Emerging infectious diseases and how to cope with them

INNOVATIVE THERAPY FOR MYCOBACTERIAL DISEASE
S.T. Cole[1]
[1]*EPFL, Science de la Vie, Lausanne, Switzerland*

Innovative therapy for mycobacterial diseases

Stewart Cole
Global Health Institute, Ecole Polytechnique Fédérale de Lausanne
CH-1015 Lausanne, Switzerland

Tuberculosis (TB) was among the first infectious diseases to be rationally treated and the golden age of TB drug discovery led not only to new antibiotics but also to the development of combination therapy. No new TB drugs had been developed since the 1960s until recently but, in response to the HIV-pandemic and widespread resistance to first- and second-line drugs, a pipeline of candidate TB drugs has been established. Some of these drugs offer potential for the treatment of other mycobacterial diseases such as leprosy, Buruli ulcer and NTM infections. The ATPase inhibitor bedaquiline is especially promising followed by benzothiazinones, highly potent compounds that kill *Mycobacterium tuberculosis* by blocking a critical step in cell wall biosynthesis. The potential impact of these and other new candidate drugs will be discussed.

Climate change

THE SUBZERO MICROBIOME: SEASONAL DYNAMICS OF BACTERIAL COMMUNITIES IN ARCTIC TUNDRA SOILS

M. Häggblom[1]
[1]*Rutgers - The State University of New Jersey, Biochemistry and Microbiology, New Brunswick, USA*

A substantial portion of the global soil carbon pool is stored in Arctic and boreal ecosystems and decomposition of this currently sequestered pool of soil organic carbon is expected to be a significant contributor to atmospheric chemistry and climate. A large portion of Arctic and boreal soil ecosystems are permanently frozen or only experience thaws for a brief time in the summer and due to the short warm season degradation of soil organic carbon in tundra soils has historically been slow and incomplete. Microbial life, however, continues into the subzero temperature range, and this activity contributes to carbon and nitrogen flux in and out of ecosystems, ultimately affecting global processes. The divergent life-styles of different microorganisms will be reflected in their ability to function in frozen soils and in their responses to environmental perturbations, leading to seasonal dynamics of activities. We seek to delineate the subzero active microbial community in Arctic tundra soils and discern their roles in soil organic matter degradation and to understand how different members of the microbiome modulate their responses to variations in temperatures and pulses of C and N substrates. Using a stable isotope probing (SIP) approach, we have shown that bacterial genome replication occurs at temperatures from 0 to -20 °C in seasonally frozen tundra soils, as well as in permafrost. Microbial degradation of plant litter is also substantial in frozen soils. Our findings indicate that Arctic and boreal soils impact greenhouse gas production/consumption while frozen, as well as when thawed. By understanding these processes in frozen soil systems, we hope to better predict the extent of C and N released as greenhouse gases which subsequently contribute to climate change.

Climate change

MICROBIAL COMMUNITIES AND METHANE DYNAMICS IN ACTIVE LAYERS OF ARCTIC SOIL PERMAFROST ECOSYSTEMS

A.T. Tveit[1], T. Urich[2], M.M. Svenning[1]
[1]Arctic and Marine Biology, Microorganisms and Plants, Tromsø, Norway
[2]Institute of Microbiology, Microbiology, Greifswald, Germany

Permafrost soils store large amounts of organic carbon that is a source of the greenhouse gases (GHG) methane (CH_4) and carbon dioxide (CO_2). The active soil layer above permafrost consists of stored plant tissue mainly of mosses and/or vascular plants, primarily grasses and sedges contributing to polymers of different complexity. This active layer inhabit a diverse community of microorganisms with members from all three domains of life (Bacteria, Archaea and Eukarya), which cooperate for degradation of the stored organic matter to the greenhouse gases (GHG) methane (CH_4) and carbon dioxide (CO_2). The majority of active microbes belong to the phyla Actinobacteria, Bacteriodetes, Chloroflexi, Firmicutes, Proteobacteria, Verrucumicrobia, Planctomycetes, and Cercozoa. Microbes within the genera *Methanomicrobiales*, *Methanobacteriales* and *Methanosarcinales* perform CH_4 production. *Methylobacter* is further a key genus for the oxidation of CH_4. The carbon flow of this Arctic ecosystem, leading to GHG emissions, is dependent on how this microbial network community respond to climate changes.

The anaerobic microbial community and network metabolism were studied in response to a temperature gradient ranging from 1 to 30 °C by combining metatranscriptomic, metagenomic, and targeted metabolic profiling. The CH_4 production rate at 4 °C was 25% of that at 25 °C and increased rapidly with temperature, with associated changes in microbial communities, metabolic network of soil organic carbon decomposition, and trophic network. Arctic peat microbiota responds rapidly to increased temperatures by modulating metabolic and trophic interactions such that CH_4 is always highly produced.

REEF MICROBIAL SYMBIOSIS IN A CHANGING CLIMATE

N. Webster[1], H. Luter[1], E. Emmanuelle Botte[1], H. Bennett[1]
[1]Australian Institute of Marine Science, A healthy and resilient GBR, Townsville, Australia

Marine sponges contain complex and diverse microbial communities that contribute to the health of their hosts. Environmental conditions which disturb the distribution, abundance or function of sponge microbes can therefore have significant consequences for host fitness and survival. Climate change scenarios predict increases in sea surface temperatures (SST) and decreases in oceanic pH during the coming century. Using a combination of experimental research and data collected from natural CO_2 seeps, we have explored how elevated SST and ocean acidification (OA) impact sponge symbiosis. Sponges at CO_2 seeps have had a lifetime of exposure to high CO_2 therefore these sites are 'natural laboratories' for OA research, allowing us to answer questions of long-term acclimatization in the microbiome. Whilst the sensitivity of the sponge microbiome to climate change varies between species, a breakdown in symbiotic function which occurs in the early stages of climate stress for some species has been clearly linked to declining host health, and in some instances mortality. The application of genomic, transcriptomic and proteomic approaches to these model marine symbioses allows us to explore the functional implications of environmental stress for sponges and thereby better predict how they will acclimate and adapt to a changing climate.

ENZYME DISCOVERY, ENGINEERING AND APPLICATION IN THE SYNTHESIS OF CHIRAL COMPOUNDS AND CASCADE REACTIONS

U. Bornscheuer[1]
[1]*Institute of Biochemistry, Dept. of Biotechnology & Enzyme Catalysis, Greifswald, Germany*

This lecture will highlight principle strategies and current challenges in enzyme discovery and protein engineering [1]. For the synthesis of chiral amines, we performed an *in silico* analysis and identified a toolbox of novel (*R*)-selective ATAs [2] as well as (*S*)-selective enzymes from a structure-guided search [3]. More recently, we could engineer (*S*)-selective ATA for the acceptance of bulky ketones for the asymmetric synthesis of a set of important chiral amines [4, 5]. We also established cascade reactions and developed for instance the efficient synthesis of e-caprolactone-oligomers through combination of three enzymes [6].

INTEGRATED SOFTWARE TOOLS AND LAB-ON-CHIP TECHNOLOGIES FOR BIG DATA IN BIOLOGY

J. Damborsky[1]
[1]*Masaryk University- Faculty of Science, Loschmidt Laboratories, Brno, Czech Republic*

Vanacek, P., Hon, J., Babkova, P., Buryska, T., Vasina, M., Chaloupkova, R., Bednar, D., Martinek, T., Prokop, Z., Damborsky, J., Integrated Software Tools and Lab-on-chip Technologies for Big Data in Biology

Millions of new protein sequences are being discovered at an incredible pace, representing an inexhaustible source of novel biocatalysts. The genetic databases are doubling every 15 months in postgenomic era [1]. The annotation of a large portion of this data lacks proper information on their biological function or includes no functional information at all. We have recently developed an integrated system for automated *in silico* exploration of protein functional diversity and robotic experimental characterization of attractive family members [2]. The workflow, which consists of: (i) identifying relevant genes by sequence and structural bioinformatics, (ii) expression analysis and activity screening, and (iii) complete biochemical and biophysical characterization, was validated against the haloalkane dehalogenase family. During the first round of the screening (carried out in 2013), the sequence-based searches identified 658 putative dehalogenases. Experimental characterization of 20 hits provided the most catalytically proficient native haloalkane dehalogenase enzyme to date, the most thermodynamically stable enzyme with melting temperature 71^{o}C, cold-adapted enzymes showing activity at near-to-zero temperatures and a new biocatalyst degrading sulfur mustard. The enzymes discovered originated from Bacteria and Eukaryota, and, for the first time, from Archaea. The second round of the screening (carried out in 2017), resulted in 520% increase of putative dehalogenases. In this round, the slowest steps in the experimental part of the platform will be replaced by newly developed lab-on-chip assays, requiring only tiny fractions (mL) of a protein material and providing dramatic increase in the throughput. Established strategy, software code and microfluidic chips can be adapted to other enzyme families, paving the way towards functional characterization of proteins produced based on data from next-generation sequencing technologies.

DE NOVO ENZYME CASCADES IN CELL FREE AND WHOLE CELL SYSTEM BIOCATALYSIS

S. Flitsch[1]
[1], *United Kingdom*

The combination of sequential biocatalytic reactions in non-natural synthetic cascades is a rapidly developing field and leads to the generation of complex valuable chemicals from simple precursors. As the toolbox of available biocatalysts continues to expand, so do the options for biocatalytic retrosynthesis of a target molecule, leading to new routes employing enzymatic transformations. The implementation of such cascade reactions requires careful consideration, particularly with respect to whether the pathway is constructed *in vitro* or *in vivo*. This lecture will showcase three successful implementations of *de novo cascades* and discuss the relative merits of *in vitro*, *in vivo* or hybrid approaches to building biocatalytic cascades. We also highlight the factors that influence the design and implementation of purely enzymatic or chemo-enzymatic, one-pot, multi-step pathways.

ENZYME ENGINEERING STIMULATED BY CHEMICAL AND BIOLOGICAL DIVERSITY

B. Hauer[1]
[1], *Germany*

Enzyme Engineering stimulated by biological and chemical diversity.

Bernhard Hauer, University of Stuttgart

Industrial Biotechnology holds the promise to manufacture chemical compounds based on efficient, green routes and using renewable substrates. Applying the tools of synthetic biology, we design novel artificial pathways to access these chemicals. However, analyzing important target molecules with a retrosynthetic perspective we have to realize that we quite often lack enzymatic functions limiting this synthetic biochemistry approach. How do we get access to these sought-after enzymatic activities? In my talk, I will discuss grasping this challenge with a pinch from biology and chemistry.

Biologists provide us with structural information and sequence date for hundreds of closely related enzymes. Comparing these different enzymes, we can extract valuable information about structure function relationships. We can learn that nature has chosen certain hot spots and amino acid residues to adapt a protein towards a new function. Hot spots, insertions and deletions or sometimes correlated sides of amino acid variations, are an ideal starting point for designing small, focused libraries of enzyme variants. This strategy was successfully applied in engineering dioxygenases with an extended substrate spectrum and P450 monooxygenases with a higher activity.

Identifying enzyme variants which catalyze new reactions is a bit more challenging. Moon shine activities or enzyme promiscuity has thought us that enzymes can do much more than converting physiological substrates. Under the order of the same catalytic mechanisms chemically related compounds can be converted and new type of reactions are performed by the very same enzyme. Even if the reactions are running with low rates promiscuous substrates are the starting point for the development of enzymes with novel functions. Key to unravel possible reaction is the careful choice of the right substrates and calls for some chemical knowledge. This approach will be illustrated based on examples with squalene hopene cyclases catalyzing non-natural Prins-reactions, Friedel-Crafts-reaction, and isomerizations.

Insights into biological diversity of enzymes and knowledge about the diversity and mechanisms of chemical reaction enable us to engineer enzymes with novel activities in our laboratories. These new *bio*catalysts go far beyond what nature has intended to catalyze so far and expand the biosynthetic options we have quite a bit. However, we also get a notion about the evolutionary options nature has built into these fantastic catalysts.

Cell-cell communication, signalling and quorum sensing

QUORUM SENSING VIA INTERNALIZED PEPTIDES IN STREPTOCOCCI

R. Gardan[1]
[1]*INRA, Institut Micalis- AgroParis Tech- Université Paris-Saclay, Jouy-en-josas, France*

Quorum-sensing (QS) is a bacterial cell-cell communication mechanism that controls gene expression at the population level via secreted signaling molecules. In Gram-positive bacteria, the signaling molecules are mostly small secreted peptides which are matured by a protease, actively released into the extracellular environment, accumulate and, once at a threshold concentration, are detected by a sensor protein. This sensing leads cells to modulate gene expression in a coordinated manner. For a long time, only mechanisms involving peptides that are extracellularly detected by histidine kinases of two component systems have been studied. However, a second activation pathway involving signaling molecules that need to be actively transported inside the cell before interacting with their receptors has emerged. These receptors form a structural family called RRNPP (for **R**gg/**R**ap/**N**prR/**P**lcR/**P**rgX) that is characterized by the presence of tetratrico peptide repeats (TPRs), a structural motif mediating protein-protein interactions. Members of this family are transcriptional regulators except Rap proteins that regulate the phosphorylation level or the DNA-binding activity of response regulators. RRNPP proteins regulate important physiological processes such as conjugation in enterococci (PrgX), sporulation (Rap) and virulence (PlcR) in bacilli. Rgg transcriptional regulators are found in the order of Lactobacillales and the family of Listeriacae. Up to now, they have only been studied in streptococci in which they control the triggering of competence for transformation, virulence, production of biofilm or of modified secreted peptides. In this presentation, different QS mechanisms involving Rgg regulators will be presented, compared to each other and to mechanisms involving other members of the RRNPP family, in an evolutionary perspective. We will also address the following questions: is it possible to inhibit or activate these Rgg-associated QS mechanisms and what are the issues of such manipulations?

