on the human pathogen *M. tuberculosis* from lineage 4 (Euro-American). MTBVAC is currently in clinical trials (phase Ib, NCT02729571) and it is based on the deletions of two virulence related genes (*phoP* and *fadD26*) *(Arbués, Vaccine, 2013)*.

Objectives

Construction the same deletions of MTBVAC in lineage 2 (Asian Beijing) and lineage 3 (African-Indian) of *M. tuberculosis*. These are modern lineages, with together with lineage 4, are highly distributed and the principal responsible of the transmission of TB in humans. Lineage-dependent protection in mouse model will be evaluated.

Methods

Suicide plasmids which contains *phoP* or *fadD26* disrupted by hygromycin resistence gene and a counter-selectable marker will be used. The antibiotic marker will be eliminated using a γδ-resolvase which acts on res sites flanking the resistance marker.

Conclusions

Constructions of MTBVAC-like vaccines are in progress. Phenotypes previously demonstrated in MTBVAC will be studied. These include: lack of cell-wall lipids phthiocerol dimycocerosates (PDIM), diacyltrehaloses and polyacyltrehaloses (DAT/PAT), down-regulated expression of *pks2*, *pks3*, *espA* among others *(Gonzalo-Asensio, PLoS One, 2008*; *Solans PLoS Pathog, 2014)* and the inability to secrete ESAT-6 *(Gonzalo-Asensio, Proc Natl Acad Sci U S A, 2014).*

Vaccines

SEARCHING FOR NEW TAGGED BRUCELOSIS VACCINES AND ASSOCIATED DIAGNOSTIC TESTS

E. Martínez-Gómez[1], Y. Gil-Ramírez[1], J.M. Blasco[2], P. Muñoz[2], M.J. de Miguel[2], A. Zúñiga-Ripa[1], I. Moriyón[1], M. Iriarte[1], R. Conde-Álvarez[1]
[1]Universidad de Navarra, Instituto de Salud Tropical. Microbiology and Parasitology, Pamplona, Spain
[2]Centro de Investigación Tecnología Agroalimentaria CITA del Gobierno de Aragón, Unidad de Sanidad Animal, Zaragoza, Spain

Backgrounds

Brucellosis, a zoonosis caused essentially by *B. melitensis* and *B. abortus*, infects livestock and humans causing heavy economic losses. A complete lipopolysaccharide (LPS) is critical for their virulence. Its O-chain is a homopolymer of N-formyl-perosamine, and carries the immunodominant epitopes.

The only useful vaccines to control brucellosis are smooth (S) live attenuated: *B. melitensis* Rev1 (small ruminants), and *B. abortus* S19 (bovine). However, the differentiation between infected and vaccinated animals (DIVA problem) is difficult, when performed soon after vaccination, since the serological diagnostic tests detect the antibody response against the O-chain that is present in both vaccines and wild-type strains.

Objectives

To develop a *Brucella* tagged vaccine and associated DIVA diagnostic tests by modifiying *Brucella* O-chain.

Methods

We tagged wild-type *B. abortus* LPS by inserting into the chromosome *wbdR,* a gene that encodes an acetyltransferase that adds an acetyl group to the perosamine of *E.coli* O157 O-chain (Ba::Tn7wbdR). We also combined insertion of *wbdR* with deletion of gene *wbkC* encoding the *Brucella* perosamine formyltransferase (Ba::Tn7wbdRΔwbkC). Both Ba::Tn7wbdR and Ba::Tn7wbdRΔwbkC carry LPS with O-chains that contain new N-acetyl perosamine-associated epitopes that are not present in *B. abortus* wild-type LPS. The strains were tested in mice. We also tagged *B. melitensis* Rev 1 vaccine strain with *wbdR* (Rev1::*wbdR)* and tested in sheep. Finally, we developed two associated serological tests (agglutination test and iELISA) for DIVA purposes.

Conclusions

The DIVA tests developed (an agglutination test and an iELISA with S-LPS antigen obtained from Ba::Tn7wbdR) allow the differentiation of mice infected with Ba-parental strain from those infected with Ba::Tn7wbdRΔwbkC or Ba::Tn7wbdR. Moreover these results were confirmed in a preliminary study in the natural host (sheep) using the Rev1::*wbdR*. Thus, introducing *wbdR* into *Brucella* vaccinal background might represent a suitable strategy to solve the DIVA problem in brucellosis.

Bergey's Manual Trust: "Higher taxonomy of uncultivated microorganisms"

GENOME-SCALE DATA RESOLVE PHYLOGENY AND CLASSIFICATION OF VARIOUS BACTERIAL PHYLA

M. Göker[1]
[1]*Leibniz Institute DSMZ, Phylogenomics, Braunschweig, Germany*

Due to the staggering advances in sequencing technology it should now be possible, in principle, to base phylogeny and classification of microorganisms on information from genome-scale data. However, genome sequencing alone will not yield an adequate taxonomic classification of *Archaea* and *Bacteria*. Adequate methods are needed to infer phylogenies from genome-scale data and taxonomic classifications from these phylogenies. This talk first recapitulates the goal of phylogenetic classification and its historic origin. I will then briefly discuss contemporary approaches in microbial systematics in conflict with this goal and comment on the relationship between phenotypic and genomic data with respect to phylogenetic classification. Next, it is discussed why phylogenies and classifications should be derived from genome-scale data despite the prevalence of horizontal gene transfer, which had led some authors to instead conclude that both the idea of a microbial tree of life and the hierarchical classification of prokaryotes should be dismissed. The lack of genome sequences for type strains of major lineages of prokaryotes is, of course, a real obstacle for a genome-based classification of microorganisms, but phylogeny-driven microbial genome sequencing projects such as the Genomic Encyclopaedia of Archaea and Bacteria (GEBA) and the One Thousand Microbial Genomes (KMG) project, which are briefly introduced, are currently solving this issue. Finally, examples for genomic approaches to obtain a phylogenetic classification of distinct phyla of prokaryotes are provided, making use of the data from such projects.

FEMS7-3307
Bergey's Manual Trust: "Higher taxonomy of uncultivated microorganisms"

CALIBRATING UNCULTURED MICROBIAL DIVERSITY WITH A GENOME-BASED TAXONOMY

P. Hugenholtz[1]
[1]*University of Queensland, Australia*

Despite decades of concerted microbiological endeavour, the great majority of microorganisms have not been cultured and characterised. This so-called "microbial dark matter" is now being revealed at an ever increasing rate by sequence-based culture independent methods. In the past few years, thousands of near complete genomes of uncultured microbes have been assembled from sequence data obtained directly from environmental and clinical sources providing the opportunity to fully articulate microbial diversity for the first time. Current estimates suggest that cultured microorganisms only capture ~15% of total microbial diversity based on evolutionary divergence of marker genes. Here we use a genome-based taxonomy founded on the existing classification of cultured organisms to calibrate and quantify the taxonomic diversity of microbial dark matter.

FEMS7-3276
Bergey's Manual Trust: "Higher taxonomy of uncultivated microorganisms"

TO BE OR NOT TO BE A MODERN AND UNIVERSAL TAXONOMY, THAT IS THE QUESTION

R. Rossello-Mora[1]
[1], *Spain*

If we want to describe the vast majority of the living diversity we cannot neglect the relevance of the methodological approach improvements. Thus Taxonomy for Prokaryotes needs to modernize by adapting the new high throughput methodologies to construct a classification that responds to the needs of a wide scientific community. Mass spectrometry for phenotyping, and genome and metagenome sequencing improvements allow a fast and relatively cost-effective recruitment of valuable information, which is currently the basis for understanding microbial diversity.

The new large-scale screening methods as MALDI-TOF MS using whole cell biomass in tandem with 16S rRNA gene sequencing allow a cheap and fast way to identify groups of organisms, putatively representing species. This approach may overcome the single strain species descriptions (SSSD), one of the major problems that taxonomy is facing. In addition and to my opinion, genome sequencing of at least the type strain of the new classified species should become a compulsory and routine requirement for any new description. As derived from the genome sequencing combined with the 16S rRNA gene sequence analysis it is possible to circumscribe most of the taxonomic categories. The submission of genome sequences in public repositories could equalize or (even better) substitute the type material required for any classification. In addition, there is a need to construct a protologue database that is interactive and searchable, linked to all metadata present in repositories, and generating a cumulative repository of taxonomic descriptions. Perhaps in the future these digitalized protologues may substitute the classical protologue texts embedded in the papers describing new taxa. Of course, phenotype needs to take again a major relevance in the description of new-cultured taxa. For this, there is a need to explore new methodologies as high-resolution mass spectrometry to substitute or complement some of the current practices that generally produce irrelevant information.

Finally, the important developments in microbial ecology, especially derived from metagenomic and single cell genomic practices, are generating genetic and genomic information that is of equivalent quality as for the cultured. If we do not want to face a divorce between taxonomy and molecular ecology, actions need to be taken, as (i) giving priority to the candidate taxa names and (ii) recognizing that the genome sequence could well become type material for a stable and universal classification.

FEMS7-3287
Bergey's Manual Trust: "Higher taxonomy of uncultivated microorganisms"

PROSPECTS AND CHALLENGES IN GENOME-BASED CLASSIFICATION OF UNCULTIVATED MICROORGANISMS

T. Long[1], G. Hughes[1], H. Lenwood[2], B. Vinatzer[1]
[1]Virginia Tech, PPWS, Blacksburg, USA
[2]Virginia Tech, Computer Science, Blacksburg, USA

Uncultivated microorganisms present challenges in regard to two core practices in bacterial taxonomy: polyphasic classification and the designation of species type strains. Therefore, uncultivated microorganisms can currently not be classified into validly named species. However, availability of genome sequences for many uncultivated microorganisms makes it possible to reconstruct genome-based phylogenies for uncultivated organisms as precisely as for cultivable organisms. Therefore, a genome phylogeny-based classification of uncultivated microorganisms is attainable. To do this in the absence of valid species names, we have used genome sequences to assign genome similarity-based Life Identification Numbers (LINs) to individual uncultivated microorganisms and to groups of closely related uncultivated microorganisms. LIN assignment was done using a prototype genome database, called LINbase, which efficiently identifies the genome in the database that is most similar to a newly up-loaded genome, calculates the average nucleotide identity (ANI) between the two genomes, and assigns a LIN based on the calculated ANI value. LINbase also provides an intuitive interface to describe any group of related organisms using any kind of metadata and to name these groups with either a validly published Latin binomial, if they represent a species, or in the case of uncultivated organisms, with any user-chosen non-Latin name. Therefore, LINbase offers an easy to use alternative for precisely classifying uncultivated microorganisms based on genome similarity. A demonstration of how to use LINbase will be included in the presentation.

European Culture Collections' Organisation (ECCO): mBRCs: the new vision for culture collections

MIRRI: CONCATENATING CULTURE COLLECTIONS VIA THE EUROPEAN RESEARCH INFRASTRUCTURE

R. Aznar[1]
[1]*Universidad de Valencia, Colección Española de Cultivos Tipo, Paterna, Spain*

MIRRI (www.mirri.org), the 'Microbial Resource Research Infrastructure' is one of the projects included in the 'European Strategy Forum on Research Infrastructures' (ESFRI) 2016 roadmap. It originates from European Culture Collections joint work, from the 80's, to become microbial domain Biological Resource Centres (mBRC) in agreement with the OECD definition and will culminate in the MIRRI launch.

The MIRRI EU funding period ended in April 2016. Negotiations at governmental level are going to decide on the CCU location and to conclude legal issues. Currently, 6 countries have signed the MIRRI MoU supporting the establishment of an ERIC legal structure and up to eight more have taken part on the meetings held with national stakeholders.

Through MIRRI, European mBRCs have strengthened their links and collaborate in different initiatives such as the preparation of the new biotechnology standard (ISO/TC 276), the development of a common strategy for quality assurance across research infrastructures (within CORBEL), participate in the RItrain Horizon2020 project which envisages the development of a new generation of executives of national and international RIs. In addition, they share knowledge concerning the implementation of the Nagoya Protocol, for example producing the MIRRI Access and Benefit Sharing Manual (DOI: https://doi.org/10.5281/zenodo.284881); they cooperate to engage governments in supporting the operative phase of MIRRI.

At national level, mBRCs are key players in driving the MIRRI implementation process and at present many of them are working to create the nodes and/or the structures that will act as the focal points in each country to serve MIRRI coordinated activities, e.g. Laboratory networks in Portugal, Joint Research Units in Italy, Excellence Thematic Networks in Spain.

The spirit of MIRRI keeps alive despite the lack of funding and continues to influence the European life science landscape.

FEMS7-3295
European Culture Collections' Organisation (ECCO): mBRCs: the new vision for culture collections

IMPLEMENTING MICROBIOLOGY EDUCATION AND TRAINING IN DIGITAL ERA

N. Lima[1]
[1]*Centre of Biological Engineering - University of Minho, Centre of Biological Engineering, Braga, Portugal*

Culture collections have a long tradition in training people that directly, or indirectly, are interested in microbial taxonomy and in microbial preservation and management. Academic (PhD and Master), advanced as well as bespoke courses on related topics in this field are regarded of true added value for the educational and microbial research community in Europe. In addition, only with modern and appealing approaches we can reverse the strong decline in numbers of trained microbial taxonomists in Europe that has been observed over the last decades. Gaps in microbial resource management training and potential synergies have been identified and the establishment of an educational community to create a knowledge-based training network and implement lifelong educational and continuing professional development courses for people working within culture collections have been developed. Training courses involved both theoretical and wet laboratory experiences in microbiology not only covering elements of taxonomy and identification of microorganisms but also isolation, characterisation, preservation and use of microbial resources are of the importance. To support these actions e-learning materials for training activities and distance courses need to be implemented with innovative approaches. On top of this, MIRRI is involved on the RItrain (The Research Infrastructure Training Programme, http://ritrain.eu/) Horizon 2020 project. RITrain envisages improve and professionalize the training of managerial and leadership staff in research infrastructures (RIs). This is vital for the future success of Europe because access to excellent RIs underpins the success of today's research and innovation. The successful management and leadership of research infrastructure requires a complex collection of competencies, especially for those working across national borders. A flexible, modular executive master's degree is under development for RI managers and leaders, including executive directors of RIs, heads of finance and administration, heads of Human Resources and communication.

NAGOYA PROTOCOL AND THE EU REGULATION ON ACCESS AND BENEFIT SHARING

G. Verkley[1]
[1]*Westerdijk Fungal Biodiversity Institute - KNAW, Collection, Utrecht, The Netherlands*

Nagoya Protocol and the EU regulation on Access and Benefit Sharing

Gerard J. M. Verkley

Westerdijk Fungal Biodiversity Institute, Uppsalalaan 8, 3584 CT Utrecht, the Netherlands

The Convention on Biological Diversity (CBD), which entered into force on December 29th, 1993, recognizes the sovereign rights of countries over their own biological resources, and aims at fair and equitable sharing of benefits arising from the utilization ('research and development") of genetic resources and associated traditional knowledge. Anyone who intends to access biological resources originating from areas within jurisdiction of a country that is a Party to the CBD, should first request for a Prior Informed Consent (PIC) and settle on Mutually Agreed Terms (MAT) with the competent authority in the country of origin, unless that Party has determined otherwise (for example, is giving free access). The Nagoya Protocol on "Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from Their Utilization" was adopted in Nagoya at the 10th Conference of the Parties of the CBD in 2010 and entered into force on October 12th, 2014. This legally binding treaty implements the CBD's third objective concerning the fair and equitable sharing of benefits arising from the utilization of genetic resources and associated traditional knowledge.

Regulation (EU) 511/2014 implements the Nagoya Protocol in the European Union. It applies from October 12th, 2014, the same day the Nagoya Protocol entered into force for the Union. To support the user community in its efforts to reach ABS compliance, the EC published a 'horizontal' guidance document (Guidance on the EU ABS Regulation implementing the Nagoya Protocol - Guidance on the scope of application and core obligations), to be followed soon by sectorial guidance documents.

MIRRI developed a Best Practice Manual to help microbial Biological Resource Centres (mBRC) to implement their ABS institutional policies with regard to genetic resources and associated traditional knowledge, and working procedures for the deposit of material in the public collection, the supply of cultures to third parties, and the delivery of other services. It also aims to increase transparency on how the mBRCs themselves conduct research on their holdings and lawfully utilize the genetic resources and associated traditional knowledge. This best practice manual was primarily designed for the management of collections of living microbial strains and their derivatives (e.g., DNA samples), but could be useful for all who receive microorganisms, use and supply them to colleagues or others outside their institutions for further use.

INDUSTRIAL SECRET VERSUS PATENT PROTECTION IN BIOTECHNOLOGY

A. Diez Diaz[1]
[1]*PONSIP, Technology Transfer, Valencia, Spain*

In order to provide a wide review of the possibilities and best practices to bring ideas to market I will cover all the aspects related from the initial idea, to key concepts of market research, to review and analysis of Patent databases, concepts on funding, IP strategy, legal aspects of the development of the project, development of the prototypes, networking and sharing information drafting the business plan and landing in the market.

I will pay special attention to how to manage the intangible assets of the invention, under the topic of industrial secret versus patent protection in biotechnology

During the process I will provide tools to answer a number of questions like:

Is my idea a new idea?

What if the idea is just an idea?

Will someone steal the idea?

Will anyone buy the invention?

How will my invention fill the market?

Founding a company in the field of life sciences is associated with high initial investments for proper equipment and also capable minds are required. Scientists who dream of founding a company will find soon find how fierce the competition for ideas is.

Nowadays also investors demand much higher standards of technological validation for start-up ideas. In order to keep their own risk low and only come on board when the prospects of a profit are appropriate and well defined.

PATENT PROTECTION IN MICROBIAL BIOTECHNOLOGY

J. Sherkow[1]
[1]*New York Law School, Innovation Center for Law and Technology, New York, USA*

CRISPR is a revolutionary advance in biotechnology: it allows molecular biologists to edit cells' DNA with ease and precision unimaginable even a decade ago. The technology is also the subject of contentious patent dispute between several universities, and governed by a maze licensing agreements among research institutions, nonprofits, biotech startups, and large pharmaceutical developers. Patents in the CRISPR space illuminate numerous problems—and advantages—of university-based intellectual property for groundbreaking technologies. The CRISPR patents herald the beginning of skepticism over interinstitutional collaboration, especially for lucrative "translational" technologies. And they have encouraged universities—otherwise committed to licensing their patents widely—to invest in for-profit surrogate companies to narrowly manage their license agreements for them. At the same time, CRISPR patents have allowed publicly minded research institutions to retain control over the technology to essentially prevent some of the technology's greatest potential abuses: runaway genetic modifications in the wild, also known as "gene drives"; seed-saving restrictions for agriculture; and germ-line human engineering. This talk will present an overview of these issues and discuss their application to future applications of CRISPR and other significant university-developed technology.

FEMS7-3309
ICSP Session: Role of genome sequence analysis in polyphasic taxonomy and prokaryotic systematic

Do we need the phenotype in the study of the systematics of Acinetobacter?

L. Dijkshoorn[1]
[1]*Department Infectious Diseases, Leiden University Medical Center, Leiden, The Netherlands*

Bacteria of the genus Acinetobacter are widespread in nature and have a complex taxonomic history. In the late 1980s, DNA-DNA hybridization (DDH) studies allowed for recognition of 20 DDH groups within the genus, seven of which were given valid species names. Since the early 2000s, the number of validly named species has risen from 7 to 54 (http://apps.szu.cz/anemec/Classification.pdf). Thirteen novel species descriptions are based on one strain only. Several novel species names are later heterotypic synonyms of previously described species. Furthermore, the genus comprises several groups of closely related species ('complexes'), members of which are difficult to distinguish phenotypically.
Novel species are, as a rule, identified using a polyphasic approach, i.e. a combination of phenotypic and genotypic methods. Recent methods for Acinetobacter include genomics (ANI), rpoB sequence analysis, mass spectrometry, analysis of fatty acids (and/or other chemotaxonomic markers), and metabolic and physiological characterization. The latter is based on a panel of ca. 40 in-house growth tests, which is more or less a standard requirement. This system is difficult to perform and no single test can be used to delimit the species. Chemotaxonomic markers have been used in a number of studies, but not systematically; markers vary and there are no libraries to compare results to. Altogether, despite the required phenotypic description in the proposal of novel species, this description does not seem to have great impact on the taxonomy of Acinetobacter. The question is whether there are alternatives for the current phenotypic characterizations or whether they can be abandoned.

ICSP Session: Role of genome sequence analysis in polyphasic taxonomy and prokaryotic systematic

POLYPHASIC TAXONOMY: STILL JUSTIFIED OR FORCE OF HABIT?

I. Sutcliffe[1]
[1]*Northumbria University, Applied Sciences, Newcastle upon Tyne, United Kingdom*

Microbial systematics provides an essential framework for the activities of all microbiologists (and other biologists) and is of increasing importance as we engage with the task of mapping microbial diversity, of which we may have only seen the tip of the iceberg. However, whilst 16S rRNA based-phylogenetic methods revolutionised microbial systematics in the late 20th century, over the past two decades the discipline has become rather conservative and formulaic, constrained by the straightjacket of the 'polyphasic' taxonomic approach to describing novel taxa (most commonly at the genus/species levels). In the same period, the advent of affordable whole genome sequencing and the definition of increasingly well-established thresholds for delineating taxa using various measures of overall genome relatedness has the potential to shepherd in an era of genome-based systematics. This should circumvent the problem that many of the phenotypic and chemotaxonomic tests commonly performed as part of the 'polyphasic' taxonomic approach are of questionable value (including poor resolution, reproducibility and a lack of specialist expertise), particularly as descriptions of taxa based on single strains remain the norm. Thus the necessity for continuing with many routine 'polyphasic' methods can be strongly questioned. Nevertheless, there appears to be some reluctance on behalf of the microbial systematics community adopt genomics-based approaches and also other powerful new technologies such as MALDI-MS based typing. New initiatives, including the likely introduction of new publication formats and databases, are thus needed in order to sustain systematics as an attractive career choice for 21st century microbiologists.

ICSP Session: Role of genome sequence analysis in polyphasic taxonomy and prokaryotic systematic

PHENOTYPIC CHECKLISTS: WHAT ARE THE ALTERNATIVES?

S. Venter[1], K. Maier[1], M. Palmer[1], J. Avontuur[1], W.Y. Chan[1], E. Steenkamp[1]
[1]University of Pretoria, Microbiology and Plant Pathology, Pretoria, South Africa

For many years bacterial taxonomist had to rely on phenotypic differences to characterize and identify species as it provided a measurable set of traits that could be used to distinguish among taxa. Over time this has caused strong dependence on a few commercial phenotyping systems, which seldom provide meaningful information on the biology of the bacterium. However, with the availability of whole genome sequences, bacterial diagnostics no longer needs to rely on this data. Apart from phylogenomics studies, genome data also provide the opportunity to deduct biologically relevant phenotype of the bacteria. Currently these predictions are based either on the construction of metabolic networks or by using specific trait predictor software. In this study, two such approaches were evaluated using a potential novel species closely related to *Bradyrhizobium pachyrhizi*. Although a number of common traits could be predicted and several shared and unique metabolic pathways were detected, a large part of these genomes could still not be linked to any function. The trait predictor software used is also limited in its scope and biological relevance. The focus of future research should be on improving the functional annotation of hypothetical proteins. These annotations will be crucial for the development of comprehensive genotype-phenotype association databases, which can be used for the predicting phenotypes and traits informative of the biology of the bacterial species under investigation. The focus of the phenotypic data collected should therefore shift from diagnostics-centered data to the characterization of the biology of the organism.

FEMS7-3279
Scientific publication explained: How to increase (or decrease) your chances of rejection

NAVIGATING THE PUBLICATION FOREST AND MAKING EDITORS AND REVIEWERS HAPPY

P. Bavoil[1], *M. Pacey*[2]
[1]*University of Maryland, School of Dentistry, Baltimore, USA*
[2]*Oxford University Press, FEMS Journals, Oxford, United Kingdom*

FEMS publishes five internationally recognised, peer-reviewed microbiology journals, all of which will be represented at the Congress and in the scientific programme. This workshop exploits the expertise of the editorial and publishing staff of the FEMS journals to take attendees from the preparation of research papers through to publication.

Through presentations, and a question and answer session with FEMS journals Editors-in-Chief, you will understand:

• what editors, reviewers and readers are looking for from authors
• how to organise and structure a paper to optimise presentation of your research
• the online submission process• the peer review process
• how to deal with comments from editors and reviewers
• what happens to a paper after acceptance for publication
• how to choose the best journal for you and your research
• open access requirements
• modern features available from the leading journals.

All may attend, but the workshop is particularly relevant to postgraduate, postdoctoral and early career researchers who wish to learn more about the publishing process.

GENOME INFORMATION PROVIDES OBJECTIVE DATA FOR THE DESCRIPTION OF NEW BACTERIAL SPECIES, SO WHAT CAN GO WRONG?

A. Pérez-Cataluña[1]
[1]*University Rovira i Virgili, Basic Health Sciences, Reus, Spain*

Backgrounds

The number of bacteria genomes has increased exponentially in recent years and new tools for defining species have been developed. However, old and classical problems still remain i.e. existence of mislabelled genomes, which impact the results of any comparison. Other problems are associated to the fact that many are draft genomes of different qualities.

Objectives

To analyse these problems using our experience with the genus *Aeromonas* and *Arcobacter.*

Methods

We have analyzed deposited genomes of *Aeromonas* and *Arcobacter* from databases and re-evaluate their identity using ANI, *is*DDH and multilocus phylogenetic analysis (MLPA). Sequences of several housekeeping genes (*atpA*, *gyrA*, *gyrB*, etc), and of the 16S rRNA genes were retrieved from the genomes to construct trees that included the same genes for all the type strains.

Conclusions

Using these tools we have discovered that 36% of the studied *Aeromonas* genomes were mislabelled and genomes deposited as *Arcobacter* sp. could be assigned to known species. Considering these findings we recommended verifying the correct identity of a genome sequence using ANI, *is*DDH or MLPA before it is submitted to the database or used for any comparison. In addition 16S rRNA gene sequences available on those genomes were sometimes incomplete. Genomes labelled with incorrect names lead other authors to incorrectly suggest lowering the well-established ANI cut-off value (>96%) for the genus *Aeromonas* to 94-95%. So sequences and genomes are objective data, however, errors can still arise by a wrong interpretation of results.

FEMS7-2762
SEM-FEMS-ASM: Omics impact and perspectives on the microbial taxonomy, diversity and ecology

MINING THE ENVIRONMENT FOR NEW EUKARYOTIC DIVERSITY

R. Massana[1]
[1]*Institut de Ciències del Mar, Marine Biology and Oceanography, Barcelona, Spain*

Backgrounds

Microbial eukaryotes are integral members of marine ecosystems in terms of cell abundance, biomass, activity, and diversity and they play crucial roles in food webs and biogeochemical cycles. They are difficult to grow in culture and often cannot be identified by regular microscopy, so a variety of molecular tools have been applied to study their diversity.

Objectives

The objective is to identify the main microeukaryotic players in marine planktonic ecosystems and to determine the ecological performance of novel lineages.

Methods

Microeukaryotic diversity is first described by sequencing a phylogenetic marker gene from mixed assemblages, and then supported by PCR-free metagenomes. Specific probes are designed to target novel lineages by FISH (Fluorescent In situ Hybridization). Single cell genomics is used to access the genomes of uncultured cells.

Conclusions

Environmental molecular surveys have unveiled a large phylogenetic diversity and the presence of novel diversity. In this talk I will focus on a set of novel lineages within the stramenopiles that account for a significant fraction of the molecular signal, the MAST lineages. The abundance, distribution and genetic structure of the main MAST groups in the marine environment will be presented using specific probes for direct observation by FISH and parallel sequencing surveys using community DNA. MAST cells are also well represented in a collection of SAGs (Single Amplified Genomes) prepared from open sea surface samples, and preliminary genomic data for these uncultured cells will be presented. Certainly, the ecological and evolutionary significance of novel protist diversity is remarkable.

SEM-FEMS-ASM: Omics impact and perspectives on the microbial taxonomy, diversity and ecology

GENOMIC INSIGHTS INTO SPECIES AND TRANSLATION OF THIS INSIGHT FOR ASSESSING SOIL MICROBIOMES

J. Tiedje[1]
[1]*Michigan State University, Center for Microbial Ecology, East Lansing, USA*

Backgrounds

Use genomic information for species resolution has gained traction over the last decade with the development and use of average nucleotide identity (ANI) and average amino acid identity (AAI) as well as use of other generally common protein coding genes. This greatly helps the resolution of taxa below the genus and especially the species level, which is the level necessary for ecologically meaningful assessment.

Objectives

The next stages needed are to use genomic information to provide some insight into ecological functions, and to resolve communities at the ecotype level, in effect narrowing the gap between sequence and ecological outcomes. To enable this, methodology is needed to assess species and ecotypes in complex communities with soil arguably the most complex at a small scale.

Methods

I will show examples of evaluating functions along a gradient of increasing genetic differences with agenus, of using the environment to reveal functional differences that reflect specialized physiologies, of characterizing diversity at a small environmental scale, and of using metagenomic sequence to assess diversity and composition at the ecofunctional and marker gene levels, and to quantify those components in communities.

Conclusions

This information provides deeper insight into the taxonomic composition to species and ecotype levels, spatial patterns and functional capabilities of soil and rhizosphere microbiomes.

AMR, public awareness, policies

AMR STRATEGY – FUTURE CHALLENGES FOR POLICYMAKING

E. Smith[1]
[1]*RAND Europe, Innovation- Health and Science, Cambridge, United Kingdom*

Antimicrobial resistance (AMR) is a public health challenge of global importance, as exemplified most recently by the UN Political Declaration on AMR. The UN Declaration demonstrates the recognition of AMR as a serious global threat by national governments and expresses unified political commitment to tackle the challenge. It also represents a remarkable result of sustained efforts to raise the profile of AMR and communicate the scale of the challenge to a wide global audience. Policy initiatives at many levels are now underway to tackle the issue at national, regional and international levels spanning the areas of new drug development, stewardship of existing antimicrobials and surveillance of their use. My talk explores the approaches being taken to address AMR in different policy contexts.

PRIORITIES IN OUR COMBAT OF ANTIMICROBIAL RESISTANCE
J. Prof Dr[1]
[1]*Radboudumc, Medicine, Nijmegen, The Netherlands*

PRIORITIES IN OUR COMBAT OF ANTIMICROBIAL RESISTANCE

Jos W.M. van der Meer

European Academies Science Advisory Council (EASAC)

and Radboud University Medical Centre, Nijmegen, The Netherlands

The discovery and development of antimicrobial drugs during the past three quarters of a century has been one of the major advances in medical sciences. Not only did these drugs contribute to the combat of prevalent infectious diseases, but they also allowed great progress in many other areas of medicine (such as intensive care medicine, sophisticated surgery and cancer chemotherapy).

Over the past decade, the resistance of microorganisms (especially bacteria) to antimicrobial drugs has dramatically increased and reached crisis proportions. The major causes of this are twofold. First of all, the indiscriminate use of antimicrobial drugs in humans, animals and agriculture has led to immense selection pressure on microorganisms, leading to widespread resistance.

Secondly, the development of new antimicrobial drugs is stagnant since the 1980s. The current situation is that worldwide many bacterial infections are not treatable anymore.

Solutions to tackle this crisis are essentially:1. Implementation of restrictive and prudent use of antimicrobial drugs in the areas mentioned above (antibiotic stewardship).
2. Development of new antimicrobial drugs and treatment strategies.

The European Academies Science Advisory Council (EASAC) has called for attention to this problem since 2007. In 2014, an EASAC workshop identified the major obstacles in drug development, and in 2016, EASAC, together with the Federation of Academies of Medicine (FEAM), amended the recommendations formulated by O'Neill and proposed the priorities for Europe.

Although many organisations in the world (including UN and WHO) are intensively involved, it is clear that only with a number of breakthroughs the current crisis can be tackled.

Antibiotics, novel approaches

DEVELOPING NOVEL ANTIMICROBIALS AGAINST GRAM-NEGATIVE PATHOGENS

O. Kuipers[1], M. Montalban-Lopez[2], J. Deng[1], Q. Li[1], A. Buivydas[1]
[1]University of Groningen, Molecular Genetics, Groningen, The Netherlands
[2]Faculty of Sciences University of Granada, Department of Microbiology, Granada, Spain

Developing novel antimicrobials against Gram-negative pathogens

Oscar P. Kuipers, Li Qian, Jingjing Deng, Andrius Buivydas, Manuel Montalbán-López

Department of Molecular Genetics, University of Groningen; o.p.kuipers@rug.nl

Antibiotic resistance in human pathogens is on the rise and this increase is not met with new approved antibiotics to combat these resistant bacteria. To solve this growing problem of resistance, alternative sources of antibiotics should be explored. One of these sources could be the class of ribosomally synthesized, post-translationally modified peptides called lantibiotics. Lantibiotics are well studied peptides that are stabilized by their characteristic rings formed with lanthionine or methyllanthione residues out of dehydrated Ser- and Thr-residues. We'll describe two different approaches to develop novel antimicrobials:

1. Biomodules for introducing various types of circular and heterocyclic modifications in lantibiotics.
2. Apply outer membrane perturbing agents to potentiate lantibiotic variants against Gram-negative pathogens.

FEMS7-0075
Antibiotics, novel approaches

ANTIBIOTICS FOR KILLING PERSISTER CELLS

K. Lewis[1]
[1]*Northeastern University, MA, USA*

We are experiencing an antibiotic crisis – our ability to discover novel compounds has diminished, and pathogens acquire and spread resistance largely unchecked. In chronic infections, the problem is exacerbated by the presence of dormant persister cells tolerant to killing by all antibiotics. As a result, chronic osteomyelitis or infections of patients with cystic fibrosis can be untreatable. In *E. coli*, stochastic expression of toxin/antitoxin modules contributes to persister formation. In *S. aureus*, we find that persisters are cells with a low level of ATP. This finding prompted us to revisit persister formation in *E. coli*, where we find a similar mechanism. A decrease in ATP is a general, and probably main, mechanism of persister formation in bacteria. A decrease in ATP provides a satisfactory explanation for the presence of drug tolerant persisters. Currently available bactericidal antibiotics kill by corrupting ATP-dependent targets such as protein or peptidoglycan synthesis. When ATP is low, targets are inactive, and cells become tolerant to killing. We identified two compounds that kill persisters without a requirement for ATP. Acyldepsipeptide dysregulates the Clip protease, forcing the cell to self-digest. Lassomycin, which we discovered from a screen of uncultured bacteria, activates the ClpC1 chaperone of the mycobacterial Clp protease, forcing it to digest ATP. We also developed a general approach to eradicate persisters with pulse-dosing of antibiotics. Teixobactin, an antimicrobial essentially free of resistance development, eradicates persisters when periodically applied to a culture of *S. aureus* in which persisters are allowed to resuscitate after application of the antibiotic.