Cell-cell communication, signalling and quorum sensing

ANTIMICROBIAL TARGETS AND BIOMARKERS-EXPLOITING ALKYLQUINOLE-DEPENDENT QUORUM SENSING IN PSEUDOMONAS AERUGINOSA

P. Williams[1]
[1]*Centre for Biomolecular Sciences, School of Life Sciences, Nottingham, United Kingdom*

In bacterial pathogens such as *Pseudomonas aeruginosa* the expression of multiple virulence and biofilm development genes is often co-ordinately controlled at the transcriptional level by global regulatory systems incorporating quorum sensing (QS). The latter constitutes a cell-to-cell communication network that integrates information at the population level, co-ordinating the metabolic status of the cells with environmental cues. QS depends on the synthesis, secretion and perception of diffusible signalling molecules that enable pathogens to synchronize their behavior. QS signal molecules, although largely considered as effectors of QS-dependent gene expression are also emerging as multi-functional agents that impact on host-pathogen interactions and influence life, development and death in single and mixed microbial populations. QS is a potential antibacterial target in pathogens where strains carrying mutations in key QS genes exhibit highly attenuated pathogenicity in animal infection models Further indications that QS systems are active during human infections are emerging from clinical studies where QS signal molecules can been detected in patient body fluids. Since QS by definition depends on small molecule ligand/receptor interactions, it offers a direct pharmacological pathway to inhibitor development since the steric requirements for optimal ligand/receptor interactions means that antagonists can be readily obtained through structural modification of native agonists. In this context, advances in our understanding of the molecular and structural biology of alkylquinolone (AQ)-dependent QS in *P. aeruginosa* have lead to the identification of multiple 'druggable' targets and small molecule inhibitors. In cystic fibrosis, the presence of AQs in plasma and urine correlates with clinical status highlighting their potential as biomarkers to aid diagnosis and assessment of the response to treatment.

CANDIDALYSIN A FUNGAL PEPTIDE TOXIN

B. Hube[1]
[1], *Germany*

The dimorphic fungus *Candida albicans* can be both, a harmless commensal of mucosal surfaces and an aggressive human pathogen in susceptible hosts. In the commensal phase, fungal cells are associated with host mucosal surfaces and co-exist with the microbiota. These conditions change during the transition to a pathogenic life style. This transition includes direct attachment to, invasion into, and damage of epithelial cells. Adhesion to host epithelial cells is mediated by surface proteins. Fungal−host surface contact during attachment can induce the production of hyphae and expression of hyphae-specific genes, which, in turn, drive further adhesion. Hyphae are not only more adhesive, but also more invasive than yeast cells. Invasion occurs via two different routes: induced endocytosis or active penetration. Most of the tissue damage is due to deep and destructive inter-epithelial invasion via elongated hyphae, along with the release of destructive factors. In fact, *C. albicans* secretes a peptide toxin, Candidalysin, which is predominantly responsible for epithelial damage.

New insights into effector function in the *U. maydis*-maize pathosystem

Regine Kahmann, Nicole Ludwig, Liang Liang, Kerstin Schipper*, Stefanie Reißmann, Daniela Assmann and Timo Glatter Max Planck Institute for Terrestrial Microbiology, Dept. Organismic Interactions, Marburg, Germany

The fungus U. maydis causes smut disease in maize. U. maydis is a biotrophic pathogen requiring living plant tissue for colonization. For a successful infection U. maydis needs to suppress plant defense responses and manipulate host physiology for its own benefit. To accomplish this, U. maydis secretes a cocktail of about 300 effector proteins. The majority of these proteins lack a functional annotation and their function remains to be uncovered. Our current work focuses on effectors expressed early during infection. Systematic deletion of the most highly expressed effector genes in this class resulted in the discovery of three mutants unable to cause disease. Their mutant phenotype resembled previously identified *stp1* (stop after penetration) mutants, and the newly identified genes were designated *stp2*, *stp3* and *stp4*. A similar phenotype was also observed for mutants lacking the essential effector *pep1* (Doehlemann *et al.,*2009*). All stp mutants* strains were able to form appressoria that penetrate maize epidermal cells, but their growth was arrested in epidermal tissue. In all cases growth arrest was accompanied with the elicitation of plant defense responses and plant cell death.Co-IP with individually tagged effectors followed by mass-spectroscopic analysis revealed that Stp1, Stp3, Stp4 and Pep1 form a complex. Stp2 is not part of the complex. We will discuss our current efforts to localize the complex and to functionally characterize its components. In this context, we are testing the possibilities that the complex could aid in translocation of other effectors, function as a regulatory complex or exist to shield the activity of Avr proteins.

CANDIDA ALBICANS CELL WALL: ROLES IN VIRULENCE, HOST INTERACTIONS AND DRUG SUSCEPTIBILITY

C. Munro[1]
[1], *United Kingdom*

The *Candida albicans* cell wall is a dynamic organelle, composed of chitin, β-1,3-glucan, β-1,6-glucan and mannoproteins. The echinocandin antifungal drugs target the cell wall by inhibiting β-1,3-glucan synthesis. The echinocandins provide effective therapy but sporadic breakthrough infections caused by resistant *Candida* isolates have been reported. *C. albicans* acquires echinocandin resistance through point mutations in the *FKS* target genes. In addition *C. albicans* responds to sub-MIC echinocandins by up-regulating chitin biosynthesis and expression of cell wall remodelling enzymes through activation of cell wall salvage pathways that involve PKC and calcium/calcineurin signalling. Cells with altered wall architecture are less susceptible to echinocandins *in vitro,* as well as in infection models. Other *Candida* species (with the exception of *Candida glabrata*) and *Aspergillus fumigatus* also activate compensatory wall remodelling when challenged with sub-MIC echinocandins, resulting in drug tolerance.

Substantial changes in the cell wall glycoproteome are triggered by cell wall and envelope stresses, including echinocandin treatment. Several predicted carbohydrate-active enzymes (CAZy) enzymes involved in modulating and cross-linking chitin and glucan (Phr1, Phr2, Pga4, Crh11, Utr2) are among the cell wall proteins (CWPs) positively regulated in response to cell wall damage. The MAP kinase, Mkc1, and the transcription factor, Rlm1, are important in the upregulation of these CWPs. Furthermore, clinical resistant isolates have higher levels of stress-activated CWPs, even in the absence of drug, indicating their walls are different to sensitive isolates. We are investigating the role of specific CWP genes in caspofungin susceptibility, paradoxical growth and host-pathogen interactions using overexpression and null mutant strains.

Pathogenic yeast

FUNGAL APPRESSORIA: PLATFORMS FOR DELIVERING SMALL MOLECULE EFFECTORS

J.F. Dallery[1], E. Adelin[2], J. Ouazzani[2], R. O'Connell[1]
[1]INRA, BIOGER, Thiverval-Grignon, France
[2]CNRS, Institut de Chimie des Substances Naturelles, Gif-sur-Yvette, France

Species of the fungal genus *Colletotrichum* cause devastating diseases on numerous major crop plants worldwide. *C. higginsianum* attacks cultivated members of the Brassicaceae but also the model plant *Arabidopsis*. Initial host cell invasion requires the differentiation of a specialized cell-type called an appressorium that mediates penetration of the plant cuticle and cell wall. Compared to other sequenced ascomycetes, the genome of *C. higginsianum* contains an exceptionally large number of genes (89) encoding secondary metabolism (SM) key enzymes. These are organized into 68 gene clusters which, as in other fungi, also contain genes encoding accessory enzymes of the same biosynthetic pathway, together with efflux transporters and pathway-specific transcription factors. A remarkable finding from transcriptome profiling was that 19 SM clusters are specifically expressed only at early stages of plant infection inside appressoria. Since each cluster potentially synthesizes one metabolite, this suggests fungal appressoria deliver a cocktail of different chemicals to the first infected host cell. At this early stage host cells remain alive, raising the possibility that these molecules function similar to protein effectors for host manipulation, rather than as simple phytotoxins. We present evidence that the coordinated and stage-specific expression of SM genes is orchestrated at two levels, namely remodelling of chromatin structure and regulation by global transcriptional activators. Progress towards the functional characterization of these metabolites will also be presented, including evidence that some metabolites can subvert plant immune responses.

FEMS7-3303
Microbiome pathogens-host: Triangulating host-pathogen interaction in microbial infections

MICROBIOME AND CLOSTRIDIUM DIFFICILE INFECTION

H. Browne[1], S. Forster[1], T. Lawley[1]
[1]Wellcome Trust Sanger Institute, Host-microbiota interactions, Cambridge, United Kingdom

Our intestinal microbiota harbours a diverse bacterial community required for our health, sustenance and wellbeing. Intestinal colonization begins at birth and climaxes with the acquisition of two dominant groups of strict anaerobic bacteria belonging to the Firmicutes and Bacteroidetes phyla. Culture-independent, genomic approaches have transformed our understanding of the role of the human microbiome in health and many diseases. However, owing to the prevailing perception that our indigenous bacteria are largely recalcitrant to culture, many of their functions and phenotypes remain unknown. Here we describe a novel workflow based on targeted phenotypic culturing linked to large-scale whole-genome sequencing, phylogenetic analysis and computational modelling that demonstrates that a substantial proportion of the intestinal bacteria are culturable. Applying this approach to healthy individuals, we isolated 137 bacterial species from characterized and candidate novel families, genera and species that were archived as pure cultures. Whole-genome and metagenomic sequencing, combined with computational and phenotypic analysis, suggests that at least 50-60% of the bacterial genera from the intestinal microbiota of a healthy individual produce resilient spores, specialized for host-to-host transmission. Our approach unlocks the human intestinal microbiota for phenotypic analysis and reveals how a marked proportion of oxygen-sensitive intestinal bacteria can be transmitted between individuals, affecting microbiota heritability.

Title : Shigella, type 6 secretion system and the microbiome

Abstract : « Cellular microbiology » has clearly biased studies on microbial pathogenesis towards focused molecular and cellular analysis of the cross-talks established between the pathogen and its target cells. « Tissue microbiology » has attempted to integrate these mechanisms into the more global scheme of the pathogen interacting with cells in their relevant context. These approaches have successfully driven the field and promoted pathogenesis research to an extraordinary degree of cellular and subcellular resolution ; they have also somewhat ignored important components of the entire pathogenic cycle such as the phases of mucosal colonisation, dissemination and transmission. Recent emergence of the microbiota on the « pathogenesis agenda » has reestablished the colonisation phase as a central issue in pathogenesis, particularly due to the need for the pathogen to secure its niche at the mucosal surface to the expence of the résident microbiota that imposes a strong barrier effect. We have developed dedicated tools to study the Shigella-microbiota-host « ménage à trois », particularly rodents models of colon infection. On these bases, we characterized two systems that secure colonization of the colonic mucosa by *Shigella sonnei* : a type 6 secretory system and a colicin that are unique to this serotype and essential to occupy the niche normally dedicated to commensal proteobacteria such as *Escherichia coli*. In addition, S. sonnei shows strong capacity to efface S. flexneri, both in vitro and in vivo, possibly explaining the current emergence of *S. sonnei* among the various Shigella serotypes that used to cause bacillary dysentery.

B. Stecher[1]
[1]*Max von Pettenkofer Institute- LMU Munich, Medicine, Munich, Germany*

A toolbox of cultured bacteria to probe the role of individual microbiota members in preventing pathogen infections

"Meta-omics" analyses are dramatically expanding our knowledge about the composition and metabolic diversity of the gut microbiota and its association with human diseases, but dissecting the function and quantitative impact of individual microbiota members remains a challenge. Protection against enteric infections, also termed colonization resistance (CR), results from mutualistic interactions of the host and its indigenous microbes. The gut microbiota of humans and mice is highly diverse and it is therefore challenging to assign specific properties to its individual members. We assembled a collection of murine bacterial strains, termed Oligo-Mouse-Microbiota and a modular design approach to create a minimal bacterial community of 12 strains that stably colonizes germ-free mice. This community provides intermediate resistance against infections with different enteric pathogens, including *Salmonella enterica* serovar Typhimurium (S. Tm) and *Clostridium difficile*. This particular phenotype allowed us to investigate, whether additional bacteria could further enhance resistance to the level of a complex, undefined microbiota. With the aid of comparative metagenomics, we created an improved version of the Oligo-MM community harboring three additional strains from a novel public culture collection (1) that provided conventional-like CR against S. Tm (2). Furthermore, supplementation of secondary bile acid producers was protective against *C. difficile* induced disease (3). In conclusion, the Oligo-MM is a highly versatile experimental system to functionally probe the role of individual microbiota members in different enteric infection models and beyond. Thus, in combination with exhaustive bacterial strain collections and systems-based approaches, gnotobiotic models can be used to generate novel insights into microbe-microbe and microbe-host interactions for the investigation of ecological and disease-relevant mechanisms in the intestine.

Title : Decrypting microbe-cell cross-talks in the intestinal crypt : microbiome and epithelial regeneration

Abstract : We have identified a limited subset of bacterial taxa called crypt-specific core microbiota (CSCM) that dwells in intestinal crypts of the caecum and colon in mice and more recently in humans. These bacteria share common metabolic properties, being strictly aerobic and non fermentative. Initially identified by metataxonomics, they have been more recently isolated and cultivated and belong to three dominant genus : Acinetobacter, Delftia and Stenotrophomonas. Intestinal crypts are sites of sustained epithelial regeneration and repair in case of injury. Intestinal stem cells are located at the bottom of the crypts, thus in direct contact with stem cells and their proliferating/differentiating lineages. The intestinal crypt thus appears like a good model to study the impact of the microbiota on tissue regeneration and repair. We have identified a MDP-Nod2 signaling pathway that provides cytoprotective capacities to stem cells upon agression by a cytotoxic drug such as Doxorubicin. Studies are on their way to decipher the relevant mechanisms of protection. Focusing on CSCM components, we have shown that they achieve a balance between controled prolifération and stimulated differentiation in a LipidA-TLR4-dependant pathway. Hence the cytoprotective and homeostatic role of CSCM is becoming central to this topic.

In search of thermodynamic principles for managing microbial communities in environmental biotechnology processes

IN SEARCH OF THERMODYNAMIC PRINCIPLES FOR MANAGING MICROBIAL COMMUNITIES IN ENVIRONMENTAL BIOTECHNOLOGY PROCESSES

T. Bouchez[1], H. Delattre[1], E. Desmond-Le Quéméner[1]
[1]Irstea, HBAN, Antony, France

Environmental microbial communities are key engines that drive earth's biogeochemical cycles. Despite their enormous diversity, microbiomes exhibit a remarkable property: the functional convergence. It characterizes their general tendency to reproduce defined functional population patterns in specific biotopes (sea water, soil, plant foliage, cheese, human body biomes...). In environmental biotechnology processes such as wastewater treatment plants or anaerobic digesters, this property allows to maintain and exploit functionally defined but taxonomically diverse mixed microbial cultures in open systems by applying selective pressures. This suggests that, beside random population immigration/emigration events, mechanistic processes largely determine functional microbial community assembly patterns. Here, we examine the contribution of energy gradients to the emergence of these patterns.

We build on a recent thermodynamic theory of microbial growth in which flux/force relationship between functional population growth rates and available energy gradients is derived from statistical physics reasoning. Coupled to mass and energy balance calculations, this relationship is used to simulate the dynamics of virtual microbial ecosystems. Simulations show that consistent ecological successions and functional community patterns arise from the model without population specific parameter calibration. Applied to activated sludge modelling, virtual communities exhibit emergent behaviours consistent with current engineering knowledge. Our approach shows how chemical species in solution determine the metabolic niches that can sustain growth, from which functionally convergent microbial community patterns arise. In the future, this approach could be used to build ecological models coupling energy balance, stoichiometry and microbial dynamics for better managing the functional abilities of microbial communities.

Innovators and imitators: how environmental bacteria conquest the chemical space

INNOVATORS AND IMITATORS: HOW ENVIRONMENTAL BACTERIA CONQUEST THE CHEMICAL SPACE

Ö. Akkaya[1], D. Perez-Pantoja[2], P.I. Nikel[3], V. de Lorenzo[4]
[1]Gebze Technical University, Molecular Biology and Genetics, Kocaeli, Turkey
[2]Programa Institucional de Fomento a la I+D+i PIDi, Universidad Tecnológica Metropolitana, Santiago, Chile
[3]The Novo Nordisk Foundation Center for Biosustainability, Cell Factories, Lyngby, Denmark
[4]Centro Nacional de Biotecnología, Systems Biology, Madrid-Campus de Cantoblanco, Spain

The still-evolving 2,4-dinitrotoluene (DNT) pathway of *Burkholderia cepacia* R34 has been studied as a case of emergence of new metabolic capabilities in environmental bacteria. The *dnt* route originated from a precursor naphthalene degradation pathway and the first enzyme (DNT dioxygenase) maintains significant activity towards its earlier substrate. Both *in vivo* reactions and the associated regulatory system mediated by the DntR transcriptional factor indicate that reactive oxygen species (ROS) generated by the faulty (i.e. uncoupled) reaction of the precursor enzymes with DNT elicit genetic diversification. This could in turn ease the solution of the biochemical and physiological problem. When the *dnt* system was transplanted to the genetically tractable background of *Escherichia coli*, mutagenesis caused by endogenously produced ROS was dependent on *rpoS* and *dinB,* and was not accompanied by a general induction of the SOS response. In addition, analysis of the type of mutations suggested that ROS-triggered genetic diversification was due not so much to misincorporation of 8-oxoguanine as to the lack of fidelity of DNA replication. When the *dnt* operon was inserted in the genome of *Pseudomonas putida* and cells were exposed to DNT, the resulting metabolic ROS did not translate in significantly higher mutagenic rates. Artificially decreasing the intracellular pool of NAD(P)H caused *P. putida dnt*+ to acquire a high genetic-diversification regime. It is thus plausible that some members of a given microbial community are prone to innovate their metabolic capacities much faster than others while the rest may benefit from such innovation through horizontal gene transfer.

CELL WALL DEFICIENT (L-FORM) BACTERIA: FROM CHRONIC INFECTIONS TO THE ORIGINS OF LIFE

Y. Kawai[1], K. Mickiewicz[1], J. Errington[1]
[1]Newcastle University, Centre for Bacterial Cell Biology, Newcastle-upon-Tyne, United Kingdom

The peptidoglycan cell wall is a defining structure of the bacteria. It is the target for our best antibiotics and fragments of the wall trigger powerful innate immune responses against infection. The genes for peptidoglycan synthesis are present in most bacterial lineages, suggesting that the wall emerged early in cellular evolution. Surprisingly, many bacteria can switch almost effortlessly into a cell wall deficient “L-form” state in which they become completely resistant to many cell wall active antibiotics. Remarkably, L-form growth is completely independent of the complex FtsZ-based division machine that is essential for proliferation of most bacteria. Proliferation occurs instead by a seemingly haphazard process involving membrane blebbing or tubulation and scission, leading to progeny of highly irregular size. The switch to this mode of proliferation seems to require only the upregulation of membrane synthesis, leading to an increased surface area to volume ratio. L-forms may provide insights into how primitive cells proliferated before the evolution of the cell wall and the ancient bacterial radiation. L-forms have also been implicated in many recurrent or chronic diseases, although these claims have been controversial. Recent results uncovering an unexpected interplay between the action of β-lactam antibiotics, endogenous lysozyme and L-form switching, which may be highly relevant to the treatment of infectious diseases, will be described.

Virology, new viruses, RNA polymerase

VIROLOGY, NEW VIRUSSES, RNA POLYMERASE

S. Cusack[1]
[1], *France*

The 'flu is caused by the highly infectious, rapidly evolving and potentially dangerous influenza virus. We study the molecular mechanisms by which the viral RNA-dependent RNA polymerase transcribes and replicates the viral genome. This is not only of fundamental interest but will also help understand avian to human interspecies transmission of the virus and promote development of new anti-influenza drugs. Influenza, which is a member of the *Orthomyxoviridae* family of segmented negative strand RNA viruses (sNSV), continues to have an enormous impact on world-wide public health. The eight distinct genome segments are individually packaged into ribonucleoprotein particles (RNPs), which are the functional replication units. Transcription, generating capped and poly-adenylated viral mRNAs, and replication, generating full-length genome or antigenome copies (vRNA and cRNA respectively), are performed by the same virally encoded RNA-dependent RNA polymerase. In general, sNSV polymerases have two unique features. Firstly, they perform transcription by the 'cap-snatching' mechanism, whereby short 5′ capped RNA fragments are cleaved from host cell mRNA by an endonuclease intrinsic to the polymerase and then used to prime synthesis of viral mRNAs. Secondly, they recognise each genome segment via their highly conserved, quasi-complementary 3′ and 5′ extremities, known as the promoter. Several recent crystal structures of promoter bound influenza A and B polymerases that shed light on multiple aspects of polymerase function will be discussed and their implication for novel anti-viral drug design targeting directly viral replication highlighted. Most recently we have shown that to gain access to nascent capped transcripts for 'cap-snatching' in the infected cell nucleus, influenza polymerase directly binds the phosphorylated C-terminal domain of cellular RNA polymerase II.

DEVELOPMENT OF AN AGAR-BASED RNA-SEQ ASSAY FOR STUDYING THE INTERACTOME OF NASAL STAPHYLOCOCCI STRAINS

G. Hermansen[1], *L. Jelsbak*[1]
[1]*Technical University of Denmark, DTU Bioengineering, Kgs Lyngby, Denmark*

Backgrounds

Staphylococcus aureus is well-known as a human pathogen but also lives as a commensal in the human nose in approximately one fifth of the population. Carriage is usually asymptomatic but the nasal cavities can function as reservoirs for infection e.g. during surgical procedures. The human nose hosts a multi-species community and it has previously been reported that *Staphylococcus epidermidis* strains can modulate *S. aureus* phenotypes. Intriguingly the cohabitation has been shown to result in inhibition of nasal colonization and biofilm formation of *S. aureus*. Even though some *S. epidermidis* products have been implicated in this inhibitory effect, a comprehensive understanding of the interactions between nasal Staphylococci isolates is needed.

Objectives

The aim of this study was to establish a robust method to map the transcriptome profiles of nasal *S. aureus* and *S. epidermidis* focusing on the differences between mono- and co-culturing.

Methods

Staphylococci strains were isolated from nasal cavities of healthy Danish individuals. A pair of *S. aureus* and *S. epidermidis* strains isolated from the same nose were used for a novel agar-based RNA-seq method enabling investigation of their interactome. The strains were grown on agar surfaces as mono- and co-cultures, respectively, and RNA was harvested after 24 hours of incubation. RNA-seq was performed and enables mapping of the expression profiles of the two nasal Staphylococci isolates.

Conclusions

Our preliminary results indicate this novel RNA-seq method can be applied to study interactions between *S. aureus* and *S. epidermidis* isolated from nasal swaps of a healthy Danish adult.

QUORUM SENSING BASED ON INTERSPECIES COMMUNICATION AMONG E. COLI SE15 AND OTHER STRAINS OF BIOFLM IN THE PATIENTS INDWELLING URINARY CATHETERS: GENOME EDITING OF CRISPR-CAS9

S.R. Kang[1], J. Kim[2], J.K. Hur[3], S.S. Lee[1]
[1]Kyonggi University, Department of Bio-engineering, Suwon, Republic of Korea
[2]Kyonggi University, Department of Life Science, Suwon, Republic of Korea
[3]Korea University, Biomedical Research Center- Anam Hospital, Seoul, Republic of Korea

Backgrounds

The predominant strains *E. coli*, *P. aeruginosa* and *S. aureus* are the most common pathogens in catheter associated urinary tract infections (CA UTIs). The CA UTIs were mainly occurred from biofilm formation by Quorum Sensing (QS) system of predominant strains. Moreover, AI-2, one of QS signal molecules, plays an important role in enabling interspecies communication. Although many bacteria species have been studied to use the AI-2 for interspecies communication to regulate various behaviors, such as biofilm formation, the molecular mechanisms of AI-2 internalization and signal transduction remain poorly understood.

Objectives

This study is to elucidate interaction between *E. coli* SE15 and other dominant strains, which frequently form biofilm on the catheter surface, via co-culture.

Methods

We then manipulated the Δ*rbsB* and Δ*luxS* in *E. coli* SE15 by using clustered regularly interspaced short palindromic repeats (CRISPR)-Cas9 system. And we observed biofilm formation assay in Δ*rbsB* and Δ*luxS* mutants of *E. coli* SE15. Moreover, Δ*rbsB* and Δ*luxS* mutants of *E. coli* SE15 were co-cultured with predominant strains *P. aeruginosa* and *S. aureus* in response to the wild type *E. coli* and analyzed AI-related genes expression by qRT-PCR.

Conclusions

Autoinducer synthesis gene *luxS* gene of *E. coli* SE15 has been affected by other dominant strains because the gene expression was more increased and rapidly initiated in co-culture than single culture. Based on these data, we concluded that *luxS* and *rbsB* affected on interaction of other predominant bacteria. Such interactions among predominant bacteria were helpful to understand their symbiosis or competition.

Bacterial RNA Secretome

TRANSCRIPTOME AND SECRETOME OF SHORT RNAS IN BACTERIAL POPULATIONS

O. Ozoline[1], *A. Bykov*[1], *K. Shavkunov*[1]
[1]*Institute of Cell Biophysics RAS, Functional Genomics and Cellular Stress, Pushchino, Russia*

Backgrounds

Switching research from individual genes to large-scale analysis of transcriptomes revealed a huge amount of untranslated RNAs with poorly understood functions. The least studied are short RNAs, including those processed from tRNAs or produced from gene ends, though their regulatory potential has been recently elucidated.

Objectives

The goal of the study was to characterize the intracellular and extracellular fractions of short (11-14 nucleotides) RNAs, in particularly those derived from “promoter islands” suppressed by H-NS.

Methods

Fractions of short RNAs from cells of *E. coli* K-12 MG1655 and novel isolate of the *Paenibacillus* genus were obtained using mirVana™ miRNA Isolation Kit. Short secreted RNAs were purified from filtered LB medium using miRNeasy Serum/Plasma Kit (Qiagen). cDNA libraries were prepared using Ion Total RNA-Seq Kit v2 and sequenced with Ion Torrent PGM. Sequence reads were mapped to the genomes with Matcher algorithm.

Conclusions

In both bacteria intracellular fractions of short RNAs mainly contained fragments of tRNAs, rRNAs and small untranslated RNAs. The proportion of RNAs derived from the “promoter islands” of *E. coli* was lower than on average over the genome; however, their abundance in the extracellular fraction was twice higher. The distribution profile of the secreted RNAs across the genomes differed, as compared to their intracellular RNAs. Cooperative culturing of two microorganisms allowed detecting evident divergence between the sets of extracellular RNAs in pure and mixed cultures. Bacteria, therefore, secrete not only proteins and small signaling molecules, but also short RNAs, which may participate in cell-to-cell communications.

Bacterial RNA Secretome

OPTIMAL RNA EXTRACTION METHOD FOR THE ANALYSIS OF BACTERIAL SMALL RNAS CONTAINED IN MEMBRANE VESICLES

C. Garcia-Bonillo[1], C. Perez-Cruz[1], E. Mercade[1]
[1]University of Barcelona, Department of Biology- Healthcare and the Environment, Barcelona, Spain

Backgrounds

Membrane vesicles (MVs) are released by many Gram-negative bacteria and *Pseudomonas aeruginosa* is one of them. Currently, the presence of *small* RNA (sRNAs) in MVs is being extensively analysed in eukaryotes but remains nearly unexplored in prokaryotes. The methodology of extraction of sRNAs may influence the results obtained in further studies.

Objectives

To determine the optimal RNA extraction method for the analysis of bacterial *s*RNAs contained in MVs in order to support future studies aimed at determining the biological roles of these sRNAs.

Methods

Three different RNA extraction methods were assayed: miRCURY™ RNA isolation kit – Cell & Plant content (EXIQON®), FastRNA™ SPIN Kit for Microbes (MP®) and miRNeasy Mini Kit (QIAGEN®). These kits were used to extract total RNA and, quality and purity of extracted RNA was determined by OD values, capillary electrophoresis and fluorimetry. The efficiency of extraction of *P. aeruginosa* PAO1 *s*RNAs (RsmZ, CrcZ and PhrS) was studied by RT-qPCR.

Conclusions

Results indicate that the kits EXIQON® and MP® extract more effectively the *small* RNAs fraction than QIAGEN®. EXIQON® is recommended to extract *small* RNAs from MVs because the obtained RNA profiles are cleaner, the protocol is easier to perform and the number of copies does not present significant differences with MP®. As the different RNA isolations methods give extensive variations in the sRNAs yields and patterns, it is crucial to select an RNA isolation approach depending on the research purpose.

BACTERIAL TRANSCRIPTOME REPROGRAMMING IN NODULES OF PEA (PISUM SATIVUM L.) SYMBIOTIC MUTANTS

V. Zhukov[1], A. Afonin[1], A. Sulima[1], A. Zhernakov[1], I. Tikhonovich[1]
[1]All-Russia Research Institute for Agricultural Microbiology, Biotechnology, Saint-Petersburg - Pushkin, Russia

Backgrounds

Nodule bacteria can fix atmospheric nitrogen in symbiosis with legume plants. In nodules of some legumes, including pea (*Pisum sativum* L.), bacteria are terminally differentiated into organelle-like structures called bacteroids. The process of terminal bacteroid differentiation (TBD) implies cell enlargement, genome amplification and membrane permeabilization. Mutations in plant regulatory symbiotic genes may lead to defects in TBD. Analysis of such model systems using transcriptomics approach can help unravel the molecular bases of TBD.

Objectives

To describe the influence of plant mutations on expression of bacterial genes in case of abnormal TBD and to find possible new factors and components playing a role in this process.