Antibiotics, novel approaches

INNOVATIVE ANTIBIOTICS FROM MICROBES: IDENTIFICATION, MODE OF ACTION AND RESISTANCE MECHANISMS

R. Müller[1]
[1]*Helmholtz Institute for Pharmaceutical Research Saarland, Microbial Natural Products, Saarbrücken, Germany*

Microorganisms are accepted as a valuable source for chemical biology tools and drug leads. An outstanding group of microorganisms is represented by the ubiquitous myxobacteria, a largely underexploited resource for natural products (NP). Analyzing the few myxobacterial genomes known to date leads to the conclusion that they contain up to 50 respective biosynthetic gene loci per strain indicating the enormous genomic potential for the production of NPs. However, only few compounds are typically known per microbial isolate. In a comprehensive MS-based study we have addressed the question of compound diversity in correlation with phylogenetic diversity and found clear and measurable evidence that new compounds are most likely to be found in currently uncharacterized microbial genera and families.

Once novel microbial NPs are identified, their potential as antibiotic drug leads is analyzed by defining pharmaceutical properties and potential resistance mechanisms of pathogens against the compound. Target identification, which is usually a complex and rather unpredictable biochemical research endeavour, has become essential for drug development for numerous reasons including the possibility to rationally optimize lead compounds based on their molecular structure-target-complex. During the last decades genomics has become an integral part of NP drug research and allows not only for directed approaches to discover new natural products: Target identification might be achieved by studying self-resistance mechanisms within the producer strains or, alternatively, by defining the molecular basis of resistance in pathogens by whole genome sequencing of evolved bacterial resistance.

The presentation will cover some examples of novel antibiotics and target identification of microbial NPs.

FEMS7-3311
Bacterial persistence and toxin - antitoxins

TOXIN-ANTITOXIN SYTEMS AND THEIR CHAPERONES

G. Pierre[1]
[1]*CNRS Toulouse University, LMGM/CBI, Toulouse, France*

Ambre SALA, Patricia BORDES, Sara AYALA, Pauline TEXIER, Nawel SLAMA, Anne-Marie CIRINESI, Valérie GUILLET, Lionel MOUREY, Samuel TRANIER, Marie-Pierre CASTANIE-CORNET and Pierre GENEVAUX

Abstract Bacterial type II toxin-antitoxin (TA) systems are small genetic modules typically composed of a toxin and a more labile cognate antitoxin, which binds and inhibits the toxin. In response to certain stress the antitoxin is rapidly degraded by proteases and the free active toxin generally targets essential cellular processes, leading to a reversible growth inhibition known to facilitate bacterial persistence to drugs, virulence and survival in response to environmental insults. *Mycobacterium tuberculosis*, the causing agent of human tuberculosis, encodes 79 putative toxin-antitoxin systems and it has been proposed that persistence induced by active toxins might be relevant for its pathogenesis. Tripartite TAC modules are atypical TA systems composed of a conserved two-component TA that is specifically controlled by a molecular chaperone related to the canonical SecB chaperone known to facilitate protein export in bacteria. In this case, the SecB-like chaperone interacts with the TAC antitoxin and protects it from both aggregation and degradation, and is thus strictly required for neutralization of the toxin by the antitoxin. How does the mycobacterial SecB-like chaperone control the toxin activation cascade, and to what extent such activation is important for *M. tuberculosis* persistence and virulence are so far unresolved questions. Herein we investigate the molecular mechanism by which classical TA systems can turn into chaperone-addicted modules as well as the specialization events that redirect a generic export chaperone towards the control of TA systems.

Bacterial persistence and toxin - antitoxins

BACTERIAL MULTIDRUG TOLERANCE, MAGIC SPOT AND TOXIN – ANTITOXINS

S. Semsey[1], *A. Harms*[1], *K. Syal*[1]
[1]*University of Copenhagen, Department of Biology, Copenhagen N, Denmark*

Bacterial persister cells evade antibiotic-induced killing by entering a physiologically slow-growing state and may cause antibiotic treatment failure and relapsing infections. Persister cells form both stochastically and in response to environmental cues, by various pathways that are usually controlled by the second messenger (p)ppGpp. Remarkably, both type I and type II toxin-antitoxin (TA) modules have been suggested to play significant roles in persister formation in several model systems. Thus, the type I TA module *hokB*/*sokB* of *Escherichia coli* K-12 induces persistence by a mechanism that depends on (p)ppGpp and the universally conserved Obg GTPase. In contrast, type II TA modules (e.g. *relBE*, *mazEF*, *tacAT* etc.) induce persistence via a pathway that depends on (p)ppGpp, Lon and polyphosphate, not only in *E. coli* but also in *Salmonella enterica*. More recently, it was shown that upregulation of drug efflux pumps (e.g. TolC) cells may also contribute to the formation of persisters. Thus, persister cells are heterogeneous, formed by multiple pathways that may be activated independently or in parallel. The latest developments in the persistence field will be discussed.

FEMS7-2613
Bacterial persistence and toxin - antitoxins

SALMONELLA FORMS INTRACELLULAR PERSISTERS WITH TACT

S. Helaine[1]
[1]*Imperial College London, CMBI, London, United Kingdom*

Persister bacteria are non-growing, antibiotic insensitive cells, the progeny of which are sensitive to antibiotics. Bacterial persistence is a common phenotype expressed by a large number of bacterial species and is thought to be responsible for relapsing infections. During *Salmonella* infection of macrophages an important proportion of bacteria enter a persister state via the action of class II toxin-antitoxin modules. These toxin-antitoxin modules encode a stable toxin that inhibits a vital cellular process and a labile, neutralising antitoxin, which is degraded under conditions of stress but otherwise binds and inactivates the toxin. We investigate the activity of three of these toxins, which are acetyltransferases and how bacteria recover from the persistent state.

FEMS7-0082
Biofilms, formation and persistance

TOWARDS KNOWING THE ENEMY: INVESTIGATION OF BACTERIAL PERSISTER PHYSIOLOGY

M.P. Brynildsen[1]
[1], *USA*

Bacterial persisters are phenotypic variants with extraordinary tolerances toward antibiotics. Persister survival during antibiotic stress has been attributed to inhibition of essential cell processes, which prevents antibiotics from corrupting their primary targets, followed by reversion to normal physiology upon removal of the antibiotic. In recent years, many studies have shed light on the genetic basis of persistence by identifying genes whose presence, absence, or abundance alter the levels of persisters in bacterial populations. However, far less is known about the physiology of persisters and how that confers survival under antibiotic stress. For example, little is known about the response of persisters to antibiotics, although the phenotype is defined based on the outcomes of antibiotic treatments. Lack of growth is a phenotypic quality that increases the likelihood bacteria would be persisters; however, most non-growing cells succumb to antibiotic treatments and it remains ill-defined what other phenotypic qualities differentiate persisters from non-persisters in growth-inhibited populations. In this talk, I will discuss my group's recent work to characterize persister physiology in order to gain a more mechanistic understanding of how persisters survive in the face of certain death.

Biofilms, formation and persistance

DYNAMICS OF RESPONSIVENESS OF BIOFILM BACTERIA

S. Haeussler[1], M. Muesken[1]
[1]Helmholtz Centre for Infection Research, Molecular Bacteriology, Braunschweig, Germany

DYNAMICS OF RESPONSIVENESS OF BIOFILM BACTERIA

Many efforts to decrease the burden of chronic infections have been made; however in spite of the initial enthusiasm and the huge literature on the identification of novel anti-biofilm compounds, to date no antimicrobials are in clinical use to specifically treat biofilm infections. An alternative option to the search for new anti-biofilm compounds is to concentrate on enhancing the activity of today´s antibiotics. Antibiotics are *very effective* in the *treatment* of bacterial infections. However, their use in the successful eradication of biofilm-associated infection relies on our ability to overcome two main problems. First, there is a need for knowledge on the resistance profile of the individual infecting bacterial isolate under biofilm-growth conditions. The replacement of susceptibility testing of planktonic bacteria by biofilm-specific resistance profiling in individual bacterial isolates might allow for a targeted anti-biofilm therapy. In addition, new treatment strategies that promote antimicrobial efficacy of antibiotics in clinical use will have to be developed to overcome the second limitation of current treatment, which is the incomplete killing of the biofilm population. New treatment regimens need to be adapted to accommodate killing of high density biofilm-associated infections and which avoid the Sisyphean fate of fast killing and reconstituting regrowth of bacterial biofilm populations.

FEMS7-3318
Biofilms, formation and persistance

IDENTIFYING GENES UNDER ADAPTIVE EVOLUTION DURING BACTERIAL BIOFILM DEVELOPMENT

J. Webb[1]
[1]*University of Southampton, Biological Sciences, Southampton, United Kingdom*

Title: Identifying genes under adaptive evolution during bacterial biofilm development

Growth of bacteria within biofilms can quickly lead to within-population genetic diversity; but the generation of this diversity and the dynamics of evolution with bacterial biofilms remain poorly understood. By using genomic approaches, we have examined genetic diversification that occurs during biofilm formation of *Streptococcus pneumoniae* and *Pseudomonas aeruginosa*. For both organisms, we discovered extensive parallel evolution between biological replicates. For *P. aeruginosa*, we used deep sequencing to carry out studies of within-population genetic diversification occurring during biofilm formation. Parallel evolution occurred between biological replicates, at the level of pathways, genes, and even individual nucleotides. For *S. pneumoniae,* whole genome sequencing of 12 colonies with a small-colony variant (SCV) phenotype, each from independent biofilm experiments, revealed that all SCVs studied had mutations within the DNA-directed RNA polymerase delta subunit (RpoE). These studies show that biofilms very generate very strong selection for certain mutations which is providing new understanding of genes that are central to biofilm development.

KILLING FOR NEW GENES - HOW VIBRIO CHOLERAE STEALS DNA FROM NEIGHBORING BACTERIA

M. Blokesch[1]
[1]*Swiss Federal Institute of Technology Lausanne EPFL, School of Life Sciences, Lausanne, Switzerland*

Killing for new genes - how *Vibrio cholerae* steals DNA from neighboring bacteria

Vibrio cholerae, the causative agent of cholera, is considered to be an important model organism for studying infectious diseases. However, compared to its pathogenic potential in humans, much less is known about the bacterium's lifestyle in its primary habitat, the aquatic environment. Such environmental habitats often contribute to pathogen emergence, which is frequently accomplished through the acquisition of novel genetic information by means of horizontal gene transfer (HGT). Natural competence for transformation as a mode of HGT plays a key role in bacterial evolution and *V. cholerae* enters the competence state upon growth on chitinous surfaces.

In this talk, I will give a brief summary about the regulatory network that drives competence in *V. cholerae*. I will also show genetic and imaging-based data that illustrate that the type VI secretion system (T6SS) of diverse pandemic *V. cholerae* strains is part of the competence regulon. T6SS is a molecular killing device, and it fosters HGT by the deliberate killing of neighboring bacteria followed by the absorption of their DNA. The extent of such DNA transfer events has not been investigated in the past. We have addressed this lack of knowledge through the analysis of transformants. These data provide evidence for the transfer of chromosomal stretches of significant length. I will conclude my presentation with the hypothesis that competence-induced kin-discriminated neighbor predation linked to DNA uptake might be a common biological theme.

EVOLUTION OF BACTERIA COLONIZING THE INTESTINAL TRACT: MUTATION VERSUS HORIZONTAL GENE TRANSFER EVENTS AS DRIVERS OF ADAPTATION

I. Gordo[1], *N. Frazão*[1]
[1]*Instituto Gulbenkian de Ciência, Evolutionary Biology, Oeiras, Portugal*

The contribution of mutation relative to horizontal gene transfer (HGT) to the evolution of bacteria inhabiting the gut microbiota is currently unknown. Here we use an *Escherichia coli* strain colonizing specific pathogen free mice to unravel the relative role of these two mechanisms for the emergence of strain diversity within the microbiota of the mammalian intestine. Through experimental evolution, next generation sequencing, phenotypic assays and microscopy we reveal the rapid occurrence of multiple HGT events, mediated by phages from the resident microbiota, to the colonizing *E. coli*. We further show that the ecological context in which colonization with a new lineage occurs is a key determinant of the mechanism of its future evolutionary change. We find that *E. coli* evolution is dominated by phage-mediated HGT when its direct competitors are present in the microbiota at high abundance, whereas otherwise it is dominated by mutation accumulation. Furthermore we demonstrate that the genome integration of incoming phages by the new *E. coli* colonizer results in immunity against phages produced by its resident competitors, allowing coexistence between phylogenetic groups A and B1 strains of *E. coli* in the mouse gut.

SIGNATURES OF RECENT EMERGENCE IN BACTERIAL PATHOGENS

J. Parkhill[1]
[1], *United Kingdom*

Identifying the mode of transmission and acquisition of nosocomial pathogens is of crucial importance in designing effective surveillance and intervention for infection control in hospitals. We have used large-scale, systematic, longitudinal surveys of important multi-drug resistant (MDR) pathogens causing bloodstream infections in UK hospitals to understand the population structure of these organisms. Whole genome sequencing and phylogenetic reconstruction of these isolates allows us to accurately reconstruct the population history of these MDR pathogens across the UK and Ireland. These population histories demonstrate two clear modes of transmission: recent clonal spread within and between hospitals, and older, more diverse populations indicative of commensal spread within the wider population. Understanding these differences will enable tailored infection control procedures to minimise nosocomial acquisition of these important pathogens.

METABOLIC DIVERSITY OF THERMOPHILIC PROKARYOTES: NEW GROUPS, NEW PROCESSES

E. Bonch-Osmolovskaya[1]
[1]*Federal Research Center of Biotechnology RAS, Winogradsky Institute of Microbiology, Moscow, Russia*

Thermophilic microbial communities are actively studied during past three decades. However, the representatives of new phylogenetic and metabolic groups of thermophiles could still be isolated. Here we describe new lithoautotrophic and organotrophic bacteria from volcanic and subsurface thermal habitats.

Volcanic environments are rich in sulfur compounds which can be used by microorganisms in catabolic processes. We found that a phylogenetically diverse thermophilic lithoautotrophs of phyla *Thermodesulfobacteria* and *Deltaproteobacteria* are capable to grow by disproportionation of elemental sulfur, thiosulfate or sulfite. They belong to new genera *Thermosulfurimonas, Dissulfuribacter, Dissulfurimicrobium, Dissulfurirhabdus*, as well as to the previously known genus *Caldimicrobium* that was found to play a pivotal role in Kamchatka Peninsula (Russia) hot springs. Representatives of genera *Thermosulfurimonas* and *Dissulfuribacter* were also found to be able to couple elemental sulfur oxidation with reduction of nitrate to ammonia. Another new metabolic group of sulfur-metabolizing thermophilic lithoautotrophic bacteria is that of obligate hydrogen-oxidizing sulfite reducers represented by *Thermodesulfitimonas* gen. nov.

Thermophilic microorganisms capable to degrade polymeric substrates are, in majority, obligate anaerobes with fermentative metabolism. We found two phylogenetic groups of bacteria that can hydrolyze polymeric substrates in the course of anaerobic respiration. Thermophilic planctomycetes of genera *Thermogutta* and *Thermostilla* grow anaerobically on various polysaccharides reducing nitrate or elemental sulfur, while bacteria of genus *Melioribacter* (phylum *Ignavibacteria*) utilize cellulosic substrates in the course of nitrate, iron or arsenate respiration. Thus, the anaerobic process of complex organic substrates mineralization is performed by a single microorganism and not by a complex microbial community as it is usually assumed.

DISCOVERY OF CARBOHYDRATE ACTIVE ENZYMES FROM HYPERTHERMOPHILIC MICROORGANISMS: GENOME AND METAGENOME

M. Moracci[1], A. Strazzulli[1], R. Iacono[2], R. Giglio[2], L. Maurelli[2], B. Cobucci-Ponzano[2]
[1]University of Naples "Federico II", Department of Biology, Naples, Italy
[2]National Research Council, Institute of Biosciences and BioResources, Naples, Italy

Hyperthermophilic Bacteria, Archaea and viruses, populating marine and terrestrial hydrothermal sites, are of interest as a source of biocatalysts because of their uncommon resistance to heat and other protein denaturants, making them attracting tools for industrial applications. In particular, carbohydrate active enzymes (CAZymes) from these sources have recognized application for innovative bioprocesses as the saccharification step of the pretreatment of lignocellulose biomass for second generation biorefineries.

In the framework of the discovery of new CAZymes for biocatalysis and biotransformations for industrial applications, we identified novel glycosidases from sequenced genomes from (hyper)thermophiles and metagenomes obtained from hydrothermal vents. Their characterization and exploitation in enzymatic cocktails for the conversion of biomass from an energy crop will be discussed.

METAGENOMICS OF HYPERSALINE ENVIRONMENTS: THE CASE OF SPIROBACTER

A. Ventosa[1], *M.J. León*[1], *B. Vera-Gargallo*[1], *C. Sánchez-Porro*[1]
[1]*University of Sevilla, Department of Microbiology and Parasitology, Sevilla, Spain*

Hypersaline environments are widely distributed on our planet. They are represented by aquatic as well as by saline terrestrial habitats. However, most microbiological studies have been focused on saline aquatic systems, which are classified as thalassohaline and athalassohaline habitats, depending on the relative proportions of salts, derived from their marine or non-marine origin, respectively.

Besides hypersaline lakes, the solar salterns-which are traditionally used for the commercial production of salt-are excellent models for studying the microbial diversity and the effect of salinity on the microbial populations. They are constituted by a series of ponds with increasing salinities, from seawater to salt saturation (designed as crystallizers). One of the salterns that has been extensively studied for the last 40 years is located in Santa Pola, Alicante (Spain), at the Mediterranean coast. These studies were based initially on culture-dependent techniques, lately on molecular approaches, and during recent years on metagenomic analyses. All these accumulated data have permitted to determine in detail the prokaryotic populations inhibiting the ponds of this saltern, and compare them with those of other salterns from different locations. As could be expected, the microbial diversity is drastically reduced with increasing salinity. At the crystallizer ponds the dominant prokaryotic groups are practically limited to Euryarchaeota, represented by members of the class Halobacteria (*Haloquadratum*, *Halorubrum*) as well as Nanohaloarchaea, and at a lower extent some Bacteroidetes (*Salinibacter*) representing the Bacteria. In contrast, the microbial population at intermediate salinity ponds is more diverse, represented by species belonging to several higher taxa (Euryarchaeota, Gammaproteobacteria, Bacteroidetes, Actinobacteria, Alphaproteobacteria, Verrucomicrobia, Firmicutes, etc.). Despite the enormous efforts in order to cultivate the representatives of these microbial groups, which has permitted the isolation of a large number of microbes representing new genera and species of Archaea and Bacteria, a large proportion of the microbial population present on these habitats has not yet been isolated in pure culture and characterized.

The analyses of the metagenomic databases derived from two concentrator ponds from Santa Pola saltern (with 19 and 13 % total salts) and one pond from another saltern located in Isla Cristina, Huelva (South Spain) with 21 % salts, have shown that a large percentage of metagenomic sequences were related to a new group of Gammaproteobacteria, closely related to the genus *Alkalilimnicola*, within the family *Ectothiorhodospiraceae*. Initially we were able to isolate a single strain of this new abundant bacterial group and named it as a new genus and species, *Spiribacter salinus*, on the basis of the peculiar morphology, being curved cells which at a later stage have a tendency to form long spiral cells. More recently, we have characterized additional strains which have been described as two new species of this genus: *Spiribacter curvatus* and *Spiribacter roseus*. Their complete genomes have been sequences and assembled into a single contig; they have genome sizes ranging from 1.7 to 1.9 Mb, showing the smallest genomes currently described for any member of the family *Ectothiorhodospiraceae*. The recruitment of their genomes with available metagenomic databases obtained from habitats with different salinities have permitted to determine that this new bacterial genus represents a group of species that are abundant on the intermediate salinity ponds (ca. 10 to 25 % salts) but are not found on marine habitats as well as at high salinities, i.e. the crystallizer ponds of the salterns. Our studies show that metagenomics, which enables to determine the microbial diversity of a natural environment, can help to generate information permitting the identification of previous unknown microbes and eventually their isolation in pure culture and further characterization.

Yeast respiratory oscillations (YROs), are robust, short period rhythms that arise spontaneously when yeast are grown aerobically under nutrient-limited conditions in continuous culture. They are characterised by transient and intense bursts of respiration and act to coordinate much of cellular metabolism. YROs share diverse features with circadian rhythms including temperature compensation, cyclic changes in redox state, coupling with the cell division cycle and period determination by casein kinase I. This suggests they either represent an ancient and conserved phenomenon that is likely to be driven by mechanisms common to all aerobic eukaryotes, or draw on general metabolic functions, however, the underlying mechanism is not known.

We have taken a systems-wide approach to understanding how rhythmicity is mediated. We have generated a comprehensive description of metabolites, proteins and protein modifications in yeast undergoing oscillations of different periodicities and used it to derive a mechanistic model. Our data identify additional features shared between circadian rhythms and YROs, reveal key processes that promote the sequential occurrence of distinct metabolic processes and show how the cyclic remodelling of cellular function is underpinned by cycles of anabolism and catabolism.

CELL WALL ADHESINS GOVERN BIOFILM FORMATION IN THE PATHOGENIC YEASTS CANDIDA GLABRATA AND CANDIDA PARAPSILOSIS

J. Fernández[1], A. Moreno[1], E. Gómez[2], A.D. De Boer[1], H.L. Dekker[3], I. De la Pinta[4], O. Bader[2], G. Quindós[4], P.W.J. De Groot[5]

[5]University of Castilla-La Mancha/Science & Technology Park Castilla–La Mancha, Molecular Mycology, Albacete, Spain

The yeast species *Candida glabrata* and *Candida parapsilosis* are, next to *Candida albicans*, among the most frequent fungal causes of mucosal and life-threatening bloodstream infections in immunocompromised persons. The cell walls of these *Candida* species plays an important role in the host-pathogen interactions that lead to the establishment of infections. Attachment to human host tissues or abiotic medical devices and subsequent biofilm formation represents the first phase in this process and is mediated by cell wall-localized adhesins. By analyzing the wall proteomes of hyper-adhesive clinical isolates using mass spectrometry and comparison to reference strains, we tested whether these isolates display differential and increased incorporation of adhesins. Wall proteome analysis identified a core proteome of about 20 proteins present in each strain under all analyzed conditions. In addition, proteomic analysis of hyper-adherent strains under biofilm-forming conditions showed (i) higher levels of adhesins that are also found in the reference strains and (ii) incorporation of novel adhesins that are not found in the reference strains. Thus, the hyperadhesive capacity of hyper-adherent *Candida* isolates seems to be correlated with increased and differential incorporation of cell wall adhesins. Current studies in our laboratory are aimed at performing functional and structural characterizations of the novel adhesins and at elucidating their role in primary host-pathogen interactions, antifungal drug resistance, and virulence.

AUTOPHAGY IN DEGRADATION OF PEROXISOMAL AND CYTOSOLIC ENZYMES OF METHANOL

A. Sibirny[1]
[1]*Institute of Cell Biology NAS of Ukraine, Molecular Genetics and Biotechnology, Lviv, Ukraine*

AUTHOPHAGY IS RESPONSIBLE FOR DEGRADATION OF CYTOSOLIC ENZYMES OF METHANOL METABOLISM IN THE YEAST *PICHIA PASTORIS*

Nina V. Bulbotka[1], Kateryna O. Levkiv[1], Olena V. Dmytruk[1] and Andriy A. Sibirny[1,2]

[1]Department of Molecular Genetics and Biotechnology, Institute of Cell Biology, NAS of Ukraine, Drahomanov Street, 14/16, Lviv 79005 Ukraine; [2]Department of Biotechnology and Microbiology, University of Rzeszow, Zelwerowicza 4, Rzeszow 35-601 Poland

Background

Methanol metabolism in the methylotrophic yeast *Pichia pastoris* metabolizes both in peroxisomes (alcohol oxidase, catalase, dihydroxyacetone synthase) and cytosol (formaldehyde and formate dehydrogenase, fructose-1,6-bisphosphatase). The shift of methanol-grown cells to glucose initiates inactivation of both peroxisomal and cytosolic enzymes. The mechanisms of inactivation of cytosolic enzymes involved in methanol metabolism are not known. Inactivation and degradation start from glucose sensing. Specific glucose sensor has been identified in *P. pastoris*, however, its functional groups responsible for glucose recognition have not been identified.

Objectives

Objectives of this work were to study role of autophagy in inactivation of cytosolic enzymes of methanol metabolism in *P. pastoris*: formaldehyde and formate dehydrogenase and fructose-1,6-bisphosphatase. We also aimed in identification of the fragments of glucose sensor Gss1 required for glucose-induced inactivation of these enzymes.

Materials and Methods

Standard methods of yeast molecular genetics (vector construction, transformation) and biochemistry (western blotting, enzyme assays) were used.

Conclusions

During inactivation of fructose-1,6-bisphosphatase, degradation of the corresponding protein occurred and proteasomal inhibitor MG-132 only slightly inhibited this process. At the same time, degradation of fructose-1,6-bisphosphatase was defective in the mutants of *P. pastoris pep4 prb1* and *ccz1Δ, mon1Δ* or *ypt7Δ* defective in vacuolar proteinases suggesting the role of vacuoles in degradation of

cytosolic enzyme of methanol metabolism. Degradation of fructose-1,6-bisphosphatase was also strongly retarded in *gss1Δ* mutant defective in glucose sensor suggesting the role of glucose signaling in this process. Thus, glucose signaling and specific autophagic degradation apparently are involved both in degradation of both fructose-1,6-bisphosphatase and alcohol oxidase.

THE IDENTITY OF HYPHAE IN A FUNGAL MYCELIUM

H. Wosten[1]
[1], *The Netherlands*

Backgrounds

Liquid shaken cultures of fungi consist of populations of micro-colonies that differ in size and gene expression. For instance, large micro-colonies express other genes encoding secreted proteins than small micro-colonies. Heterogeneity is also observed between zones and within a zone of micro-colonies. The latter came to a surprise since fungi were assumed to share a common cytoplasm, in particular within a particular zone, due to large pores in the septa that compartmentalize hyphae.

Objectives

We studied the mechanisms underlying the paradox between heterogeneity and an assumed continuous cytoplasm, and its consequences for the role of individual hyphal compartments.

Methods

We used laser dissection combined with fluorescence microscopy and modeling.

Conclusions

The majority of septa of growing hyphae of *Aspergillus* and *Penicillium* are closed by Woronin bodies. Modelling showed that even open septa of these fungi act as a barrier for inter-compartmental cytoplasmic mixing. Growth speed of apical compartments was not affected when they were dissected from subapical compartments. These compartments started to branch when the apical compartment was damaged.

Apical compartments are self-providing units with subapical compartments functioning as a back-up system for branching when the apical compartment is damaged while exploring its substrate. The self-providing nature of compartments explain why hyphae within and between zones of a micro-colony are heterogeneous with respect to gene expression and molecular composition.

GENOME CENTRIC METAGENOMICS IN ENVIRONMENTAL MICROBIOLOGY

M. Albertsen[1]
[1]*Aalborg University, Center for Microbial Communities, Aalborg, Denmark*

Small subunit (SSU) ribosomal RNA (rRNA) genes have been the standard phylogenetic markers for the study of microbial evolution and diversity for decades. However, the essential reference databases of full-length rRNA gene sequences are underpopulated, ecosystem skewed, and subject to primer bias; which hampers our ability to study the true diversity. In this talk, I will present out latest method development that combines poly(A)-tailing and reverse transcription of SSU rRNA molecules with synthetic long-read sequencing, to generate millions of high quality, full-length SSU rRNA sequences without primer bias. We applied the approach to complex samples from seven different ecosystems and obtained more than 1,000,000 SSU rRNA sequences from all domains of life. The novel diversity is overwhelming and include several potentially new archaeal phyla of the deeply branching Asgard Archaea, which are previously suggested to bridge the gap between prokaryotes and eukaryotes. This approach will allow expansion of the rRNA reference databases by orders of magnitude and will enable a comprehensive census of the tree of life. With a fully populated SSU tree of life, it will be possible to prioritize efforts towards making a fully populated genome tree of life. To demonstrate the progress with these efforts, I will also discuss our recent progress on extraction of complete (closed) genomes from metagenomes using high-throughput long-read Nanopore sequencing.

IMMUNE RESPONSES INVOLVED IN ENDOSYMBIONT CONTROL AND HOST HOMEOSTASIS

A. Heddi[1]
[1]*INSA Lyon, BioSciences, Villeurbanne, France*

Many insects sustain long-term relationships with intracellular symbiotic bacteria that provide them with essential nutrients. Such endosymbiotic relationships have likely emerged from ancestral infections of the host by free-living bacteria, the genomes of which experience drastic gene losses and rearrangements during the host-symbiont coevolution. While it is well documented that endosymbiont genome shrinkage results in the loss of bacterial virulence genes, whether and how the host immune system evolves towards the tolerance and control of bacterial partners remains poorly understood.

Insect immune system is permanently struggling to keep beneficial symbionts while activating defense effectors to prevent pathogenic infections. We showed that weevils have selected a 'compartmentalization strategy' that consists in secluding endosymbionts within specialized host cells, the bacteriocytes, thus preventing direct symbiont contact with the host systemic immune system. I will address here recent advances in the understanding of the bacteriocyte immune and cellular regulations involved in endosymbiont maintenance and control. I will focus on the cereal weevils *Sitophilus* spp*.,* in which bacteriocytes form bacteriome organs that strikingly evolve in structure and number according to insect development and physiological needs. I will discuss how weevils track endosymbiont dynamics through at least two mechanisms: i- antimicrobial peptide synthesis that regulates endosymbiont cell cytokinesis and helps to maintain a homeostatic state within bacteriocytes, and ii- cellular processes such as apoptosis and autophagy, that adjust endosymbiont load to the host developmental requirements, hence ensuring a fine-tuned integration of symbiosis costs and benefits.

Insect-microbe interactions

MOLECULAR MECHANISMS UNDERLYING DROSOPHILA SPIROPLASMA ENDOSYMBIOSIS

B. Lemaitre[1]
[1]*EPFL, Global Health Insitute, Lausanne, Switzerland*

Virtually every species of insect harbors facultative bacterial endosymbionts that are transmitted from females to their offspring, often in the egg cytoplasm. These symbionts play crucial roles in the biology of their hosts. Many manipulate host reproduction in order to spread within host populations. Others increase the fitness of their hosts under certain conditions, for example by increasing tolerance to heat or by protecting their hosts against natural enemies. We are dissecting the interaction between *Drosophila* and its native endosymbiont *Spiroplasma poulsonii*. *Spiroplasma* are members of the Mollicutes, a wall-less eubacterial group related to the Gram-positive lineage, which are very widespread and is likely to be present in over 5% of all insect species.

Our study has shown that *S. poulsonii* resides in large numbers in the hemolymph (the insect blood) of larvae and adults. Surprisingly *S. poulsonii* cells are neither detected nor affected by the *Drosophila* immune system, but their proliferation is constrained by the availability of hemolymph lipids. We hypothesize that this dependence on lipids couples the proliferation of *S. poulsonii* to the nutritional state of its host. We have also provided strong evidences that the ability of Spiroplasma to protect *Drosophila* against infestation by parasitoid wasps (a parasite of *Drosophila*) relies on a competition for host lipids. Recently, we have also shown that *Spiroplasma* uses the yolk uptake machinery to colonize the germ line, thus ensuring an efficient vertical transmission.

Spiroplasma is also a male killer, and it has been hypothesized that this reproductive manipulation is one of the driving forces that maintains this facultative endosymbiont in fly populations. In collaboration with the Fukatsu laboratory (Japan), we have shown that *Spiroplasma* targets the dosage compensation system of *Drosophila*, a machinery that is assembled only in males to regulate X chromosome expression. We are currently investigating in further details the mechanism of male killing. In parallel, our laboratory has sequenced the genome of several strains of *S. poulsonii* and developed new approaches to cultivate (for the first time) this bacterium *in vitro* and to transform it. These works pave the route to the genetic manipulation of this symbiont.

We believe that the fundamental knowledge generated on the *Drosophila-Spiroplasma* interaction will serve as a paradigm for other endosymbiont-insect interactions (ex. W*olbachia*) which are less amenable to genetic studies.

Insect-microbe interactions

EXPERIMENTAL EPIDEMIOLOGY AND ANTIBIOTIC RESISTANCE TRANSMISSION

A. Moya[1,2,3]
[1]*Institute for Integrative Systems Biology, Evolutionary Systems Biology of Symbionts, Valencia, Spain*
[2]*CIBER, Epidemiology and Public Health, Madrid, Spain*
[3]*Foundation for the Promotion of Sanitary and Biomedical Research FISABIO, Genomicas and Health Area, Valencia, Spain*

Background

Antibiotic resistance is recognized as one of the major challenges in public health. The global spread of antibiotic resistance is the consequence of a constant flow of information across multi-hierarchical interactions, involving cellular (clones), subcellular (resistance genes located in plasmids, transposons, integrons) and supracellular (clonal complexes, genetic exchange communities, microbiotic ensembles) levels.

Objectives

In order to study such multi-level complexity, we propose to establish an experimental epidemiology model for the transmission of antibiotic resistance with the cockroach *Blatella germanica*

Methods

Here I report the results of a series of preliminary experiments with *B. germanica* populations that allow to conclude that this animal is an appropriate model for experimental epidemiology: a) the composition, transmission and acquisition of gut microbiota and endosymbionts*;* b) the effect of different diets on gut microbiota; c) the effect of antibiotics on host fitness; d) the evaluation of the presence of antibiotic resistance genes in natural- and lab-reared populations; and e) the preparation of plasmids harboring specific antibiotic resistance genes.

Conclusions

The basic idea is to have populations with higher and lower antibiotic exposure, simulating the hospital and the community, respectively, and with a certain migration rate of insects between populations. In parallel, we present a computational model based on P-membrane computing that will mimic the experimental system of antibiotic resistance transmission. The proposal serves as a proof-of-concept for the development of more complex population dynamics of antibiotic resistance transmission that are of interest in public health, that can evaluate procedures and design appropriate interventions in epidemiology.

MODELLING REGIME SHIFTS IN NUTRIENT-CYCLING MICROBIAL COMMUNITIES

T. Bush[1], I. Butler[2], A. Free[3], R.J. Allen[4]
[1]University of Edinburgh, School of Physics and Astronomy, Edinburgh, United Kingdom
[2]University of Edinburgh, School of Geosciences, Edinburgh, United Kingdom
[3]University of Edinburgh, School of Biological Sciences, Edinburgh, United Kingdom
[4], United Kingdom

Microbes play a crucial role in biogeochemical cycles on microscopic, macroscopic and planetary scales, by shuttling chemical elements between oxidized and reduced forms. Understanding and predicting how nutrient-cycling microbial ecosystems respond to environmental changes is therefore of great importance. In particular, we would like to know how and when “regime shifts”, or drastic changes in community function, happen. I will describe recent work on the development of mathematical models for simple sulphur-cycling microbial communities, in which we show that the response of a community to environmental change can be drastically different depending on the details of the microbial growth kinetics. In particular, saturation of the growth rate with respect to nutrient availability can lead to extreme sensitivity of community structure and function to environmental change.