Methods

To assess gene expression levels, we used 5'-MACE (Massive Analysis of cDNA Ends) technology developed by GenXPro GmbH (Frankfurt-am-Main, Germany), which involves sequencing of 5'-part of each transcript on Illumina HiSeq2000. The total RNA was extracted from the following sources: i) free-living culture of *Rhizobium legominosarum* bv. *viciae* RCAM1026, ii) nodules of wild type pea line SGE, iii) set of mutants in pea genes *sym33*, *sym40* and *sym26* obtained on SGE background, which demonstrate block on sequential stages of TBD.

Conclusions

Bacterial genes crucial to cooperative metabolism of micro- and macrosymbiont were identified, along with a number of multi-drug resistance genes possibly modulating the effects of NCR peptides (plant anti-microbial agents promoting TBD) in nodules.

This work was supported by Russian Science Foundation [grant 14-24-00135 for AAM, ZAI, TIA and grant 16-16-00118 for ZVA, SAS].

ECOLOGICAL INTERPLAYS IN THE TRANSITION TO MULTICELLULARITY

B. Baselga Cervera[1], *M. Travisano*[2]
[1]*Universidad Complutense de Madrid, Animal Production, MAdrid, Spain*
[2]*University of Minnesota, College of Biological Sciences, st. Paul, USA*

Backgrounds

Throughout the history of life, the evolution from single-celled to pluricellular organisms emerged, somehow serendipity, more than 20 times under separate scenarios. This mayor evolutionary transition constituted a source of novelty that reshaped the Earth's biodiversity and ecology. Notwithstanding recent discoveries both experimentally and in the fossil record, the underling processes and mechanisms of multicellularity arise are poorly understood.

Objectives

The complex interplays between organisms and their environments, lead to multiple interactions, features and properties. Thus, ecological conditions might have played a significant role during the transition to multicellularity and it persistence. Here, we examined the implications of different environmental conditions, related with resources availability, in the origin of multicellularity from an ecological perspective.

Methods

By means of experimental evolution and capitalizing the advantages of using the model organisms *Saccharomyces cerevisiae*, we have performed two different 2x2 factors experiments based on the original experiment of Ratcliff et al. (2012). Each experiment presented two types of environmental conditions: YPD rich media and Minimal media, and two types of treatment; no selection and settling selection, starting from differentness ancestral populations: a unicellular *S. cerevisiae* strain (Y55) and an evolved multicellular strain, snowflake yeast strain.

Conclusions

The evolution from unicellular to multicellular phenotypes took place in minimal media under setting selection, however we found different phenotypic distributions among replicates. The recently evolved snowflake yeast phenotype strain did not return to its ancestral unicellular phenotype in any of the environmental conditions. Ecological differences can lead to different results in the evolution of multicellularity.

Environmental Microbiology

CONSISTENT DYNAMICS AND COMMUNITY ASSEMBLY PATTERNS DIRECTLY ARISING FROM THERMODYNAMIC THEORY OF MICROBIAL GROWTH

H. Delattre[1]
[1]*IRSTEA, HBAN, antony, France*

Backgrounds

Microbial communities are key engines that drive earth biogeochemical cycles. Developing models able to capture and predict their dynamics and community assembly patterns is therefore of outmost importance for the study of global earth ecological equilibria and the development of innovative microbial biotechnology processes. However, ecosystem models today exhibit only limited abilities in predicting microbial dynamics and require the calibration of multiple population specific empirical equations.

Objectives

In order to build more generic models, there is a need to more thoroughly capture the fundamental drivers of microbial growth and to mathematically express how they contribute to the emergence of the many community assembly patterns observed in nature.

Methods

We simulate the dynamics of microbial functional communities using a kinetic model of microbial growth based on statistical physics (Desmond-Le Quéméner & Bouchez, 2014). We show how the theory coupled to simple mass and energy balance calculations offer a parsimonious explanation for many well-known microbial community assembly patterns along redox gradients.

Conclusions

Strikingly, considering only these simple physical assumptions, we show that consistent microbial dynamics, successions and functional community assembly patterns can be obtained, without population-specific parameter calibration, for systems ranging from pure cultures to communities of multiple populations.

HOW DO MARINE BACTERIA INTERACT WITH THE AMOEBA ACANTHAMOEBA CASTELLANII ?

R. Guillonneau[1], *C. Baraquet*[1], *M. Molmeret*[1]
[1]*Université de Toulon, MAPIEM EA 4323, La Garde, France*

Backgrounds

Amoebae are common in soils, freshwater and marine ecosystems. They are suspected to have an important role in most microbial ecosystems, especially in biofilm. However the interaction between these protozoa and marine bacteria is poorly investigated

Objectives

The aim of this work is first to study interactions between different marine bacteria and the axenical amoeba *Acanthamoeba castellanii* in order to identify different behavioural patterns. The second objective is to understand if, in this context, the bacterial biofilms could provide any sort of advantage against this predator.

Methods

Bacteria-specific antibodies were used during the co-culture experiments for confocal laser scanning microscopy observations while amoebas were labelled with DAPI. Transmission electronic microscopy was also used to visualize intracellular localisation of bacteria.

Conclusions

These marine bacteria presented different profiles of interaction with *Acanthamoeba castellanii.* They appeared to be localized in different intracellular compartments or to behave in a singular manner. For instance, *Persicivirga mediterranea* (TC4) was located in the amoeba nucleus, which could at least in part protects the bacteria from phagolysosomal digestion. *Shewanella sp.* (TC11) appears to be within suspected expelled fecal balls after its interaction with the amoeba. The objective was to identify the different bacterial behaviour within the host cell, and to understand if these behaviours could trigger specific outcomes when the protozoa is added to monospecific and multispecies biofilms. This is one of the first study comparing different isolated marine bacterial species in presence of the amoeba *A. castellanii*.

THE MICROBIAL ECOSYSTEM OF THE GREENLAND ICE SHEET SURFACE

C.S. Jacobsen[1], K. Cameron[2], S. Marek[3]
[1]Aarhus University, Environmental Sciences, Roskilde, Denmark
[2]Geological Survey of Denmark and Greenland, Department of Geochemistry, Copenhagen, Denmark
[3]Charles University, Department of Ecology, Pragh, Czech Republic

Backgrounds

The surface of the Greenland ice sheet (GrIS) harbors a simple yet unique microbial ecosystem. The biological active margin of the ice sheet is more than 200 000 km^2, can be up to ~100km wide, and has tended to increase in area each year within recent history. This ecosystem contains microbial communities that are important for biogeochemical processes and surface melt and that are likely important for the injection of biota and nutrients into downstream environments.

Objectives

Our research suggests that the GrIS surface receives a “baseline” cell supply via deposition of atmospheric waters, and that wind-borne dust deposited on the ice sheet likely contains additional cells and may provide limiting nutrients for microbial growth. Ablation areas with high dust concentrations and longer melt seasons are therefore expected to contain higher numbers of active microbes compared to the accumulation area.

Methods

Geochemical anlysis, qPCR and amplicon seqiencing.

Conclusions

Within the ablation area, significant differences exist between the bulk and potentially active bacterial communities collected at the margin and the interior of the GrIS, with a higher total abundance but lower proportion of active bacteria at the margin. Higher microbial activity in the interior compared to the margin is also supported by productivity measurements. Nitrate had no significant effect on the abundance and community structure, which suggests that this system is not nitrate limited. In terms of diversity, we do not find a core, uniform bacterial community across the biologically active area of the GrIS; instead, km-scale variations between the microbial communities exist.

MONITORING BACTERIAL DEPOSITION IN POROUS MEDIA BY PREDATORY BACTERIA

R. Sungthong[1], *W. T. Sloan*[1], *A. J. Pinto*[2]
[1]*University of Glasgow, School of Engineering, Glasgow, United Kingdom*
[2]*Northeastern University, Department of Civil and Environmental Engineering, Boston- MA, USA*

Backgrounds

Bacterial deposition in porous media is an important microbial property affecting range of environmental technologies, e.g., prevention of pathogen dispersion towards groundwater, optimization of subsurface bioremediation, and development of biofiltration in water treatments.

Objectives

In order to optimize the biofiltration by exploiting predatory bacteria, we assessed how these bacteria behave through porous media of sand-packed columns and how they influence the transport and deposition of a coliform bacterium, *Escherichia coli* through the columns.

Methods

Bdellovibrio bacteriovorus HD100 and its saprophytic mutant (HI100) were utilized as predatory bacteria.

Conclusions

Our findings revealed that only ~20% of HD100 cells could deposit in the columns, and such amount of deposited HD100 cells could diminish the deposition rate of *E*. *coli* cells in the same columns by up to 35%. However, up to 55% of *E*. *coli* cells pre-deposited in the columns was removed after dosing with HD100 cell suspension. Although pre-saturated cell-free culture (CFC) broth of strain HI100 in the columns did not show significant effect on the deposition rate of *E*. *coli* cells, it could remove up to 50% of *E*. *coli* cells pre-deposited in the columns. The viability of *E*. *coli* in the column effluents did not change after dosing with HD100 cell suspension or CFC broth of strain HI100, suggesting that either deposition or detachment of *E*. *coli* cells was a result of the interfacial interactions with predatory bacteria and/or their extracellular metabolites. This study provides new insights into an attempt for implementing microbial management in the optimization of biofiltration design and performance.

HOW TO TRANSMIT A GUT BACTERIAL SYMBIONT IN SOCIAL INSECTS?

M. Zhukova[1], *P. Sapountzis*[1], *M. Schiøtt*[1], *J.J. Boomsma*[1]
[1]*University of Copenhagen, Centre for Social Evolution- Department of Biology, Copenhagen, Denmark*

Backgrounds

The transmission of bacterial symbionts across host generations is crucial for the direction and efficiency of host-symbiont coevolution. Specialized gut microbes of ants are peculiar because within-colony horizontal transmission can produce exclusive vertical transmission across generations. Colony life may thus alleviate constraints in the pupal stage where direct transmission from larval- to adult guts is impossible, particularly when the pupal environment is predictable.

Objectives

We analysed gut microbiome changes across developmental stages and traced the bacterial transmission routes of two abundant gut symbionts of *Acromyrmex* and *Atta* leafcutter ants, which are important functional herbivores in the New World tropics.

Methods

We analysed Illumina MiSeq 16S rRNA gene amplicon sequencing data to determine gut bacterial communities at different developmental stages. We also measured bacterial abundance using droplet digital PCR, and used confocal and electron microscopy to visualize bacteria in different gut tissues.

Conclusions

The larval and pupal guts contained several bacterial species that also occur in the fungus gardens, while adult workers hardly have these bacteria in spite of eating the same fungal material. Non-parasitic *Wolbachia* were most abundant across developmental stages in *Acromyrmex*, but *Atta* had mostly Mollicutes in the worker guts. *Wolbachia* appears to be transovarially transmitted, but Mollicutes were absent in eggs and scarce/absent in larval and pupal guts. After eclosion, callows acquired Mollicutes through interactions with other workers and failed to obtain these bacteria in isolation, suggesting that Mollicutes are socially transmitted. Both pathways result in exclusive vertical transmission across generations and should therefore facilitate host-symbiont coevolution in similar ways.

EFFECT OF (SUB)LETHAL LEVELS OF FOOD-RELATED STRESSES (BIOCIDES AND PROCESSING TREATMENTS) ON THE EMERGENCE OF ANTIMICROBIAL RESISTANCE THROUGHOUT THE FOOD CHAIN

A. Alvarez-Molina[1], D. Fernández[1], C. Andrés[1], M. López[1], M. Prieto[1], A. Alvarez-Ordóñez[1]
[1]Universidad de León, Food Hygiene and Technology, León, Spain

Backgrounds

The latest report on Antimicrobial Resistance (AMR) by EFSA/ECDC shows a trend towards an increase in the detection of foodborne pathogens with multi-drug resistance (MDR) and the appearance of AMR to some antibiotics which are the last effective treatment for MDR infections.

Objectives

This study assessed the contribution of disinfection and food processing treatments to the generation of AMR. We aimed at isolating AMR mutants of *Salmonella spp, Listeria monocytogenes* and *Escherichia coli* after serial (sub)lethal treatments of Ultraviolet (UV) light, non-thermal atmospheric plasma (NTAP) and biocides (peracetic acid, benzalkonium chloride, sodium hypochlorite).

Methods

Five strains of *Salmonella* spp., three of *L. monocytogenes* and four of *E. coli* were grown overnight in BHI and exposed to repeated cycles (10 cycles) of treatment at various (sub)lethal intensities. After each cycle, survivors were recovered and grown in fresh broth to initiate a new treatment cycle, and an aliquot was stored under freezing. Frozen samples were grown overnight in BHI and spread plated on Mueller-Hinton agar plates supplemented with inhibitory concentrations (established for the wild-type strains) of ampicillin, cefotaxime, ciprofloxacin, erythromycin, gentamycin, streptomycin, tetracycline, colistin and vancomycin. Resistant variants were pheno-typically characterized in terms of their resistance against various clinically relevant antibiotics.

Conclusions

Our results confirm that disinfection practices and food processing technologies used in food industries may select for AMR microorganisms that pose a serious risk to the food chain. Whole Genome Sequencing of the most relevant strains will be carried out in the future to identify mutations responsible for the AMR phenotypes.

MONITORING TETRACYCLINE RESISTANCE IN CHEESE BY FUNCTIONAL METAGENOMICS

A.B. Florez Garcia[1], *L. Vazquez*[1], *B. Mayo*[1]
[1]*IPLA-CSIC, Departamento de Microbiología y Bioquímica, Villaviciosa-Asturias, Spain*

Backgrounds

Metagenomics techniques have been successfully applied for monitoring antibiotic resistance genes in environmental, animal, and human ecosystems. However, in spite of the food chain being claimed to be a key player in the spread of antibiotic resistances, metagenomics approaches have been scarcely used in foods.

Objectives

In this work, we report on the prevalence and evolution of tetracycline resistance (Tc^r) determinants in a blue-veined, raw milk cheese by functional metagenomics.

Methods

The same cheese batch was sampled at manufacturing (day 3) and ripening (day 60) stages. Dilutions were plated in the presence of tetracycline on non-selective and selective conditions for lactic bacteria. DNA from cultures in the counting plates was then isolated and used to construct four fosmid libraries. Clones were analysed by restriction enzyme digestion, PCR and sequencing.

Conclusions

Four different Tc^r genes were identified among 300 clones, *tet*(A), *tet*(L) *tet*(M), and *tet*(S). *tet*(A), *tet*(M), and *tet*(S) were detected in libraries at day 3 and *tet*(L) was the single gene identified in the two libraries at day 60, suggesting an evolution of the Tc^r gene types along with that of the microbial populations during ripening. Six representative clones were completely sequenced. All Tc^r genes characterized in this study resided on plasmids and/or were flanked by insertion sequences, mobilization- and conjugation-associated protein-encoding genes.

- Metagenomic techniques can be a valuable tool to evaluate the resistome of cheeses and other fermented dairy products.
- Raw-milk made cheeses should be considered as reservoirs of Tc^r genes with a high potential for horizontal transference.

ADAPTIVE RESPONSE OF LISTERIA MONOCYTOGENES BIOFILMS TO A DEHUMIDIFICATION STRESS

J. Esbelin[1], C. Chambon[2], D. Viala[2], M. Hebraud[1,2]
[1]French National Institute for Agricultural Research, Centre Auvergne-Rhône-Alpes- UMR MEDiS- Site de Theix, Saint-Genès Champanelle, France
[2]French National Institute for Agricultural Research, Centre Auvergne-Rhône-Alpes- PFEMcp- Site de Theix, Saint-Genès Champanelle, France

Backgrounds

Listeria monocytogenes is a foodborne pathogen able to adhere and form biofilms on various surfaces. Associated with a high mortality rate, it is one of the major biological concerns in food hygiene. Since few years, industries attempt to reduce the environmental impact of hygiene operations in the workshops of refrigerated food processing, through optimized use of dehumidification after cleaning disinfection treatments

Objectives

Our study was focused on the adaptive response of *L. monocytogenes* cells, growing in biofilms, to a dehumidification stress mimicking food plants conditions.

Methods

The intracellular and surfaceome subproteomes were analyzed by shotgun proteomics through three complementary extraction methodologies (enzymatic shaving, biotinylation and cell fractionation). *L. monocytogenes* EGD-e and L028 biofilms were grown on stainless steel discs at 25°C during 24h, pre-adapted to 10°C and placed in a desiccation chamber where the air Relative Humidity was stabilized to 75%. The different subproteomes were analyzed after 3h and 24h dehumidification by comparison with non-stressed biofilms.

Conclusions

Among the surface proteins identified, 21 and 29 were differentially expressed during dehumidification for EGD-e and L028, respectively. Three of them were common to both strain, an autolysin, Iap and an ABC transporter. Among intracellular proteins, 38 and 65 were differentially expressed in EGD-e and L028 respectively. Five proteins were common to the two strains. The majority of these proteins belongs to information pathway (35%) and intermediary metabolism (25%) functional categories. These results could contribute to a better comprehension of mechanisms involved in the resistance and persistence of this pathogen in food plants despite the daily hygiene procedures.

VANCOMYCIN RESISTANCE IN LACTOBACILLUS SP. IS AN EVOLUTIONARY TRAIT AND NOT DEPENDENT ON FERMENTATIVE PATTERNS

G.M. Knudsen[1], B. Stuer-Lauridsen[1], Y. Agersø[1], E.J. Boll[1], A. Wind[1]
[1]Chr. Hansen, Identification, Hørsholm, Denmark

Backgrounds

Some species of *Lactobacillus* such as *L. plantarum* are vancomycin resistant, whereas others such as *L. acidophilus* are sensitive. For food and feed cultures, the European Food Safety Authority (EFSA) set cut-off values to identify antimicrobial resistant strains as they may contain transmissible antibiotic resistance. For the heterogeneous group of *Lactobacillus* sp. the cut-off values are mainly based on fermentative status i.e. homofermentative species being sensitive and heterofermentatives being resistant. However, the homofermentative *L. mali* is vancomycin resistant.

Objectives

The aim of this study was to elucidate the vancomycin resistance pattern of the *Lactobacillus* genus.

Methods

A BlastX search of the genome of *L. mali* LBA-20315 against the ResFinder database was performed, but no hits with more than 50% identity (E value > $1.9x10^{-54}$) to vancomycin resistance genes were detected. To investigate the vancomycin resistance pattern in a broader context, the susceptibility towards vancomycin of 25 species (N= 398) was investigated. In addition to *L. mali,* vancomycin resistance was observed within the homofermentative species *salivarius* and *farciminis*. The presence of genes involved in vancomycin resistance i.e. *ldh*, *aad*, *lar* and *ddl* was investigated in 11 species and no correlation with vancomycin resistance was observed. However, phenotypic vancomycin resistance correlated with different alleles of *ddl* encoding a D-alanine-D-alanine ligase also referred to as *vanA*.

Conclusions

Thus, this study indicates that vancomycin resistance is an evolutionary trait depending of variation within the *ddl* gene causing intrinsic resistance and is independent of fermentative status. Sequencing of further species is ongoing to support these conclusions.

Food Microbiology, omics driven molecular physiology

LIQUID CHROMATOGRAPHY-HIGH RESOLUTION MASS SPECTROMETRY-BASED METABOLITE PROFILING OF SALMONELLA ENTERICA BIOFILM

A. Lamas[1], P. Regal[1], B. Vazquez[1], A. Cepeda[1], C.M. Franco[1]
[1]University of Santiago de Compostela, Analytical Chemistry- Nutrition and Bromatology, Lugo, Spain

Backgrounds

Salmonella enterica is responsible for foodborne diseases worldwide. *Salmonella* strains persist in the food chain partially thanks to their ability to produce biofilm. Environmental conditions and surfaces affect in different ways the biofilm formation. There are few studies defining in detail the particular metabolome of these structures under different scenarios

Objectives

The aim of this study was stablishing the metabolite profile of the *Salmonella* biofilms cells growth under different conditions.

Methods

Two strains of *S.* Typhimurium and *S.* Enteritidis with great ability to produce biofilm were used. The strains were allowed to form biofilm under different environment conditions and the metabolites were measured using LC-HRMS profiling.

Conclusions

Metabolomics appears as a good tool to explore the biofilm formation pathways in *Salmonella*.

TRANSCRIPTIONAL AND TRANSLATIONAL CHANGEOVER DURING B. SUBTILIS SPORE GERMINATION

B.N. Swarge[1], D. Beaty[1], W. Roseboom[2], S. Brul[3], C.G. de Koster[2], L.J. de Koning[2]
[1]Swammerdam Institute for Life Sciences- University of Amsterdam,
Molecular biology and Microbial Food Safety- Mass spectrometry of Biomacromolecules, Amsterdam, The Netherlands
[2]Swammerdam Institute for Life Sciences- University of Amsterdam,
Mass spectrometry of Biomacromolecules, Amsterdam, The Netherlands
[3]Swammerdam Institute for Life Sciences- University of Amsterdam,
Molecular biology and Microbial Food Safety, Amsterdam, The Netherlands

Backgrounds

In response to nutrient limitation Gram positive organisms like *Bacillus subtilis* form dormant spores. These cellular entities are survival capsules, resistant to chemical and environmental assaults. They pose challenges to the food and medical sectors. Upon contact with germinants spores return to vegetative life through a process called 'germination and outgrowth'. Spores reactivate their metabolism and develop in vegetative cells. The molecular machinery that triggers and progresses the germination is still unsettled.

Objectives

Gain insight in the germination molecular machinery by mapping the progression of the transcriptome and proteome changeover during germination and outgrowth of spores.

Methods

For the time-resolved monitoring of the transcriptome and the proteome *of B. subtilis spores* during germination, the spores are sampled in time-intervals from germination initiation to the stage of vegetative cell outgrowth. Intact and purified RNA is isolated from spores, at each time-point, for transcriptome analysis. We thus trace the different functional groups of genes expressed during the germination and outgrowth process. Next, the changes in the proteome are quantitatively monitored relative to the proteomes of ^{15}N metabolically labelled dormant spores and ^{15}N metabolically labelled vegetative cells.

Conclusions

The time-resolved transcriptomics and proteomics data provide new insight in the cellular control level of novel protein synthesis during the awakening of spores. The data will offer input for the development of a mathematical model of the germination process.

Host-microbe interactions, gut microbiome and health

THE PHYLOGENETIC CORE OF THE HUMAN PAN-MICROBIOME

D. Aguirre de Cárcer[1]
[1]*Unidad de Genética, Ciencias, Madrid, Spain*

Backgrounds

Whether or not there is a 'core' gut microbiome, consisting of bacterial groups common to all healthy humans, remains an open question with important scientific and medical implications. Unfortunately, the strong variability in gut microbiome composition persistently observed across individuals has so far hindered efforts towards its detection.

Objectives

The present study analyzes the human gut core pan-microbiome in terms of 16S rRNA OTUs present in all individuals, where such OTUs have been produced dynamically over a range of phylogenetic depths, as opposed to using an arbitrary fixed threshold which represents the dominant practice in the field.

Methods

This approach was applied in the meta-analysis of three large and comprehensive datasets (totaling 2,243 individuals; > 150M sequences).

Conclusions

The results show that the human gut pan-microbiome contains a preeminent compositional phylogenetic core, defined in terms of discrete units of varying depth along the bacterial phylogeny, whose members are present in all individuals studied.

This result provides a new conceptual framework with great potential for advancing our understanding of the ecosystem. In addition to providing a novel perspective on (i.e.) the study of community assembly, the results obtained in this study should guide the selection of more meaningful combinations of bacterial species (or genomes) in many frequent *in vivo*, *in vitro*, or *in silico* experimental scenarios. Furthermore, the results should be used as a revised list of "most wanted" bacteria to guide future genome sequencing and isolation efforts, significantly as it also includes information on the biologically meaningful breadth of the targeted group's pan-genome.

DIFFERENCES IN THE NEONATE MICROBIOME AFTER HOME OR HOSPITAL DELIVERY

J. Combellick[1], S. Hakdong[2], S. Dongjae[3], H. Hagan[1], M.G. Dominguez Bello[4]
[1]New York University, Rory Meyers College of Nursing, New York, USA
[2]Sejong University- South Korea,
College of Life Science- Department of Food Science and Biotechnology, Seoul, Republic of Korea
[3]Sejong University, College of Life Science- Department of Food Science and Biotechnology, Seoul, Republic of Korea
[4]New York University, School of Medicine, New York, USA

Backgrounds

Hospitalization for delivery is considered a foundation of obstetric care. In the U.S. more than 99% of deliveries occur in the hospital. However in many countries—notably those in Scandinavia—home birth is recognized as a safe alternative for low-risk women. Currently there is limited investigation of how the neonatal microbiome develops in the absence of all interventions, including hospitalization. We hypothesize that hospital exposure at birth affects the neonate intestinal microbiota.

Objectives

To characterize the intestinal microbiota of newborns following home and hospital delivery and to investigate differences related to hospitalization during the first month of life.

Methods

A prospective cohort study was conducted to compare breast-fed vaginally delivered infants born at home (n=10) or in the hospital (n=10). Consecutive sampling was performed on infant feces at 7 time points from delivery through day 28. The V4 region of the 16S rRNA gene of 212 samples was sequenced using Illumina MiSeq platform. Sequences were analyzed using the QIIME pipeline.

Conclusions

Hospitalization for birth alters the microbiome of neonates. The gut microbiome differed significantly between home and hospital born neonates (PERMANOVA p=<0.005), with babies born at home showing higher fecal *Bacteroides*, and *Bifidobacterium*, *Streptococcus*, and *Lactobacillus*, at one or more time points after the first week of birth, and lower proportions of *Clostridium* (Day 21), Enterobacteriaceae family (Day 28). More research is needed to determine the health significance of these differences. These results are relevant to health care system policies that support home birth in low-risk women.

EVALUATION OF METAGENOMIC METHODS FOR THE STUDY OF THE GUT MYCOBIOME

A. Frau[1], B. Campbell[1], A. Darby[2], J. Kenny[3], N. Hall[4], J. Anson[5], C. Probert[1]
[1]University of Liverpool, Institute of Translational Medicine- Cellular and Molecular Physiology, Liverpool, United Kingdom
[2]University of Liverpool, Institute of Integrative Biology- Functional and Comparative Genomics, Liverpool, United Kingdom
[3]University of Liverpool, Institute of Integrative Biology- Centre for Genomic Research, Liverpool, United Kingdom
[4]Earlham Institute, -, Norwich, United Kingdom
[5]Royal Liverpool University Hospital NHS, Infection and Immunity, Liverpool, United Kingdom

Backgrounds

Metagenomics has revolutionized the study of the gut microbiome but most methods are tailored for bacteria.

Objectives

The mycobiome likely plays a key role in intestinal diseases and hence metagenomic methods need to be adapted to study this. Here, we evaluated two DNA extraction methods and 5 primer sets.

Methods

Genomic DNA was extracted from seven characterised fungal cultures (*C. albicans*, *C. tropicalis*, *C. neoformans*, *M. furfur*, *S. cerevisiae*, *A. fumigatus* and *P. crysogenum*) using either the PSP Spin Stool DNA kit (Stratec), with and without extra bead-beating (6 min, 0.1 and 0.5 mm zirconia beads), or the QIAamp Fast DNA Stool Mini Kit (QIAGEN), and compared using 18S rRNA qPCR. Subsequently, stool was spiked with cells and spores from the same species and gDNA extracted (as above). DNA from spiked stool samples and a mock community were amplified and sequenced. Five primer sets were tested (18S rRNA, ITS1, ITS2-2X and 28S rRNA) for HiSeq Illumina sequencing.

Conclusions

Results: 1) the extra bead-beating did not increase the extraction; 2) the Stratec Kit extracted more gDNA from *C. albicans* VS *A. fumigatus* (Cp=29.1 SD=0.52 and Cp=31.9 SD=0.51), the reverse occurred with QIAGEN kit (Cp=34.3 SD=0.74 and Cp=26.6 SD=0.06); 3) on stool DNA similar amounts of 18S rRNA copies/ng of DNA were observed with both kits. Sequencing data are being currently evaluated: this will show how extraction methods and primer sets influence analysis of the mycobiome. In conclusion, the method of DNA extraction and primer design influence results and interpretations of the mycobiome.

HOST-MICROBIOTA INTERACTIONS IN INFLAMMATORY ARTHRITIS

L. Lam[1], D. Regan-Komito[1], J. Faith[2], T. Griseri[1], F. Powrie[1]
[1]University of Oxford, Kennedy Institute of Rheumatology, Oxford, United Kingdom
[2]Mount Sinai School of Medicine, Genetics and Genomic Sciences, New York, USA

Backgrounds

The gut is the primary site of host-commensal symbiosis, but disequilibrium can drive inflammatory disease and damaging systemic immune responses. Spondyloarthropathies are a form of inflammatory arthritis, the most common of which is ankylosing spondylitis (AS), characterized by joint deformation and fusion throughout the body. Intriguingly, over 70% of AS patients have subclinical intestinal inflammation and 15-25% develop inflammatory bowel disease. Additionally, arthritis is the most common extraintestinal manifestation of IBD. Together, these findings suggest a gut-joint connection in AS pathogenesis.