DIVERSITY, STRUCTURE, AND NOVEL PHYSIOLOGIES IN MICROBIAL COMMUNITIES IN RAPID SAND FILTERS

B.F. Smets[1], A. Gülay[1], A. Palomo[1], S.J. Fowler[1], T. Sicheritz-Pontén[2]
[1]Technical University of Denmark, Dept of Environmental Engineering, Kgs Lyngby, Denmark
[2]Technical University of Denmark, Dept of Bio and Health Bioinformatics, Kgs Lyngby, Denmark

Rapid sand filtration (RSF) is frequently used to treat high-quality groundwater for drinking water production. Microbial density in RSFs is high and communities typically colonize the porous mineral matrix that coats the sand grains.
Microbes are assumed responsible for the removal of NH_4^+, Fe^{2+}, Mn^{2+}, CH_4, H_2S - the main constituents in groundwaters – although the details have remained obscure.
We have initiated a description of the diversity, abundance, and distribution of microbial communities across various RSFs, from which we have identified a core RSF microbiome, abundance of functional guilds, and spatial distribution patterns. Across all RSFs, *Nitrospira* abundance exceeded abundance of canonical Ammonium Oxidizing Bacteria (AOB).
Through metagenomic analysis, highly abundant composite population genomes belonging to the *Nitrospira* genus were recovered that harbor the metabolic capacity for complete ammonia oxidation (comammox).
DNA and RNA stable isotope probing (SIP) based on ^{13}C-labeled bicarbonate incorporation was subsequently performed on RSF samples under continuous loading and with nitrification inhibitors. SIP results provided the first insights into the *in situ* activity of comammox *Nitrospira* and novel nitrifiers in a complex microbiome.
Novel nitrifiers belonging to *α* and *β* proteobacteria were detected as central players in nitrification in RSFs, supported by evidence from SIP and metagenomics.
Here, we are obtaining a first comprehensive insight into the phylogeny and physiology of the microbes that drive the nitrogen cycle in RSFs.

CONTROL OF CELL MORPHOGENESIS IN ROD-SHAPED BACTERIA

C. Billaudeau[1], A. Chastanet[1], Z. Yao[1], C. Cornilleau[1], R. Carballido-Lopez[1]
[1]INRA, Micalis, Paris, France

Control of cell morphogenesis in rod-shaped bacteria

How cells control their shape and size is a long-standing question in cell biology. Many rod-shaped bacteria elongate their sidewalls by the action of cell wall synthesizing machineries that are associated to actin-like MreB dynamic cortical patches. However, little is known about how elongation is regulated to enable varied growth rates and sizes. We have used total internal reflection fluorescence microscopy (TIRFM) combined with automated single particle tracking (SPT) analysis to visualize the dynamics and properties of MreB isoforms, as a proxy for cell wall synthesis, in cells of the model Gram-positive bacterium *Bacillus subtilis* and of the model Gram-negative *Escherichia coli* growing under different nutrient conditions and upon nutrient shift. We show that although both organisms present a similar mechanism of cell elongation they use orthogonal strategies to adapt to growth regime variations. We have also shed light on the current controversy of whether (and why) MreB proteins assemble into diffraction-limited structures or elongated filaments, and used super-resolution microscopy (TIRF-SIM) to elucidate the nanostructure of MreB assemblies.

Microbiological macromolecular assemblies

STRUCTURE AND FUNCTION OF CONTRACTILE INJECTION SYSTEMS

P. Leiman[1]
[1]*University of Texas Medical Branch, Department of Biochemistry and Molecular Biology, Galveston, USA*

Backgrounds

The process of protein and DNA translocation across lipid membranes is central to the function of any organism. The Type VI Secretion System (T6SS) translocates a range of substrates that vary in their size, properties, and secretion selection mechanisms into the external milieu and sometimes directly into the cytoplasm of neighboring cells. T6SS is orthologous to a contractile tail of a bacteriophage, which is used by the phage for translocation of proteins and DNA in the opposite direction — from the capsid located outside of the cell into the cell's cytoplasm. T6SS and phage tails consist of a sheath enveloping a tube with a spike-shaped protein at its tip. T6SS-secreted substrates are associated with the spike or loaded into the tube. The sheath in this assembly is a stretched-out spring that can contract and drive the tube and the spike through the cell envelope, and this constitutes the translocation event. The sheath-tube structure is locked in a high energy metastable state by the baseplate, which is also responsible for triggering the contraction of the sheath.

Objectives

To describe the mechanism of the structural transformation of the sheath in quantitative terms and relate it to T6SS and phage tail function.

Methods

Molecular modeling of the atomic structure that was obtained with the help of cryo-electron microscopy.

Conclusions

The contraction is accomplished by a massive structural rearrangement of the sheath in which its mesh-like topology is preserved and the subunits move as rigid bodies.

STRUCTURAL AND MOLECULAR BIOLOGY OF BACTERIAL SECRETION SYSTEMS
G. Waksman[1]
[1], *United Kingdom*

Structural and Molecular Biology of Type IV Secretion Systems

Gabriel Waksman[1]

[1] Institute of Structural and Molecular Biology at UCL and Birkbeck, Malet Street, London, WC1E 7HX, UK

Type IV secretion (T4S) systems are molecular machines used for the transport of macromolecules across the bacterial cell envelope. T4S systems are highly versatile. Conjugative T4S systems translocate DNA from a donor to a recipient bacterium and contribute to bacterial genome plasticity, spread of antibiotic resistance or other virulence trait among bacterial pathogens. In some bacteria such as *Helicobacter pylori* (Cag PI), *Brucella suis* (VirB/D), or *Legionella pneumophila* (Dot, Icm), T4S systems are directly involved in pathogenicity as they mediate the secretion of virulence factors (DNA or toxins) into host cells. The archetypal T4S system, the VirB/D system, was defined in *Agrobacterium tumefaciens* where it is naturally responsible for the delivery of the T-DNA to the plant host-cell. Conjugative T4SS as well as the *A. tumefaciens* VirB/D system comprise 12 proteins (VirB1 to 11 and VirD4). Recently, structures of large complexes formed by several of these proteins and their substrates have become available for conjugative T4S systems shedding unprecedented light on T4S system secretion mechanism.

ROLE OF GUT MICROBIOTA IN RESPONSE TO STRESS

T. Dinan[1]
[1]*University College Cork, Department of Psychiatry and APC Microbiome Institute, Cork, Ireland*

Role of gut microbiota in response to stress

Ted Dinan MD, PhD, Department of Psychiatry and APC Microbiome Institute, University College, Cork

Evidence is accumulating to suggest that gut microbes may be involved in neural development and function, both peripherally in the enteric nervous system and centrally in the brain. While evidence is still limited in psychiatric illnesses, there are rapidly coalescing clusters of evidence which point to the possibility that variations in the composition of gut microbes may be associated with changes in the normal functioning of the nervous system. Studies in germ-free animals indicate aberrant development of the brain monoaminergic system together with memory deficits and autistic patterns of behaviour. These deficits can be partially normalised if there is early gut colonisation.

There are marked differences in the gut microbiota between patients with major depression and healthy controls. Following a cocktail of antibiotics we conducted a faecal microbiota transplant in rats with faeces from depressed patients or healthy controls. Those rats receiving a transplant from depressed patients developed a depressive phenotype with alteration in corticosterone release and tryptophan metabolism.

That bacteria might have a positive mental health benefit is now becoming clear. Such bacteria may influence the capacity to deal with stress, reducing anxiety, perhaps positively impacting on mood and are now called psychobiotics. Whether, they are capable of acting like and in some circumstances replacing antidepressants remains to be seen. The mechanisms of psychobiotic action are gradually being unravelled. It has been show that *Lacobacillus rhamnosus* has potent anti-anxiety effects in animals and does so by producing major changes in the expression of GABA receptors in the brain. The changes in these receptors are mediated by the vagus nerve which connects the brain and gut. When this nerve is severed no effect on anxiety or on GABA receptors is seen following psychobiotic treatment.

Communication between the brain and gut is bidirectional and complex. Increased understanding of this axis and the role of the gut microbiota may aid the development of therapies not just for functional bowel disorders but for mood disorders also.

Microbiota-host interactions

THE ROLE OF THE EARLY LIFE MICROBIOTA ON HOST HEALTH

L. Hall[1]
[1]*Institute of Food Research, Gut Health & Food Safety, Norwich, United Kingdom*

A 'healthy' intestinal epithelial barrier is essential for host wellbeing and is maintained through a tight monolayer of intestinal epithelial cells (IECs) and balanced interactions with the resident microbiota. Notably a breakdown of this interface has been associated with intestinal inflammatory pathologies including Inflammatory Bowel Disease (IBD), and may be linked to alterations in the microbiota, including a reduction in *Bifidobacterium*. Here I will discuss our data which suggests that *Bifidobacterium* can positively influence epithelium responses *in vivo* during both health and disease via specific modulation of the IEC transcriptome and regulatory networks, including downregulation of cell death pathways. Using KO mouse models and mutant bacterial strains we have uncovered key interactions between bifidobacterial (i.e. exopolysaccharide) and host (i.e. MyD88) molecules, which serve to reduce pathological epithelial cell injury. These data highlight the importance of maintaining healthy homeostatic cross-talk with specific microbiota members and open up mechanistic pathways that could be targeted for future therapies.

DISSECTING CAUSALITY OF FECAL MICROBIOTA IN HUMAN METABOLISM AND OBESITAS

M. Nieuwdorp[1]
[1], *Amsterdam, The Netherlands*

Alterations in (small) intestinal microbiota are associated with obesity and insulin resistance, with the latter usually characterized by low grade endotoxemia. Recent intervention stuies showed that specific bacterial species in fecal samples are altered upon treatment with metformin in type 2 diabetes mellitus patients (Forslund, Nature 2015). We previously showed that fecal transplantation (infusing intestinal microbiota from lean donors) in male recipients with metabolic syndrome has beneficial effects on the recipients' microbiota composition and glucose metabolism via lowering plasma endotoxin levels (Vrieze, Gastroenterology 2012) and followup studies suggest that this beneficial effect can be divided in responders (70%) and non responders (30%) based on butyrate producing microbiota engraftment (Kootte, manuscript in preparation). Intruigingly, oral treatment with sodiumbutyrate for 4 weeks only induced beneficial effects on insulin sensitivity only in healthy subjects whereas no effects are seen in metabolic syndrome subjects (Bouter, manuscript in preparation). Combined our data suggest that specific intestinal bacterial strains might be developed as therapeutic for cardiometabolic diseases such as insulin resistance, NASH and obesity and these probiotics will most likely be superior to orally providing beneficial metabolites. Moreover, it is expected that the driving mechanisms might be driven by immunological, genetic and microbiota based factors.

Mosquito-borne viruses

WEST NILE VIRUS IN EUROPE

B. Luisa[1]
[1]*University of Padova, Department of Molecular Medicine, Padova, Italy*

West Nile virus (WNV) is a mosquito-borne flavivirus that has recently re-emerged in Europe. First isolated in Uganda in 1937, the virus was responsible for epidemic outbreaks in Africa and in the Middle East and of sporadic infections in Europe until 1996, when a large outbreak of neuroinvasive disease occurred in Romania. Since then, almost all Eastern, Central, and Southern European Countries reported human outbreaks and sporadic cases, especially during the recent years. Phylogenetic analyses of WNV lineage 1 and lineage 2 strains that circulate in Europe showed that, notwithstanding a high genetic diversity, these strains are derived from a limited number of independent introductions, most likely from Africa through migrating birds, followed by local spread and evolution. Following the re-emergence of WNV, European countries have intensified surveillance activities and control programs. However, the dynamics of virus re-emergence and spread and the mechanisms involved in its establishment into new areas are still poorly understood. Improvements have been also made in the diagnosis of WNV infection with the development of new laboratory tests, but the diagnosis remains challenging and many cases are not recognized. Important aspects of WNV pathogenesis have been clarified in experimental models and this information is crucial for the development of vaccines and antiviral drugs. However, the mechanisms involved in human disease are still largely unknown and require further research. The novel findings on the ecology, molecular epidemiology, pathogenesis, clinical features, and diagnosis of WNV infection in humans will be discussed, with special focus on Europe.

THE EVOLUTION OF WEST NILE VIRUS IN THE USA AND THE ROLE OF VECTOR-VIRUS INTERACTIONS IN PATTERN OF TRANSMISSION

A. Ciota[1], S. Bialosuknia[2], L. Kramer[2]
[1], USA
[2]Wadsworth Center- New York State Department of Health,
Division of Infectious Diseaes- Arbovirus Laboratory, Slingerlands- NY, USA

West Nile virus (WNV; *Flaviviridae, flavivirus*) has been endemic in New York State (NYS) since its 1999 introduction, yet prevalence in Culex mosquitoes varies substantially over small spatial and temporal scales. It is unclear if viral genetics plays a role in this variability, as genetic and phenotypic characterization on local scales has generally been lacking. In addition, mutant swarms of circulating strains have not been fully characterized despite the documented role of minority variants in viral fitness and virulence. In an effort to characterize WNV variability within epidemiologically relevant scales, we performed phylogenetic analyses on WNV isolates from the U.S. obtained from1999-2015 and focused exclusively on New York State isolates. In addition, we performed full-genome, deep-sequencing and genetic analyses on 15 WNV isolated in 2012 from *Cx. pipiens* from an endemic focus in Suffolk County, NY. Our results indicate continued evolution and seasonal maintenance, yet also widespread mixing and high levels of genetic diversity within geographic foci and individual seasons throughout the U.S. Well supported local clusters with shared amino acid differences were identified and suggest local evolutionary pressures and the potential for phenotypic variability. Intra-host diversity of focal isolates was also high, with polymorphism at levels >1.0% identified in approximately 10% of the WNV genome. Although most minority mutations were not shared, mutational hotspots shared among local isolates were identified, particularly in C, NS1 and NS2A genes. The most polymorphic region, positions 3198-3388 of the NS1 gene, was comprised predominately of non-synonymous mutations, suggesting a selective advantage for amino acid diversity in this region. The data provide insight into the movement and local evolutionary pressures of WNV in mosquitoes, and provide a baseline to study the role of genetics in regional variability of WNV prevalence and disease.

Within-host evolution of dengue viruses in their mosquito vector

Louis Lambrechts
Department of Genomes & Genetics, Institut Pasteur-CNRS, Paris, France

Abstract

Like other pathogens with high mutation rate and rapid replication, dengue viruses evolve during the course of an infection. We used deep sequencing to monitor the evolutionary dynamics of dengue virus populations during infection of several genetic backgrounds of their main mosquito vector *Aedes aegypti*. Our results showed that initial infection of the mosquito's midgut was randomly founded by only a few tens of individual virus genomes. The overall level of viral genetic diversity generated during infection was predominantly under purifying selection but differed significantly between mosquito genotypes. Thus, in addition to random evolutionary forces and the purging of deleterious mutations that shape dengue virus genetic diversity during vector infection, our results also pointed to a novel role for vector genetic factors in the genetic breadth of virus populations. Together, our findings illustrate how identifying the evolutionary forces acting on dengue virus populations within the mosquito can shed light on vector-virus interactions and between-host viral evolution.

Protein folding and protein secretion pathways

REGULATION AND FUNCTION OF TYPE III EFFECTORS FROM XANTHOMONAS

U. Bonas[1]
[1]*Martin-Luther-Universität, Institut für Biologie/Genetik, Halle, Germany*

Pathogenicity of most Gram-negative plant-pathogenic bacteria depends on the type III secretion (T3S) system which translocates effector proteins (T3Es) into the eukaryotic cell cytosol. We study the interaction between *Xanthomonas campestris* pv. *vesicatoria* (*Xcv*) and its host plants pepper and tomato. The bacteria enter the plant tissue via natural openings or wounds and settle down in the intercellular spaces; they do not invade the plant cells. Plant cell contact and special media induce the expression of the T3S system components and most T3Es. In susceptible plants, T3Es interfere with host cell processes to the benefit of the pathogen and allow its proliferation. In resistant plants, single resistance genes mediate recognition of individual T3Es often resulting in the induction of a hypersensitive response (HR), a rapid and localized programmed cell death restricting bacterial growth. *Xcv* injects more than 30 different T3Es into the plant cell, termed Avr (avirulence protein) if they were identified many years ago, or Xop (Xanthomonas outer protein). Among the T3Es from *Xcv* are plant immunity suppressors, cell death inducers, a ubiquitin ligase, the transcription factor AvrBs3 (a "TALE") and proteins of unknown function. Selected T3Es will be discussed.

ASSEMBLING COMPLEXES BETWEEN B-BARRELS AND LIPOPROTEIN

S.H. Cho[1], J.F. Collet[2]
[1]de Duve, Biochemistry, Brussels, Belgium
[2]Université catholique de Louvain, de Duve Institute, Brussels, Belgium

Backgrounds

Bacterial lipoproteins are a very diverse group of proteins characterized by the presence of an N-terminal lipid moiety that serves as a membrane anchor. Lipoproteins have a wide variety of crucial functions, ranging from envelope biogenesis to stress response. In Gram-negative bacteria, lipoproteins can be targeted to various destinations in the cell, including the periplasmic side of the cytoplasmic or outer membrane, the cell surface or the external milieu.

Objectives

One of the objectives of our lab is to understand how lipoproteins can reach the cell surface of Escherichia coli and other Gram-negative bacteria.

Methods

By focusing on the lipoprotein stress sensor RcsF, we dissected the molecular mechanism allowing this protein to become surface-exposed.

THE TYPE VI SECRETION SYSTEM: A BACTERIAL KILLING MACHINE

A. Filloux[1]
[1]*Imperial College London, Department of Life Sciences, London, United Kingdom*

The type VI secretion system (T6SS) is a weapon of bacterial warfare and host cell subversion. The Gram-negative pathogen *Pseudomonas aeruginosa* has three T6SSs involved in colonization, competition and full virulence. The H1-T6SS is a molecular gun firing seven toxins, Tse1-7, challenging survival of other bacteria and helping *P. aeruginosa* to prevail in specific niches.The characterization of the T6SS structure largely benefited from the knowledge acquired from the phage tail molecular details. Indeed the T6SS has been proposed to be a supra-molecular bacterial complex that resembles phage tails. The T6SS nanomachine thus include a tail tube or Hcp, a puncturing device or VgrG and a contractile sheath made of TssBC. Contraction of the sheath propels the tail tube and the puncturing device on which is associated the various toxins into the prey cells. The baseplate-like component of the phage tail is yet to be characterized in the T6SS. Striking similarities are emerging which make possible the elaboration of a model and further understanding of the evolutionary pathways which have distinguished two molecular devices similar in structure but distinct in function.

SPATIOTEMPORAL ORGANISATION IN THE BACTERIAL OUTER MEMBRANE AND ITS ROLE IN COLICIN IMPORT

C. Kleanthous[1]
[1], *United Kingdom*

Bacteriocins are species-specific protein antibiotics deployed by Gram-negative bacteria to kill their neighbours during competition for resources. They are implicated in the stable co-existence of bacteria within microbiomes, are exploited by pathogens and commensals alike and are effective therapeutics in animal models of infection. Protein bacteriocins (~40-60 kDa) kill susceptible organisms by binding to a specific receptor and translocating a cytotoxic domain (an enzyme or ionophore) across the cell envelope through a series of protein-protein interactions. We have been exploiting colicins, bacteriocins specific for *Escherichia coli*, as probes of the structure and architecture of the cell envelope and in particular the outer membrane. Using non-translocating colicins as high affinity labels of outer membrane proteins (OMPs) in live bacterial cells, we have shown recently that OMPs are both spatially and temporally organized and that this organization lies at the heart of how OMPs are turned over, which answers a longstanding question in the field. Spatiotemporal OMP organization is a new concept with unknown biological ramifications. My talk will focus on recent studies where we demonstrate that the impact of spatiotemporal OMP organization can be felt across the cell envelope and that bacteriocins likely exploit spatiotemporal OMP organization in order to translocate into Gram-negative bacteria.

THE SOIL RESISTOME

P. Simonet[1], *J. Nesme*[1], *E. Topp*[2]
[1]*Ecole Centrale de Lyon, Ampère, Ecully, France*
[2]*Agriculture and Agri-Food Canada, Department of Biology, London, Canada*

Does application of antibiotic molecules to farm soil significantly increase resistance genes abundance?

In a context where pathogens acquire resistance to more and more antibiotic treatments in hospital settings a number of questions are raised regarding mobilization, acquisition and dissemination of antibiotic-resistance traits between and within bacterial populations. Since antibiotic resistance genes (ARG) are common features of many saprophytic soil bacteria a significant ARG reservoir is readily accessible to previously sensitive pathogens by means of horizontal gene transfer (HGT). It is known since decades that environmental bacteria and pathogens share resistance genes hence the importance to clearly establish transmission routes of such traits in order to prevent their dissemination.

Crop fertilization using manure from animals previously treated with antibiotics is a major anthropogenic entry point of these pharmaceuticals in soils. A number of risk-assessment studies focused on the effect of manure fertilization on soil bacterial community and showed that such practice can indeed increase ARG abundance. Such studies are however most often depicting short- to mid-term impact and cannot distinguish what is leading increase in resistance genes abundance. Our objective was therefore to assess if long-term (1999-present) impact of repeated antibiotic molecules input would have a similar impact on soil bacterial communities, in absence of manure. Can similar concentrations of antibiotic select for resistance traits and increase their dissemination potential in absence of organic matter and intrinsic bacterial community added to soil *via* manure?

To test this hypothesis we analyzed environmental DNA extracted from soil samples under crop rotation and treated yearly with veterinary antibiotics (tylosin, chlortetracycline and sulfonamides) for 15 years (1999-present). Antibiotic molecule concentration added to soil each year represented similar amount to what is conventionally found in antibiotic-treated animal manure. Contaminated soil plots examined in this analysis represents a 12 years time frame (2001 - 2012) of this long-term experimental setup. No correlation between increased antibiotic concentration added to soil and antibiotic-resistance gene abundance could be established with our results and the soil bacterial community is not significantly affected by such treatment. Investigation of ARG and mobile genetic element promoting gene transfer between bacterial lineages (*i.e.*: from environmental bacteria to pathogens) has also been analyzed. It shows that co-abundance is frequent in sequence datasets obtained from soil samples. However, new sequence analysis methods are needed to determine if co-abundance is indeed a sign of co-occurrence on the same molecule, explaining increased transfer potential and successful ARG dissemination.

FEMS7-1181
Resistome

NOVEL TECHNOLOGIES TO STUDY THE RESISTOME

W. van Schaik[1]
[1]*University of Birmingham, Institute of Microbiology and Infection, Birmingham, United Kingdom*

The human gut microbiome is a complex ecosystem, containing hundreds of bacterial species. While many of these species have a symbiotic or commensal relation with their host, the human gut also serves as a reservoir for opportunistic pathogens and antibiotic resistance genes ('the resistome'). Culture-independent analyses of metagenomic DNA have revealed that antibiotic resistance genes are common in the gut microbiota of both healthy individuals and hospitalised patients. The resistome can be characterized by a variety of culture-independent analyses, including high-throughput quantitative PCR, metagenomic shotgun sequencing and functional metagenomics (i.e. the generation of large clone libraries that can be screened for antibiotic resistant clones).
I will present studies from my group in which these different techniques were used to characterize the resistome of hospitalised patients that received intensive antibiotic therapy. These data show that the resistome is highly dynamic under antibiotic therapy and that commensal bacteria (e.g. Bacteroidetes and Clostridium) are major reservoirs of antibiotic resistance genes in the human gut. Finally, I will discuss the pros and cons of different approaches to characterize the resistome and present to what extent rapid resistome characterisation can be used to guide targeted antibiotic therapy and/or infection control measures.

METAGENOMICS AND CULTUROMICS

J. Holden[1], S. Rangama[1], I. Lidbury[1], V. Clark[1], S. Djordjevic[2], P. Hawkey[3], E. Wellington[1]
[1]University of Warwick, School of Life Sciences, Coventry, United Kingdom
[2]University of Technology Sydney, The ithree institute, Sydney, Australia
[3]Heartland Hospital and University of Birmingham, Institute of Microbiology and Infection, Birmingham, United Kingdom

How are antimicrobial resistance genes disseminated into the environment and help their hosts survive?

Infections caused by antimicrobial resistant bacterial pathogens are global and represent an increasingly important public health problem. A critical component in controlling dissemination is the identification of pathogen reservoirs. We have identified the environment as a further potential component of the pathogens' complex transmission cycle. Once outside the enriched mammalian host (or culture media), cells can be in an altered physiological state, as pathogens can enter a resilient but quiescent state in order to survive the biotic and abiotic stresses of the environment. Culture independent methods are required to quantify these cells, and culture dependant methods have been relied on to establish if they are viable and potentially capable of causing infection. However many pathogens can survive and grow in the environment and genetically interact with indigenous environmental bacteria or protozoans. In addition with the increase in surgical procedures and improvements in medical care certain bacteria regarded as 'environmental' have caused infections and been exposed to antibiotics and disinfectants. Waste water treatment plants (WWTPs) and manure treatments can spread antimicrobial resistant (AMR) gut bacteria into the environment usually in mixtures with amoebae, other protozoans, and comprise both pathogenic and commensal bacteria[1-3]. The fate of these bacteria is uncertain and their turnover difficult to determine due to continued inputs and depletion via natural processes. What is clear is that many pathogenic *E. coli* are capable of surviving long periods of time in hostile environments and carry multi-drug resistance plasmids some with pathogenicity determinants which are readily mobilised to other host backgrounds if conditions are appropriate.

The genomes of a range of *E. coli* strains isolated from downstream of WWTP effluent outflows provided evidence of extensive conservation of traits and prevalence of IncFIA, IncFIB replicon types and these were further investigated for plasmid and gene diversity, fitness and gene expression. Results revealed differences in fitness putatively associated with plasmid presence and variations in the exoproteome and resistance gene expression related to gene location and growth conditions. We hypothesize that plasmids are integral to strain fitness and survival[4].

SYNTHETIC APPROACHES OF TRANSLATIONAL CONTROL

K. Jung[1], *W. Volkwein*[1], *J. Lassak*[1]
[1]*LMU Munich, Biology, Martinsried, Germany*

Aims:

Our studies aim to create a generic EF-P variant, which is standardized and constitutively active independent of species-specific posttranslational modifications. Furthermore, we aim to develop a new toolbox for the translational control of protein levels.

Methods:

The amber suppression system is used to incorporate unnatural amino acids. All synthetic protein variants are tested for functionality *in vivo* using reporter strains.

Results:

Translation of proteins with a stretch of consecutive prolines causes ribosome stalling. To overcome this stop, bacteria depend on a specific translation elongation factor P (EF-P), being orthologous and functional identical to eukaryotic/archaeal elongation factor e/aIF-5A (1-3). EF-P binds to the ribosome between the peptidyl-tRNA binding site (P-site) and the tRNA exiting site (E-site) and stimulates peptide bond formation. In their active form both EF-P and e/aIF-5A are post-translationally modified at a positively charged amino acid, which protrudes towards the peptidyl-transferase center. While archaeal and eukaryotic IF-5A depend on hypusination of a conserved lysine, the EF-P modification strategies in bacteria vary. In *Escherichia coli* and *Salmonella enterica* a lysine of EF-P is extended by β-lysinylation and subsequently hydroxylated, whereas in *Pseudomonas aeruginosa* and *Shewanella oneidensis* an arginine in the equivalent position is rhamnosylated (4). In addition to structural constrains of polyproline stretches, some EF-P dependent proteins require this motif to fine-tune the protein output. We replaced the conserved lysine with various unnatural amino acids, and screened for active EF-P variants *in vivo* using reporter strains.

In parallel, a new toolbox for the translational control of proteins was generated. This toolbox is based on the combination of amber suppression and stalling motifs and allows tight translational control of protein levels in various bacterial species.

Conclusion:

Translational control allows fine-tuning of the protein output.

FINE AND SPECIALITY CHEMICAL PRODUCTION USING SYNTHETIC BIOLOGY

E. Takano[1]
[1]*University of Manchester, Manchester Institute of Biotechnology, Manchester, United Kingdom*

We aim to design and construct organisms with new functionalities of unprecedented scope, by exploiting synthetic biology for metabolic engineering; e.g. by harnessing our ability to readily sequence complete genomes and to rewrite/re-design pathways on a large scale.

We explore these possibilities in the context of high-value chemical production, utilising the Design/Build/Test/Learn cycle at the Parts, Devices and Systems level. Many microorganisms already have the machinery to produce diverse bioactive molecules that can be used in health, agriculture and food (Cimermancic et al., 2014). As a first step towards re-engineering these high-value chemical biosynthesis pathways for enhanced productivity and diversity, we aim to understand the interchangeability of biosynthetic parts (Diez et al., 2015) and created a minimal information database for natural products with the support from the natural products community (Medema et al., 2015). We have designed and assembled pathways using the identified parts (Leferink et al., 2016) and will engineer orthogonal transcription mechanisms (based on signalling molecule circuits (Biarnes-Carrera et al., 2015) and bacterial microcompartments (Chessher et al., 2015). In addition, we are expanding our collection of computational tools for the detection and analysis of secondary metabolite biosynthesis gene clusters, to enrich our library of parts and building blocks for pathway engineering (Weber et al., 2015). We also use computational modelling (constraint-based descriptions of bacterial metabolism) to identify suitable overproduction hosts and pinpoint biosynthetic bottlenecks to target for further cellular engineering in a synthetic biology strategy (Breitling et al., 2013). And finally, we combine this analysis with high-resolution mass spectrometry analysis, which we also employ for the debugging of the engineered systems (Jankevics et al., 2012).

We have these tools in the Design/Build/Test/Learn cycle of the recently established BBSRC/EPSRC-funded Manchester Synthetic Biology Research Centre, SYNBIOCHEM, where they provide a platform for the high-throughput engineering of fine and speciality chemicals production in microbial systems.

METAGENOMICS AND SYSTEMS MICROBIOLOGY

P. Bork[1]
[1]*EMBL, SCB, Heidlebeg, Germany*

Microbiomics at different scales: From the human gut to the ocean

The human gut microbiome can now be readily studied using metagenomics (Qin et al., Nature 2010) and harbours more than 1000 species that are associated with important functions, but also with more than 30 common human diseases. I touch upon a few community properties such as species interactions or resilience. Perturbations such antibiotics intake, but also that of other drugs can have a lasting impact (e.g. Forslund et al., Nature 2015) as has faecal microbiota transplantation (Li et al., Science 2016). Using single nucleotide variation (Schloissnig et al. 2013) we can monitor at high resolution specific commensal or pathogenic strains in stool samples, for example in response to diet, but also learn, how the gut microbes colonise us, at birth and after. As most of our gut microbes are coming from the environment, it is crucial to study biodiversity and interactions of microbes at planetary scale. The feasibility of such a global approach is illustrated by the TARA oceans project surveying the microbial diversity of this vast ecosystem by studying plankton from 35000 samples collected from all major ocean regions (Bork et al., Science 2015 and refs therein).

EVOLUTION OF TRANSCRIPTIONAL REGULATION IN BACTERIA

M.S. Gelfand[1]
[1]*A.A.Kharkevich Institute for Informatin Transmission Problems, RTC Bioinformatics, Moscow, Russia*

Comparative genomic techniques applied to dozens of sequenced bacterial genomes allow for highly reliable computational identification of transcription-factor (TF) binding sites and RNA regulatory elements. This, in turn, creates an opportunity for the analysis of evolution of regulatory networks and co-evolution of TFs and TF-binding DNA motifs. The regulatory interactions turn out to be extremely labile, and while the general principles of regulatory evolution are yet to be discovered, it is clear that it may involve large-scale network restructuring involving loss, gain, and duplication of TFs; breakdown, contraction, and expansion of regulons; conversion of local regulators into global ones etc. Similarly, integration of TF phylogenetic trees and data on their DNA motifs yields identification of co-evolving positions that frequently turn out to form contacts in 3D structure.

Systems microbiology

THEORY OF MICROBIAL GENOME EVOLUTION

E.V. Koonin[1]
[1], *USA*

Bacteria and archaea have small genomes tightly packed with protein-coding genes. This compactness is commonly perceived as evidence of adaptive genome streamlining caused by strong purifying selection in large microbial populations. However, by comparing predictions of population-genetic models to comparative genomic data, we show that new genes acquired by microbial genomes, on average, are adaptive. Evolution of bacterial and archaeal genomes is highly dynamic and is dominated by horizontal gene transfer and gene loss. Many microbes have open pangenomes, where each newly sequenced genome contains more than 10% 'ORFans', genes without detectable homologues in other species. A quantitative analysis of microbial genome evolution using a simple, steady-state evolutionary model reveals two sharply distinct classes of microbial genes, one of which (ORFans) is characterized by effectively instantaneous gene replacement, whereas the other consists of genes with finite, distributed replacement rates. These findings imply a conservative estimate of the prokaryotic genomic universe size, which appears to contain at least a billion distinct genes.

ENZYME AND METABOLITE CONCENTRATIONS ARE TIGHTLY BALANCED TO OPTIMALLY UTILIZE THE CYTOSOL'S SOLVENT CAPACITY

H. Dourado[1], V. Maurino[2], M. Lercher[1]
[1]Heinrich Heine University, Computer Science and Biology, Düsseldorf, Germany
[2]Heinrich Heine University, Biology, Düsseldorf, Germany

Title: *In vivo* Enzyme and Substrate Concentrations are Balanced at Minimal Combined Mass

A fundamental problem in biology is how cells organize their resource investment. Microbial metabolism, for example, typically involves hundreds of enzymes and metabolites, but it is unclear according to which principles their concentrations are set. Reasoning that natural selection will drive cells towards achieving a given physiological state at minimal cost, we derive a general equation that predicts the concentration of a metabolite from the concentration of the most abundant and costly enzyme consuming it. For effectively irreversible reactions, this relationship depends only on the enzyme's substrate affinity (K_m) and on the molecular cost ratio of enzyme and metabolite.

Simulations of cellular growth as well as experimental data demonstrate that relative costs are approximately proportional to molecular masses. The resulting model predicts *in vivo* metabolite concentration from enzyme concentrations with high accuracy across data from *E. coli* and diverse eukaryotes (R^2=0.85, mean fold-error 1.63), without fitting any free parameters. The corresponding organizing principle – the minimization of the summed mass concentrations of solutes – may facilitate reducing the complexity of kinetic models and will contribute to the design of more efficient synthetic cellular systems.