Objectives

While microbial dysbiosis is strongly associated with inflammatory arthritis, it is unclear how altered intestinal community composition modulates systemic immune responses. IgA secreted at mucosal surfaces coats different species of intestinal bacteria and is a critical mediator of homeostasis. While commensal microbiota may be coated with IgA, pathogens elicit high-affinity responses, making IgA coating a powerful metric for identifying specific bacteria that trigger inflammation.

Methods

The proposed research will use differential immunoglobulin A coating of fecal bacteria coupled with 16S rRNA sequencing (IgA-SEQ) to identify immunopathogenic members of the microbiota. IgA+ and IgA- bacteria from will be collected by fluorescence-activated cell sorting in both ankylosing spondylitis (AS) patients and healthy controls.

Conclusions

In parallel with IgA-seq, patient libraries of bacterial isolates will be generated using high-throughput cultivation platforms. To identify immunomodulatory microbes, IgA+ and IgA- bacterial consortia will be screened in gnotobiotic mouse models of AS. This work has the potential to identify host-microbiota interactions that drive local intestinal inflammation and systemic joint disease.

[4]HUCA, Cirugía General, Oviedo, Spain
[5]Hospital de Cabueñes, Servicio de Cirugía General y del Aparato Digestivo, Gijón, Spain
[6]University of Oviedo, Functional Biology, Oviedo, Spain

Backgrounds

In recent years, the relationship between cholesterol, bile salt metabolism, intestinal microbiota and its potential implication in health is been elucidated. However, the composition and role of the biliary microbiota remains obscure. The characterization of the human bile microbiota as a whole has been hampered by difficulties in accessing biological samples and the lack of adequate methodologies to assess molecular studies.

Objectives

The aim of this work was to generate new knowledge of human bile microbial profiles, functions and activities in patients with choleolithiasis vs healthy individuals, and identify possible dysbiosis associated with this pathology.

Methods

To characterize the biliary microbiome of patients with cholelithiasis and healthy subjects we collected bile samples from 15 gallstone patients and a comparable control group. We performed with Illumina technology high throughput sequencing of 16S rDNA amplicons, together with whole metagenome shotgun of selected bile samples.

Conclusions

A high diversity was present in the biliary microecosystem, with main fila represented: *Firmicutes*, *Bacteriodetes*, *Actinobacteria* y *Proteobacteria*. Significant differences in the relative abundance of different taxa present in the bile of both groups were found. Sequences belonging to the family *Propionibacteriaceae* were more abundant in bile samples from healthy subjects, meanwhile in patients with choleolithiasis members of the families *Bacteroidaceae, Prevotellaceae* y *Veillonellaceae* were more frequently detected.

Sequencing of total DNA from bile of three healthy subjects and functional analysis allowed us to observe that the main COG functions and categories were similar to that describe in the human intestinal microbiome.

GUT PHAGEOMICS: YET ANOTHER VIEW OF HUMAN GUT MICROBIOME

A. Shkoporov[1], A. Forde[1], K. Daly[1], S. McDonnell[1], J. Nolan[1], O. O'Regan[1], L. Draper[1], S. Stockdale[1], M. Dalmasso[1], F. Ryan[1], A. McCann[1], P. Ross[1], C. Hill[1]
[1]APC Microbiome Institute, Gut Phageomics Lab, Cork, Ireland

Backgrounds

A healthy human gut is populated by an enormously diverse and dense consortium of microorganisms. While the bacterial component of this consortium has received significant attention in the last decade, relatively little is known about viral (and in particular, the phage) component. While metagenomic sequencing provides a powerful tool for studying phage populations, little has been done to standardise or validate sequencing and bioinformatic analysis strategies, or to analyse the impact of potentially confounding factors such as storage or handling conditions.

Objectives

1) To develop and validate a protocol for metagenomic analysis of viral/bacteriophage populations in human faeces 2) To compare reproducibility and resolution of this protocol with the more traditionally used 16S rDNA amplicon sequencing methodology. 3) To analyse operator-to-operator reproducibility of the protocol, the impact of sample storage at various temperatures, the effect of repeated freeze/thaw cycles, and the addition of exogenous viral standards for absolute quantification of VLPs.

Methods

Faecal samples collected from healthy and patient cohorts were enriched for virus like particles. Viral/bacteriophage DNA was extracted and sequenced using the Illumina HiSeq platform.

Conclusions

The gut phageome sequencing method developed in this study provides an essential complementary tool to 16S amplicon sequencing for studying (and quantifying) organisms in the gut microbiome. The accuracy and reproducibility of results compare favourably between the methods and phageomics provides a valuable additional view of human gut microbiota structure and composition. Rapid storage and limited freeze-thaw cycling of faecal samples is recommended for optimum results.

THE CONSTRUCTION OF THE CURATED PRETERM GUT MICROBIOME DATABASE (PGMD)

K. Wong[1], P. Fleming[1], M. Millar[2], R. Hutchinson[1], M. Wilks[2], F. Stacey[3], K. Costeloe[1], W. Wade[4]
[1]Blizard Institute Queen Mary University of London, Centre for Genomics and Child Health, London, United Kingdom
[2]Barts and the London NHS Trust, Department of Infection, London, United Kingdom
[3]Homerton University Hospital NHS Foundation Trust, Neonatal Intensive Care Unit, London, United Kingdom
[4]Blizard Institute Queen Mary University of London, Centre for Immunobiology, London, United Kingdom

Backgrounds

The global survival rate for very low birthweight preterm babies has significantly increased over the past 30 years. Morbidity and mortality have shifted from early respiratory failure to intermediate complications such as late-onset sepsis and necrotising enterocolitis (NEC). Investigations into the pathophysiology underpinning NEC are centred on interactions between the preterm infant gut and its microbiome, with recent studies typically using culture-independent techniques such as 16S rRNA gene community profiling and next-generation sequencing to characterise the preterm gut microbiome.

Objectives

Currently available DNA sequence nucleotide databases are typically very large and often include a significant proportion of erroneous or poor-quality 16S rRNA gene sequences. The aim of this study was to construct a 16S rRNA gene Preterm Gut Microbiome Database (PGMD) that is both curated and site-specific, thus providing a robust resource for future preterm gut microbiome studies.

Methods

High-quality full-length 16S rRNA gene sequences representing all bacterial species reported in the literature for the preterm infant gut were compiled. Data from an experimental community profile dataset was used to interrogate the database. Where sequences showed ≥98.5% similarity to named species not in the database, those species were added. Un-named phylotypes represented by a high-quality reference sequence were also added. All species-level taxa were assigned a unique PGMD number.

Conclusions

The first iteration of the PGMD is comprised of 623 species-level taxa from the phyla *Acidobacteria*, *Actinobacteria*, *Armatimonadetes*, *Bacteroidetes*, *Deinococcus-Thermus*, *Firmicutes*, *Fusobacteria*, *Proteobacteria* and *Tenericutes*. The PGMD is a source of phylogeny-designated taxa useful for investigators involved in understanding the human microbiome.

Microbial Ecology

TOP-DOWN REGULATION OF PROKARYOTIC GROWTH EFFICIENCY IN TEMPERATE FRESHWATER PELAGIC ENVIRONMENTS

A.S. Pradeep Ram[1], *J. Colombet*[1], *A. Thouvenot*[2], *T. Sime Ngando*[1]
[1]*Université Clermont Auvergne, LMGE- UMR CNRS 6023, AUBIERE, France*
[2]*Université Clermont Auvergne, Athos Environnement, AUBIERE, France*

Backgrounds

In aquatic systems, limited data exists on the impact of mortality forces such as viral lysis and flagellate grazing when seeking to explain factors regulating prokaryotic metabolism.

Objectives

We explored the relative influence of top-down factors (viral lysis and heterotrophic nanoflagellate grazing) on prokaryotic mortality and their subsequent impact on their community metabolism in the euphotic zone of 21 temperate freshwater lakes located in the French Massif Central.

Methods

Viral lysis was determined from frequency of visibly infected prokaryotic cells by transmission electron microscopy whereas heterotrophic nanoflagellate grazing potential was calculated from flagellate clearance rate estimates.

Conclusions

Prokaryotic growth efficiency (PGE, index of prokaryotic community metabolism) determined from prokaryotic production and respiration measurements varied from 5 to 74% across the lakes. Viral and potential grazer induced mortality of prokaryotes had contrasting impact on PGE. Potential flagellate grazing was found to enhance PGE whereas viral lysis had antagonistic impacts on PGE. The average PGE value in the grazing and viral lysis dominated lake water samples was 35.4% (± 15.2%) and 17.2% (± 8.1%) respectively. Selective viral lysis or flagellate grazing on prokaryotes together with the nature of contrasted substrates released through mortality processes can perhaps explain for the observed variation and differences in PGE among the studied lakes. The influences of such specific top-down processes on PGE can have strong implications on the carbon and nutrient fluxes in freshwater pelagic environments.

Microbial Ecology

COMMUNITY ECOLOGY OF AEROBIC ANOXYGENIC PHOTOTROPHIC (AAP) BACTERIA AT VARIOUS TEMPORAL AND SPATIAL SCALES

A. Auladell[1], P. Sánchez[1], J.M. Gasol[1], I. Ferrera[1]
[1]Marine Sciences Institute - ICM-CSIC, Dept. of Marine Biology, Barcelona, Spain

Backgrounds

Aerobic anoxygenic phototrophs (AAPs) are photoheterotrophic microorganisms that require organic substrates for growth, but can derive a portion of their energy harvesting light using bacteriochlorophyll *a*. Their ecology, metabolism and physiology have been intensively studied during the last two decades, but there is still a lack of large-scale analyses needed to unravel their spatio-temporal dynamics.

Objectives

Here, we focus in the community ecology of AAPs by analyzing the diversity of their marker gene *pufM* in large metagenetic (PCR-amplification and Illumina sequencing) and metagenomic datasets from 2 global circumnavigation expeditions, Tara Oceans and Malaspina, as well as from a decade-long time-series in the NW Mediterranean Sea (Blanes Bay Microbial Observatory).

Methods

At the spatial scale, we observed that variation in community structure was driven both by geographical location and by environmental conditions. In most stations phylogroups associated with the *Gammaproteobacteria*, *Roseobacter* and *Rhodobacter* were dominant but, interestingly, in some stations half of the sequences could not be associated to any defined phylogroup. At temporal scales, seasonality clearly differentiated AAP communities and half of the variation was explained by day length, temperature, water transparency, chlorophyll *a*, salinity and phototrophic nanoflagellates abundance. Comparing spatial and temporal scales, we observed that although higher richness was observed at temporal scales in a single site, dissimilarities between samples at spatial scales presented more variation, which increased with geographical distance.

Conclusions

Our work shows that a combination of large genetic studies with global and eulerian sampling have the most powerful potential to discern the spatio-temporal dynamics of marine microbial communities.

[6]Icelandic Institute of Natural History- IS-600, Botany, Akureyri, Iceland
[7]Real Jardín Botánico-CSIC, Mycology, Madrid, Spain

Backgrounds

One key consequence of glacier recession, as effect of climatic change, is the creation of new habitats for colonization. In glacier forefields, primary succession occurs simultaneously in soils and rocks recently discovered offering a type of natural experiment in which temporal colonization dynamics can be analyzed.

Objectives

A chronosequence established at Breiðamerkurjökull Glacier forefield, was used as a framework to analyze primary microbial succession processes in subarctic regions. This outlet glacier stretches to southeast from Vatnajökull Glacier and has been dramatically retreating during the 20th century.

Methods

Soil samples from different succession stages were collected. Microbial community structure was analyzed by high-throughput amplicon sequencing. Potential microbial activity (microbial respiration, N mineralization) as well as different soil attributes were also measured in these samples.

Conclusions

Microorganisms play a fundamental role in the initial colonization of exposed soils after glacier ice retreat. They are the only colonizers at soils close to the glacier front and are functionally relevant in later successional stages. High-throughput amplicon sequencing of fungal and bacterial communities revealed that the structure of microbial communities from soils close to the glacier front considerably differed to that found in later successional stages. After a first abrupt change in community composition at the beginning of the succession, changes occur smoothly but showed a clear trend along the chronosequence. We found a significant decrease in soil pH, and a significant increase in the size of both, the soil organic matter and the organic and mineral N pools, in parallel with the succession process. Rates of microbial respiration and N mineralization also significantly increased with time of exposure after glacier retreat. Hence, our results demonstrate that primary succession along this chronosequence is accompanied by both a replacement of microbial taxa and changes in soil functionality.

Microbial Ecology

SOIL MICROBIAL DIVERSITY: A COMPARISON OF METAGENOMICS AND CULTUROMICS APPROACHES

C. Dumolin[1], *P. Vandamme*[1]
[1]*Ghent University, Biochemistry and Microbiology, Gent, Belgium*

Backgrounds

Novel insights in the tree of life revealed staggering numbers of uncultivated bacterial lineages. Harnessing this novel biotechnological potential requires prior cultivation. Although metagenomics studies are considered the gold standard for analyzing microbial diversity, large scale isolation and identification campaigns, i.e. ”culturomics “, may reveal organisms that went undetected via metagenomics. A combined approach, is therefore paramount to determine the microbial diversity and to exploit its biological functionalities.

Objectives

The aim of the present study was to determine the microbial diversity in an old-growth forest soil sample using both metagenomics and culturomics.

Methods

A plain soil sample of the Aelmoeseneie forest (Gontrode, Belgium) was collected. For metagenomic analyses, DNA was extracted using the Mobio Powersoil kit. Total DNA was sequenced on the Illumina HiSeq platform. The cultivable microbial diversity of the same soil sample is studied via an in-house developed culturomics pipeline, based on the automated picking of isolates and dereplication via MALDI-TOF MS. We aim to isolate and identify 25,000 bacterial isolates.

Conclusions

Shotgun metagenomic sequencing yielded >237,000 reads, correlating to a bacterial richness of >800 species. This diversity is dominated by *Proteobacteria* (55%), *Actinobacteria* (35%) and *Acidobacteria* (3%). *Proteobacteria* are mainly represented by *Alphaproteobacteria* with *Rhizobiales* (78%) and *Rhodospirillales* (7%) as main orders. *Actinobacteria* are dominated by the *Corynebacteriales* order (31%); interestingly, 8% of the total DNA sampled represented *Mycobacterium* reads. The culturomics analysis is ongoing; in summer 2017 half of the culturomics data, i.e. referring to the isolation and identification of about 12,500 isolates, will be available and presented.