VIRUSES FROM HYPERSALINE ENVIRONMENTS

J. Antonio[1], M.D. Ramos-Barbero[1], T. Viver[2], J. Villamor[1], S. Fernando[1], M.G. Manuel[1], K. Konstantinos T.[3], R.M. Ramon[2]
[1]University of Alicante, Physiology- Genetics and Microbiology, Alicante, Spain
[2]IMEDEA, Marine Microbiology Group, Esporles, Spain
[3]Georgia Institute of Technology, School of Biological Sciences, Atlanta, USA

Hypersaline environments harbor the highest virus concentrations reported for aquatic systems as well as abundant prokaryotic communities with a relatively low diversity albeit a very high microdiversity, often explained as a response to virus predation. Therefore, they offer a unique and amenable scenario to study virus-host interactions in nature, away from the bias of laboratory systems.

With different modifications and nuances, models describing virus-host interactions assume that viruses infect the most abundant host communities, in a *Kill-the-winner* manner. Taking profit of the conditions offered by hypersaline systems, we have developed an experimental setting to analyze the fate and dynamics of an abundant bacterial population (*the winner*) inoculated in a crystallizer pond inhabited by a mature and stable microbial community. The goal was to analyze not only the effect of viral lysis on the targeted population but the changes induced in the microbial and virus assemblages.

Using a multiphasic approach including microscopy, cell and virus metagenomics, metatranscriptomics and virus isolation, we have followed the dynamics of the introduced host (a strain of the abundant and cosmopolitan Bacteroidetes Salinibacter ruber that was isolated from the analyzed saltern 15 years ago but was absent at the time of inoculation) and the rest of the microbial community. Changes in the host population were accompanied by a bloom of its viruses, likely wide host viruses infecting other strains previously present in the pond, that changed their diversity throughout the experiment time, as unveiled by the comparison of their genomes retrieved by cultivation and metagenomics.

PHAGES RARELY ENCODE ANTIBIOTIC RESISTANCE GENES: A CAUTIONARY TALE FOR VIROMOLOGY

E. François[1], R. Simon[2], S. Matthew B[2], P. Marie-Agnès[3]
[1]CNRS, Biology, Clermont-Ferrand, France
[2]The Ohio State University, Department of Microbiology, Columbus, USA
[3]Micalis Institute- INRA, Microbiology, Jouy-en-Josas, France

Despite their importance in natural ecosystems, the functional potential of viruses is yet to be determined at a community scale. Viral metagenomes provide a way to capture this potential, yet the recurrent presence of cellular DNA within these metagenomes hampers their analysis.
Here, we developped various bioinformatic strategies to detect cellular DNA. Considering only viromes with no cellular DNA detected, a significant number of cellular metabolism genes was retrieved in these viromes, suggesting that the presence of auxiliary genes involved in various metabolic pathways within viral genomes is a general trend in the virosphere.
We also developped strategies to detect Antibiotic resistance genes (ARGs) in viromes, as it has been suggested recently that ARGs are frequently encoded in phage genomes. Reanalysis of available human- or mouse-associated viromes for ARGs and their genomic context suggested that bona fide ARG attributed to phages in viromes were previously overestimated and reassert that ARGs are rarely encoded in phages.

COMPARATIVE GENOMICS OF THE GIANT PANDORAVIRUSES

M. Legendre[1], P. Olivier[1], A. Chantal[1], C. Jean-Michel[1]
[1]IMM, IGS, Marseille, France

In the early 1990s, an Amoeba parasite was serendipitously discovered from the water samples of a cooling tower in Bradford (UK). It turned out that this microorganism, misinterpreted as an intracellular bacterium, harbored a characteristic icosahedral viral morphology. It was actually the first giant virus ever discovered, named Mimivirus. Since then, a lot of effort has been made to discover new families of giant viruses from various environments, either through metagenomics surveys, or by direct isolation using Acanthamoeba as bait. In 2013, a new family of completely different giant viruses, the Pandoraviruses, was successfully isolated from sediments in Chile and Australia. These viruses exhibit a large ovoid particle of 1x0.5µm and hold the record of the largest viral genome with up to 2.5 Mb, reaching that of small parasitic eukaryotes. Right after, Pithovirus and Mollivirus, the members of two other giant virus families were discovered in Siberian permafrost samples. When compared with each other, these giant viruses show very little overlap in their gene content, which makes it difficult to understand their mode of evolution. By sampling various environments and geographical locations we have discovered new Pandoraviruses. We now have 6 complete genomes in hand, which allow us to perform comparative genomics. Furthermore, we used a compendium of “omics” data (i.e. genomics, transcriptomics and proteomics) to thoroughly annotate those genomes and tentatively answer this question: What makes a Pandoravirus?

The human microbiome: education, communication, collaboration

THE HUMAN MICROBIOME - A COLLABORATIVE VENTURE

J. Jass[1]
[1]*Örebro University, School of Science and Technology, Örebro, Sweden*

Evidence has shown that the human microbiome has significant impact on health and disease. The human microbiome is the sum of all the microbial communities in association with different niches of the human body. It consists of diverse microbiota, including micro-eukaryotes and prokaryotes as well as viruses, with concerted physiological properties and is in balance with our own tissues. Thus the human microbiome has been considered a separate virtual organ. It is yet unclear what defines a healthy or diseased microbiome and how it may be manipulated to our benefit. Individual host and microbiota diversity and other compounding factors make it difficult to attribute specific features to improving health and reducing the risk of disease. The foundation of microbiome research is metagenomics, however, the advancement of other omics' methods such as metabolomics, and the ability to cultivate previously un-culturable microbes has allowed more complex structure –function analysis. The challenges that microbiome research faces today include the genetic diversity of human population, the functional diversity of the microbial communities, nutrition, diet, gender and lifestyle. This complexity is compounded by the large data sets that are often not comparable due to a lack of standardized approaches, and the inadequate tools for analysis. Thus there is a need for the development of innovative tools and increased training in handling and interpreting microbiome data. To improve our understanding of the human microbiome it is essential to develop multi-national and multi-disciplinary collaborative ventures that will generate novel research strategies.

The human microbiome: education, communication, collaboration

I, SUPERORGANISM
J. Turney[1]
[1]*not applicable, not applicable, Bristol, United Kingdom*

I wrote one of the first books in English about the human microbiome. The topic poses interesting problems for the (would-be) popular writer. How to convey useful things about a world that is, normally, invisible? How to avoid giving unwarranted support to monocausal explanation and simple mechanisms - that is, being true to what we actually know about cell biology and the complexity of human systems? How to do that without simply repeating on every other page: it is all extremely complicated!? And finally, how to choose helpful metaphors in a domain that has not yet established any very helpful public discourse, and indicate that they *are* metaphors?

Many of these challenges are common to science writing about other subjects. I'll discuss whether they are harder to solve for this topic, and how one might try to do that as science communication about the microbiome develops.

The human microbiome: education, communication, collaboration

THE HUMAN MICROBIOME: AN INTRODUCTION

A. Walker[1]
[1]*Rowett Institute, University of Aberdeen, Aberdeen, United Kingdom*

The human body is home to an extremely abundant and diverse collection of microbes. Indeed, some areas of the body, such as the large intestine, are colonised by some of the densest microbial communities found anywhere in nature.

The complexity of the human microbiome is truly humbling. Thousands of different species are capable of colonising the human body, and it has been estimated that our microbes encode more than 10 million unique genes (which is around 500 times more than the human genome). There is also huge microbiome variation between different individuals, and between bodily sites within the same individual.

Regardless of underlying microbiome variation, under normal circumstances our resident microbes are considered to play a number of key roles in the maintenance of human health. Conversely, the microbiome can also be a driver of disease. An emerging concept over the last decade has been that of “dysbiosis”, whereby the composition of the microbiota shifts from one that is generally benign or beneficial to host health to one that is deleterious for the host, and it is now clear that alterations in the microbiota are correlated with a whole range of diseases.

This has meant that public, academic and commercial interest in the microbiome has rocketed over the last decade. There is now a concerted effort, involving researchers around the world, to manipulate the microbiome for therapeutic purposes. There have been a number of encouraging advances, but much work remains to be carried out before we truly understand the role the microbiome plays, and how we might reproducibly alter it in beneficial ways.

A key challenge for educators, and those involved in knowledge exchange with the public, is to try and communicate exciting advances, while cutting through the hype that surrounds this field of research. In my talk I will give an overview of current knowledge, and provide some examples that may be useful as teaching resources.

HIGH THROUGHPUT CUSTOM ENGINEERING OF INDUSTRIAL YEAST STRAINS

E. Brevnova[1]
[1]*Ginkgo Bioworks, Organism Engineering, Boston, USA*

There is an emerging demand for sourcing plant-derived compounds (nutraceuticals, flavors, fragrances, sweeteners, etc.) from engineered microbes. While recent advances in synthetic biology and metabolic engineering provide feasible approaches to engineering such organisms, commercial success for developing these “cultured” ingredients presents specific challenges. Unlike biofuels, where efforts can be focused on one particular molecule given the enormous market size, cultured ingredients require developing different organism lines in a rapid and low cost fashion.

Scalable solution for bio-manufacturing of various organisms with multiple pathway engineered is provided by our state of the art foundry that continues to grow. Organism development at Ginkgo leverages our foundry to accelerate the design/build/test pipeline and empowered by combining computer-aided engineering software tools, cheap gene synthesis and high resolution-accurate analytical methods. Application of these approaches in combination allows rapid progress toward significant decrease of cultured ingredient production cost through strain and process optimization. Furthermore, improvements in manufacturing organisms lend to opportunities outside of cultured ingredients.

Examples of accelerated organism engineering of yeast industrial strains using Ginkgo technology will be demonstrated.

ENABLING THE PRODUCTION OF GLYCOSYLATED BIOPHARMACEUTICALS IN YEAST

N. Callewaert[1]
[1]*VIB and Ghent University, Center for Medical Biotechnology, Ghent, Belgium*

Glycan structures characterize the molecular environment immediately outside of all cell types and hence have critical functions in interactions of any cell with its environment (cell-cell, cell-pathogen, cell-molecule). The field of glycobiotechnology is concerned with understanding and re-engineering of these glycosylation-dominated interactions. In particular, the understanding of the synthetic pathways and functions for eukaryotic N- and O-glycosylation, gained over the past few decades, has enabled the rewiring of these pathways for the benefit of pharmaceutical applications. Based on the conservation of the core pathways between eukaryotes, it has been possible to transfer the efficient synthesis of particular human-specific glycan structures to other eukaryotes such as yeasts. This is enabling the cost-effective production of biopharmaceutical proteins with glycosylation patterns customized to particular therapeutic functionality (e.g. targeting to particular glycan receptors, or customized for particular pharmacokinetic behaviour). I will illustrate our work with regard to the production of human IgG-like glycosylation patterns in yeast (1), and the production of mannose-6-phosphate modified lysosomal enzymes for the treatment of human inherited lysosomal storage diseases (2). Whereas these synthetic biology endeavours were geared towards copying the synthesis of complex mammalian glycan structures in other eukaryotes, more recently we have generated cells (including yeast) in which glycosylation complexity has been reduced to the bare minimum, while still being compatible with eukaryotic cell life and protein productivity. This 'GlycoDelete' technology (3) opens up many new structural biology and biopharmaceutical applications.

ENGINEERING OF LIPID METABOLISM IN SACCHAROMYCES CEREVISIAE

V. Siewers[1], *J. Nielsen*[1]
[1]*Chalmers University of Technology, Biology and Biological Engineering, Göteborg, Sweden*

Fatty acids serve as precursors for a number of industrially relevant molecule classes such as alkanes, alkenes, fatty alcohols and different types of esters including wax esters. These can be applied as biofuels, but also as ingredients in the food, cosmetics and pharmaceutical industry. Our aim is to develop sustainable production processes for these compounds through metabolic engineering of *Saccharomyces cerevisiae*.

In contrast to oleaginous yeasts, *S. cerevisiae* does not naturally accumulate large amounts of lipids. One approach is therefore the development of platform strains. This includes the streamlining of acetyl-CoA and acyl-CoA metabolism for increased precursor supply, but also efforts to modulate the fatty acid profile of these strains. A second approach is the screening of heterologous enzymes and pathways leading to the formation of the desired products.

STRATIFIED MICROBIAL COMMUNITIES IN THE OXIC-ANOXIC TRANSITIONS OF DEEP HYPERSALINE ANOXIC BASINS

D. Daffonchio[1]
[1]*KAUST- King Abdullah University of Science and Technology, BESE, Thuwal - Jeddah, Saudi Arabia*

The dissolution of ancient buried deep-sea evaporites by water penetrating fractures determined by tectonic movements has determined the formation of the so-called Deep Hypersaline Anoxic Basins (DHABs) in different oceanic regions. These brine pools are located at depths ranging from few hundreds of meters below sea level to almost 4000 meters such as some in the Mediterranean Sea. The chemical nature of the dissolved evaporites has largely driven the composition of the DHABs brines that present extreme conditions of high salinity, anoxia and generally a high content of hydrogen sulfide. The chemistry of the brines and the extreme conditions selected unique communities of microbial extremophiles with many novel unusual endemic phylotypes that do not have any cultivated representative. The most active component of these unique ecosystems is the transition zone between the oxic water column and the anoxic brines where the environmental conditions change in few meters depth with a sharp increase of salinity and density and dramatic increases and decreases of electron donors and acceptors concentrations. The sharp changes of redox couples along such chemoclines drive the stratification of microorganisms with different metabolisms and their coexistence in a narrow vertical portion of the water column. Here, the diversity and functional features of the stratified microbiomes in chemically different DHABs of the Red Sea is presented, individuating the functional network interactions within the stratified microbial assemblage.

ROLE OF BACTERIAL AND ARCHAEAL COMMUNITY MEMBERS INVOLVED IN ANAEROBIC OXIDATION OF METHANE

M. Jetten[1]
[1]*Soehngen Institute of Anaerobic Microbiology, Radboud University Nijmegen, Nijmegen, The Netherlands*

Anaerobic oxidation of ammonium by anammox bacteria or anaerobic oxidation of methane by M*ethylomirabils oxyfera* bacteria and *Methanoperedens* Archaea are recent discoveries in the nitrogen and methane cycle catalyzed by novel so-called impossible microbes [Strous et al 1999 Nature 400: 446-449; Raghoebarsing et al 2006 Nature 440: 918-921; Haroon et al 2013 Nature 501:578-581]. These anaerobic processes share many interesting aspects. Both anaerobic ammonium and methane oxidation processes were once deemed to be biochemically impossible and non-existent in nature, but have now been identified as important players in global nitrogen and methane cycling. Molecular studies showed that anammox bacteria can make the rocket fuel hydrazine by novel multiheme complexes [Kartal et al 2011 Nature 479: 127-130; Dietl et al Nature doi: 10.1038/nature15517] that are located in a unique bacterial organelle surrounded by ladderane lipids [van Niftrik & Jetten 2012 MMBR 76(3):585-596 doi: 10.1128/MMBR.05025-11]. The *M. oxyfera* bacteria turned out to have a new intra-aerobic metabolism. They are able to produce their own oxygen by conversion of 2 NO into O_2 and N_2 by a putative NO dismutase [Ettwig et al 2010 Nature 464: 543-548]. *Methanoperedens* Archaea can couple the reverse methanogenesis pathway to reduction of nitrate. Molecular surveys have indicated that these organisms are wide spread in anaerobic ecosystems around the globe where they most probably interact in an intricate anaerobic food chain. Furthermore all three microorganisms can be applied in sustainable, cost effective wastewater treatment for the removal of methane and nitrogen compounds and are investigated within the center of excellence in anaerobic microbiology (www.anaerobic-microbiology.eu) funded by the Netherlands Gravitation program 024.002.002 SIAM and ERC AG EcoMOM 339880.

Anaerobic communities

HIGH-THROUGHPUT SEQUENCING ANALYSIS REVEALED MICROBE INTERACTIONS DURING PCB DETOXIFICATION IN CONTAMINATED MARINE SEDIMENTS

B. Matturro[1], *S. ROSSETTI*[1]
[1]*IRSA-CNR, WATER RESEARCH INSTITUTE, ROME, Italy*

Backgrounds

Polychclorinated biphenyls (PCBs) are among the most toxic contaminants widely found in several matrices including marine sediments. Anaerobic reductive dechlorination (RD) is the only bioprocess known to reduce such compounds to harmless or less toxic forms. Despite RD has been widely investigated, little is known about the identity and metabolic potentials of PCB-dechlorinating bacteria in real contaminated marine sediments.

Objectives

This study aimed to estimate the biodiversity and the bioremediation potential of PCB contaminated marine sediments.

Methods

The core microbiome of marine sediments taken from three different sites affected by PCB contamination was analysed by Next Generation Sequencing (NGS). Marine sediments were used to construct anaerobic microcosms with and without the addition of external electron donors to stimulate PCB reductive dechlorination.

Conclusions

The study revealed that the autochthonous bacteria were able to sustain the process using the sole sediment organic carbon. RD was observed in all microcosms and was particularly marked in the marine sediment affected by long-term contamination (up to 47% of PCB decrement was observed already after 70 days of anaerobic incubation).
Further, free-sediment microbial enrichments by using PCE as model contaminant were selected from all microcosms. They were mainly composed by > 80% of a novel non-*Dehalococcoides Chloroflexi* belonging to *Dehalococcoidia* class involved in the RD process.
Overall this study sheds light on the identity of both dechlorinating and flanking populations which support the RD process.

BACTERIAL COMMUNICATION ENTERS DIGITAL AGE -MEMBRANE VESICLES DELIVER OF QUORUM SENSING MOLECULE-

K. Morinaga[1], M. Toyofuku[1,2], J. Uhl[3], H. Shimamura[1], N. Obana[1], P. Schmitt-Kopplin[3,4], L. Eberl[2], N. Nomura[1]
[1]University of Tsukuba, Department of Life and Environmental Sciences, Tsukuba, Japan
[2]University of Zurich, Department of Plant and Microbial Biology, Zurich, Swaziland
[3]Helmholtz Zentrum München-German Research Center for Environmental Health, Research Unit Analytical BioGeoChemistry, Munich, Germany
[4]Technische Universität München, Chair of Analytical Food Chemistry, Munich, Germany

Backgrounds

Many Gram-negative bacteria use *N*-acyl-homoserine lactones (AHLs) as signal molecules to communicate with each other. The acyl side chains of AHLs contain 4 to 18 carbons, which are often additionally modified. Given the limited diffusibility of long chain AHLs it has remained a mystery how these signals are released from cells into aqueous environments.

Objectives

Paracoccus denitrificans produces *N*-hexadecanoyl-AHL (C16-HSL) that partitions with the cell membrane. Like many bacteria *P. denitrificans* can form membrane vesicles (MVs), which serve various biological functions. In this study, we investigated the role of MVs in C16-HSL based cell-cell communication.

Methods

MV was collected from cell culture by ultracentrifugation. C16-HSL delivery was monitored by using AHL reporter strains. In-frame gene deletion mutants were generated by homologous recombination. C16-HSL concentration was quantified by UHPLC-qToF-MS.

Conclusions

Our results show that C16-HSL was enriched in MVs and we determined that the AHL concentration contained by a single MV is high enough to trigger QS-regulated gene expression in a bacterial cell. The influence of MVs on C16-HSL-controlled cell aggregation in *P. denitrificans* was investigated and compared to free C16-HSL. In contrast to the conventional QS model in which free diffusion of signals is assumed, we propose a novel MV-based mechanism for binary trafficking of hydrophobic signal molecules, which may be particularly relevant for bacteria that live in open aqueous environments. Furthermore, MVs showed varying propensities to different bacteria, suggesting that the signals are targeted to certain cell types.

A BIOGEOCHEMICAL AND MOLECULAR PERSPECTIVE INTO AN ORGANIC SULFUR AND NITROGEN CYCLE INTERACTION

P. Salgado[1], R. Kiene[2], M.A. Moran[3], H. Ribeiro[1], C. Magalhães[1]
[1]Interdisciplinary Centre of Marine and Environmental Research - CIIMAR, EcoBioTec Laboratory, Matosinhos, Portugal
[2]University of South Alabama, Department of Marine Sciences, Mobile, USA
[3]University of Georgia, Department of Marine Sciences, Athens, USA

Backgrounds

Previous research has confirmed a novel interaction between the marine organic sulfur and nitrogen cycles, whereby methanethiol (MeSH), a dimethylsulfoniopropionate (DMSP) degradation intermediate, inhibits the final step of the denitrification pathway, limiting nitrogen loss through dinitrogen (N_2) and enhancing nitrogen release via N_2O, a potent greenhouse gas.

Objectives

The present study aimed to evaluate how MeSH regulates the N_2O reduction step of denitrification at the transcription level.

Methods

We investigated the effect of increasing MeSH additions on cell suspensions of *Ruegeria pomeroyi* DSS-3 and quantified the denitrification transcripts of *nirS*, *norB* and *nosZ* genes, encoding the nitrite, nitric oxide and nitrous oxide reductases respectively, through quantitative real-time reverse transcription polymerase chain reaction (RT-qPCR). Also, we quantified the N_2O production in the MeSH treatments using an electron-capture detector (GC/ECD).

Conclusions

N_2O accumulation was exacerbated with increased MeSH concentrations, an expected pattern based on previous studies. The *nirS* and *norB* transcripts did not reveal significant differences in the different MeSH treatments. For the *nosZ* transcription signature, we expected to obtain an inversely proportional inhibition along the progressive MeSH additions, however we obtained the opposite pattern revealing an overexpression of the *nosZ* transcript. These results indicate that MeSH isn't inhibiting *nosZ* transcription but rather might be up-regulating it. The accumulation of N_2O after MeSH addition therefore may result from an inhibitory interaction at the protein level, interfering with functioning of the nitrous oxide reductase.

A NOVEL PATHWAY THAT LINKS THE SULFUR AND NITROGEN CYCLES: ANAEROBIC OXIDATION OF ELEMENTAL SULFUR COUPLED TO RESPIRATORY AMMONIFICATION OF NITRATE

G. Slobodkina[1], A. Mardanov[2], N. Ravin[2], A. Frolova[1], N. Chernyh[1], E. Bonch-Osmolovskaya[1], A. Slobodkin[1]
[1]Winogradsky Institute of Microbiology,
Research Center of Biotechnology of the Russian Academy of Sciences, Moscow, Russia
[2]Institute of Bioengineering, Research Center of Biotechnology of the Russian Academy of Sciences, Moscow, Russia

Backgrounds

In many natural and anthropogenic environments, biogeochemical cycles of nitrogen and sulfur are linked due to the activity of autotrophic microorganisms. However to date, sulfur-dependent dissimilatory nitrate reduction to ammonium has been demonstrated only with sulfide as an electron donor. Respiratory ammonification of nitrate (also known as dissimilatory nitrate reduction to ammonium, DNRA) is the microbial process that determines the retention of nitrogen in an ecosystem.

Objectives

We detected a novel pathway that couples the sulfur and nitrogen cycles.

Methods

Thermophilic anaerobic bacteria *Thermosulfurimonas dismutans* and *Dissulfuribacter thermophilus*, isolated from deep-sea hydrothermal vents, grew autotrophically with elemental sulfur as an electron donor and nitrate as an electron acceptor producing sulfate and ammonium. The genomes of both bacteria contain a gene cluster that encodes a putative nitrate ammonification enzyme system. Nitrate reduction occurs via a Nap-type complex. The reduction of produced nitrite to ammonium does not proceed via the canonical Nrf system because nitrite reductase NrfA is absent in the genomes of both microorganisms. The genomes of *D. thermophilus* and *T. dismutans* encodes a complete sulfate reduction pathway, while the Sox sulfur oxidation system is missing in both bacteria.

Conclusions

Thus, in high-temperature environments, nitrate ammonification with elemental sulfur may represent an unrecognized route of primary biomass production. Moreover, the anaerobic oxidation of sulfur compounds coupled to growth has not previously been demonstrated for the members of *Thermodesulfobacteria* or *Deltaproteobacteria*, which were considered exclusively as participants of the reductive branch of the sulfur cycle.

ESCHERICHIA COLI FTSA ASSEMBLES INTO POLYMERIC RINGS ON MEMBRANES THAT ALIGN FTSZ PROTOFILAMENTS AND ANTAGONIZE THEIR BUNDLING

M. Krupka[1], V. W. Rowlett[1], D. Morado[2], H. Vitrac[3], K. Schoenemann[1], J. Liu[2], W. Margolin[1]
[1]The University of Texas McGovern Medical School, Microbiology and Molecular Genetics, Houston, USA
[2]The University of Texas McGovern Medical School, Pathology and Laboratory Medicine, Houston, USA
[3]The University of Texas McGovern Medical School, Biochemistry and Molecular Biology, Houston, USA

Backgrounds

Bacteria such as *Escherichia coli* divide using a protein machine called the divisome that spans the cytoplasmic membrane. Key divisome proteins on the cytoplasmic side of the membrane include the tubulin-like **FtsZ**, which forms GTP-dependent protofilaments, and the actin-like **FtsA**, which tethers FtsZ to the membrane. ZipA and the **Zap** proteins act to **bundle FtsZ protofilaments** and join FtsA and FtsZ to form a septal ring.

Objectives

An FtsZ gain-of-function mutant, FtsZ* enhances FtsZ polymer bundling *in vitro* and is resistant to excess FtsA, which is normally toxic for cells. This prompted us to hypothesize a **novel role for FtsA** as an inhibitor of FtsZ protofilament bundling.

Methods

To provide genetic evidence that FtsA antagonizes FtsZ protofilament bundling *in vivo*, we overproduced FtsA in FtsZ overbundling and underbundling conditions, by overexpressing and deleting the *zap* genes, respectively. To demonstrate this bundling inhibition *in vitro* we employed a **lipid monolayer assay** followed by electron microscopy and 3D tomography analysis.

Conclusions

FtsA overproduction antagonizes the FtsZ overbundling triggered by ZapA protein and exacerbates the *zap* deletion phenotype. Unlike FtsA proteins from other bacterial species that form long polymers *in vitro*, ***E. coli* FtsA strikingly assembles into arrays of minirings** on lipid monolayers. These FtsA minirings promote FtsZ assembly into long, often parallel protofilaments and **prevent them from bundling**. These *in vitro* data support our *in vivo* evidence that FtsA antagonizes FtsZ protofilament bundling, and suggest that the oligomeric state of FtsA may influence FtsZ higher order structure and divisome function.

CELL WALL PROTEINS INVOLVED IN DIFFERENTIAION AND CELL-CELL COMMUNICATION IN MULTICELLULAR CYANOBACTERIA

I. Maldener[1], *J. Bornikoel*[1], *E. Bok*[1], *K. Forchhammer*[1]
[1]*Interfaculty Institute of Microbiology and Infection Medicine, Microbiology/Organismic Interactions, Tübingen, Germany*

Backgrounds

In order to differentiate specialized cells, the filamentous cyanobacterium *Anabaena* sp. strain PCC 7120 processes its peptidoglycan in the intercellular septa by forming semi-regular arranged nanopores. This nanopore array allows the formation of septal junctions for cell-cell communication and is necessary for cell differentiation. Previously we showed that the cell wall lytic protein AmiC2 of *Nostoc punctiforme*, a homologue of cell division protein AmiC from *E. coli,* is involved in nanopore formation.

Objectives

We performed a functional study of the homologues of NlpD (the activator of AmiC in *E. coli*) and AmiC1 from *Anabaena* to investigate their role in cell-cell communication, nanopore array formation and differentiation of functional heterocysts, and hence diazotrophic growth. To study the cell wall modification on molecular level, we investigated the chemical composition and the structure of the peptidoglycan of *Anabaena* wild-type and cell wall mutants.

Methods

Creation of mutants
Fluorescence microscopy
Electron microscopy
FRAP studies
Sacculi isolation
UPLC
MS

Conclusions

Mutants in *nlpD1* and *amiC1 are* strongly hampered in nanopore formation and cell-cell communication. Even they differentiate heterocysts and show low N_2 fixation rates, they cannot grow diazotrophically, possibly because they cannot transfer the fixed nitrogen compounds. This confirms the importance of nanopore formation by these cell wall enzymes and the role of septal junctions in metabolite exchange. In conclusion we could show that the peptidoglycan of *Anabaena* exhibits unique features and represents a dynamic structure. It influences vital processes in the complex life style of multicellular cyanobacteria and is important for the survival in changing environments.

THE TORTOISE AND THE HARE: A ROLE FOR CONSTRICTION IN CELL SIZE HOMEOSTASIS

S. Manley[1], A. Lambert[1], A. Vanhecke[1], S. Holden[2], A. Archetti[1], F. Schaber[1], E. Goley[3]
[1]Ecole Polytechnique Federale de Lausanne EPFL, Institute of Physics, Lausanne, Switzerland
[2]Newcastle University, Centre for Bacterial Cell Biology- Institute for Cell and Molecular Biosciences, Newcastle, United Kingdom
[3]Johns Hopkins University School of Medecine, Department of Biological Chemistry, Baltimore, USA

Super-resolution fluorescence microscopy offers new insights into the subcellular organization and cell-cycle mechanics of bacteria. Previously, we have shown that with automation and optimized illumination, we can obtain large statistics on bacteria shape and protein organization over the cell cycle.

Underlying bacterial cell size homeostasis is the "adder rule": a constant addition of length or volume per cell cycle. However, its mechanism is poorly understood. We study the enforcement of this rule by dissecting single cell shape dynamics with time-lapse structured illumination microscopy (SIM). Examining a hyperactive constriction mutant of septal peptidoglycan remodeling (FtsWI*), and treatment with a peptidoglycan synthesis inhibitor (fosfomycin), we find that onset and duration of constriction together determine elongation.**

MEMBRANE VESICLE FORMATION THROUGH CELL DEATH

M. Toyofuku[1], *N. Nomura*[1], *L. Eberl*[2]
[1]*University of Tsukuba, Life and Environmental Sciences, Tsukuba, Japan*
[2]*University of Zurich, Department of Plant and Microbial Biology, Zurich, Switzerland*

Backgrounds

Membrane vesicles (MVs) that are released by both Gram-negative and Gram-positive bacteria are involved in many biological processes, including horizontal gene transfer, virulence, phage decoy and cell-to-cell communication, and also have impact on human health. Despite their biological importance, little is known about the mechanisms of MV biogenesis.

Objectives

Our study aimed at understanding how MVs are produced in bacteria using *Pseudomonas aeruginosa* and *Bacillus subtilis* as model organisms.

Methods

MVs were isolated by ultracentrifugation and quantified with membrane specific fluorescent dyes. RNA associated with MVs was sequenced to gain insight of the genes involved in MV formation. To understand the procedure of MV biogenesis in detail, we used different live cell imaging techniques.

Conclusions

Live cell imaging showed that a subpopulation of the cells undergo explosive cell lysis and generate MVs in *P. aeruginosa*. RNA-seq of MV-associated RNA revealed that genes related to stress response were enriched in MVs. Among these genes, an endolysin gene was found to be critical to trigger explosive cell lysis. Endolysins are conserved among bacteria and are typically related to phage or bacteriocin release. Likewise, an endolysin was also found to be involved in MV formation of *B. subtilis*. In contrast to explosive cell lysis in *P. aeruginosa*, endolysin-triggered MV formation in *B. subtilis* proceeded through a pinhole in the cell wall that allowed the extrusion of membrane material (named bubbling cell death). Our results show that the widely distributed endolysin genes triggers MV formation through cell death in both Gram-positive and -negative bacteria, albeit *via* different mechanisms.

POLAR INSERTION OF THE OUTER MEMBRANE COMPONENTS AND HETEROGENEITY OF THE OUTER MEMBRANE OF BRUCELLA ABORTUS

V. Vassen[1], C. Formosa-Dague[2], C. Valotteau[2], C. Feuillie[2], N. Auberger[3], S. Vincent[3], Y. Dufrêne[2], J.J. Letesson[1], X. De Bolle[1]
[1]University of Namur, Research Unit in Biology of Microorganisms, Namur, Belgium
[2]Catholic University of Louvain, Institute of Life Sciences, Louvain-la-Neuve, Belgium
[3]University of Namur, Bio-Organic Chemistry Laboratory, Namur, Belgium

Backgrounds

Brucella abortus is an α-proteobacteria and one of the etiological agents of brucellosis, a worldwide-spread zoonosis. Bacteria belonging to the order Rhizobiales are characterized by unipolar growth. Labeling of envelope using Texas red succinimidyl ester (TRSE) revealed the new pole and the constriction site as proposed growth sites in *B. abortus*.

Objectives

Since the new material is incorporated at the new growing pole and the constriction site, we are interested in the insertion of the different layers of the bacterial envelope: lipopolysaccharide (LPS), outer membrane proteins (Omp) and peptidoglycan (PG).
Moreover, the general organization of the outer membrane with regard to its heterogeneity will be studied.

Methods

B. abortus 544 was fully labeled with monoclonal antibodies directed against smooth (S)-LPS or Omp25 or fluorescent D-amino acid HCC-amino-D-alanine (HADA) and absence of these signals after growth corresponds to newly incorporated materials.
Additionally, the insertion of new LPS was shown using a rough (R) strain in which the synthesis of O-chain, and thus S-LPS, was inducible. Furthermore, the structure of the outer membrane of fixed bacteria was examined by using Atomic Force Microscopy (AFM).

Conclusions

Labeling experiments showed that new S-LPS, Omp25 as well as PG are incorporated at the proposed growth sites, i.e. the new pole and the constriction site. Moreover, none of these structures seems to be mobile under the conditions in which they were observed.
Study of the outer membrane by AFM confirmed preliminary data of the appearance of R-LPS clusters on the wild type cells.

FEMS7-2514
Bioactive metabolites

A MINIMAL MODEL OF PHOTOTROPHIC GROWTH TO EXPLAIN PROTEOME ALLOCATION IN CYANOBACTERIA

M. Faizi[1], *R. Steuer*[1]
[1]*Institute for Theoretical Biology, Department of Biology- Humboldt University of Berlin, Berlin, Germany*

Backgrounds

Cellular metabolism must continuously adapt to a multitude of changing environmental conditions to ensure best possible growth. The need for continuous adaptation is in particular true for phototrophic organisms that rely on harvesting the sun's energy to survive and grow. Phototrophic metabolism is assumed to be carefully orchestrated to meet cellular demands for energy requirements, to avoid photodamage, and to provide sufficient storage compounds for periods of darkness.

Objectives

Our focus is to understand the underlying mechanisms of phototrophic growth and the adaptive properties of cellular metabolism. Recent studies on heterotrophic bacterial growth investigated the implications of cellular proteome allocation on cellular growth. That is, how do cells allocate their finite resources to different cellular processes, and how does this allocation impact metabolism and growth?

Methods

Current mathematical descriptions of bacterial growth show that the relationships that govern optimal resource allocation can be derived from coarse-grained kinetic models. Here, we present a minimal dynamic model of phototrophic growth that adapts its coarse-grained proteome to different light and CO_2 conditions.

Conclusions

The model predicts relationships that govern optimal resource allocation of phototrophic growth and is able to reproduce cyanobacterial growth laws based on minimal assumptions about key parameters.

Bioactive metabolites

BACTERIAL SECONDARY METABOLITE PRODUCTION VIA HETEROLOGOUS GENE CLUSTER EXPRESSION IN PSEUDOMONAS PUTIDA

A. Loeschcke[1], *A. Domröse*[1], *R. Weihmann*[1], *K.E. Jaeger*[1], *T. Drepper*[1]
[1]*Heinrich-Heine-University Düsseldorf, Institute of Molecular Enzyme Technology, Jülich, Germany*

Backgrounds

The wealth of bacterial secondary metabolites includes numerous compounds with relevant bioactivities such as antibiosis or cytotoxicity.

Objectives

To enable biotechnological access *via* heterologous biosynthesis in an amenable host, cloning of the relevant genes, their transfer, stable maintenance and functional expression has to be accomplished. Moreover, the host cell metabolism is required to provide a suitable metabolic background for establishing a biosynthetic pathway. Therefore, effective genetic tools are required that allow the effective cloning and heterologous expression of large gene clusters in diverse bacterial hosts.

Methods

We have developed the molecular genetic tools TREX and yTREX, that consist of gene cassettes enabling i) the straightforward yeast recombinational cloning of large gene clusters, ii) the conjugational transfer of a TREX-labeled gene cluster into bacterial hosts and iii) its stable integration into the host chromosome *via* transposition. iv) Finally, expression of the gene cluster can be realized by random integration downstream of a chromosomal promoter or by employment of convergent T7 RNA polymerase-mediated expression.

Conclusions

We could demonstrate several key benefits of the TREX tools. Straightforward one-step recombination in yeast enabled rapid cloning of several gene clusters, including carotenoid, prodigiosin, violacein and phenazine biosynthesis clusters that range in size from 6 to 21 kb. Using *Pseudomonas putida* as host, random genomic gene cluster integration enabled identification of naturally highly transcribed chromosomal regions suitable for gene cluster expression, and metabolite production at mg scale. The presented tools thus offer new perspectives in the fields of genome mining and synthetic biology.

ANTIMICROBIAL ACTIVITY OF PEPTIDES DERIVED FROM LYTA AUTOLYSIN AGAINS STREPTOCOCCUS PNEUMONIAE

E. Roig[1], *M. Beatriz*[1], *S. Manuel*[2], *S. Jesús Miguel*[1]
[1]*Universidad Miguel Hernández, Instituto de Biología Molecular y Celular, Elche Alicante, Spain*
[2]*Universidad Miguel Hernández, Dpt. Vegetal Production and Microbiology, Elche Alicante, Spain*

Backgrounds

Streptococcus pneumoniae (pneumococcus) is one of the major bacterial pathogens that causes several diseases with high social impact such as pneumonia, meningitis and otitis media. Vaccination and antibiotic treatment are two strategies to combat this pathogen, which are incomplete due to the high serotype variety and the increasing antibiotic resistance, so that the search and development of new antimicrobials are necessary.

Objectives

Choline-binding proteins (CBPs) of *S. pneumoniae* are an attractive target for antimicrobials because they are essential for bacterial viability and virulence, and are common to all serotypes. All CBPs are composed of a choline-binging module (CBMs) which consist of repetitive motifs (CBRs, choline-binding repeats), rich in aromatic amino acids. It has been reported that C-LytA (CBMs from the LytA amidase) in vitro competes with their parental cell-wall hydrolases and inhibit their function. Taking advantage of the fact that a single CBR (239-252 of LytA) acquires a stable conformation in solution we have studied the structure and the antimicrobial effect of this peptide and its derivatives obtained from the duplication and triplication of sequence.

Methods

The structure of CBR-derived synthetic peptides was studied by circular dichroism. Then we performed viability assays of pneumococcal cultures treated with these peptides. A clear enhancement in antimicrobial effect was observed as the number of peptide sequence repeats was increased.

Conclusions

We have unveiled the structural determinants of peptides derived from CBRs for the design of new antipneumococcal drugs.

FEMS7-2214
Cell surfaces and signal transduction

NITROGEN FIXING SYMBIOSIS AND BACTERIAL CELL CYCLE ARE LINKED IN SINORHIZOBIUM MELILOTI

S. Xue[1], E. Biondi[1]
[1]IMM, LCB, Marseille, France

Backgrounds

In all domains of life, proper regulation of the cell cycle is critical to coordinate genome replication, segregation and cell division. In some groups of bacteria, *e.g. Alphaproteobacteria,* tight regulation of the cell cycle is also necessary for the morphological and functional differentiation of cells. During the symbiosis in *Medicago* species, the alphaproteobacterium *Sinorhizobium meliloti* undergoes an elaborate cellular differentiation within host root cells. This differentiation results in massive amplification of the genome, cell branching and elongation, and loss of reproductive capacity.

Objectives

In the closely related alphaproteobacterium *Caulobacter crescentus*, cellular differentiation is tightly linked to the cell cycle via the activity of the master regulator CtrA, and recent research in *S. meliloti* suggested that CtrA might also be key to cellular differentiation during symbiosis. Depletion of CtrA causes cell elongation, branching and genome amplification, similar to that observed in nitrogen-fixing bacteroids.

Methods

We showed that the cell cycle regulated proteolytic degradation of CtrA is essential in *S. meliloti* and all mutants of the CtrA degradosome are impaired in the differentiation process. As CtrA must be absent in mature bacteroids allowing a proper nitogen fixation we hypothesized that CtrA proteolysis may play a crucial role in bacteroid development and possibly triggered by NCR plant peptides.

Conclusions

Our findings provide valuable insight into how highly conserved genetic networks can evolve, possibly allowing complex differentiation programs such as the bacteroid differentiation in *S. meliloti.*

Cell surfaces and signal transduction

FOLLOWING COLICIN TRANSLOCATION TO THE ESCHERICHIA COLI CYTOPLASM ONE MOLECULE AT A TIME

M.L. Francis[1], *P. Rassam*[1], *C. Kleanthous*[1]
[1]*University of Oxford, Biochemistry, Oxford, United Kingdom*

Backgrounds

Gram-negative bacteria often release toxic bacteriocins into their immediate environment as a means of competing with closely related microorganisms. Colicins are potent bacteriocins expressed and released by *E. coli* that bind to outer membrane protein receptors with high affinity and, following contact with proteins in the periplasm and inner membrane, translocate a cytotoxic domain into the cell by a poorly understood mechanism. Cell-death occurs in minutes through depolarization of the cell, hydrolysis of peptidoglycan precursors or digestion of nucleic acids in the cytoplasm. The dogma in colicin research is that a single molecule is sufficient to kill a cell, although this has yet to be formerly demonstrated.

Objectives

The aim of this research was to develop fluorescence-based microscopy tools to visualise colicin entry into *E. coli* as a test of this hypothesis and to probe the mechanism of translocation through the cell envelope.

Methods

We have developed fluorescence widefield and total internal reflection fluorescence (TIRF) microscopy methods for investigating the import of single colicin E9 molecules in *E. coli*.

Conclusions

We demonstrate that ColE9 fluorescently-labelled in its C-terminal endonuclease domain retains catalytic activity and cytotoxicity. Using this fluorescently-labelled ColE9 we have for the first time visualised the translocation of individual colicin molecules to the cytoplasm of *E. coli*, tracked the diffusion of these single molecules *in vivo* and demonstrated that import is dependent on the proton motive force. This research will describe current progress in exploiting these newly developed tools in understanding bacteriocin translocation in bacteria.

Cell surfaces and signal transduction

MICROBES, METALS AND NANOWIRES

G. Reguera[1]
[1]*Michigan State University, Microbiology and Molecular Genetics, East Lansing, USA*

Backgrounds

In Nature, highly efficient and diverse consortia of microbes cycle carbon and other elements in electrochemical reactions that discharge metabolic electrons onto soluble and insoluble metals. One group in particular, *Geobacter* bacteria, uses nanoscale, conductive protein filaments or pili to bind and transfer electrons to iron oxide metals and to soluble metal contaminants such as the uranyl cation, which is reductively precipitated outside the cell. Interestingly, the *Geobacter* pili are composed of a single peptide subunit, which polymerizes in a helical fashion such that contacts are formed between the side chains of aromatic residues to promote fast rates of charge hopping. Furthermore, structural studies identified ligands on the pilus surface that could function as metal traps for the uranyl cation and other cationic metals. Once bound, the metals are positioned in close proximity to a terminal tyrosine residue of the pilus multistep hopping path to promote their reductive precipitation.

Objectives

To investigate protein nanowires as a new paradigm in biological electron transfer
To harness the properties of conductive nanobiomaterials in nanotechnological applications

Methods

Methods interface micro fabrication, atomic force microscopy and biological techniques to study protein nanowires and integrate them into electronic devices.

Conclusions

The nanoscale dimensions of the pili and their ability to transport charges and immobilize metals offer unique opportunities for applications in nanotechnology. On the other hand, recombinant techniques can be applied to develop sustainable manufacturing protocols for the mass-production of peptides and protein nanowires. Further, genetic engineering can be used to functionalize the nanomaterials for their selective and specific integration into nanoelectronic devices. Of special significance is the ability of these nanomaterials to bind and reductively precipitate metal contaminants such as uranium, a process that could be harnessed to develop sensors and deployable devices for bioremediation.

Cell surfaces and signal transduction

THE LIPOPROTEIN EXPORT SIGNAL OF BACTEROIDETES

F. Lauber[1], G.R. Cornelis[1], F. Renzi[1]
[1]UNamur, Biology, Namur, Belgium

Backgrounds

The phylum Bacteroidetes includes human pathogens and commensals as several members of the human microbiota that contribute to the control of gut homeostasis and protection against pathogens. A hallmark of these bacteria is the presence of surface-exposed multi-protein membrane complexes (Sus-like systems) that are encoded by specific polysaccharide utilization loci (PUL). These systems are unique and have a crucial role in the biology of Bacteroidetes since they allow the uptake and catabolism of a large variety of nutrients, mainly polysaccharides coming from the host. Sus-like systems are mainly composed of lipoproteins anchored to the outer membrane and facing the external milieu. This lipoprotein localization is uncommon in most studied Gram-negative bacteria while it is widespread in Bacteroidetes.

Objectives

Little is known on how these complexes assemble and in particular on how lipoproteins are transported at the bacterial surface.

Methods

By bioinformatic analyses, we identify a lipoprotein export signal (LES) at the N-terminus of surface-exposed lipoproteins of the human pathogen *Capnocytophaga canimorsus* corresponding to K-$(D/E)_2$ or Q-A-$(D/E)_2$. We show that, when introduced in sialidase SiaC, an intracellular lipoprotein, this signal is sufficient to target the protein to the cell surface. Mutational analysis of the LES in this reporter system showed that the amino acid composition, the position of the signal sequence and the global charge are critical for lipoprotein surface transport. Furthermore, we identify a LES in other Bacteroidetes species.

Conclusions

Overall these findings suggest the presence of a common new bacterial lipoprotein export pathway that flips lipoproteins across the outer membrane of Bacteroidetes.

FEMS7-2877
Cell surfaces and signal transduction

BUILDING A MEMBRANE ON THE OTHER SIDE OF THE WALL
T.J. Silhavy[1]
[1]*Princeton University, Molecular Biology, Princeton, USA*

Building a membrane on the other side of the wall

Thomas J. Silhavy

Princeton University

The outer membrane (OM) of Gram-negative bacteria functions as a protective barrier. It is unusual because the OM bilayer is asymmetric; the inner leaflet is composed of phospholipids (PLs), but the outer leaflet is made of lipopolysaccharide (LPS). Two kinds of proteins are found in the OM. Lipoproteins (Lpps) are inserted into the inner leaflet of the OM by posttranslationally attached lipid moieties. Integral OM proteins are β-barrel proteins (OMPs). I will present an historical overview of how the structure of the Gram-negative cell envelope was discovered and then summarize what is currently known about the assembly pathways for LPS, Lpps and OMPs in *Escherichia coli*. What's missing is information about the assembly pathway for phospholipids (PLs).

Several years ago we discovered a retrograde PL transport system that function to maintain OM asymmetry. I will describe a dominant mutation in the gene for the OM lipoprotein component of this transport system that leads to cell death under starvation conditions in media with limited cation concentrations. Death occurs not by rapid cell lysis, but by a novel mechanism involving flow of PLs from the inner to the OM that results in rupture of the inner membrane and the slow leakage of cytoplasmic contents. Our data may provide insights into the long-standing question of how PLs are transported to the OM.

Communicating Microbial Science to Society: from Virtual to Hands-on Strategies

SMALL WORLD INITIATIVE (SWI)
N. Broderick[1]
[1]*Molecular and Cell Biology, University of Connecticut, USA*

The Small World Initiative is a novel introductory research course that addresses a human health crisis – the need for new antibiotics. Launched by Dr. Jo Handelsman at Yale University in 2012 and piloted by 26 institutions in 2013, the program has rapidly expanded to 185 institutions across 12 countries. Through the course, students: a) discover and characterize antibiotic-producing bacteria from soil, b) extract their metabolites, and c) contribute their data with student researchers from around the globe. This initiative integrates two critical elements. First, it provides an early discovery-based research experience for students, which encourages STEM retention. Second, the course seeks to positively impact human health by crowdsourcing the discovery of new antibiotics. Recently, SWI has expanded to high schools in the US, UK, Ireland, and Spain. While we continue to grow these programs, we are developing future phases: establishing throughput and educational chemical labs to move leads into the drug discovery pipeline, and additional professional development opportunities for faculty and students. The next phase of the program is well poised and we look forward to the addition of new collaborators to join our mission and promote antibiotic discovery through the curiosity and creativity of young scientists across the world.

A LABORATORY ACTIVITY USING BACTERIOPHAGES, THE FORGOTTEN WEAPON AGAINST BACTERIA

S. Campoy[1], *C. Pilar*[1], *J. Aranda*[1], *M. Sánchez-Osuna*[1], *J. Barbe*[1], *M. Llagostera*[1]
[1]*Universitat Autònoma de Barcelona, Departament de Genètica i de Microbiologia, Cerdanyola del Vallès, Spain*

Backgrounds

Soon after their discovery, 100 years ago, phages were used to treat patients suffering from dysentery or cholera and to promote wound recovery. Although the results were promising, interest in phage therapy waned until it was mostly forgotten, as penicillin and other antibiotics became widely available. Today, the emergence of multidrug-resistant bacteria has rekindled the interest in bacteriophages as antibacterial tools. Despite phages are the most divers and abundant entities in our planet and their multiple applications, biology students remain largely unaware of these entities and are offered few opportunities to explore them in the laboratory.

Objectives

In this activity, students are introduced to the discovery of bacteriophages and encouraged to design an experiment demonstrating the possible use of lytic phages as biocontrol agents and comparing their efficacy with that of other antimicrobial agents. Further, they also formed hypotheses about the expected results and then, using quantitative data, tested their validity.

Methods

Experimental data were obtained by measuring absorbance and cell viability of *Salmonella enterica* sv Typhimurium LT2 cultures treated with either the P22 lytic derivative bacteriophage or different antibiotics (streptomycin, ampicillin or spectinomycin).

Conclusions

The obtained data, combined with class data or student autonomous learning, contributed to providing insights into the lytic and lysogenic cycles of bacteriophages, the molecular processes that finally kill the bacteria, and the appearance resistant bacteria. Further, using the scientific method, students were able to explore the nature of antimicrobial agents and the possible use of phages, phage cocktails, and phage derivative compounds as antibacterial tools.

[1]Universidad Complutense de Madrid, Departamento de Microbiología II- Facultad de Farmacia, Madrid, Spain
[2]Universidad Complutense de Madrid, Departamento de Microbiología III- Facultad de Biología, Madrid, Spain
[3]Universidad Complutense de Madrid, Departamento de Sanidad Animal- Facultad de Veterinaria, Madrid, Spain
[4]Universidad Complutense de Madrid,
Departamento de Sanidad Animal y VISAVET- Facultad de Veterinaria, Madrid, Spain

Backgrounds

WHO considers Antimicrobial Resistance (AMR) among the greatest threats to human health. Therefore, education in AMR awareness currently stands as a major priority in scientific communication. The Small World Initiative (SWI) is an educational crowdsourcing programme created in the USA in 2012: college students perform both field and lab work to isolate novel bacterial strains with antimicrobial bioactivities from environmental samples. Involving students in a real discovery experience inspires young students to pursue scientific careers and successfully spreads AMR awareness.

Objectives

Our objective was adapt SWI to the particular educational environment of Spain, in which curricular decisions are taken early in academic life, essentially at the High School level. At the same time, we wanted to involve Microbiology students at the University, bridging the gap between Higher and Secondary Education.

Methods

We adopted a service-learning strategy: teams of 4-6 volunteer University students, supervised by 19 Microbiology Faculty members, creatively implemented SWI on groups of 10-30 students in High Schools in the region of Madrid. A total 130 College students from 6 different Degrees worked on 22 local High Schools, where over 500 students collected and analyzed 250 soil samples. Blogs and social networks were exploited to communicate the experience and surveys were used to assess its impact at diverse levels.

Conclusions

We present our encouraging conclusions on how the pilot SWI@Spain experience contributed to (i) raising AMR awareness in our community; (ii) the formation of University students by an alternative service-learning pedagogical methodology; (iii) the motivation of High School students towards science-oriented University degrees.

SIMPLE PROTOCOL FOR MOLECULAR FINGERPRINTING OF HUMAN ORAL MICROBIOTA SAMPLES IN LAB CLASSES

A.C. Henriques[1], P. De Marco[1]
[1]IUCS, IINFACTS, Paredes, Portugal

Backgrounds

The increasing significance of molecular biology in different circumstances of our daily life implies that it is very important that biomedical students deal with the principles and techniques underpinning its application. Human DNA fingerprinting is a major tool in identifying individuals and in evidence matching. However, this technique can be difficult to reproduce in practical classes.

Objectives

Create a practical class activity suitable for undergraduate students that elucidates how human oral microbiota is diverse and individually unique.

Methods

Here we report on distinct PCR profiles obtained when amplifying saliva DNA of a score of distinct individuals with RAPD primer BOXA1R. RAPD is a simple method efficiently used for discrimination between bacterial strains and is used in this instance to obtain personalized fingerprints of each individual's oral microbiota.

Conclusions

We present real results with undergraduate students confirming that this procedure is easily feasible in practical classes. Based on the results presented, we suggest a laboratory activity for undergraduate Molecular Biology / Microbiology students.

FEMS7-0754
Communicating Microbial Science to Society: from Virtual to Hands-on Strategies

GETTING INTO THE SWING OF THINGS - COMMITTING TO LIFELONG LEARNING AND DEVELOPMENT (FROM UNDERGRADUATES TO ACADEMICS)

B. Fahnert[1]
[1]*Cardiff University, Cardiff School of Biosciences, Cardiff, United Kingdom*

Backgrounds

In a rapidly changing world, where jobs are no longer for life or change beyond recognition, lifelong learning is required of everyone. Educators need to support learners early on in understanding this need and developing necessary skills and reflection. So initial Personal Development Planning prepares and becomes Continuous Professional Development. Equally, these educators need sufficient opportunity for pedagogic training, also perceived as valuable by undergraduates and benefitting academic career establishment/advancement. Teaching professionalism is not developed through traditional academic apprenticeship (i.e. doctoral studies), and -along with high graduate employability rates- has become a focus for Higher Education Institutions to boost institutional reputation.

Objectives

Better understand behaviour and drivers around committing to lifelong learning at two stages:

a) graduate attributes and career skills development
to inform practice when equipping/empowering undergraduates for successful transition into employment;
b) teaching training for early career academics
to achieve long-term benefit for all stakeholders.

Methods

Stakeholder and discourse analyses and ethically cleared mixed method studies (interviews, questionnaires) were conducted, qualitatively analysing experiences and perceptions of:

a) under/postgraduates, academics, employers, alumni;

b) teaching training participants and non-participating academics.

Conclusions

In both contexts behaviour is affected by conflicting demands on time at present and obtaining intangible benefits for an unknown future.

Undergraduates prioritise subject rather than career skills unless incentivised, which still does not guarantee meaningful engagement.

Challenges to teaching training were e.g. non-peer trainers, unfamiliarity with terminology and using qualitative methodology/findings.

Using identified drivers to tailor developmental provision and communication with stakeholders towards cultural change is outlined.

SOCIAL NETWORKS AS KEY TOOLS IN MICROBIOLOGY DIVULGATION

J.D. Flores Felix[1], P. García-Fraile[2], P. Martínez-Hidalgo[1], M. Marcos-García[1], L. Celador-Lera[1], A. Díez-Méndez[1], X.A. Cruz-González[1], A. Jimenez-Gomez[1], R. Rivas[1]
[1]University of Salamanca, Microbiología y Genética, Salamanca, Spain
[2]Academy of Science of the Czech Republic, Department of Microbiology, Prague, Czech Republic

Backgrounds

YouTube is the major online video platform, with a high diversity of contents and over a billion of users from all around the world. Therefore, this platform has a high potential as education and divulgation tool. The combination of this platform with the social networks, such as Facebook or Twitter, has a great potential to introduce academic contents to a non-academic audience

Objectives

Our aim was to use of social networks as a tool to improve the diffusion of the Microbiology using multimedia contents guested in YouTube, increasing the number of potential spectators reached by our videos about microbiology techniques hosted in of YouTube channel.

Methods

We created different profiles in YouTube, Facebook and Twitter. The Youtube profile was linked to own channel, which has with 215 subscriptions and counts more than 30.000 video visualizations. On Facebook, we opened a Facebok Page named “Microbiología y Genética. Interacciones Planta-Microorganismo. USAL” (translated into English: Microbiology and Genetics. Plant-Microbes Interactions. USAL”) and on Twitter we created the profile @MicrobioUSAL. Then, we shared our Microbiology YouTube videos on our social networks.

Conclusions

We have seen than YouTube is a useful tool to disseminate microbiology contents into academic and non-academic fields and moreover, the use of social networks such as Facebook and Twitter to share the videos hosted on YouTube allowed us to increase the number of spectators, proved by peaks in the numbers of visualizations and minutes with clear activity during few hours following their shares on the social networks.

"HOW ARE MICROBES USEFUL TO US?": MICROBIOLOGY LEARNING IN EUROPEAN RESEARCHER'S NIGHT.

A. Jiménez-Gómez[1], X. Cruz-González[1], J.D. Flores-Félix[1], L. Celador-Lera[1], A. Diéz-Mendez[1], E. Menéndez[2], M. Marcos-García[1], P. García-Fraile[3], R. Rivas[1]
[1]University of Salamanca, Department of Microbiology and Genetics, Salamanca, Spain
[2]Instituto de Ciências Agrárias e Ambientais Mediterrânicas, ICAAM, Evora, Portugal
[3]Academy of Science of Czech Republic., Institute of Microbiology, Prague, Czech Republic

Backgrounds

European Researcher's Night is one of the most important scientific events in Europe. It takes place every year on the last Friday in September. More than 30 countries and over 300 cities participate organizing scientific dissemination activities, showing to citizens what researchers really do for society and increasing the possibility to promote research careers to young people. In addition, Microbiology is one of the subjects which does not have an important relevance in the current high schools' curricula, and however has a big relevance in our lives. Moreover, microbiology requires from society the comprehension of many complicated concepts, which are easy to learn if taught in a practical way.

Objectives

In this context, our main objective was to offer society the possibility of seeing colonies of microorganisms cultured in Petri dishes, observing different samples under the microscope and showing the essential importance of microorganism in many key points of our daily life.

Methods

The activity was carried out in one of the microbiology laboratories of the University of Salamanca (Spain). The 40 participants were divided into small groups and were rotating to perform the different activities in one-hour sessions. The language used was suited to the different age of the participants (between 14 and 70 years old) and the topics presented were selected according to general society interests.

Conclusions

The experience was gratifying and positive not only for the participants but also for the researchers who organized the activity. It was an exchange of questions and answers which showed the general doubts of the society about Microbiology. The success of the activities shows us that the topics presented were interesting to both children and adults.

STUDENT-GENERATED MULTIPLE-CHOICE PRE-EXAM QUESTIONS: AN EFFECTIVE TOOL FOR PARTICIPATORY LEARNING IN MICROBIOLOGY

M. Marvasi[1], M. Teplitski[2], M. Di Cesare[1], C.J. Krediet[3]
[1]Middlesex University, Natural Sciences, London, United Kingdom
[2]University of Florida, Water and Soil Science, Gainesville, USA
[3]Eckerd College, Marine Biology Department, St. Petersburg, USA

Backgrounds

It is commonly recognized that the act of creating questions enhances learners' understanding of course materials and promotes deep learning. Student-generated questions that involved higher cognitive skills (compared to a simple recall) have been linked to self-directed learning and improved conceptual understanding.

Objectives

In this multi-year study, students designed multiple-choice pre-exam questions during a Microbiology course aimed at higher levels of learning, followed by their discussion. Students were instructed to construct questions on the higher domains of Bloom's taxonomy. We tested the hypothesis that this intervention improves student learning.

Methods

Learning gains were measured as student achievement on the exam following the intervention, and compared to student achievement on the traditional exam (prior to which a review session was focused on instructor-led recitation of the key concepts). Over the duration of the experiment 162 students chose to participate in this study from 2009 to 2015.

Conclusions

Following the intervention in all years, average grade on the post-intervention exam increased by 7.4% points. It is important to point out that not all students benefited equally from this activity. The lowest quintiles improved their scores on the second exam in a range of 6.8% to 9.9% percentage points, respectively. Students who were in the 3rd quintile based on the results of the first exam demonstrated the highest achievement improving their performance on an average by 12.3% percentage points. The students within the forth quintile improved their performance by 10.8% percentage points. Such gains were not observed in the semesters when the intervention was not implemented.

PARTICIPATORY WORKSHOPS: THERE IS NOT AGE TO DISCOVER MICROBIOLOGY

M. Orruño[1], *I. Arana*[2]
[1]*Faculty of Pharmacy - University of the Basque Country UPV/EHU, Immunology- Microbiology and Parasitology, Vitoria-Gasteiz, Spain*
[2]*Faculty of Science and Technology - University of the Basque Country UPV/EHU, Immunology- Microbiology and Parasitology, Leioa, Spain*

Backgrounds

Every year the University of the Basque Country (UPV/EHU) organizes the Science Week (ZientziaAstea). This annual event, aimed at audiences of all ages, tries to bring science to a non-specialist public by means of workshops, scientific shows, conferences and other activities. The microbiology has been present in this event from the first edition.

Objectives

To try to transmit microbiology in a more efficient and participatory way.

Methods

In recent years we have launched 2 workshops aimed at children and adults. The first workshop we implemented, *Microorganisms working*, tries to refute the bad image of microorganisms and to highlight their benefits and their ecological and industrial relevance. Among others, attendees can taste several foods and beverages obtained with microbial participation and discover that microorganisms are involved in the production processes of numerous common household product.

As the format was not the most suitable to keep the attention of the younger participants, we decided to launch a new workshop specifically aimed at children between 6 and 12 years, *Small microbiology for small scientists,* which tries to introduce children the microbial world through games and activities. They can use a microscope to discover the microbial diversity in natural samples, simulate the bacterial growth or become aware of their own *microbiological fingerprint*.

Conclusions

The workshops have been quite successful, with all the available places filled and a high level of satisfaction among attendees. In addition, the children's workshop has been exported to other fairs and adapted to schools.

STANDARDISED METHODS IN PRACTICAL LAB WORK GENERATES IMPORTANT KNOWLEDGE FOR STUDENTS, SCIENTISTS AND THE FOOD SAFETY AGENCIES

C.S. Svanevik[1], B.T. Lunestad[1]
[1]National Institute of Nutrition and Seafood Research, Contaminants and Biohazards, Bergen, Norway

Backgrounds

The background for this work was to use standardised laboratory methods for both practical and theoretical teaching in seafood microbiology, where the achieved data also generates new knowledge for scientist and the government. As contaminated water is globally the main vehicle for microbial pathogens in most regions, we find that teaching future microbiologist and employees in the food industry on the importance of hygienically satisfactory water, microbiological analyses and how to ensure good water quality and safety, is highly relevant.

Objectives

This work present a complete experimental design for water analyses as a tool to teach students the methods and other key elements in microbiology, including food safety, environmental dissemination and survival of microorganisms, laboratory practices, water legislation and critical evaluation of results.

Methods

Analyses for the detection culturable bacteria (ISO 6222) and of fecal contamination in water (ISO 4788:1990, 4792:1990, 7899-2:2000) were used as an educational tool during a University course in seafood microbiology over a ten-year period (2006-2015). In addition to the lab results, the achieved knowledge among the students was examined by two retrospective questionnaires (about water analysis and lab course) conducted during June 2015. The questionnaires were circulated and made available for students back to 2006.

Conclusions

The questionnaires revealed that the laboratory course is highly appreciated, and that many students remembered important aspects of the water analysis, even after several years. The questionnaire results were consistent with our perception that some students find calculation of dilutions difficult to comprehend.

HANDS-ON STAINING TECHNIQUES TO LEARN ABOUT BACTERIA

A. Martins[1,2], C. Dias[1,2], M.J. Fonseca[2,3], F. Tavares[1,2]
[1]Faculdade de Ciências da Universidade do Porto, Departamento de Biologia, Porto, Portugal
[2]CIBIO - Centro de Investigação em Biodiversidade e Recursos Genéticos/InBIO Laboratório Associado, Microbial Diversity and Evolution, Porto, Portugal
[3]Universidade do Porto, Museu de História Natural e da Ciência da Universidade do Porto MHNC-UP, Porto, Portugal

Backgrounds

Practical work-based approaches have long been regarded as privileged educational tools in biology education. These practices lead to opportunities for students to develop conceptual, procedural and attitudinal skills.

Objectives

1. Assess the impact of a practical approach based on staining procedures on the learning process concerning bacteria;
2. Clarify misconceptions about bacteria;
3. Acquaint students with microscopy and staining techniques;
4. Foster the development of critical observational skills.

Methods

The activity, trialed and tested with 15/16 year-old students, included the observation and identification of prokaryotic cell structures using the optical microscope, and microscope slides prepared by the students and from collections. Data was gathered through a pre-/post-test design mixed-method approach with the use of an out-group. Statistical analyses were carried out using IBMS' SPSS v.21.

Conclusions

The findings revealed the overcoming of frequent bacteria-related misconceptions. Experimental group students listed notions such as "show non defined nucleus" [16 (post-test)vs.11(pre-test);$\chi2(1)=12.07;p<0.001$] or "with capsule which confers resistance" [6 vs. 0;$\chi2(1)=5.14$; $p=0.02$]. Both groups agreed that microscopy is important to diagnose bacteria (Expgroup:M=4.27;Dp=1.20;Z=340.5;p<0.001,d=0.14; Cntgroup:M=4.48;Dp=0.70;Z=300; p<0.001, d=0.01) and perceived laboratory work as an important learning tool (Expgroup:M=4.90; Dp=0.31;Z=465;p<0.001;d=0.42; Cntgroup:M=4.93; Dp=0.27;Z=378;p<0.001;d=0.50), allowing them to understand issues addressed in their classes (Expgroup:M=4.79;SD=0.48;Z=-1.42;p=0,15;d=0.16; Cntgroup:M=4.67;SD=0.48;Z=378;p<0.001;d=0.16). Regarding microscopy techniques, students emphasized their impact, namely at a motivational level, stating that these allow to "study bacteria in more detail".
The laboratory activity implemented had a positive effect in the participants' conceptual learning (morphology and physiology of the bacterial cell) and allowed the development of their procedural capabilities, as well as of their critical thinking skills.

Communicating Microbial Science to Society: from Virtual to Hands-on Strategies

DEVELOPING COMMON CURRICULUM AND IMPROVING TEACHING APPROACHES OF MICROBIOLOGY EDUCATION

A. Netrusov[1], A. Trchounian[2]
[1]M.V. Lomonosov Moscow State University, Microbiology, Moscow, Russia
[2]Yerevan State University, Biochemistry- Microbiology & Biotechnology, Yerevan, Armenia

Backgrounds

Microbiology is one of the major subjects in Biology Education. New achievements of biology and formed basic and applied microbiology problems, on the one hand, the mobility of students and the labor market demands in microbiology specialists, on the other hand, require the development of a common (European or international) curriculum of academic microbiology [1].

Objectives

Microbiology in undergraduate education appears in two directions (areas) - General Microbiology and Applied (Medical) Microbiology.

Methods

By study and comparison of the microbiology programs for different universities, the following is proposed.

Conclusions

The new curriculum of General Microbiology may include three modules: (1) structure of the microbial cell (morphology), physiology, biochemistry and genetics of microorganisms; (2) biodiversity, ecology and systematics of microorganisms; (3) types, methods and directions of microbial biotechnology. A certain part of the program (to a quarter of volume) can include regional microbiology problems associated with microbial diversity, prevention of microbial diseases and environmental problems. It is important to highlight the objectives and output to ensure practical relevance. Special courses in undergraduate and graduate microbiology education in-depth subjects are in two areas and three modules.

To improve teaching approaches the problematic (interactive) lectures, practical classes and laboratory work, tests, and various forms of individual work should be implemented. The ratio of lectures and laboratory work should be offered approximately equal. Laboratory work must be carried out accordingly by general (international) protocols. Also important are consistent actions for the implementation to include assessment of the knowledge and learning feedback.

EAM Workshop: Survival and Persistance

POST-TRANSCRIPTIONAL REGULATORY NETWORKS IN LEGIONELLA PNEUMOPHILA: KEY TO THE SURVIVAL IN EXTRA- AND INTRACELLULAR ENVIRONMENTS

C. Buchrieser[1], T. Sahr[1], G. Oliva[1], F. Impens[2]
[1]Institute Pasteur, Genomes and Genetics, Paris, France
[2]Ghent University, VIB Medical Biotechnology Center, Ghent, Belgium

Backgrounds

Legionella pneumophila, the causative agent of the pneumonia-like Legionnaires' disease, is commonly found in aquatic habitats where it multiplies within protozoa. *L. pneumophila* is able to survive and replicate in the hostile intracellular environment of a protozoan cell (or a human macrophage during disease). Once *L. pneumophila* has replicated to high numbers, it is released in the water (or the lung) where low nutrient extracellular conditions are present. To tolerate or exploit these conditions this bacterium has evolved a biphasic lifecycle wherein it alternates between a replicative and a transmissive phase. Genes that allow replication and to scavenge nutrients from the host are expressed when nutrients are available whereas genes that allow transmission and survival in the extracellular environment like virulence factors, motility and resistance against several stress factors are expressed, when nutrients are limited. The key regulator governing this adaptation thereby allowing the bacterium's intra- and extracellular survival is the RNA-binding protein CsrA.

Objectives

Our aim was to identify all targets of CsrA to understand how *L. pneumophila* adapts to the different conditions it encounters.

Methods

We used transcriptomics, proteomics, RNA-Immunoprecipitation followed by deep sequencing (RIPseq), together with biochemical, phenotypical and molecular analyses to identify the *L. pneumophila* CsrA targets genome wide.

Conclusions

Comparison of a wild type and a *csrA* mutant strain identified 478 RNAs with potential CsrA interaction sites and also led to the discovery of a new mode of action of CsrA that allows to regulate genes comprised in the same operon, independently.