METAGENOMIC SNAPSHOT: MEASURING PATTERNS BY GEOGRAPHICAL LOCATIONS IN MARINE METAGENOME DATA USING NEWLY ADOPTED GENOTYPING-BY-SEQUENCING

H.J. Seong[1], C.Y. Hwang[2], H.H. Won[3], W.J. Sul[1]
[1]Chung-ang University, Systems Biotechnology, Anseong, Republic of Korea
[2]Korea Polar Research Institute, Division of Polar Biology and Ocean Sciences, Incheon, Republic of Korea
[3]Sungkyunkwan University- Samsung Medical Center,
Samsung Advanced Institute for Health Sciences and Technology, Seoul, Republic of Korea

Backgrounds

Dealing with huge quantity and high complexity of metagenomic data is a very difficult and time-consuming process. In addition, a new metagenomic approach is required to simply identify genetic variation.

Objectives

We demonstrated more effective metagenomic approach to analyze particular sequences related to restriction enzyme sites for targeting reduced numbers of genes than to estimate whole genome sequences.This approach was applied to analyze the marine metagenome by genotyping-by-sequencing (GBS) method, which was used to analyze plant genomes with large genome sizes.

Methods

Metagenomic GBS was demonstrated with marine epipelagic samples collected on 10 locations across from East Sea to Bering approximately 8000 km apart on July, 2013. These samples were processed by a restriction enzyme *Ape*KI and then sequenced by Illumina HiSeq, yielding 74.4 million reads. These restriction site-associated sequences were analyzed to characterize taxonomic diversity and functional profiling of microbial community directly. Moreover, metagenomic GBS reads were grouped, aligned, and Shannon entropy-analysis using UCLUST, MUSCLE, and in-house script from Oligotyping respectively. Entropy in sequence variation among sorted clusters by functional category was measured to evaluate their rate of SNPs variations.

Conclusions

Nucleotide and amino acid substitutions were discovered that indicate micro genetic diversity associated with evolutionary histories according to geographical patterns. Besides profiling microbial community and functional pathway, metagenomic GBS can analyze evolutional study based on nucleotide variation. GBS to metagenomic analysis was applied as a snapshot for understanding the highly dynamic ecosystem quickly to resolve budget and time-consuming issues with identification of micro genetic diversity through comparing each samples.

Microbial Ecology

ESTIMATING MICROBIAL COMMUNITY STRUCTURE USING METABOLIC NETWORKS

K. Takemoto[1]
[1]*Kyushu Institute of Technology, Department of Bioscience and Bioinformatics, Iizuka, Japan*

Backgrounds

Microbes interact with one another via metabolic interactions etc., and they compose ecological communities. It is important to untangle such ecosystems in medical and environmental sciences. In this context, microbial ecological networks are often studied. In general, such networks are estimated based on time-series data on species abundance, obtained from 16S rRNA data, for example. However, such estimation methods have fiscal constraints; moreover, they are not useful for understating microbial ecosystems at the molecular level, despite the importance of metabolite interactions in microbial ecosystems.

Objectives

Thus, I developed a novel method for estimating microbial community structure using metabolic network analysis: Estimator of COmmunity Structure based on MetabOlic networkS (ECOSMOS).

Methods

For this, I considered reverse ecology [R. Levy, E. Borenstein, Adv. Exp. Med. Biol. 751, 329 (2012)]. In particular, cooperative interactions (i.e., complementary support of nutrients) and competitive interactions (i.e., scramble for nutrients) are calculated based on nutrient metabolites identified using graph-theoretic algorithms. In addition to this, I used random matrix theory [S. Suweis et al. Nat. Commun. 6, 10179 (2015)], and evaluated ecological community stability based on the strength of interactions and species abundance.

Conclusions

ECOSMOS considers metabolic interactions between organisms, and it estimates ecological networks from at least one sample. I applied ECOSMOS to actual examples, and found interesting results. For example, the gut microbiota in healthy subjects were highly stable. Cooperation and stability of soil microbial community increase after environmental perturbations. ECOSMOS enhances our understanding of microbial ecological community. ECOSMOS is available from takemoto08.bio.kyutech.ac.jp/ecosmos-lite/

REAFFILIATION OF EDWARDSIELLA TARDA FISH ISOLATES TO THE NEW SPECIES EDWARDSIELLA PISCICIDA AND EDWARDSIELLA ANGUILLARUM

N. Buján[1], S. Balboa[1], J. L. Romalde[1], A. E. Estévez[1], B. Magariños[1]
[1]Fac. Bioloxía-CIBUS & Instituto de Acuicultura,
Microbioloxía e Parasitoloxía- Universidade de Santiago de Compostela, Santiago de Compostela, Spain

Backgrounds

Edwardsiella is a genus belonging to the family *Enterobacteriaceae*, described in 1965 by Ewing and MacWhorter. Until 2012, the genus consisted of 3 species: *E. hoshinae*, *E. ictaluri* and *E. tarda*. Based on genetic studies two novel species, *E. piscicida* and *E. anguillarum* were described in 2013 and 2015 respectively. *E. piscicida* compiled only pathogenic strains isolated from fish showing phenotypic characteristics identical to *E. tarda*. The capacity to ferment mannitol and arabinose is the unique characteristic distinguishable for *E. anguillarum*, but is not enough to a *bona fide* identification

Objectives

The description of the new *Edwardsiella* species made necessary a deeper study of the phylogeny of the genus to clarify the position of isolates previously classified as *E. tarda*.

Methods

A total of 57 strains and 4 genomes retrieved from the GenBank database of *Edwarsiella* were used in this work. All strains were previously identified by classical phenotypical tests.
Seven gene loci were selected, including 16S rRNA gene, *adk*, *atp*D, *dna*J, *gln*A, *hsp*60 and *tuf*, to perform the MultiLocus Sequence Analysis (MLSA).
The OrthoANI values among the genomes were calculated using OAT (v0.93). Moreover, estimated DNA-DNA hybridization was determined by the genome-to-genome distance calculator (GGDC2.1).

Conclusions

The results indicate that *Edwardsiella* isolates obtained from fish and previously identified as *E. tarda* should be reclassified as *E. piscicida* or *E. anguillarum*. The scarce phenotypic differences among *E. tarda*, *E. piscicida* and *E. anguillarum* made necessary the use of molecular techniques to a correct identification of these species.

Molecular Taxonomy, Genomics and Phylogeny

COMPARATIVE GENOMIC FEATURES OF BACILLUS VELEZENSIS, BACILLUS AMYLOLIQUEFACIENS AND BACILLUS SIAMENSIS

B.H. Chun[1], K.H. Kim[1], S.E. Jeon[1], C.O. Jeon[1]
[1]Chung-Ang University, Department of Life Science, Seoul, Republic of Korea

Backgrounds

Three *Bacillus* groups (*B*. *velezensis*, *B*. *amyloliquefaciens*, and *B*. *siamensis*) are not differentiated based on 16S rRNA gene sequences because they are very closely related each other. Therefore, using pan-genomes of the three *Bacillus* groups we investigated the phylogenetic relatedness and compared their genomic and metabolic features.

Objectives

The aim of this study is to investigate the comparative genomic and metabolic features of three *Bacillus* groups with high phylogenetic relatedness.

Methods

Genomes that were possibly affiliated to the three *Bacillus* groups were retrieved from GenBank based on >98% of 16S rRNA gene sequence similarities and >95% of average nucleotide identity values to their respective type strains. After removing low quality genomes using the CheckM program, the comparative genomic and metabolic features of three *Bacillus* groups were investigated using pan-genome.

Conclusions

The 64 high quality genomes of *B*. *velezensis* (54), *B*. *amyloliquefaciens* (6), and *B*. *siamensis* (4) were selected and A phylogenetic analysis based on 16S rRNA gene sequences showed that the three *Bacillus* groups were undifferentiated phylogenetically, while a phylogenetic analysis using 1,957 core genes showed that they were clearly differentiated into three different phylogenetic lineages. The three *Bacillus* groups had similar COG distribution patterns, but their molecular phenotype-based relatedness was differentiated into three groups. The comparative genome analysis of three *Bacillus* groups showed that all *B*. *velezensis* strains harbor a macrolactin gene cluster, while all *B*. *siamensis* strains have a xanthine metabolic gene cluster.

Molecular Taxonomy, Genomics and Phylogeny

ENTOMOPATHOGEN ID: A MULTI-LOCUS SEQUENCE ALIGNMENT RESOURCE FOR ENTOMOPATHOGENIC FUNGI

C. Dunlap[1], J. Ramirez[1], D. Labeda[2]
[1]NCAUR, Crop Bioprotection, Peoria, USA
[2]NCAUR, Mycotoxin Prevention and Applied Microbiology research unit, Peoria, USA

Backgrounds

The ability to correctly identify entomopathogenic fungi is an important step in developing biopesticides and effectively communicating research results. Over the years, identifying entomopathogenic fungi has evolved from a system based on diagnostic morphological and physiological characters to molecular DNA based systems. Internal transcribed spacer (ITS) sequences have become the barcode of choice when identifying unknown fungi. While ITS sequencing is a great tool for identifying unknown fungi, it often lacks sufficient resolution to accurately identify common entomopathogenic fungi. The problem is further compounded by not having a curated database of reference sequences based on type material to compare sequences against.

Objectives

Develop a web-based Multi-Locus Sequence Alignment resource for common Hypocrealean entomopathogenic fungi.

Methods

The Entomopathogen ID Multi-Locus Sequence Alignment resource is a curated sequence database built on sequences from MLSA and other taxonomic studies of common Hypocrealean entomopathogenic fungi spanning the taxonomic families of Cordycipitaceae, Clavicipitaceae and Ophiocordycipitaceae.

Conclusions

The database provides a new resource to improve the taxonomic characterization of this group of fungi.

POLYSACCHARIDE DECOMPOSERS AMONG HALOPHILIC ARCHAEA - A SYSTEMATIC GENOMIC AND PHENOTYPIC APPROACH

R.L. Hahnke[1], J.P. Meier-Kolthoff[1], M. Göker[1], B.J. Tindall[1]
[1]DSMZ, Microorganisms, Braunschweig, Germany

Backgrounds

Some *Bacteria* and *Archaea* taxa are known to thrive in carbohydrate-rich habitats as decomposers of particulate organic matter. In contrast, few polysaccharides have been tested and few taxa have been systematically investigated for polysaccharide degradation.

Objectives

With the aim of obtaining deeper insights into the evolution of carbohydrate metabolism in *Halobacteria*, we tested type strains in the family *Natrialbaceae* (*Archaea*) for their potential and ability to decompose polysaccharides.

Methods

Strains were incubated in media with NaCl concentrations of 10–32%, low nutrient concentrations and azurin-crosslinked polysaccharides in microtiter plates. Genome-scale phylogenies were inferred from whole proteomes using the Genome BLAST Distance Phylogeny (GBDP) approach. Genes encoding carbohydrate active enzymes were retrieved from the genome by matching the CAZy database.

Conclusions

Strains belonging to the genera *Halopiger* and *Halostagnicola* were rich in CAZymes, but strains belonging to the genera *Natronococcus*, *Natrinema*, *Natronorubrum*, *Natronolimnobius*, *Natronobacterium*, *Halobiforma* and *Halovivax* were not. Surprisingly, the diversity of polysaccharide decomposition differed significantly within the genera *Haloterrigena* and *Natrialba*. Galactomannan, pachyman, Barley-β-glucan and CM-cellulose were hydrolyzed only above 23% NaCl. Furthermore, the ability to grow on polysaccharides is directly correlated to the presence of genes of the semi-phosphorylated Entner-Doudoroff pathway in their genomes.

The results presented here demonstrate the advantage of a combined genomic and phenotypic approach to the systematic high-throughput screening of polysaccharide decomposition in prokaryotic taxonomy. Furthermore, the results provide additional information for the description and classification of microbial species and led to the discovery of so far hidden physiological features.

Molecular Taxonomy, Genomics and Phylogeny

A PROTEIN SEQUENCE SET FOR MULTILOCUS SEQUENCE ANALYSIS (MLSA) AND PHYLOGENOMIC AFFILIATION IN THE MARINE ROSEOBACTER LINEAGE

B. Nogales[1], *M. Mas-Lladó*[2], *R. Bosch*[1]
[1]*University of the Balearic Islands UIB and IMEDEA UIB-CSIC, Microbiology, Palma de Mallorca, Spain*
[2]*University of the Balearic Islands, Microbiology, Palma de Mallorca, Spain*

Backgrounds

The Roseobacter lineage (*Rhodobacteraceae*, *Alphaproteobacteria*) is an important group of marine bacteria. Robust phylogenetic reconstructions using concatenates of a variable number (i.e. 52-78) of single-copy, conserved protein sequences have been done. This provides a backbone for the affiliation of new isolates. However, the pace of genome sequencing in this lineage requires continuous reevaluation of a *core* protein set useful for phylogeny.

Objectives

In this study we propose a set of fourteen protein sequences for MLSA in the Roseobacter lineage that reproduces correctly the phylogeny of the lineage and can be used for the affiliation of new isolates.

Methods

To define the MLSA protein set we calculated a *core* proteome using 96 Roseobacter genome sequences (114 proteins). We retrieved the conserved residues, concatenated them and calculated a phylogenetic tree by maximum parsimony. After calculating individual trees for each protein we selected fourteen of them (4,462 amino acid positions) whose concatenated sequences reproduced better the topology of the *core* proteome tree. To check the usefulness of this MLSA protein set we included 69 additional genome sequences and calculated a new tree (4,412 aligned positions).

Conclusions

We observed differences only in the grouping of two isolates belonging to the two most deeply-branching genomic groups and in the intra-group branching order of a third genomic group. Therefore, most of the isolates were placed in the expected genomic group and genus, confirming the usefulness of this approach for the rapid and robust affiliation of new isolates of the Roseobacter lineage.

ARCOBACTER LACUS SP. NOV. AND ARCOBACTER CAENI SP. NOV., TWO NEW SPECIES ISOLATED FROM RECLAIMED WATER

A. Pérez-Cataluña[1], M.J. Figueras[1], N. Salas-Massó[1]
[1]Universitat Rovira i Virgili- IISPV,
Unidad de Microbiología - Departamento de Ciencias Médicas Básicas - Facultad de Medicina y Cien cias de la Salud, Reus, Spain

Backgrounds

The genus *Arcobacter* belongs to the family *Campylobacteraceae* and differs from *Campylobacter* on the basis of the capacity of the species to growth at low temperatures. Since its description in 1991, 24 species had been added to the genus.

Objectives

In the present study we performed a taxonomic study using a polyphasic approach including genome information of two strains (RW43-9 and RW17-10) recovered from secondary treated wastewater.

Methods

The first identification with the *rpoB* gene sequencing, revealed on the basis of the phylogenetic analysis that those strains formed two potentially new linages. A phylogenetic analysis of the 16S rRNA gene and of the concatenated sequences of 5 housekeeping genes (*atpA*, *gyrA*, *gyrB*, *hsp60* and *rpoB*) i.e. MLPA was performed. In addition, genomic DNA was sequenced and used for genomic comparison. The Average Nucleotide Identity (ANI) and the *in silico* DNA-DNA hybridization (*is*DDH) was calculated between the genomes of the two new taxa and their nearest species. Phenotypic characterization of these two strains was also performed.