EAM Workshop: Survival and Persistance

BACTERIAL SURVIVAL STRATEGIES

M. Vicente[1], *A. Sánchez-Gorostiaga*[1]
[1]*Centro Nacional de Biotecnología- CSIC, Microbial Biotechnology, Madrid, Spain*

The role of FtsZ in bacterial survival

Filamentation helps bacteria to be less susceptible to antibiotics, to evade phagocytosis by the immune system, or to escape protist predators in marine environments (reviewed in Justice *et al.*, 2008 *Nat Rev Microbiol***6**: 162-168). Division-inhibited filaments provide a survival strategy against damages induced by host intracellular stress, nutrient limitation, inhibition of metabolic pathways or DNA damage produced by oxidative free radicals. Inhibition of the FtsZ activity by SulA is one of the filament-inducing mechanisms to counteract stress during host pathogen interaction. This process is reversible and once the activity of FtsZ is resumed at later infection steps the host-induced filaments can proliferate rapidly.

We found that the very low levels of FtsZ present in synthetically FtsZ-deprived cells (VIP205), has unexpected and severe pleiotropic effects on the global physiology of *E. coli* culminating in a reduced resilience that compromises bacterial survival. At the non-permissive conditions, cells of a FtsZ conditional mutant (PAT84) in which the GTPase activity and bundling are reduced, do not divide. In contrast to FtsZ-deprived VIP205 cells, the viability of the conditional PAT84 mutant or the SulA inhibited filaments is not affected because the amount of the FtsZ protein remains unperturbed and these filaments sustain no other damage that might compromise their survival.

Based on our results, we propose that the quest for new antibacterial compounds targeting FtsZ should be directed to decrease the number of FtsZ molecules instead of inhibiting the activity of the protein.

BACTERIOPHAGES AND ANTIBIOTIC RESISTANCE IN CYSTIC FIBROSIS

M. Brown-Jaque[1], L. Rodriguez Oyarzun[1], T. Cornejo-Sánchez[2], S. Gartner[3], J. de Gracia[3], S. Rovira[3], A. Alvarez[3], J. Jofre[1], J.J. González-López[2], M. Muniesa[1]
[1]Universidad de Barcelona, Genetics- Microbiology and Statistics, Barcelona, Spain
[2]Hospital Vall d'Hebron- Vall d'Hebron Institut de Recerca VHIR, Clinical Microbiology, Barcelona, Spain
[3]Hospital Universitario Vall d'Hebron, Cystic Fibrosis Unit, Barcelona, Spain

Backgrounds

Cystic fibrosis (CF) is a relevant genetic disease whose morbidity and mortality is related to lung affectation and its complications. Antibiotics are used to prevent bacterial colonization of patients; however, their effectiveness is compromised by the development of resistances. Bacteriophages are the least explored mechanism of transfer of resistance to antibiotics in clinical settings.

Objectives

To study the occurrence of bacteriophages harbouring seven antibiotic resistance genes (ARGs) in sputum samples of patients with CF to determine their role as vehicles of ARGs.

Methods

The study was conducted with sputum samples of 71 CF patients of ages from 9-63 years-old visiting the CF unit of Hospital Vall d'Hebron in Barcelona. A control group of 21 non-CF patients was included in the study. ARGs in phage packaged DNA were determined and quantified by TaqMan qPCR assays after phage DNA extraction.

Conclusions

bla$_{TEM}$ was the ARG with more positive samples and number of gene copies per ml of sputum (25%; 2.74 GC/ml), followed by *bla*$_{CTX\text{-}M\text{-}9}$ (27%; 2.46 GC/ml), *bla*$_{CTX\text{-}M\text{-}1}$ (25%; 2.30 GC/ml), *bla*$_{OXA\text{-}48}$ (16.7%; 2.03 GC/ml), and *qnrS* (8.3%; 1.19 GC/ml); *qnrA* and *mecA* showed the lowest values and prevalence. Prevalence presented statistical differences in patients < 18 years-old for *bla*$_{CTX\text{-}M\text{-}1}$ and *bla*$_{OXA\text{-}48}$. Generally ARGs presented greater prevalence in control group excepting *bla*$_{CTX\text{-}M\text{-}1}$ and *mecA* whose prevalence, even if low, is higher in the CF patients. Average quantity of ARGs of CF patients was higher than in the control group excluding *bla*$_{TEM}$ and *qnrA*.

FEMS-ESCMID

LOW COST, HIGH THROUGHPUT, IN VIVO SCREENING OF NOVEL ANTIMICROBIALS FOR EFFICACY AND TOXICITY USING TRULARV™ GALLERIA MELLONELLA

O. Champion[1]
[1]*University of Exeter, BioSystems Technology, Exeter, United Kingdom*

Backgrounds

Multi-drug resistant (MDR) bacteria are an emerging threat in the modern world and new antimicrobial drugs are urgently being sought. One approach is to identify naturally occurring compounds produced by microorganisms. Historically, Actinobacteria have been a rich source of antimicrobials, but there are many species yet to be tested.

Objectives

In this study several thousand crude actinomycete extracts, were screened for antimicrobial activity, and approximately fifty lead extracts identified. The challenge we faced was how to further screen these extracts for efficacy and toxicity in an infection model. *Galleria mellonella* larvae can be used as an inexpensive, ethical and simple to use whole organism infection model. Previously reported studies have shown that there is good correlation between the results of *G. mellonella* infection experiments and existing drug efficacy data in humans.

Methods

Extracts were tested for efficacy and toxicity in, research grade *G. mellonella* (TruLarv™) larvae in a high-throughput assay. In this study larvae were infected with *Pseudomonas aeruginosa* NCTC10662 and concurrently dosed with one of the fifty crude extracts. To assess their efficacy, survival of the larvae was measured in a time course experiment. In parallel, to evaluate the toxicity of complex bacterial extracts maximum half lethal dose (LD_{50}) of the compounds in larvae was calculated.

Conclusions

We were therefore able to identify extracts containing bioactive compounds with low toxicity *in vivo* prior to their subsequent purification and testing in mammalian models.

ANTIBIOTIC RESISTANCE GENES IN THE BACTERIOPHAGES DNA FRACTION OF HUMAN FECAL SAMPLES AND BACTERIA ISOLATED FROM FECES

M. Brown-Jaque[1], W. Calero-Cáceres[1], P. Espinal[2], J. Rodríguez[2], E. Miró[2], J.J. González-López[3], T. Cornejo-Sánchez[3], J.C. Hurtado[4], F. Navarro[2], M. Muniesa[1]
[1]Universidad de Barcelona, Genetics- Microbiology and Statistics, Barcelona, Spain
[2]Hospital de la Santa Creu i Sant Pau, Microbiology service, Barcelona, Spain
[3]Hospital Vall d'Hebron- Vall d'Hebron Institut de Recerca VHIR, Clinical Microbiology, Barcelona, Spain
[4]Hospital Clínic, Microbiology service, Barcelona, Spain

Backgrounds

Bacteriophages are the most abundant entities in the world. They transfer genes between various bacterial genera and species acting as mobile genetic elements, contributing to bacterial genetic variability. Recent studies report that phage particles are reservoirs of antibiotic resistance genes (ARG) in different biomes suggesting the possible spread of ARG in phage particles by the human and animal population.

Objectives

To quantify ARGs in the viral DNA fraction of human fecal samples and to detect temperate bacteriophages carrying ARG incorporated as prophages in the genome of fecal bacterial isolates from healthy human carriers.

Methods

The study was performed using 139 human fecal samples from healthy individuals and 82 *Escherichia coli* and *Klebsiella pneumoniae* isolates from these fecal samples. The occurrence of inducible prophages in the strains was analyzed by mitomycin C treatment. ARGs were quantified by TaqMan qPCR assays in phage DNA extracted from feces and from phage particles induced from isolates.

Conclusions

bla$_{\text{TEMt}}$ was the most prevalent and abundant ARG in the viral DNA fraction of feces, followed by *qnrA*, *sul1*, *bla*$_{\text{CTX-M-9t}}$ and *armA*. Less than 10% of samples showed *qnrS*, *mecA*, *bla*$_{\text{CTX-M-1t}}$, and *bla*$_{\text{OXA-48t}}$.

bla$_{\text{TEMt}}$ and *bla*$_{\text{CTX-M-9t}}$ were the most prevalent ARG in phage particles induced from the strains. *sul1, bla*$_{\text{CTX-M-1t,}}$ *qnrS* and *qnrA* were less prevalent but also present in phages induced from strains.

Accordingly, ARGs are present in DNA of phage particles isolated from feces and in phages induced from fecal clinical isolates.

FEMS-ESCMID

ANTIMICROBIAL PEPTIDES AND THE EVOLUTION OF RESISTANCE

B. Papp[1]
[1]*Biological Research Centre, Synthetic and Systems Biology Unit, Szeged, Hungary*

Cationic antimicrobial peptides (CAPs) are promising novel alternatives to traditional antibacterial agents, but the overlap in resistance mechanisms between small-molecule antibiotics and CAPs are unknown. Does evolution of antibiotic resistance decrease (cross-resistance) or increase (collateral sensitivity) susceptibility to CAPs? We systematically addressed this issue by studying the susceptibilities of a comprehensive set of antibiotic resistant *Escherichia coli* strains towards 24 antimicrobial peptides. Strikingly, antibiotic resistant bacteria frequently showed collateral sensitivity to CAPs, while cross-resistance was relatively rare. We identified clinically relevant multidrug resistance mutations that simultaneously elevate susceptibility to certain CAPs. Transcriptome analysis revealed that such mutations frequently alter the lipopolysaccharide composition of the outer cell membrane and thereby increase the killing efficiency of membrane-interacting antimicrobial peptides. On the basis of these findings, we identified CAP-antibiotic combinations that rescue the activity of existing antibiotics and selectively eradicate antibiotic resistant bacteria. Our work provides a proof of principle for the development of peptide based antibiotic adjuvants that enhance antibiotic action and block evolution of resistance.

FEMS-ESCMID

A LONG-TERM EPIGENETIC MEMORY SWITCH CONTROLS BACTERIAL VIRULENCE BIMODALITY

I. Ronin[1], N. Katsowich[2], I. Rosenshine[2], N. Q. Balaban[1]
[1]The Hebrew University in Jerusalem, Racah Institute of Physics, Jerusalem, Israel
[2]The Hebrew University in Jerusalem, Department of Microbiology and Molecular Genetics, Jerusalem, Israel

Backgrounds

Phenotypic diversity in clonal populations of pathogens has been shown to enhance infection efficiency. When pathogens enter the host, sensing of environmental cues activate the expression of virulence genes. In contrast, the transition of pathogens from activating to non-activating conditions is poorly understood.

Objectives

The aim of this study was to examine whether phenotypic variability plays a role in the virulence of a model organism, enteropathogenic *E. coli* (EPEC), a human specific pathogen, during infection and in the transition to non-activating conditions.

Methods

We employed the high-throughput ScanLag methodology to systematically detect phenotypic variability in cultures of EPEC. The analysis revealed a bimodal growth rate in EPEC populations. Mathematical modeling followed by experimental validation exposed a mechanism leading to the establishment of a long-term hysteretic memory-switch resulting in the stable co-existence of non-virulent and hyper-virulent subpopulations.

Conclusions

We showed that long-term hysteretic memory drives the constitutive expression of the major virulence factors of the pathogen, even upon shifting to conditions that do not favor their expression, and identified *per* operon as the key factor for the hysteretic switch. This unique hysteretic memory-switch may be common in pathogenic bacteria, resulting in increased disease severity, higher infection persistency and improved host-to-host spreading.

[2]SILS-UvA, MBMFS & Van Leeuwenhoek Centre for Advanced Microscopy, Amsterdam, The Netherlands
[3]SILS-UvA, Mass Spectrometry of Biomacromolecules & MBMFS, Amsterdam, The Netherlands
[4]SILS-UvA, Mass Spectrometry of Biomacromolecules, Amsterdam, The Netherlands
[5]SILS-UvA, Van Leeuwenhoek Centre for Advanced Microscopy, Amsterdam, The Netherlands

Bacterial spores are ubiquitous in nature and can withstand both chemical insults and physical stresses. Spores can survive food preservation processes and upon outgrowth cause food spoilage as well as safety risks. The risk is exacerbated by the heterogeneous germination and outgrowth behaviour of isogenic spore populations. Our studies focus on the mechanisms involved in normal spore structure development. Live-imaging systems, such as SporeTracker, allow us to analyse at single cell level spore germination and outgrowth. A major unknown factor in spore heterogeneity is the observation that not all cells sporulate simultaneously. Hence spore protein composition is likely inherently heterogeneous. Here we discuss approaches to synchronize *Bacillus subtilis* spore formation, and analyse spore proteins as well as germination and outgrowth physiology. Using in *B. subtilis* an IPTG-inducible *kinA* gene that allows us to titrate the amounts of phosphorylated KinA we reached, in agreement with previous analyses, a steep switch in the population from below 5% spores to above 95%. *B. subtilis* spores were heterogeneous in the intensity of GFP and mCherry labelled GerAA and GerD fusion proteins as well as their clustering into one or more foci (germinosomes). Upon triggering spore germination we followed Ger protein fluorescence dynamics as well as intracellular pH dynamics using IpHluorin under control of the ptsG promoter. Current efforts focus on Ger protein interaction with SpoVA channel proteins, coupling molecular data to heterogeneity in spore physiology, its description with mathematical models as well as the time-resolved analysis of the biogenesis of the protective spore coat.

Food microbiology-safety

COMPARATIVE GENOMICS OF ST121 LISTERIA MONOCYTOGENES REVEALS CONSERVATION AND DIVERSITY OF PROPHAGES AND POTENTIAL FITNESS ADAPTATIONS TO FOOD AND FOOD PRODUCING ENVIRONMENTS

L. Ciolacu[1], K. Rychli[1], E. Harter[1], E. Wagner[1], A. Müller[1], A. Zaiser[1], M. Wagner[1], S. Schmitz-Esser[1,2]
[1]Institute of Milk Hygiene- Milk Technology and Food Science,
Department for Farm Animal and Public Health in Veterinary Medicine, Vienna, Austria
[2]Iowa State University, Department of Animal Science, Ames, USA

Backgrounds

The food-borne pathogen *Listeria (L.) monocytogenes* is able to survive for months and even years in food production environments. Particularly strains belonging to sequence type (ST)121 are often found to be abundant and to persist in the food production environments.

Objectives

The aim of the study was to elucidate genetic determinants characteristic for *L. monocytogenes* ST121.

Methods

We sequenced the genomes of 14 ST121 strains and compared them with currently available *L. monocytogenes* ST121 genomes. In total, we analyzed 70 ST121 genomes deriving from 16 different countries and sources.

Conclusions

All ST121 genomes show a high degree of conservation sharing at least 99.7% average nucleotide identity. The main differences between the strains were found in prophage content and prophage conservation. Additionally, we experimentally characterized two ST121 strain-specific genetic features: the transposon Tn*6188* and the novel stress survival islet (SSI-2) *lin0464*/*lin0465*. All strains harbor the novel SSI-2, consisting of homologues of the *L. innocua* genes *lin0464* and *lin0465,* a transcriptional regulator and a putative pfpI protease. Deletion of *lin0465* resulted in reduced survival under oxidative and alkaline stress conditions, suggesting a role in stress response. Tn*6188*, a transposon responsible for increased tolerance against quaternary ammonium compounds, present in 92.8% of all ST121 strains. 97.1 % of the ST121 strains contain a truncated *internalin A* (*inlA*) gene. Only one of the seven human ST121 isolates encodes a full-length *inlA* gene. *L. monocytogenes* ST121 strains are highly similar harboring highly conserved regions which most likely provide fitness adaptations to survival in food and food production environments.

AN HIGH-THROUGHPUT MOLECULAR TOOL FOR HIGHLIGHTING THE EUKARYOTIC FOOD MICROBIAL COMMUNITIES: APPLICATION ON 12 FRENCH CHEESE VARIETIES

J. Denonfoux[1], S. Ferreira[1], L. Garnier[2], A.S. Sarthou[2], P. Bonnarme[2], F. Irlinger[2], E. Dugat-Bony[2]
[1]Genoscreen, Recherche- Développement et Innovation- Communautés microbiennes, Lille, France
[2]AgroParisTech- INRA, UMR Génie et Microbiologie des Procédés Alimentaires- GMPA, Thiverval-Grignon, France

Backgrounds

Cheese fermentation process is deeply related to culture and tradition. Indeed, the manufacturing processes shapes the chemistry and microbiology of cheeses, which contribute to express their organoleptic properties. France alone represents almost 1000 different cheese varieties harboring each a specific, dense microbiota (2–3 × 10^9 cells/g cheese). Recently, the use of metagenomics combined with high-throughput sequencing (HTS) technologies offer the opportunity to profile cheese microbial populations on a large scale. Even if the knowledge associated with the bacterial communities of cheeses is well documented, it remains still missing for the eukaryotic fraction.

Objectives

The GenoScreen company and the French National Institute for Agricultural Research (INRA) associated their expertise to develop a HTS tool for investigate the eukaryotic microbiota associated with 60 cheeses belonging to 12 traditional French cheese varieties.

Methods

The high throughput ITS2 amplicon sequencing associated with bioinformatic processing was used to characterize the fungal community composition down to the species level.

Conclusions

The results showed that major differences were observed between rind and core samples and also according to cheese varieties and manufacturing processes. Occurrence analysis revealed the presence of widespread taxa as well as operational taxonomic units (OTUs) specific to one or several cheese varieties. We highlighted as well some cheese varieties such as Saint-Nectaire and Soumaintrain still hosted unknown species that may account for a large proportion of the total community.
Finally, this molecular tool could be employed as a large-scale for deep microbial inventory in food processing-industry products.

FEMS7-0353
Food microbiology-safety

THE ORIGIN OF FOOD MICROBIOME: PROCESSING ENVIRONMENT AS SOURCE OF CONTAMINATION

D. Ercolini[1]
[1], *Italy*

Microorganisms inhabiting food-processing environments play an important role in defining the food initial contamination pattern and therefore influencing the shelf-life and the quality of the final product. Monitoring the presence of spoilage microorganisms in food-processing environment and mapping the possible contamination routes is necessary to prevent microbial spread along the processing chain and consequently the transition to the finished product. However, facility-resident microbiota was sometimes addressed as a source of microbes that may be beneficially involved in the manufacturing process.
Different food processing and manufacturing environments were analysed by culture-independent high-throughput sequencing, including beef, dairy and ready-to-eat meals processing plants. Swabs were collected from plant surfaces, tools and operators' hands. Moreover, food products from the same manufactures were also evaluated. The presence of a resident microbiota was highlighted, consisting of a few species well adapted to the considered environment, where food residues and exudates can act as substrates. This resident microbiota can be the source of food contamination and proliferate during storage to unacceptable levels, compromising food quality and safety. Nevertheless, depending on the type of manufacturing considered, food processing microbiota may sometimes play a positive role. Indeed, cheese manufacturing plants often harbour lactic acid bacteria, beneficially involved in the fermentative and ripening processes.
Therefore, depending on the nature of the micro-organisms and on the type of food manufacturing process, the environmental microbiota can exert positive functional activities or be a hazard for product quality and safety. Food-environment relationship deserves to be further explored, having the potential to affect the food processing dynamics and the quality of the final products.

INTERACTIONS WITH DIFFERENT YEAST STRAINS PROMOTE A COMMON AND SPECIFIC TRANSCRIPTOMIC RESPONSE IN S. CEREVISIAE

J. Tronchoni[1], J.A. Curiel[1], P. Morales[1], R. Gonzalez[1]
[1]ICVV CSIC-Universidad de La Rioja-Gobierno de La Rioja, Enologia, Logroño, Spain

Backgrounds

New wine biotechnology trends include the use of non-*Saccharomyces* starter cultures. In a previous work, we showed the reciprocal effect of two wine yeast strains co-cultivated in scaled lab fermentation. Different non-*Saccharomyces* wine yeast species are potential strains to be used as co-inoculated starters.

Objectives

We analysed the transcriptional response to co-cultivation by an industrial yeast strain of *S. cerevisiae*. The *S. cerevisiae* wine strain was grown in a mixed culture with three different yeast strains, all of them can be found in a winery environment. Focused in the initial stages of wine fermentation, the answer of *S. cerevisiae* is analysed in order to uncover common and specific responses to different yeast interactions.

Methods

Fermentations were carried out in bioreactors using synthetic grape must to mimic industrial conditions. Experiments were done in triplicate. RNAseq data was used to analysis the yeast transcriptome.

Conclusions

Different yeast species promote a common response in *S. cerevisiae* with particular characteristics. The general answer found in the three yeast assayed is related to glucose uptake and glycolysis, membrane lipid metabolism, cell wall and the use of alternative nitrogen sources. One particularly interesting observation was that under conditions of co-cultivation with *T. delbrueckii*, *S. cerevisiae* by-passes normal nitrogen and glucose catabolite repression, up-regulating a series of genes that are usually transcribed under low concentrations of sugars (low affinity glucose transporters), or growing on non-preferred nitrogen sources. One illustrative example, found in all mixed cultures, is the *DAL* cluster gene family, up-regulated during co-cultivation.

DYNAMICS, ARCHITECTURE AND MATRIX CHARACTERIZATION OF BIOFILMS DEVELOPED BY CAMPYLOBACTER JEJUNI

H. Turonova[1], *R. Briandet*[2], *T.R. Neu*[3], *O. Tresse*[4]
[1]*University of Chemistry and Technology Prague, Dept. of Biochemistry and Microbiology, Prague 6, Czech Republic*
[2]*INRA, MICALIS, Paris, France*
[3]*Helmholtz Centre for Environmental Research – UFZ, Department of River Ecology, Magdeburg, Germany*
[4]*INRA, SECALIM, Nantes, France*

Backgrounds

Campylobacter jejuni has been reported as the leading cause of bacterial foodborne infections in developed countries, with significant increase over the past years. Despite the fastidious growth requirements, *C. jejuni* is able to survive in the environment without permanent loss of viability and virulence. The mechanisms responsible for its survival remain unknown, but one of the survival strategies might be linked to biofilm formation.

Objectives

This work focused on a detailed characterization of dynamics, spatial organization and matrix composition of *C. jejuni* biofilms, including the role of oxygen in the biofilm formation process.

Methods

The objectives were achieved by analysing biofilms of two characterized strains using confocal laser scanning microscopy, transmission electron microscopy (TEM), and fluorescent lectin binding analysis (FLBA) performed with 73 different lectins.

Conclusions

Both strains of *C. jejuni* were able to form biofilms within 17 h of cultivation. Biofilm architecture differed between the two strains, ranging from finger-like structure with voids and channels to compact multilayer-like structure that could be circumvented by a higher expression of *cosR* regulator. Exposure of cells to oxygen enriched conditions enhanced biofilm development. FLBA screening revealed strain-specific patterns with only 6 lectins interacting with the biofilm matrix of both strains. Interestingly, the biofilm matrix bound a fucose-specific lectin not previously detected within *C. jejuni*. Thioflavin T and curcumin assay paired with TEM highlighted the presence of amyloids in cell envelope without association with specific cell appendages. Taken together, these data provide new insights on structure and composition of *C. jejuni* biofilms.

FUNCTIONAL ANALYSIS OF THE GUT MICROBIOTA USING SINGLE CELL ISOTOPE PROBING

D. Berry[1]
[1]*University of Vienna, Department of Microbiology and Ecosystem Science, Vienna, Austria*

Backgrounds

Microbial communities are essential for human nutrition and health. It remains challenging, however, to identify the activity and function of microbial cells under natural conditions.

Objectives

This talk will focus on how microbes can be studied at the single cell level using molecular methods combined with isotope probing and chemical imaging tools.

Methods

I will introduce a new method to determine the general activity of cells using heavy water (D2O) and Raman microspectroscopy and will give examples of how this can be used to study gut microbiota utilization of a range of compounds, including mucosal proteins, host-derived amino acids, and dietary and mucosal sugars, polysaccharides, and glycans.

Conclusions

Single-cell activity measurements can give novel insights into the function of microbes in complex communities. Future directions for these exciting new techniques will also be highlighted.

FEMS7-0566
Future diagnostic approaches

NONINVASIVE COLORIMETRIC DETECTION OF FOODBORNE PATHOGENS BASED ON THE TRAPPING OF VOLATILE METABOLITES

E. Perret[1], M. Vrignaud[1], Z. Buniazet[1], P.R. Marcoux[2], P.L. Joly[1], J. Hue[1], I. Texier-Nogues[1]
[1]CEA, Division micro-Technologies for Biology and Healthcare, 38054 Grenoble cedex 9, France
[2]CEA, Division micro-Technologies for Biology and Healthcare, Grenoble, France

Backgrounds

We bring new low-cost disposable sensors for a convenient monitoring of microbial VOC (volatile organic compounds). There is a growing interest for the monitoring of microbial VOC as they can be used for noninvasive detection and identification of microorganisms. But the actual protocols often rely on expensive techniques, such as GC-MS (gas chromatography-mass spectroscopy).

Objectives

The method we develop is based on trapping and sensing VOC, thanks to transparent porous glasses. These show a very large surface for gas adsorption and can change color when capturing target gas. The main application we study is the detection of foodborne pathogens.

Methods

The porous glasses we use as sensors are made via polycondensation. It yields transparent nanoporous glasses with properties depending on monomers. Two types of sensors were made, that change color upon gas trapping: i) sensors for the detection of sulfide compounds, ii) sensors for enzyme-generated nitrophenol. Sulfide sensors are initially pale yellow and turn red-orange when detecting target VOC. Nitrophenol sensors are colorless and get yellow when trapping target gas. As in standardized methods, 25g of food sample was mixed with 250g of buffered peptone water. The mixture was homogenized in a stomacher bag and then incubated at 37°C. A sensor stuck to the bag wall could trap VOC emitted by liquid culture medium.

Conclusions

Salmonella can be detected either through the detection of H2S, or the nitrophenol emitted by C8-esterase enzymatic activity. *S. aureus* can be detected with the nitrophenol generated by a-glucosidase activity, in less than 8h (starting from 100 cfu/mL).

[6]microTEC Gesellschaft für Mikrotechnologie mbH, -, Duisburg, Germany
[7]CETAQUA, -, Cornellá de Llobregat - Barcelona, Spain

Backgrounds

Waterborne diseases are illnesses caused by pathogenic microorganisms that are present in contaminated water sources.

Analytical methods applied in diagnostic microbiology lab are usually performed manually and have some drawbacks, being one of them the long time-to results. For example *Legionella* detection by culture isolation can take up to 12 days.

New rapid methods could overcome the disadvantages of conventional analysis performed in the laboratory and achieve a rapid detection of waterborne pathogens to prevent outbreaks of waterborne diseases and the spread of waterborne pathogens.

Objectives

The main objective of CYTO-WATER project is to deploy a new platform for on-line monitoring of *Legionella* and *E. coli* in industrial and environmental water samples.

Methods

An automated water concentration module that includes Celltrap® concentrating filters, a microfluidic system for sample preparation and an image reader will be integrated resulting in the CYTO-WATER system.

Each component has been validated individually to make sure that they meet the market specifications. The integrated CYTO-WATER system will be validated according to ISO 16140-2:2016 in the laboratory comparing with conventional analysis methods (culture isolation and qPCR) in order to determine whether the method is suitable for detecting and quantifying microorganisms in water samples.

Conclusions

The CYTO-WATER platform could be placed, for example, in an industrial cooling tower, avoiding sampling and transport to the laboratory. The device will be a valuable tool for detection of possible bacterial contamination in a reduced timeframe with decision making capability.

ABSOLUTELY QUANTIFICATION AND CHARACTERIZATION OF VIABLE GUT MICROBIOTA

S. Tamburini[1], J.C. Clemente[2]
[1]Icahn School of Medicine at Mount Sinai, Department of Genetics and Genomic Sciences, New York, USA
[2]Icahn School of Medicine at Mount Sinai,
Department of Genetics and Genomic Sciences- Department of Medicine- Division of Clinical Immuno logy, New York, USA

Backgrounds

The human gut contains trillions of microorganisms that modulate health and disease in the host, but it is currently unclear how many total and viable bacteria live in a gram of fecal samples. Microbiome studies usually characterize the composition of the microbiota without taking into account the total amount of bacteria and their viability. These studies are thus limited by the fact that sequencing alone cannot distinguish whether the sequenced DNA originates from a viable, damaged, or dead bacterial cell.

Objectives

To absolutely quantify at single cell level the viable and dead population of bacteria that live in the human gut and the bacterial composition of these two bacteria subpopulation.

Methods

We applied fluorescence-activated cell sorting (FACS) combined with viability fluorescent markers, 16S ribosomal (rRNA) gene sequencing and statistical methods for absolutely quantifying at single cell level the concentration of total and viable bacterial cells and their taxonomic shape in healthy subjects

Conclusions

The FACS analysis identified that a gram of gut microbiota from healthy subjects contains on average $1.15x10^{11} \pm 0.3x10^{11}$ bacterial cells composed of a largest subpopulation of viable bacteria (72%) and a smallest one of dead bacteria (28%) with $8.46x10^{10} \pm 3.35x10^{10}$ and $2.65x10^{11} \pm 1.03x10^{10}$ cells/g, respectively. The 16S rRNA data showed consistent differences between viable and dead cells. Beta diversity analysis further highlighted the difference between the subset of viable and dead cells per subject and between subjects, suggesting that accounting for bacterial viability is critical in microbiome studies.

EXPLORING THE BOUNDARIES OF LIFE WITH GIANT VIRUSES

J.M. Claverie[1]
[1]*Mediterranean Institute of Microbiology, IGS UMR7256, Marseille, France*

Exploring the boundaries of Life with giant viruses

Beginning with the discovery of Mimivirus in 2003 [1], 15 years of exploration of this unexpected new branch of virology led us to the identification of four distinct families of large double-stranded DNA viruses all of which infect the same protozoan host, Acanthamoeba [2]. Beyond the immediate and simple fascination brought about by the mere size and shape of their particles, the alien nature and the diversity of their gene content is raising considerable doubt in our capacity to reconstruct their evolutionary history using the known genome modification processes within the accepted framework of Neo-Darwinism. Following a quick review of the known giant virus families and of their most distinctive properties, I will expose my doubts on the capacity of traditional phylogenetic thinking (and approaches) to ever figure out a scientifically sound theory for the origin of (all) viruses.

MAPSEQ: BRINGING SPEED, ACCURACY AND CONSISTENCY IN RIBOSOMAL RNA SEQUENCE ANALYSIS

J.F. Matias Rodrigues[1], J. Tackmann[1], T.S.B. Schmidt[2], C. von Mering[1]
[1]University of Zurich, Institute of Molecular Life Sciences, Zurich, Switzerland
[2]European Molecular Biology Laboratory, Bioinformatics Group, Heidelberg, Germany

Backgrounds

Metagenomic sequencing has become crucial to the study of microbial communities, but meaningful analysis and integration of such data has been hampered by technical limitations, between-study variability and inconsistencies between taxonomies used.

Objectives

With the improvements in speed, accuracy and consistency of rRNA marker gene analysis by MAPseq we aim to enable a more consistent comparison of results and conclusions between metagenomic studies so that the rich context provided by existing data can be more readily explored.

Methods

The increased computational efficiency and higher accuracy are due to several innovations in the MAPseq algorithm tailoring it to sequence searches in large 16S/18S rRNA databases consisting of highly similar sequences. These innovations include an improved kmer-counting method based on a pre-clustered database, full alignment for high scoring segment pairs, and a sensitive algorithm to compute classification confidence. In addition, we provide a curated reference of full-length rRNA sequences pre-clustered into hierarchical OTUs and with several taxonomic categories which include, among others, the Living Tree Project and NCBI taxonomies.

Conclusions

MAPseq is a framework for reference-based rRNA metagenomic analysis that is 15x faster and up to 30% more accurate than existing solutions, providing in a single run multiple taxonomy classifications and hierarchical OTU mappings, for datasets of virtually any size. When inferring OTU presence and abundance, MAPseq achieves superior consistency over uclust when analyzing sequencing runs targeting different regions (V1V3 and V3V5) of the 16S rRNA gene in identical samples from the Human Microbiome Project.

Genomics, evolution, phylogeny

CONFECTION - A CONJUGATIVE PLASMID MEDIATED METHOD TO INTRODUCE CRISPR-CAS9 GENOME EDITING COMPONENTS INTO EUKARYOTIC CELLS

P. Ruotsalainen[1], *M. Jalasvuori*[1]
[1]*University of Jyväskylä, Department of Biological and Environmental Science, Jyväskylä, Finland*

Backgrounds

The RNA-directed genome editing via CRISPR/Cas9 is an efficient and highly specific tool for gene editing of eukaryotes. At present CRISPR/Cas9 gene engineering system is usually delivered to eukaryotic cells by a viral vector. However the drawbacks of viral vectors are their immunogenicity and cytotoxicity and potential insertional mutagenesis (integration of viral genome into eukaryotic genome). Also the packaging capacity is low and the preparation of viral vector is laborious and requires appropriate bio-safety facilities.

Objectives

The aim of our research is to develop a novel transfection method named confection.

Methods

In confection plasmids expressing CRISPR/Cas9 gene engineering system, are transferred to eukaryotic cells via bacterial conjugation channels provided by conjugative IncP plasmid. These plasmids have been shown to be able to deliver DNA from bacterial cells to eukaryotic ones.

Conclusions

Compared to viral vectors, larger gene sequences can be transferred at once by confection. Bacterial cells also provide a self-renewing and replicating editing library, which is easy to modify for targeting desired genes. Confection may have various *in vitro* and *in situ* genome editing applications.

WHOLE-GENOME SEQUENCING IMPROVES MS-BASED PROTEOTYPING OF CLINICALLY-RELEVANT BACTERIA

F. Salvà-Serra[1], H. E. Jakobsson[1], L. Gonzales-Siles[1], R. Karlsson[1], F. Boulund[2], D. Jaén-Luchoro[1], S. Yazdan[1], A. Johnning[3], E. Kristiansson[3], E. R. B. Moore[4]
[1]University of Gothenburg, Department of Infectious Diseases, Gothenburg, Sweden
[2]Karolinska Institute, Department of Microbiology Tumor and Cell Biology, Stockholm, Sweden
[3]Chalmers University of Technology, Department of Mathematical Sciences, Gothenburg, Sweden
[4]University of Gothenburg, Culture Collection University of Gothenburg, Gothenburg, Sweden

Backgrounds

The prevalence of bacteria with resistance to multiple antibiotics is increasing worldwide. The primary reason can be attributed to the global misuse of antibiotics. To diminish this problem, it is critical to be able to detect and characterise bacteria causing infection rapidly and correctly. Mass-Spectrometry-based 'Proteotyping' is a rapid, culture-independent method that can detect and identify bacteria and their metabolic features (e.g., antibiotic resistance and virulence factors). However, Proteotyping relies on a comprehensive and reliable genome sequence database.

Objectives

1- Recover whole-genome sequences from public databases.

2- Determine whole-genome sequences of additional strains of clinically-relevant and closely-related bacterial species.

3- Verify the taxonomic assignment of the whole-genome sequence data.

4- Incorporate new sequence data into an internal database to increase the accuracy and resolution of Proteotyping results.

Methods

Bacteria are disrupted with bead beating; cellular proteins are trypsin-digested into peptides. These peptides are analysed, using LC-MS/MS, to obtain mass spectra profiles that are matched against a reference peptide database. The determined peptide sequences are matched against genome sequence database. The database includes sequences of all complete genomes from RefSeq, additional genomes from GenBank and additional *in-house* sequenced genomes. The taxonomic affiliations of the genome sequences are verified, using ANIb.

Conclusions

More than 100 whole-genome sequences have been determined. Enlarging and curating the genome sequence database has markedly improved the accuracy and resolution of proteomic analyses for Proteotyping. Misclassified genomes exert direct and marked effects, dramatically decreasing the number of discriminatory peptides and reducing the efficacy of Proteotyping.

Genomics, evolution, phylogeny

INFECTION OF MICROBIOTA BY BACTERIOPHAGES CAN BE CONSIDERED A NEW GROUP OF VIRAL DISEASES OF MAMMALS INCLUDING HUMANS

G. Tetz[1], V. Tetz[1]
[1]Human Microbiology Institute, Human Microbiology, New York, USA

Backgrounds

Increased intestinal permeability and translocation of gut microbiota from the intestinal lumen predispose patients to—and may be one of the main triggers of various mammalian diseases.

Objectives

The objective of this study was to assess the effect of microbiota treatment with bacteriophages on the intestinal permeability *in vivo* and to evaluate the possibility that the infection of microbiota by bacteriophages may affect mammals.

Methods

We studied alterations in the host macroorganism and increased intestinal permeability as a result of a direct effect of bacteriophage cocktail. Healthy adult, albino Wistar rats, weighing 180–220g were given daily (for 10 days) phage cocktail (1.5 ml of $1x10^6$ plaque forming units/ml) active against Enterobacteriaceae, Staphylococcaceae, Streptococcaceae, and Pseudomonadaceae families. The lactulose-mannitol ratio was used as a marker of intestinal permeability. Circulating immune complexes (CIC) were evaluated as markers of endogenous intoxication. Metagenomic analysis was used to characterize the composition of microbiota before and after phage challenge.

Conclusions

Results: After 10 days of challenge, the rats showed weight loss, decreased activity. They displayed a significantly elevated lactulose:mannitol ratio with the mean increase 2.4 fold. The level of CIC was more than 2.5 times higher as compared to before treatment, indicating endogenous intoxication, caused by leaky gut. Metagenomic analysis revealed phage-induced altered microbiota composition.

Conclusions: To our knowledge, this study for the first time indicates the link between bacteriophages and mammalian pathologies associated with increased intestinal permeability such as systemic inflammatory and psychological or autoimmune disorders. This study demonstrates that increased intestinal permeability may be induced by bacteriophages that affect microbiota. We propose that infection of microbiota by bacteriophages can be considered a new group of viral diseases of mammals including humans.

Genomics, evolution, phylogeny

INSIGHTS INTO THE EVOLUTION OF PATHOGENS THROUGH MUMMY STUDIES

A. Zink[1], *F. Maixner*[1]
[1]*Institute for Mummies and the Iceman, EURAC Research, Bolzano, Italy*

Insights into the evolution of pathogens through mummy studies

The molecular analysis of ancient pathogen DNA represents a unique opportunity for the study of infectious diseases in skeletal and mummified human remains. Within the last years, a wide range of bacterial, protozoal and viral infections have been detected in ancient tissue samples by the characterization of specific DNA fragments. The introduction of next generation sequencing (NGS) technologies in the study of ancient human remains has further improved the opportunity to study human evolution, population dynamics, and disease evolution. In several studies, new important findings regarding the evolution and spread of some major infectious diseases, such as plague, tuberculosis and leprosy were revealed.

One of the first mummies in which this technology has been successfully applied, is the Tyrolean Iceman, commonly known as Ötzi. By using metagenomic diagnostics and targeted genome capture, we determined the presence of the stomach pathogen *H. pylori* and reconstructed its complete genome. Subsequent sequence analysis classified the ancient *H. pylori* as a virulent strain that is now associated with inflammation of the gastric mucosa. Comparative analysis of ancient housekeeping gene fragments and comparative whole-genome analyses assigned the 5,300-year-old bacterium to a nearly pure representative of the bacterial population of Asian origin, suggesting that the African *H. pylori* population arrived in Europe within the past few thousand years, which is later than previously proposed.

In this presentation, the major results of the application of NGS for the study of pathogens are presented and discussed with regard to the perspectives and probable limitations in mummy research.

METABOLIC PATHWAYS ASSOCIATED WITH SULFUR METABOLISM

I. Cardoso Pereira[1]
[1]*Instituto de Tecnologia Quimica e Biologica Antonio Xavier- Universidade NOVA de Lisboa, Bacterial Energy Metabolism Laboratory, Oeiras, Portugal*

Metabolic pathways associated with sulfur metabolism

Prokaryotes play a critical role in the biogeochemical sulfur cycle, both in the oxidation (and disproportionation) of reduced sulfur compounds, performed by chemotrophic and phototrophic sulfur oxidizing bacteria, as well as in the reduction of sulfate or other sulfur oxides performed by sulfate reducing bacteria and archaea. These microorganisms have a considerable impact on the geochemistry of anoxic environments as well as the global redox state of the planet over geological times.

The metabolic pathways involved in dissimilatory sulfur metabolism involve a series of proteins that are unique to these pathways and common to reducing and oxidizing organisms, indicating a specific role in sulfur chemistry and a common evolutionary origin [1].

In this talk I will discuss recent work on the role of some of these proteins in sulfur metabolism, with a special focus on the DsrAB/DsrC/DsrMKJOP system [2], the QmoABC/AprAB system and the Hdr system, and how they contribute to energy conservation.

UNVEILING MICROBIAL FUNCTIONAL CAPACITIES AND ACTIVITIES IN THE N CYCLE AT THE ANTARCTIC SUMMER COASTAL WATERS

B. Díez[1,2], M.E. Alcamán[1,2], F. Laura[2,3]
[1]Pontificia Universidad Católica de Chile, Molecular Genetics and Microbiology, Santiago, Chile
[2]Center for Climate and Resilience Research CR2, -, -, Chile
[3]Universidad de Concepción, Department of Oceanography, Concepción, Chile

Backgrounds

Antarctic marine waters are defined as one of the most HNLC regions of the planet. Nitrate (NO_3^-) and ammonium (NH_4^+) are the major forms of inorganic nitrogen used by phytoplankton. However, the significance of other N pathways in this cycle is poorly understood in Antarctic waters.

Objectives

The structure, functional activity and rates related to the N cycle of the microbial communities inhabiting surface waters of Chile Bay (62º 27’ 600’’ S 59º 40’ 600” W), in the South Shetland Islands, were analyzed during the summer of 2014.

Methods

Metagenomics, metatranscriptomics and *in situ* assimilation of ^{15}N, $^{15}NO_3$, and $^{15}NH_4$ as well as ^{13}C isotopes were the methodology used.

Conclusions

Our results under a typical HNLC condition, 1.9 µM P (PO_4) and 26.4 µM N (NO_3 and NO_2), showed low N_2 fixation rates (0.07 to 0.53 nmol N L^{-1} d^{-1}) and high $^{15}NO_3$ and $^{15}NH_4$ assimilations rates during light condition. The later processes are coupled with high ^{13}C fixation rates (600-2300 nmol C L-1 d-1), and a markedly high phototrophic activity during daytime by Calvin related to Diatoms and Haptophyta. Our analysis demonstrated the major abundance and activity of Proteobacteria (Gammaproteobacteria and Alphaproteobacteria), and Flavobacteria. Interestedly, ammonia-oxidizing archaea belonging to the genus *Nitrosopumilus* (Thaumarchaeota) and some Proteobacteria (*Nitrosomonas*) seem to be active chemoautotrophs, responsible for the nitrification process, according with the *amo*A gene activity. Thaumarchaeota are also possibly responsible for the nitrifier-denitrification (detoxifying nitrite), with potential contribution to N_2O production in these marine Antarctic waters, according with the *nir*K gene activity.

SULFIDE AT LOW PH IS NOT YOUR ENEMY, BUT YOUR ALLY

A.P. Florentino[1], A.J.M. Stams[1], I. Sanchez Andrea[2]
[1]Wageningen University, Microbiology, WAGENINGEN, The Netherlands
[2]Autonomous University, Microbiology, Madrid, Spain

Backgrounds

Mining industry activity and the natural oxidation of metallic sulfide-ores generate acidic sulfur-rich and highly metalliferous waters, generally termed acid mine drainage. This is of great environmental concern as some heavy metals are highly toxic and produce long term harm to water quality and biodiversity.

Objectives

Prokaryotes of the reductive sulfur cycle play a role in the remediation of such waters, as the reductive process of sulfur compounds leads to the formation of sulfides that can precipitate metals as metal sulfides. Besides, the process consumes protons, which leads to an increase of pH to circumneutral values. Therefore, our objective was to isolate novel microbial key player of this process.

Methods

Enrichments of sulfate and sulfur reducers with various electron donors at low pH and mesophilic conditions were obtained from sediments of the acidic Tinto river (Spain).

Conclusions

This resulted in isolation of a whole set of novel acidophiles: sulfate reducing bacteria (two novel proposed species *Desulfosporosinus acididurans* and *Desulfosporosinus methalovorans,* and a new genus proposed as *Desulfobacillus acidiphilis*); sulfur reducers (a new genus, *Lucifera butyrica*, and a new species, *Desulfurella amilsii)*. Functional characterization of the isolates combined with proteomic analysis under specific conditions have helped to gain insights into their metabolism, unveiling novel pathways in the reductive sulfur cycle and novel strategies to cope with low pH. The ability of those microorganisms to thrive at acid rock drainage environments and to face moderate concentrations of heavy metals in solution make them potential candidates to combine ecological relevance with biotechnological application.

METHANE CYCLING IN A LARGE FRESHWATER LAKE

B. Schink[1], *J. Deutzmann*[1]
[1]*University of Konstanz, Biology, Constance, Germany*

Methane is produced in the deeper layers of the sediment of Lake Constance and is reoxidized nearly completely within the oxygen-supplied upper 3 – 5 mm of the sediment. The methane-oxidizing community is rather heterogeneous, including largely type I methanotrophs. Novel methane-oxidizing bacteria were isolated in oxygen-limited cultivation devices, and growth could be improved by addition of methanol-oxidizing partners. At methane seeps in the Eastern part of the lake, higher numbers of methanotrophs were detected, and the predominant methane oxidizers differed also qualitatively from those at reference sites. Besides aerobic methane oxidation, nitrite-dependent anaerobic methane oxidation by NC10-like bacteria appeared to be dominant, especially in sediments at greater water depths (> 40 m). Sulfate-dependent methane oxidation was not detected. Our results show that the diversity of methane oxidation in a freshwater lake is far greater than expected until only a few years ago.

SELECTIVE INHIBITORS OF MICROBIAL SULFATE REDUCTION: ASSESSING RESISTANCE TO AND RESILIENCE AGAINST INHIBITION

M. Stoeva[1], G. Nalula[2], N. Garcia[2], Y. Cheng[3], J. Coates[1]
[1]UC Berkeley, Plant and Microbial Biology, Berkeley, USA
[2]UC Berkeley, Integrative Biology, Berkeley, USA
[3]Lawrence Berkeley National Laboratory, Climate and Ecosystem Sciences Division, Berkeley, USA

Backgrounds

Hydrogen sulfide is a toxic and corrosive gas, produced by the activity of sulfate-reducing microorganisms (SRM). Owing to the environmental, economic and human-health consequences of sulfide, there is interest in developing inhibitors of SRM. Perchlorate is emerging as a promising inhibitor; however, a comprehensive analysis of its effects in communities is lacking.

Objectives

The aim of this work is to assess the inhibitory dynamics of perchlorate in sulfidogenic communities.

Methods

Sulfidogenic continuous-flow systems are treated with perchlorate and SRM number, sulfide production and community structure are monitored pre-, during and post-treatment. The data generated is used to create a mathematical model of how a simple SRM community responds to perchlorate.

Conclusions

Sulfide production decreases with perchlorate treatment, and 16S-amplicon sequencing and qPCR show a drop in SRM abundance; all parameters recover post treatment. Rates of inhibition and rebound fit the generated model, confirming that perchlorate acts as a bio-competitive inhibitor, slowing the growth of SRM. The model is subsequently validated by varying parameters identified as important: the perchlorate concentration and the level of surface-attachment. Further, we quantify susceptibility to perchlorate across several SRM in various contexts and are currently characterizing the mechanism of this susceptibility via proteomics. Finally, indirect effects of perchlorate (bio-competitive exclusion of SRM by dissimilatory perchlorate-reducing bacteria, DPRB) are tested by amending reactors with DPRB. Results confirm that at low perchlorate concentrations, SRM inhibition results from indirect effects.

This study thus provides a holistic overview of the sensitivity of sulfidogenic communities to perchlorate, as well as mechanisms underlying these patterns.

THE MULTIPLEX PHASE INTERLOCKER – A NOVEL AND ROBUST MOLECULAR DESIGN SYNCHRONIZING TRANSCRIPTIONAL CELL CYCLE DYNAMICS

T.D.G.A. Mondeel[1], C. Linke[1], S. Tognetti[2], M. Loog[3], H.V. Westerhoff[1], F. Posas[2], M. Barberis[1]
[1]University of Amsterdam, Synthetic Systems Biology, Amsterdam, The Netherlands
[2]Universitat Pompeu Fabra, Departament de Ciències Experimentals i de la Salut, Barcelona, Spain
[3]University of Tartu, Institute of Technology, Tartu, Estonia

Backgrounds

The eukaryotic cell cycle is robustly designed, with networks of interacting molecules organized in regulatory motifs that ensure its precise timing. This is governed by a transcriptional oscillator interlocked with waves of cyclin-dependent kinase (cyclin/Cdk) activity. Although details about cyclin transcription are available, a lack of understanding exists about regulatory motifs responsible for the precise timing of waves of cyclin activation.

Objectives

We have recently identified a transcriptional mechanism that regulates the relative timing of waves of mitotic (Clb) cyclin expression in budding yeast. This involves the Forkhead transcription factor (TF) Fkh2. Here we investigate the robustness of molecular designs interlocking Clb waves through Fkh2-mediated signaling, with the aim to unravel the network motif(s) responsible for timely cyclin/Cdk1 dynamics

Methods

An integrated computational and experimental framework is presented. A kinetic model of the cyclin/Cdk1 network is simulated under a quasi-steady state assumption, and fitted to *in vivo* time course data of Clb dynamics. Robustness analyses are then performed by testing 1024 possible network motifs for their ability to fit Clb oscillations. Experimental validation supports computational analyses, revealing the Clb/Cdk1-Fkh2 axis to be pivotal for timely transcriptional dynamics.

Conclusions

A novel regulatory motif synchronizing Clb waves, coined as *Multiplex Phase Interlocker*, is unraveled. This motif uniquely describes a molecular timer (TF) that relies on separate inputs (cyclin/Cdk1 complexes) converging on a common target (TF itself). Within the motif, a progressive TF (Fkh2) activation may be realized by the sequential Clb/Cdk1 complexes. Altogether, our integrative approach reveals a conserved design principle in cell cycle control.

THERMODYNAMIC ANALYSIS OF THE METABOLISM OF AMMONIA-OXIDISING BACTERIA SUGGESTS A NOVEL MECHANISM OF ENERGY HARVESTING

R. González-Cabaleiro[1], C. Tom[2], O. Dana[1]
[1]Newcastle University, School of Chemical Engineering and Advance Materials, Newcastle upon Tyne, United Kingdom
[2]Newcastle University, School of Civil Engineering and Geosciences, Newcastle upon Tyne, United Kingdom

Backgrounds

The biochemistry and bioenergetics of the metabolism of ammonia-oxidising bacteria (AOB) shows an inefficient and constrained metabolism. Only 52.8% of the energy released when a mole of ammonium is consumed and less than half of the electrons liberated in the process can be directed to the autotrophic anabolism. Paradoxically, AOB seem to thrive in challenging conditions: growing readily in virtually any aerobic environment, except the laboratory pure culture.

Objectives

We have sought to understand this enigma by analysing in detail the metabolism of the AOB.

Methods

We have used biochemical and thermodynamic modelling to calculate the maximum possible energy harvest of AOB metabolism. The results obtained have been compared with the experimental growth yields measured.

Conclusions

The model predicts a maximum autotrophic yield of 0.16 gBio/gN (0.13 gBio/gN when maintenance is considered). Observed yields should be lower than this value, but in reality they vary between 0.04 and 0.45 gBio/gN. Thermodynamics and experimental data can only be reconciled if AOB have an extra source of energy at least some of the time. Chemoheterotrophic growth of AOB only offers a partial explanation since it only occurs in specific conditions and there is ample evidence of CO_2 fixation by AOB. Alternative source of energy could be realised if the ammonia monooxygenase reaction was coupled to an energy harvesting mechanism. In particular, co-metabolism could confer a direct energy benefit on the cell. If this was true, it would explain the robust growth of AOB in mixed communities and account for the putative inefficiency of their metabolism.

IMPROVED PROMOTER SEQUENCE MODELS FOR DE NOVO TRANSCRIPTION FACTOR BINDING SITE PREDICTION IN BACTERIA

I. Sultan[1], S. Schbath[1], V. Fromion[1], P. Nicolas[1]
[1]INRA-Institut National de la Recherche Agronomique,
Applied Mathematics and Computer Science from Genomes to the Environment MaIAGE,
Jouy en Josas, France

Backgrounds

Unravelling gene regulatory networks helps understanding many features about an organism. Over the past decades, powerful algorithms and approaches have been developed for the discovery of transcription factor binding sites (TFBSs) but these tools are still unable to automatically identify *de novo* the main regulons of a bacteria from genomic and transcriptomic data.

Objectives

In this work, we present a new statistical model and Markov Chain Monte Carlo (MCMC) algorithm that attempt to overcome some limitations of the available approaches. In particular, available algorithms for motif discovery based on mixture models do not take into account the overlapping of TFBSs. Whereas, available data on *Escherichia coli* suggest that overlapping is a major feature of bacterial promoter architecture (more than one third of the binding sites overlap with at least one other site). Moreover, with the advent of precise transcription start site (TSS) maps derived from RNA-Seq protocols targeting transcript 5'-ends, it is now relevant to examine the exact position in the promoter region when searching for TFBSs.

Methods

Our statistical model of promoter sequences accounts for the overlapping between TFBSs as well as their exact positioning with respect to the TSS. All the parameters are estimated in a Bayesian framework using a dedicated MCMC algorithm. The algorithm is trans-dimensional to allow adjusting the width of position weight matrix describing each motif and the number of parameters to describe its preferred position.

Conclusions

Results on *Listeria monocytogenes* regulatory network will be presented and strategies to incorporate expression data across conditions will be discussed.

CHARACTERISATION OF METABOLIC BURDEN IN BACTERIAL SYSTEMS

S. Wagner[1], K. Pflüger-Grau[1], A. Kremling[1]
[1]Technical University of Munich, Systems Biotechnology, Garching, Germany

Backgrounds

In biotechnological approaches it is often necessary to introduce a multiplicity of genes into a bacterial host system as e.g. *Escherichia coli*. Such a heterologous expression can cause a competition for limited cellular resources as ribosomes, polymerases, and other precursors.

Objectives

In order to understand the cellular processes and limitations during foreign protein production, we set out to quantitatively describe the distribution of the resources between the intrinsic processes needed for maintenance and the extra load introduced by the heterologous pathway.

Methods

To this end, we analysed cellular behavior under a systematic variation of heterologous load. Additionally to the process parameters, we are able to record *on-line* the transcriptional and translational rates of the heterologous load. This is achieved by the introduction of a specially-designed plasmid into the cells that allows us to monitor and quantify the expression of a desired gene *in vivo*. To assess the cellular fitness, we investigated the cellular capacity as described by Ceroni *et al***.** (Quantifying cellular capacity identifies gene expression designs with reduced burden. Nature Methods 12: 415–418**,** (2015)) in terms of resource-distribution.

Conclusions

With this setup, we were able to quantify mRNA and protein production rates, as well as stabilities. Besides the expression process, cellular fitness was monitored. Because of the easily measurable fluorescence signals, this system has the potential to be a valuable tool for the systematic high-throughput analysis of pathway fine-tuning. Bottlenecks can be identified and, at the end of the day, circumvented or avoided.

EVALUATION AND ASSESMENT OF ANTIBIOTIC RESISTANCE IN THE PRISTINE ESTUARY OF INDIAN SUNDARBANS, A WORLD HERITAGE SITE

A. Bhattacharyya[1], *M. Bhattacharyya*[1], *A. Ghosh*[2]
[1]*University of Calcutta, Biochemistry, Kolkata, India*
[2]*Bose Institute- Kolkata, Biochemistry, Kolkata, India*

Backgrounds

Antibiotic resistance is one of the principle challenges throughout the globe for the clinical microbiologists in recent times. Previously, only the hospital wastes or highly contaminated sewage in densely populated areas were found to be the point sources of antibiotic resistant bacteria but very recently the so called pristine natural environments and even as densely forested estuarine areas are being reported to be point source of antibiotic resistance.

Objectives

The objective of this study was to understand the abundance and the dynamics of bacterial antibiotic resistance in the pristine mangrove sediment of Indian Sundarbans, a world heritage site (UNESCO). To achieve this goal we adopted strategies for functional screening of multi-drug resistant bacterial species and made an attempt to elucidate the probable reasons for the spread of this phenomenon in light of *bla*-TEMgene abundance.

Methods

Bacterial strains were isolated, identified and characterized using standard techniques. The effect of antibiotics on multi-drug resistant bacterial isolates was further quantitatively evaluated in both planktonic and biofilm lifestyles. Furthermore, the population dynamics of multi-drug resistant bacteria in the sediment was assessed quantitatively using the q-PCRtechnique.

Conclusions

Results:

117 ampicillin resistant bacteria were isolated including 18 multi-drug resistant strains. Environment typical (*Halobacillus, Jeotgalicoccus*) and atypical (*Bacillus, Staphylococcus*) organisms were found among the isolates showing high MIC to different antibiotics.The q-PCR results showed 0.6%-4.2% abundance of the*bla*-TEM gene in thesediment microbiome. Biofilm dynamics were found to be species and drug specific.

Conclusions:

The results showed a high incidence of multi-drug resistance in the isolated strains. The phylogenetic interrelatedness of the *bla*-TEM genes indicated a possible common primary ancestor. Such a distribution of *bla*-TEM could be achieved through possible horizontal gene transfer. The biofilm lifestyle plays a key role in the development of considerable resistance in the isolated organisms.

FINDING THE BALANCE – CONVERGENCE IN HEALTH DISCIPLINES
K. Queenan[1], R. Kock[1]
[1]Royal Veterinary College, Pathobiology and Population Sciences, Hatfield, United Kingdom

Finding the balance – convergence in health disciplines

Richard A Kock Professor Wildlife Health and Emerging Diseases and Kevin Queenan

Royal Veterinary College London rkock@rvc.ac.uk

Pressures for novel approaches for human, animal and environmental health are arising from a number of directions and from a perception that emerging diseases are threatening reversal in gains made in health generally over the 20th Century. Concerns relate both to the global rise in infectious disease outbreaks in the last decades (Smith et al 2014) and the (re-) emergence of human and animal pathogens and antimicrobial resistance, as well as non-communicable diseases. The latter are commonly associated with urbanisation of populations and changing food systems leading to increasing malnutrition, rising physical and mental health concerns and associated diseases such as obesity, allergies, air pollution-induced lung disease and gastrointestinal disease from a shifting microbiome (Rook 2013). Moreover, there are concerns about ecosystems health, threatened populations of a number of plant and animal species and a degrading environment affecting biodiversity and the ability to produce food in a sustainable way.

All these emergent health problems show complex epidemiologies, involve multiple, closely interrelated species and risk factors. Proponents of One Health state that modern problems require a holistic systemic approach, beyond the current focus on sectoral, technological solutions to individual diseases, and towards a better understanding of the current drivers of ill-health and of the changing environment and interface between species (Fischer et al 2016). It is proposed that a One Health approach is necessary to tackle the challenges through accepting that their complexity requires interdisciplinarity, in particular applying natural and social sciences to human and animal health in the context of a sustainable environment and engaging the whole of society in all aspects. Hence, One Health promotes an integrated approach to health that aims to break up artificial boundaries created by disciplines and sectors.

Underpinning the paradigm is recognition of the importance of resilience in any biological system: factors that erode resilience are critical to loss of equilibrium and to systems change which can be expressed in terms of health at any scale (Horowitz and Wilcox 2005). Sheldon & Verhulst (1996) described mechanisms whereby the partitioning of finite energy resources among competing, costly physiological functions, are a prime cause of variation in immune defences. Possible examples of this are in arctic species responses to a rapidly shifting climate, where extraordinary energy demands driven by climate extremes, lead apparently to a collapse in immune function, raised parasite opportunism and mass mortality events (Kutz et al 2015; Fey et al., 2015).

Studies directed at this interface are now taking off but there are many institutional, disciplinary, financial (Bromham et al 2016) and societal constraints on One Health which will need to be overcome. Academic initiatives are contributing to the development of methods and frameworks for action (Coker at al., 2011; Min B. et al., 2013) including regional alliances or projects such as the Network for Evaluation of One Health (NEOH), the International Association of Ecological Health, the USA based One Health Initiative, the One Health Platform and a variety of other smaller groups. The veterinary profession has been a significant contributor to this process, along with Public Health professionals and it is gradually attracting a wider community of scientists and practitioners with objectives ranging from establishing collaboration between clinicians and researchers in the human and animal field, to deeper examination of the political economies of health in a more structural socio-political context (Wallace et al., 2015). The growing interest in this area is also reflected in the number of new academic courses including at under- and postgraduate level in One Health. There is for example a joint face-to-face joint Masters course at the Royal Veterinary College and London School of Hygiene and Tropical Medicine, now in its fourth year drawing students from veterinary, medical, biomedical, pharmacy, natural sciences, psychology, political science and economics backgrounds.

While the One Health paradigm is still evolving and causes controversy over its definition (Kingsley and Taylor 2016; Mi et al., 2016), there is a general agreement that modern challenges need integrated, systems-based approaches. Conversion of science into policy in the One Health arena will require some radical changes in emphasis in both the academic and practical expression of health sciences and systems.

ONE HEALTH: PLANTS, ANIMALS, HUMANS, AND FOODBORNE DISEASE

S. Maloy[1]
[1], *USA*

Although infectious diseases have always plagued humans, the frequency of emerging and re-emerging infectious disease has been increasing over the last several decades. These diseases are typically caused by (i) new pathogens that are transmitted to humans or animals following environmental disturbance or acquisition of novel virulence traits, or (ii) existing and known pathogens that have spread to new geographic areas or populations. Understanding how and why emerging pathogens arise has relied heavily on genomic and metagenomic approaches. Environmental reservoirs of virulence genes, such as exotoxin genes and antibiotic resistance genes, provide the raw materials for evolution of new pathogens following horizontal gene transfer to new hosts or exposure of naïve hosts to opportunistic pathogens from the environment. Evolution of new strains of *Salmonella enterica* and *Escherichia coli* clearly demonstrate the impact of disruption of the environment on transmission to animals and humans. The One Health initiative integrates insights from environmental science, veterinary medicine, and human medicine to develop upstream approaches to prevent disease. Several examples will demonstrate how implementation of One Health approaches can prevent the transmission of food-borne diseases.

BIOCONTAMINATION OF SURFACES AND WATERS INSIDE THE INTERNATIONAL SPACE STATION

E. Perrin[1], G. Bacci[1], A. Mengoni[1], F. Canganella[2], G. Bianconi[2], L. Garrelly[3], S. Amalfitano[4], C. Levantesi[4], S. Rossetti[4], S. Perero[5], M. Ferraris[5], R. Fani[1]
[1]University of Florence, Department of Biology, Sesto Fiorentino Florence, Italy
[2]University of Tuscia, Department of Biological- Agrofood and Forestry sciences DIBAF, Viterbo, Italy
[3]GL-Biocontrol, GL-Biocontrol, Clapiers, France
[4]National Research Council of Italy, Water Research Institute, Monterotondo Roma, Italy
[5]Polytechnic of Turin, Department of Applied Science and Technology DISAT, Torino, Italy

Backgrounds

Space exploration requires the development of methods for preventing, monitoring and controlling biocontamination within human confined environments. These methods need to be automated, simple, lightweight and with minimal consumables. Space and terrestrial monitoring as well as prevention/mitigation methods are currently working separately, rather than in synergy. The Horizon 2020 Biowyse project foresees development and demonstration of an integrated biocontamination control system for water and humid areas.

Objectives

Previous experiments provided valuable information for the Biowyse project. The Viable ISS (financially sponsored by the Italian Space Agency and supported by NASA) study involves the evaluation of the microbial biofilm development on space materials. Samples included in Viable ISS are composed of both metallic and textile space materials, that are placed both inside and outside of four foam lined Nomex bags, each one subjected to a different pre-treatment procedure. These bags were exposed inside International Space Station from 2011 to 2016. Vials with samples of potable water used on ISS were also included.

Methods

Different methodologies were used for the determination of the bacterial load on surfaces and water samples (cultivation on LB agar, ATP-metry, Flow-Cytometry, qPCR). The composition of the microbial communities was determined through 16S rDNA high-throughput sequencing.

Conclusions

Silver pre-treatment were found to be the most effective, while the microbiota composition was mainly influenced by human presence.

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 687447

A FRAMEWORK FOR GUT-BRAIN AXIS ANNOTATION FROM METAGENOMIC DATA

M. Valles-Colomer[1], *J. Raes*[1]
[1]*VIB - KU Leuven, Department of Microbiology and Immunology- Rega Institute, Leuven, Belgium*

Backgrounds

There is evidence of bidirectional communication between the gut microbiota and the nervous system, potentially playing a role in brain development, brain physiology, and behavior. One of the main mechanisms of gut-brain communication is the metabolism of neuroactive compounds by the gut microbiota, with either a beneficial or detrimental effect on the host. Although metagenomic sequencing provides both insights into species composition and their functional potential, dedicated tools are needed to facilitate gut-brain axis systematic analysis and interpretation.

Objectives

To identify the microbial functional properties involved in the gut-brain axis, and assess associations between microbial features and mental wellbeing from human fecal metagenomic datasets.

Methods

We assembled a metabolic reconstruction framework describing the microbial pathways leading to synthesis or degradation of nervous system-interacting compounds based on extensive literature review. This manually-curated framework consists of a set of gut-brain modules (GBM), each containing the alternative enzymes (orthologous groups) associated to the conversion of a certain neuroactive compound by the gut microbiota. After assessing GBM distribution in gut microbial reference genomes, we applied the framework in a general population cohort (N=1100) to identify associations between gut microbial functional potential and wellbeing indicators.

Conclusions

We assembled a gut-brain analysis framework and by applying it in a large general population cohort we identified bacterial functional properties (GBMs) and taxonomic groups that are significantly associated with host wellbeing.

Plant-bacteria interactions under omics spotlights

THE PSEUDOMONAS PUTIDA TYPE VI SECRETION SYSTEM (T6SS) IS A PLANT WARDEN AGAINST PHYTOPATHOGENS

P. Bernal[1], L.P. Allsopp[1], M.A. Llamas[2], A. Filloux[1]
[1]Imperial College London, Life Sciences, London, United Kingdom
[2]Estación Experimental del Zaidín-Consejo Superior de Investigaciones Científicas, Environmental Protection, Granada, Spain

Backgrounds

Bacterial type VI secretion systems (T6SSs) are molecular weapons designed to deliver toxic effectors into prey cells. These nanomachines play an important role in inter-bacterial competition and provide advantages to T6SS active strains in polymicrobial environments.

Objectives

Here we analyse the genome of the biocontrol agent *Pseudomonas putida* KT2440 and identify three T6SS gene clusters (K1-, K2- and K3-T6SS). Besides, ten T6SS effector/immunity pairs were found, including putative nucleases and pore-forming colicins. We show that the K1-T6SS is a potent antibacterial device which secretes a toxic Rhs-type effector Tke2. Remarkably, *P. putida* eradicates a broad range of bacteria in a K1-T6SS-dependent manner, including resilient phytopathogens which demonstrates that the T6SS is instrumental to empower *P. putida* to fight against competitors. Furthermore, we observed a drastically reduced necrosis on the leaves of *Nicotiana benthamiana* during co-infection with *P. putida* and *Xanthomonas campestris*. Such protection is dependent on the activity of the *P. putida* T6SS.

Methods

We have used a battery of bioinformatic tools including Phyre2 to perform structural-base homology prediction, PyMOL to build structural alignments and MEGA6 to construct the phylogenetic tree. Secretion, growth inhibition and *in vitro* inter-bacterial competition assays were performed. *In planta* bacterial competition assays were carried out on *Nicotiana benthamiana* leaves.

Conclusions

Many routes have been explored to develop biocontrol agents capable of manipulating the microbial composition of the rhizosphere and phyllosphere. Here we unveil a novel mechanism for plant biocontrol which needs to be considered for the selection of plant wardens whose mission is to prevent phytopathogen infections.

Plant-bacteria interactions under omics spotlights

QUORUM-SENSING AND QUORUM-QUENCHING IN PLANT HOST-PATHOGEN INTERACTIONS

D. Faure[1]
[1]*CNRS, I2BC, Gif Sur Yvette, France*

Quorum-sensing (QS) relies cell density and gene expression in a wide range of bacteria which interact with plants, including symbionts and pathogens. Quorum quenching encompasses all the processes that disturb QS signaling, such as QS-signal degrading enzymes and QS inhibition compounds that may be produced by the plant host or microbiota. QS and quorum quenching molecular actors will be presented, and their involvement in host-bacteria interactions will be exemplified, as well as their potential uses for protecting plants.

[5]Helmholtz Zentrum München- German Research Center for Environmental Health, Research Unit Microbe-Plant Interactions, Neuherberg, Germany
[6]Justus Liebig University of Giessen, Bioinformatics and Systems Biology, Giessen, Germany

Backgrounds

The growth-promoting fungus *Piriformospora indica* harbors an endobacterium which is frequently detected in low abundance in fungal lab cultures by fluorescence in situ hybridization and quantitative PCR. The endobacterium was isolated and identified as *Rhizobium radiobacter* (syn. *Agrobacterium tumefaciens*). While the endobacterium grows in pure culture (strain *Rr*F4), the fungus could not be completely cured. Thus, the role of the endobacterium in the tripartite symbiosis with plants is still unclear.

Objectives

First, genome data were generated and root colonization studies were performed to learn more about the function of the endofungal bacterium. In contrast to other endofungal bacteria, the genome of *Rr*F4 is not reduced in size. Instead, it shows high similarity to the genome of the plant pathogenic *A. tumefaciens* C58, except vibrant differences in tumor-inducing (pTi) and accessory (pAt) plasmids, explaining the loss of pathogenicity. Similar to *P. indica*, *Rr*F4 promotes plant growth and induces systemic resistance in plants. GUS- and GFP-tagged *Rr*F4 showed the proliferation of *Rr*F4 in axenic barley and Arabidopsis roots colonizing the rhizodermis and cortical tissue of the root hair zone similar to *P. indica*, but, unlike its fungal host, *Rr*F4 can penetrate into the root stele typical for plant growth promoting bacteria

Methods

Transcriptome data were generated from axenic culture experiments of tripartite interactions of *P. indica,* the endobacterium and barley and dipartite interactions of *Rr*F4 and barley.

Conclusions

The barley transcriptome gave a first inside into the microbe specific response of barley and the transcriptome of *Rr*F4 showed for the first time the specific biological activity of the endobacterium on crop plants if it is released from the fungal host.

Plant-bacteria interactions under omics spotlights

SMALL RNA DISCOVERY IN PLANT PATHOGENS AND SYMBIONTS

F. Narberhaus[1]
[1]*Ruhr University Bochum, Microbial Biology, Bochum, Germany*

Small regulatory RNAs (sRNAs) control gene expression in all domains of life, and are important regulators in plant-associated bacteria (1). Using next-generation sequencing approaches, we and others identified more than 600 sRNA candidates in the phytopathogen *Agrobacterium tumefaciens* (2,3,4). Several of them are differentially expressed in response to growth or stress conditions suggesting a regulatory function. The sRNA AbcR1 (ABC regulator1) accumulates during stationary phase and controls the expression of multiple ABC transporters by two distinct single-stranded regions (5,6). One of its negatively-controlled targets is the *atu2422* mRNA, which encodes a substrate binding protein for proline and gamma-aminobutyric acid (GABA), a plant-secreted defence molecule. The absence of AbcR1 resulted in accumulation of Atu2422 and increased GABA import (5).

Recent results on AbcR1, another sRNA that also controls ABC transporter genes, and a sRNA that regulates growth, motility and antibiotic resistance will be presented.

IMPACT OF PLANT DOMESTICATION ON MICROBIOME ASSEMBLY

J.M. Raaijmakers[1], J. Perez[1], V. Carrion[1]
[1]NIOO-KNAW, Microbial Ecology, Wageningen, The Netherlands

Backgrounds

The rhizosphere microbiome is pivotal for plant growth and health, contributing to nutrient acquisition and stress tolerance. Microbiome assembly is driven in part by the plant genotype, but little is known about the impact of plant domestication on microbiome assembly of economically important food crops.

Objectives

Here, we investigated rhizobacterial community composition in modern and wild accessions of common bean (*Phaseolus vulgaris*) grown in agricultural soil from the highlands of Colombia, one of the centers of common bean diversification.

Methods

DArT-based genotyping and phenotyping of local common bean accessions showed substantial genetic and root architectural differences between wild and modern bean accessions. Wild accessions showed a higher specific root length and root density than the landrace and modern accessions. Rhizobacterial community analyses combined with modeling showed that species abundance is explained by niche-based distributions, with 13.5% of the variability in community composition determined by the bean genotype.

Conclusions

Along the bean genotypic trajectory, going from the most ancestral to the most modern (based on inbreeding coefficient and homozygosity), we observed a gradual decrease in the relative abundance of Bacteroidetes, mainly Chitinophagaceae and Cytophagaceae, and an increase in relative abundance of Actinobacteria and Proteobacteria, in particular Nocardioidaceae, and Rhizobiaceae. Collectively, the results indicate that domestication of common bean affected rhizobacterial community assembly. The impact of these microbiome shifts on plant growth and health will be discussed.

CRISPR-CAS SYSTEMS INTERACTIONS WITH DNA REPAIR PATHWAYS SHAPE CRISPR-CAS SYSTEMS DISTRIBUTION AMONG BACTERIAL GENOMES

A. Bernheim[1], C. Basier[2], A. Calvo Villamanan[2], E.P. Rocha[1], M. Touchon[1], D. Bikard[2]
[1]Institut Pasteur, Genomes and Genetics, Paris, France
[2]Institut Pasteur, Microbiology, Paris, France

Backgrounds

CRISPR-
Cas systems confer bacteria and archea an adaptative immunity against phages and other invading g enetic elements playing an important role in bacterial evolution. Only 47% of bacterial genomes harbor a CRISPR-Cas system despite their high rate of horizontal transfer. Hypothesis such as the cost of autoimmunity or the trade off between a constitutive or an inducible defense system have been put forward to explain this paradox.

Objectives

We propose that the genetic background plays an important role in the process of maintaining a CRISPR-Cas system after its transfer. More precisely we hypothesized that CRISPR-Cas systems interact with DNA repair pathways.

Methods

To test this idea, we detected DNA repair pathways and CRISPR-Cas systems in bacterial genomes and studied their co-occurences. We report both positive and negative associations that we interpret as potential antagonistic or synergistic interactions. We then focused on one interaction (Type II-A and NHEJ) to validate our result experimentally and explore molecular mechanisms behind those interactions.

Conclusions

Our results suggest that the presence of NHEJ impairs Type IIA CRISPR-Cas systems by limiting the acquisition of new spacers and that conversely type II-A CRISPR-Cas systems limits NHEJ efficiency. Our findings give insights on the complex interactions between CRISPR-Cas systems and DNA repair mechanisms in bacteria and provide a first example on the necessity of accommodation of CRISPR-Cas systems to a specific genetic context to be selected and maintained in bacterial genomes.

TRANSCRIPTION PROFILE OF THE BACTERIAL GENOME: A REVOLUTIONARY PARADIGM
A. Ishihama[1]
[1]*Hosei University- Micro-Nano Technology Research Center, Frontier Bioscience, Koganei- Tokyo, Japan*

Transcription Profile of the Bacterial Genome: A Revolutionary Paradigm
Akira ISHIHAMA

Hosei University, Micro-Nano Technology Research Center, Tokyo 184-8584, Japan

After the complete genome sequencing, the research frontier of bacterial molecular genetics shifted toward understanding the regulation of whole set of genes on the genome in bacteria growing under stressful environments in nature. The model prokaryote, *Escherichia coli*, contains a total of more than 4,500 genes, but the total number of RNA polymerase (RNAP) is only about 2,000 molecules per genome. The regulatory targets of RNAP are, however, modulated through modulation of its promoter selectivity after two-steps of the protein-protein interplay with 7 species of the sigma factor in the first step, and more than 300 species of the transcription factor (TF) in the second step. To get insight into the molecular mechanisms underlying transcription regulation of the genome, we have been involved for more than 20 years for identification of the regulatory targets for all sigma factors and all TFs using two newly developed *in vitro* systems: 1) the Genomic SELEX screening of the regulatory targets for each regulator, and 2) the PS-TF screening for identification of the regulators controlling each promoter. In parallel, we determined the intracellular concentrations of all these regulatory proteins. Noteworthy is that all these experiments were carried with use of a single and the same *E. coli* K-12 strain. Taken all these data together, we will be able to predict the expression of all genes in the *E. coli* genome under given conditions. Here I will overview the current state of our research of the regulation of genome transcription and some novel findings.

[3]Centre for Genomic Regulation CRG and Universitat Pompeu Fabra UPF, Bioinformatics and genomics programme, Barcelona, Spain

Backgrounds

Evolution of whole-genome techniques allowed to discover thousands of potential non-coding RNAs, including those transcribed in antisense direction. In E. coli, their ratio to the total amount of annotated genes can reach 22%. The reasons of such a widespread antisense transcription and possible mechanisms for asRNAs' action are not yet understood.

Objectives

The aim of this work was to analyse the profile of asRNAs within the genes coding for transcription factors in E. coli strains growing on different carbon sources.

Methods

E. coli K-12 MG1655 wt, exuR and dps mutants were grown aerobically on M9+0.2% glucose/glucuronate for 4/8 hours. RNA was isolated using Ambion RNAqeous kit. cDNA libraries were prepared and then sequenced on Illumina HiSeq2000 as 50nt single end reads. Data were analysed using Matcher GeneCount.

Conclusions

We analysed profiles of 160 E. coli MG1655 genes coding for transcription factors (76% from all annotated regulators). Antisense transcription was registered within most of the studied loci and was absent only in 18 genes (11%). In most cases, both constant asRNAs and those responding to environmental changes, such as carbon source and growth phase, were registered. Effects of two regulatory proteins were also detected: ExuR as a metabolic regulator, and Dps as a structural protein. The most striking effect was registered for leuO, which transcription in both sense and antisense direction was significantly downregulated by Dps. Being in line with a concept of widespread antisense transcription, our findings do not fully support the idea that bacterial asRNAs are the products of transcriptional noise.

Profiling the functional landscape of bacterial cells

DISCOVERING NOVEL GENES AND FUNCTIONS IN BACTERIA BY COMBINED RNASEQ AND RIBOSEQ

K. Neuhaus[1], *S. Scherer*[2]
[1]*ZIEL Institute for Food & Health, Core Facility Microbiome/NGS, Freising, Germany*
[2]*Technische Universität München, Lehrstuhl für Mikrobielle Ökologie, Freising, Germany*

While NGS allows rapid global detection of transcripts, it remains difficult to distinguish ncRNAs from short mRNAs. To detect potentially translated (novel) RNAs in enterohemorrhagic *E. coli* (EHEC), we used an improved protocol for bacterial ribosomal footprinting (RIBOseq). This allowed distinguishing ncRNA from mRNA. A high ratio of ribosomal footprints per transcript (ribosomal coverage value, RCV) is expected to indicate a translated RNA, while a low RCV should point to a non-translated RNA.

Based on their low RCV, novel non-translated EHEC transcripts were identified as putative ncRNAs, representing both antisense and intergenic transcripts. A number of those novel ncRNAs had expressed homologs in *E. coli* MG1655. Surprisingly, the annotated ncRNAs in EHEC, several showed an RCV similar to protein-coding genes, had RIBOseq patterns matching annotated genes in other enterobacteriaceae, and seem to possess a Shine-Dalgarno sequence. Taken together, this suggests that such ncRNAs may encode small proteins instead of being solely non-coding.

Finally, we found a larger number of intergenic novel ORFs that are translated. These novel ORFs are generally shorter and, therefore, might have been missed by previous annotations and experiments. Thus, RIBOseq is a powerful tool to detect and analyze translational events.

Profiling the functional landscape of bacterial cells

THE ROLE OF THE ESCHERICHIA COLI GENERAL STRESS RESPONSE IN ADAPTING TO LONG TERM RESIDENCE IN A SOIL ENVIRONMENT

C. O'Byrne[1], *Y. Somorin*[1]
[1]*Bacterial Stress Response Group, Microbiology, Galway, Ireland*

Backgrounds

Studies have shown that RpoS, the regulator of the general stress response in *Escherichia coli*, can lose functionality through mutation of the *rpoS* gene when nutrients are limiting or during routine laboratory culture. A unique collection of long-term soil-persistent *E. coli* strains was investigated to determine if their general stress response had been altered during the adaptation to a comparatively nutrient poor soil environment.

Objectives

The study investigated the role of RpoS in soil adaptation and also the role of curli-mediated biofilm.

Methods

The study investigated the integrity of the *rpoS* locus as well as the expression and activity of RpoS. Mutants lacking *rpoS* were constructed and their ability to survive in soil was assessed. The role of RpoS in surviving predation by protozoa was also determined. Biofilm and curli expression was measured in soil adapted strains and correlated with their ability to attach to soil particles.

Conclusions

RpoS was found to be fully conserved in the soil strains and mutants lacking this sigma factor were highly compromised for soil survival. RpoS was found to play a role is resisting low moisture content and in protecting against protozoal predation. Some strains were found to produce limited biofilm and these were shown to be defective for curli expression. Whole genome sequence analysis of these strains revealed alterations in c-di-GMP signalling in these strains. The results suggest that loss of curli expression could contribute to dissemination in a soil environment.

DISSECTING NUCLEATION, GROWTH AND INHIBITION OF BACTERIAL FUNCTIONAL AMYLOIDS AT SINGLE FIBER RESOLUTION

I. Van den Broeck[1], M. Sleutel[1], N. Van Gerven[1], H. Remaut[1], C. Feuillie[2], Y. Dufrêne[2], C. Valotteau[2]
[1]Vrije Universiteit Brussel, Structural Biology Brussels, Brussels, Belgium
[2]Université catholique de Louvain, Institute of Life Sciences, Louvain-la-Neuve, Belgium

Backgrounds

Curli are functional amyloids produced by proteobacteria as part of the extracellular polymer matrix that holds cells together into biofilms.

Objectives

The molecular events during curli nucleation and fiber extension remain largely unknown.

Methods

Here, we combine observations from curli amyloidogenesis in bulk solutions with real-time *in situ* nanoscopic imaging at the single fiber level.

Conclusions

We show that curli display polar growth, and we detect two kinetic regimes of fiber elongation. At high concentration, fibers exhibit steady-state kinetics with a constant instantaneous rate of growth. At low subunit concentration, however, single fibers exhibit stop-and-go dynamics characterized by bursts of steady growth, alternated with periods of stagnation. Curli follow a one-step nucleation process, where monomeric species contemporaneously fold and oligomerize into minimal fiber units that have growth characteristics identical to the mature fibrils. Kinetic data and interaction studies of curli fibrillation in the presence of the natural inhibitor CsgC show the inhibitor binds curli fibers and predominantly acts at the level of fiber elongation.

Surprises in microbial metabolism

ETHANOLAMINE UTILIZATION IN STREPTOMYCES COELICOLOR M145.

A. Bera[1], S. Krysenko[1], A. Matthews[1], N. Okoniewski[2], A. Kulig[1], W. Wohlleben[1]
[1]Interfaculty Institute of Microbiology and Infection Medicine, Microbiology and Biotechnology, Tübingen, Germany
[2]Interfaculty Institute of Microbiology and Infection Medicine, Microbial Bioactive Compounds, Tübingen, Germany

Backgrounds

Non-motile, soil-dwelling *Streptomyces* are able to withstand unfavorable, rapid changing conditions despite constant confrontation with nutrient limitation and pollutants in the soil. Primary nitrogen compounds assimilated by actinobacteria include: ammonium, nitrate, amino acids, urea, amino sugars and peptides. Our studies revealed that *S. coelicolor* can also utilize ethanolamine as a sole nitrogen source. Ethanolamine is a major constituent of bacterial and eukaryotic cell membranes in the form of phosphatidylethanolamine. The well-established model for bacterial ethanolamine utilization involves ethanolamine ammonia-lyase. However, *S. coelicolor* lacks this enzyme and uses so far unknown pathway for the ethanolamine utilization.

Objectives

Here, we report discovery and characterization of a novel gene *glnA4* encoding a glutamine synthetase like enzyme (γ-glutamyl-ethanolamide synthetase) involved in the first step of the ethanolamine utilization pathway in *S. coelicolor.* The GlnA4 catalyzes an ATP-dependent condensation of ethanolamine with L-glutamate to form γ-glutamyl-ethanolamide. We could show that this enzyme accepts as a substrate also ethylendiamine and ethylamine, resulting in the synthesis of the γ-glutamyl-ethylamineamide and γ-glutamyl-ethylamide (L-theanine), respectively.

Methods

The GlnA4 has been overexpressed, purified and characterized biochemically using an *in vitro* assay based on GS activity assay. The product of the reaction catalyzed by GlnA4 was confirmed by HPLC/MS. The deletion of *glnA4* resulted in a growth defect on ethanolamine as a sole nitrogen source. The *glnA4* mutant accumulated ethanolamine intracellularly as confirmed by HPLC. RT-PCR revealed that the expression of *glnA4* was induced by ethanolamine and repressed by ammonium.

Conclusions

First step of the novel ethanolamine utilization pathway was characterized in *S. coelicolor*.

DECIPHERING A BACTERIAL METABOLIC PATHWAY: THE AEROBIC TRIGONELLINE DEGRADATION PATHWAY IN A. BAYLYI ADP1

N. Perchat[1], P.L. Saaidi[1], E. Darii[1], C. Pelle[1], M. Besnard-gonnet[1], V. De Berardinis[1], M. Dupont[1], A. Gimbernat[1], M. Salanoubat[1], A. Perret[1], C. Fischer[1]
[1]CEA-IG UMR8030 CEA/UEVE/CNRS, UMR8030 CEA/UEVE/CNRS, Evry Cedex, France

Backgrounds

Unknown metabolic pathways are still hampering functional annotation of genomes and experimental research is needed for providing access to gene function.

Objectives

We aimed to investigate the undescribed metabolism of trigonelline (N-methylnicotinate), a pyridine compound synthesized by plants to resist draught stress that soil bacteria use as a carbon, nitrogen and energy source. Our laboratory focuses on the experimental search of gene function by addressing these questions in *A. baylyi* ADP1. This gram-negative, non-pathogenic and nutritionally versatile strictly aerobic soil bacterium is easily amenable to genetic manipulations due to its natural competency.

Methods

By using a complete single-gene deletion mutant collection, previously constructed in our laboratory, we identified a cluster of genes involved in the degradation of trigonelline. The role of each enzyme of the pathway was then investigated through an untargeted LC/MS-based metabolomic approach and further refined by solving the structure of the different catabolic intermediates (some of them being new metabolites, not present in the databases) and performing enzymology studies with the recombinant proteins.

Conclusions

The breakdown of the N-methylpyridine ring provides succinate and methylamine, which are further catabolized by the cells. The wide occurrence of this pathway in bacteria of soil and marine origins emphasizes the ecological importance of this overlooked compound. Our work is contributing to the functional annotation of genomes and expands our knowledge of the bacterial metabolite repertoire.

Surprises in microbial metabolism

GLUTATHIONE TRANSFERASES IN DEGRADATION OF LIGNOCELLULOSIC MATERIALS

E. Gelhaye[1], *M. Rouhier*[1]
[1]*Université de Lorraine, UMR 1136 INRA/UL Interactions Arbres / Microorganismes, Vandoeuvre, France*

Backgrounds

Wood decaying fungi have developed unique features allowing them to use complex carbon sources. The adaptation of these organisms to their life style is due at least in part of the existence of extracellular degrading systems. Besides these extensively studied extracellular systems of degradation, wood decaying (and more globally complex organic matter degrading) fungi possess also extended detoxification systems in comparison with other fungi belonging to other trophic types. A comparative genomic approach revealed indeed the presence of an extended multigenic family encoding glutathione transferases (GSTs) in the genomes of wood decayers

Objectives

From structural, biochemical and physiological studies, our aim is to understand the physiological functions of this multigenic family of GSTs in relation with the degradation of complex biomass.

Methods

Phylogenetic analysis.Transcriptomic and proteomic approaches. Biochemical and structural characterization of recombinant proteins. Studies of proteins/ligands interactions.

Conclusions

During the last few years, our group has strongly invested in the biochemical and structural characterization of various isoforms from different fungal models and in particular from *Phanerochaete chrysosporium*. These studies have revealed that the activity of these enzymes could be split off into two functional groups catalyzing opposite reactions, namely: glutathionylation and deglutathionylation. The characterized isoforms are also able to interact with various molecules present in wood from various tree species, such as flavonoids, terpenes] or resulting of the wood biodegradation. Some of these fungal GSTs are also structurally related to the bacterial GSTs involved in lignin degradation. We will discuss the potential use of these GSTs in biotechnology

FUNCTIONAL CHARACTERIZATION OF 3-KETOSTEROID 9A-HYDROXYLASES IN RHODOCOCCUS RUBER STRAIN CHOL-4

G. Guevara[1], M. Rocha[1], A. Blanco-Rivero[1], J.M. Navarro-Llorens[1], J. Perera[1]
[1]Unversidad Complutense de Madrid, Biochemistry and Molecular Biology I, Madrid, Spain

Backgrounds

The 3-Ketosteroid 9α-Hydroxylase, also known as Ksh [androsta-1,4-diene-3,17-dione, NADH:oxygen oxidoreductase (9α-hydroxylating); EC 1.14.13.142)], is a two component Rieske non-heme monooxygenase made up of the oxygenase subunit (KshA) and the reductase subunits (KshB). KshAB is a key activity in bacterial steroid catabolism in combination with a 3-ketosteroid-Δ^1-deydrogenase activity (KstD), being both responsible of the steroid nucleus (rings A/B) breakage. Ksh initiates the opening of the steroid ring by the 9α-hydroxylation of the C9 carbon of 4-ene-3-oxosteroids (e.g. AD) or 1,4-diene-3-oxosteroids (e.g. ADD), transforming them into 9α-hydroxy-4-androsten-3,17-dione (e.g. 9OHAD) or 9α-hydroxy-1,4-androstadiene-3,17-dione (e.g. 9OHADD), respectively. *Rhodococcus ruber* strain Chol-4 isolated from a sewage sludge sample is able to grow in minimal medium supplemented with steroids, showing a large catabolic capacity. Three different *kshA* and one *kshB* genes have been found in *R. ruber* Chol-4 genome.

Objectives

The aim of this work is the functional characterization of the *ksh* genes found in the Chol-4 strain genome.

Methods

For this work, several methods have been followed: growth studies of single, double and triple mutants on different substrates, mutant complementation and biotransformation studies on resting-cells and grown cells.

Conclusions

KshA2 is needed for the degradation of steroid substrates with short side chain while KshA3 is needed for the degradation of those substrates with longer side chains. KshA1 is a more versatile enzyme related to the cholic acid catabolism but it also collaborates with KshA2 or KshA3 in the general degradation of steroids.

UTILIZATION OF THE PLANT SUGAR SULFOQUINOVOSE BY BACTERIA PROCEEDS IN METABOLIC ANALOGY TO THE GLUCOSE PATHWAYS

D. Schleheck[1]
[1]*University of Konstanz, Biology Department, Konstanz, Germany*

Sulfoquinovose (SQ; 6-deoxy-6-sulfoglucose) is the polar headgroup of the sulfolipid (SQDG) in all plants, algae and in most photosynthetic bacteria, and SQ degradation by bacteria represents an important component of the biogeochemical sulfur cycling. Two pathways for primary degradation of SQ are known thus far. First, a 'sulfo-glycolytic pathway' as found in *Escherichia coli* K-12, which proceeds in direct analogy to the glycolysis (Embden-Meyerhof-Parnas) pathway; SQ is catabolized *via* 6-deoxy-6-sulfofructose-1-phosphate to dihydroxyacetone phosphate (DHAP), which is utilized for growth, and to 2,3-dihydroxypropane-1-sulfonate (DHPS), which is excreted. Second, an Entner-Doudoroff-type of pathway in *Pseudomonas putida*, in which SQ is catabolized *via* 2-keto-3,6-dideoxy-6-sulfogluconate (KDSG) to pyruvate, which is utilized for growth, and to 3-sulfolactate (SL), which is also excreted. The excreted DHPS and SL can be degraded completely by other aerobic bacteria, i.e., inclusive release of the DHPS/SL-sulfur in form of sulfate. Currently we are revealing, most likely, a third type of pathway for SQ in *Bacillus* species. Further, we explore complete SQ degradation in bacterial communities under anoxic conditions, which yields hydrogen sulfide (H_2S) in contrast to sulfate as with aerobic communities. Hence, it appears that primary SQ degradation proceeds in metabolic analogy to glucose utilization, but excludes a desulfonation reaction, and that anaerobic, fermentative degradation of dietary SQ may be a relevant, but yet unrecognized pathway and source of H_2S in the gut-microbiomes of herbivores and omnivores.

SMOKE SIGNALS, OR HOW SALMONELLA TURNS OFF ENTEROCOCCUS ANTIBIOTIC RESISTANCE

D. Thomas-Lopez[1], L. Carrilero[1], N. Montero[1], A. Hoefer[1], J. Zivanovic[2], J. Miljkovic[2], M. Filipovic[2], B. Gonzalez-Zorn[1]
[1]Faculty of Veterinary Medicine and VISAVET - Complutense University of Madrid, Animal Health, Madrid, Spain
[2]Institute of Biochemistry and Cellular Genetics - University of Bordeaux, CNRS UMR 5095, Bordeaux, France

Backgrounds

Hydrogen sulfide (H_2S) is a gas produced by many bacteria through the 3MST pathway. Its role in different fields, including antibiotic resistance, is nowadays being elucidated. Interestingly, the pathogen *Salmonella* Typhimurium possesses a second mechanism, classically known as the *phsABC* operon, for the production of H_2S.

Objectives

Our objectives are both to unravel the functions of the *phsABC* operon and to understand the purpose of multiple H_2S producing mechanisms coexisting in *S.* Typhimurium, with regards to the H_2S production, internal sulfhydration, antibiotic resistance and interaction with other species.

Methods

The *phsABC* operon of *S.* Typhimurium ATCC14028 was deleted in-frame by using pKD46, pKD13 and pCP20. *E. faecalis* JH2-2 and *E. faecium* ATCC19434 antibiotic susceptibility tests were performed following official guidelines. When needed, they were incubated in presence of H_2S coming either from *S.* Typhimurium or from a chemical source.

Conclusions

The *phsABC* pathway is the only mechanism used by *S.* Typhimurium to produce extracellular H_2S but it plays a small role in internal sulfhydration. However, when exposing other bacteria to *S.* Typhimurium wild-type and ***Δphs*** strains, we have obtained a surprising result: both *E. faecalis* and *E. faecium*, major nosocomial pathogens worldwide, lose their intrinsic resistance to cephalosporins in the presence of H_2S produced by a physically separated *S.* Typhimurium. Results were confirmed by exposing enterococci to a chemical H_2S source. This astonishing result not only opens the door to new therapeutic options for infections caused by these multiresistant pathogens, but also raises new questions about aerial interaction among microorganisms.

The viral world revisited: from viroids to giant viruses

LESSONS LEARNED FROM GIANT VIRUSES STUDIES

C. Abergel[1], F. Elisabeth[1], S. Jeudy[1], S. Santini[1], M. Legendre[1], J.M. Claverie[1], M. Trauchessec[2], Y. Couté[2]
[1]CNRS-AMU, Structural and Genomic information, Marseille, France
[2]CEA-INSERM-UGA, BIG-BGE, Grenoble, France

Acanthamoeba are infected by a remarkable diversity of large dsDNA viruses the infectious cycles of which have been characterized using genomics, transcriptomics and electron microscopy. Given their gene content and the persistence of the host nucleus throughout their infectious cycle, the Marseilleviridae were initially assumed to fully replicate in the cytoplasm. Unexpectedly, we found that their virions did not incorporate the virus-encoded transcription machinery, making their replication nucleus-dependent. I will present the characterization of the Noumeavirus and Melbournevirus infectious cycle which revealed an unanticipated evolutionary intermediate between exclusively cytoplasmic viruses and nuclear viruses.

FEMS7-0953
The viral world revisited: from viroids to giant viruses

VIROIDS: FILLING THE LOWER SIZE NICHE OF THE BIOLOGICAL SCALE

R. Flores[1]
[1], *Spain*

Discovery around 1970 of potato spindle tuber viroid (PSTVd), the first subviral pathogen with autonomous replication, overthrew viruses from the lowest step of the biological scale. Sequencing of PSTVd revealed its minimal size (359 nucleotides), circular structure with a predicted rod-shaped conformation, and lack of protein-coding ability. This compact conformation, composed by double-stranded segments flanked by loops stabilized by non-canocal interactions, exists *in vivo* and is crucial in replication and trafficking. Most of the approximately 30 viroids known, which resemble PSTVd in having a rod-like structure with a central conserved region (CCR) and nuclear replication, form the family *Posiviroidae*. Avocado sunblotch viroid and three other viroids, which lack a CCR but can form hammerhead ribozymes and replicate in plastids, are grouped into the family *Avsunviroidae.* Viroid replication occurs through a rolling-circle mechanism catalized by host enzymes in the *Pospiviroidae* complemented by ribozymes in the *Avsunviroidae.* The presence in plants infected by members of both families of viroid-derived small RNAs (vd-sRNAs) resembling those generated by Dicer-like enzymes indicate that viroids, like viruses, are targeted by the RNA silencing machinery of their hosts. These vd-sRNAs load the Argonaute core of the RNA-induced silencing complex (RISC), and some containing the pathogenicity determinant of certain viroids direct RISC to cleave specific host mRNAs, providing a plausible mechanism of pathogenesis. Their unique properties make viroids candidates for being molecular relics of the RNA world that preceded the present one based on DNA and proteins. Therefore, viroids are structurally, functionally and evolutionarily independent of viruses.

[5]Institut de Ciènces del Mar ICM-CSIC-, Institut de Ciènces del Mar ICM-CSIC, Barcelona, Spain
[6]University Miguel Hernández, Departamento de Producción Vegetal y Microbiología-, San Juan, Spain

Backgrounds

Viruses have a central influence on global biogeochemical cycles due to their control of microbial populations. However, many of the uncultured viruses are still unknown, hindering our ability to answer fundamental biological, ecological and evolutionary questions about microbial communities in nature.

Objectives

Here, we adapted single-cell genomic technologies to unveil the genomics of natural viral communities that metagenomics and culturing techniques are unable to reveal.

Methods

More than 2,000 single-viruses were separated, one at a time, using fluorescence-activated virus sorting (FAVS) from natural marine environments (surface and mesopelagic Mediterranean Sea and bathypelagic Atlantic Ocean), and 44 viral Single Amplified Genomes (vSAGs) were randomly selected.

Conclusions

Metagenomics and protein-sharing network analyzes showed that these vSAGs are novel highly abundant and microdiverse viral populations from global ocean virome. This indicates that marine vSAGs best represent the uncultured, predominant viral species and genera that dominate the oceans, overlooked by current methodologies.To analyzed why the representative vSAGs have not discovered before, we simulated different levels of viral microdiversity in a natural population. Results showed that viral assembly of microdiverse populations is complicated and was unable to decipher properly that natural genetic microdiversity. Therefore, our analyzes show that single-virus genomics overcome the limitations of current methodologies, and aid to unravel the ecological roles of those 'yet-hidden and secret' viruses from natural viral communities.

The viral world revisited: from viroids to giant viruses

BACTERIOPHAGES IN HYDRA AND THEIR ROLE IN THE METAORGANISM MAINTENANCE

J. Lange[1], T. Bosch[1], T. Lachnit[1]
[1]Zoological Institute- CAU Kiel, Biology, Kiel, Germany

Backgrounds

All multicellular organisms are associated with a host-specific bacterial community. This association is beneficial for both partners and together they form a complex organism termed “metaorganism”. Previous studies have focused on bacteria as key components, while viruses have been mostly disregarded in this context.

Objectives

We expect phages to play a major role as regulators within metaorganisms. We hypothesize that phages are important drivers of the metaorganism homeostasis and function as a part of the immune system.

Methods

The fresh water polyp *Hydra* is a perfect organism to test this hypothesis because it is associated with both a specific bacterial and viral community. We screened our bacteria culture collection for prophage signatures and show that 50% of *Hydra* associated bacteria contain prophages. Six of them are active and inducible by antibiotics and environmental stressors. With cross-infection experiments we analyzed the host range of these phages, of which three feature a broad host range, including the phage of *Hydras* main colonizer *Curvibacter* sp.. To evaluate the role of this dominant phage in homeostasis we conducted recolonization experiments with germfree *Hydra*. We show that *Curvibacter* phage is also active *in vivo* and have the ability to control bacteria directly on *Hydra*. Furthermore we could show *in vivo* that the phage is not only inducible by environmental stressors but also by foreign bacteria, which is triggered by quorum sensing molecules.

Conclusions

Finally we conclude that phages are important for the maintenance of the metaorganism homeostasis and may also function as a part of the immune system.

The viral world revisited: from viroids to giant viruses

THE FIRST PHLEBO-LIKE VIRUS INFECTING PLANTS: A CASE STUDY ON THE ADAPTATION OF NEGATIVE-STRANDED RNA VIRUSES TO NEW HOSTS

B. Navarro[1], M. Minutolo[2], D. Alioto[2], F. Di Serio[1]
[1]Institute for Sustainable Plant Protection CNR, National Research Council of Italy, Bari, Italy
[2]DIpartimento di Agraria, Università degli Studi di Napoli "Federico II", Portici, Italy

Backgrounds

Concave gum (CG) is a virus-like disease of citrus first described in the early 1930s, the etiology of which is still unknown.

Objectives

Identification of viruses associated with CG disease

Methods

Next generation sequencing of cDNA libraries from symptomatic and non-symptomatic citrus plants, field surveys and phylogenetic analyses

Conclusions

A novel negative-stranded RNA virus has been identified and shown to be closely associated with CG disease. The new virus, tentatively named citrus concave gum-associated virus (CCGaV), has a bipartite genome composed of a negative-sense RNA1 coding for the RNA-dependent RNA polymerase (RdRp), and an ambisense RNA2 encoding the nucleocapside (N) and a putative movement protein (MP). RNA signatures in viral RNAs and phylogenetic analyses of RdRP and N proteins highlighted the close relationships of CCGaV with members of the genus *Phlebovirus,* which are arthropod-transmitted viruses infecting mammals, and with some phlebo-like viruses exclusively infecting arthropods. The putative CCGaV MP has the typical features of MPs grouped in the 30K superfamily and is phylogenetically related to the MPs of the plant-infecting viruses of the family *Ophioviridae*. Based on these data, CCGaV can be considered the first phlebo-like virus infecting plants. Implications of these findings in the evolutionary events that allowed the adaptation of the ancestor negative-stranded RNA virus(es), likely infecting arthropods, to plant hosts will be examined. The need of creating a new genus for classifying this bipartite negative-stranded RNA virus, and the impact of specific detection methods developed in the frame of this study on sanitation and certification programs of citrus will be also discussed.

THE ROD-SHAPED VIRUS SIRV2 - A MODEL FOR STUDIES ON VIRUS-HOST INTERACTIONS IN HYPERTHERMOPHILIC ARCHAEA

D. Prangishvili[1]
[1]*Institut Pasteur, Department of Microbiology, Paris, France*

Backgrounds

Viruses that parasitize hyperthermophilic archaea, with their astoundingly diverse, unique morphotypes and the vast majority of genes without identified functions and homologues in the extant databases, constitute one of the least understood parts of the virosphere and only recently are starting to gradually reveal their secrets (for review, see Prangishvili, 2013. *Annu. Rev. Microbiol.* 67: 565-585).

Objectives

I will summarize the current knowledge on one of the model systems for studies on hyperthermophilic archaeal viruses, the *Sulfolobus islandicus* rod-shaped virus 2, SIRV2 —a member of the family *Rudiviridae*—, and discuss the recent advances towards understanding molecular details of its life cycle, including virion entry, morphogenesis and egress, as well as viral genome transcription and replication.

Methods

Diverse

Conclusions

The morphological and genomic distinctiveness of hyperthermophilic archaeal viruses extends to the mechanisms underlying their interactions with the host cells.