Conclusions

The differential phenotypic characteristic between the strains RW 43-9 and RW17-10 and its nearest species are the ability to growth in TSA supplemented with 5% sheep blood at 37ºC and 42ºC in anaerobiosis and the inability to growth in minimal medium, respectively. These findings together the MLPA analysis and the values of ANI (<96%) and isDDH (<75%), demonstrate that these strains represent two new species, for which the names *Arcobacter lacus* (type strain RW43-9^T=CECT 8994^T=LMG 29062^T) and *Arcobacter caeni* (type strain RW17-10^T =CECT 9140^T=LMG 29151^T) are proposed.

One Health and human Pathogenicity

IGG PROTEASES IN CANINE MYCOPLASMAS

D.R. Brown[1], *D.L. Michaels*[1]
[1]*University of Florida, Infectious Diseases and Pathology, Gainesville Florida, USA*

Backgrounds

Certain streptococci encode endoproteases that cleave IgG at a specific epitope between the hinge and CH2 glycosylation sites. The IgG consequently loses all lymphocyte FcγR-mediated effector function and cannot activate complement. Orthologs differ among streptococcal species in their narrow selectivity for IgG of the hosts to which the bacteria are normally restricted, a feature thought to reflect fine-tuned adaptation to host immune defenses.

Objectives

We sought to identify streptococcal IgG protease orthologs in the genomes of mycoplasmas.

Methods

Mycoplasma canis, *Mycoplasma cynos*, *Mycoplasma opalescens*, *Mycoplasma spumans* and *Ureaplasma canigenitalium*, all normally found in dogs, encode the core sequence of the enzyme (GenBank Protein Cluster PCLA_442768). Its genomic context differs among species and some have N- or C-terminal fusions with other mycoplasmal proteins, which suggests origins by horizontal transfer possibly from *Streptococcus canis*. We compared non-synonymous to synonymous amino acid substitutions within the core sequence in streptococci and mycoplasmas but found little evidence that site-specific diversifying selection drives adaptation to the IgGs of different hosts. A predicted mannose and glucosamine ligand-binding exosite, possibly responsible for inital interactions with substrate IgG, was conserved in *M. canis*, *M. opalescens* and *U. canigenitalium* but degenerate in *M. cynos* and *M. spumans*. The IgG in normal dog serum was degraded in the signature pattern of streptococcal IgG proteases when incubated with *M. canis* but not with *M. cynos*.

Conclusions

We conclude that the IgG protease in certain mycoplasmas is evolutionarily, structurally and functionally related to streptococcal orthologs and may confer previously unrecognized immunosuppressive effects during mycoplasmosis of dogs.

One Health and human Pathogenicity

DISULFIDE BOND FORMATION IN GASTRIC PATHOGEN HELICOBACTER PYLORI: AN ACHILLAES' HEEL FOR SECRETION OF PRO-INFLAMMATORY VIRULENCE PROTEINS

C. Creuzenet[1], J. Lester[1], S. Kichler[1], H. Atanassov[2], C. Bodet[2], B. Oickle[1], S. Fairweather[1], M. Perivier[2], A. Oberc[1], J. Chahal[1], D. Ratnayake[1], C. Burucoa[2]
[1]Western University, Microbiology and Immunology, LONDON, Canada
[2]University Hospital, LITEC, Poitiers, France

Backgrounds

H. pylori causes gastritis, gastric ulcers and cancers but the mechanisms of virulence are not fully understood. It produces secreted proteins which may play a role in eliciting gastric inflammation, including the Helicobacter cysteine rich protein HcpE (HP0235) whose biological function is unknown.

Objectives

To investigate if HcpE is secreted by *H. pylori* and is involved in host / pathogen interactions, and identify components essential for its production.

Methods

This work uses anti-HcpE ELISA and Western blots, knockout mutagenesis, phenotypic analyses and biochemical assays.

Conclusions

We demonstrate that HcpE is secreted by many strains as a soluble protein and in association with outer membrane vesicles. We show that infected patients produce anti-HcpE antibodies, indicating in situ HcpE production. We show that HcpE comprises many disulfide bonds and identify DsbK (HP0231) as a folding factor necessary for HcpE production, and show that recombinant DsbK can refold unprocessed, reduced HcpE *in vitro*. This highlights the first biologically relevant substrate for DsbK. Furthermore, we show that DsbK has DiSulfide Bond (Dsb) forming activity on reduced lysozyme and has DsbA-like activity upon expression in *E. coli*, despite its similarity with DsbG. Also, we show a role of DsbK in redox homeostasis in *H. pylori*. Finally we show an important role for DsbK and HcpE in host-pathogen interactions, including murine gastric colonization and pro-inflammatory cytokine production in human gastric explants and in murine splenocytes. Both proteins will be investigated as therapeutic targets to treat *H. pylori* infections and prevent gastric ulcers and cancers.

PIECING TOGETHER YSCX FUNCTION: THE CRITICAL PROTEIN IN YERSINIA TYPE III SECRETION SYSTEM

J.M. Gurung[1], A.A.A. Amer[1], S. Chen[2], M.S. Francis[1]
[1]Umeå University, Department of Molecular Biology, Umeå, Sweden
[2]Chinese Academy of Sciences, Wuhan Institute of Virology, Wuhan, China

Backgrounds

Yersinia bacteria utilize a type III secretion system (T3SS) to target effector toxins into the host cells which promote mutualistic or pathogenic associations. T3SS's are comprised of ~25 structural proteins many of whose functions remain obscure. In *Yersinia*, YscX and YscY are two poorly characterised proteins. However, the absence of Ysc-Yop T3SS in *yscX* or *yscY* null mutant suggests that YscX and YscY are important Ysc-Yop T3SS constituents. This may arise from a need to form a binary interaction involving YscX-YscY or a ternary interaction with the inner membrane export component YscV.

Objectives

Study the contribution of YscX secretion towards T3S function.

Methods

To understand the role of YscX, we initially investigated the functional interchangeability between genetically conserved members of YscX-YscY protein families from diverse bacteria. Our study suggested that the function of YscX might be specific to *Yersinia* despite reciprocal binding to YscY and YscV family members. To further dissect the uniqueness of YscX function, we scrutinized the role of YscX N-terminus in secretion of itself and other T3S proteins. Site-directed mutagenesis and defined domain swapping revealed YscX N-terminus to be central for Ysc-Yop activity as it prevented YscF needle assembly and abolished T3SS activity. Critically, the inability of these YscX variants to impede T3SS was not due to the disruption of their secretion ability or destabilization of binary and ternary interactions.

Conclusions

Hence, the YscX N-terminus is dual functional; on the one hand it is a secretion recognition motif and on the other, a novel structural component necessary for the correct assembly of the Ysc-Yop T3SS.

PSEUDOMONAS AERUGINOSA PHOSPHOLIPASES AND LECTINS ARE POTENTIAL THERAPEUTIC TARGETS

F. Kovacic[1], F. Bleffert[1], T. Schwabroch[1], C.H. Strunk[1], M. Caliskan[1], J. Granzin[2], M. Siebers[3], P. Dörmann[3], L. Rahme[4], R. Batra-Safferling[2], K.E. Jaeger[1,5]
[1]Institute of Molecular Enzyme Technology- Heinrich-Heine-University Düsseldorf, Bacterial Enzymology, Jülich, Germany
[2]Institute of Complex Systems- Forschungszentrum Jülich GmbH, ICS-6: Structural Biochemistry, Jülich, Germany
[3]Institute of Molecular Biotechnology- Universität Bonn, IMBIO, Bonn, Germany
[4]Harvard Medical School, Department of Microbiology and Immunology, Boston, USA
[5]Institute of Bio- and Geosciences- Forschungszentrum Jülich GmbH, IBG-1: Biotechnology, Jülich, Germany

Backgrounds

Pseudomonas aeruginosa is a Gram-negative opportunistic pathogen infecting immunocompromised humans with high mortality rates. Many virulence factors, among them phospholipases and lectins contribute to biofilm formation and high antibiotic resistance of *P. aeruginosa*.

Objectives

Phospholipases are involved in bacterial adaptation, host membrane damage and modulation of host lipid signaling. We have studied a novel phospholipase A which may contribute to the biosynthesis of lipid messengers related to virulence and biofilm formation. The lectin LecB is located at the cell surface and mediates bacterial attachment to human tissue during initial biofilm formation. We have tried to elucidate the so far unknown LecB secretion pathway.

Methods

PlbF as a novel phospholipase A of *P. aeruginosa* was shown to hydrolyze membrane phospholipids *in vitro* and *in vivo* releasing medium chain fatty acids. It acts as a virulence factor as shown by a *Drosophila melanogaster* infection model and is involved in biofilm formation. Screening of a transposon mutant library of *P. aeruginosa* using a high-throughput enzyme-linked lectin assay resulted in the identification of approximately 30 strains significantly affected in LecB secretion with targeted genes involved in the biogenesis of the flagellum and type-IV pili involved in cell attachment and biofilm formation.

Conclusions

The novel phospholipase PlbF may be linked to a virulence mechanism involving cell signaling in *P. aeruginosa*. The lectin LecB may be co-secreted with flagellin *via* a type-III secretion system. These data suggest that that lectin and phospholipase may represent potential targets for treatment of *P. aeruginosa* infections.

PROPIONIC ACID INDUCES RAPID EVOLUTION OF CROHN'S DISEASE ASSOCIATED AIEC

M. Ormsby[1], L. Meikle[1], A. Mcintosh[1], S. Johnson[1], R. Goldstone[2], C. Edwards[3], D. Smith[2], D. Wall[1]
[1]Infection- Immunity and Inflammation, Bacteriology, Glasgow, United Kingdom
[2]Biological Chemistry- Biophysics and Bioengineering, Heriot-Watt University, Edinburgh, United Kingdom
[3]School of Medicine, Human Nutrition, Glasgow, United Kingdom

Backgrounds

Crohn's Disease (CD) is a multi-factorial disease that occurs in genetically susceptible individuals, resulting in inflammation of the digestive tract. Concurrently, the use of antibacterial compounds, particularly short chain fatty acids (SCFAs), has increased dramatically in recent years in both agriculture and human food. One such SCFA, propionic acid (PA), inhibits *Salmonella* and *Campylobacter* colonisation of poultry. Here we show that the bacterial pathotype adherent and invasive *Escherichia coli* (AIEC), that has been isolated in increased numbers from CD patients, can use PA as a carbon source for growth.

Objectives

Our work aims to elucidate the adaptation that pre-exposure to PA may have on the ability of AIEC to colonise the human intestinal tract, outcompeting the native microflora.

Methods

Continued growth of the AIEC type strain LF82, in PA, resulted in; an increased rate of growth; greater adherence to Caco-2 intestinal epithelial cells; and a greater propensity to form biofilms under anaerobic conditions. PA use was also seen to induce shedding of inflammatory bacterial micro-compartments, with upregulation of both the *pdu* and *eut* operons, for 1,2-propanediol and ethanolamine use, respectively. Both metabolites are known to allow pathogens such as *Salmonella* Typhimurium to out-compete the native microflora during intestinal inflammation.

Conclusions

As antibiotic use has previously been implicated in the horizontal transmission of *E. coli* between poultry and humans, this work highlights the risk associated with using alternative antimicrobials such as PA in both agriculture and human food potentially evolving *E. coli* strains that are specifically adapted to life in the inflamed CD gut.

CHARACTERIZATION OF THE LUNG MICROBIOME IN LEGIONELLA-ASSOCIATED PNEUMONIA AND ITS EVOLUTION DURING ANTIBIOTIC TREATMENT

A.E. Pérez Cobas[1,2], C. Ginevra[3,4], C. Rusniok[1,2], J. Sophie[3,4], C. Buchrieser[1,2]
[1]Institute Pasteur, Biology of Intracellular Bacteria, Paris, France
[2]CNRS UMR 3525, 75724, Paris, France
[3]Centre National de Référence des Légionelles, Hospices Civils de Lyon, Lyon, France
[4]Centre International de Recherche en Infectiologie- Université Lyon 1- UMR CNRS 5308- U1111 Ins erm, Ecole Normale Supérieure de Lyon, Lyon, France

Backgrounds

Pneumonia represents a major public health problem with a high rate of morbidity and mortality worldwide. Despite the explosion of microbiome (MC) analyses, very little is known about the lung MC, especially with respect to bacterial pneumonia. The lung MC seems to contribute to the stimulation of the immune system and to inflammation. It thus plays possibly a role in the response to lung infections.

Objectives

Here we characterized the dynamics of the lung MC during bacterial infection and antibiotic therapy.

Methods

We collected broncheoalveolar samples from patients with pneumonia caused by *Legionella pneumophila* during around two months of hospitalisation and performed a longitudinal analysis of their lung MC. We characterized the bacterial and fungal diversity of these samples by deep sequencing (Illumina) of the 16S rRNA gene (bacteria) and the ITS region (fungi).

Conclusions

During infection the bacterial fraction of the lung MC was characterized by a low diversity and a dominance of the pathogen, as *L. pneumophila* represented more than 50% of the identified bacteria. Antibiotic treatment led to a strong change in the MC as we observed a marked decrease in the abundance of *L. pneumophila* and an increase in the bacterial diversity. The commonly identified bacteria of the lungs such as *Prevotella*, *Fusobacterium* or *Staphylococcus* were recovered. In contrast, the composition and diversity of the fungal fraction was more homogeneous. However, the fungal diversity was higher during infection probably because of a colonization advantage of fungi due to the loss of the bacterial MC during antibiotics treatment.

UNCOMMON VIRULENCE POTENTIAL IN ST-14 KPC-3 KLEBSIELLA PNEUMONIAE: A HIGH RISK CLONE IN PORTUGAL

C. Caneiras[1], L. Lito[2], J. Melo-Cristino[2,3], A. Duarte[1]
[1]Research Institute for Medicines iMed.ULisboa - Faculty of Pharmacy - University of Lisbon, Department of Microbiology and Immunology, Lisboa, Portugal
[2]Centro Hospitalar Lisboa Norte, Laboratory of Microbiology, Lisboa, Portugal
[3]Institute of Molecular Medicine - Faculty of Medicine - University of Lisbon, Institute of Microbiology, Lisboa, Portugal

Backgrounds

The emergence of KPC-type carbapenemases in *Klebsiella pneumoniae* poses a serious threat to public health worldwide and have recently undergone a relevant increasing prevalence in Portugal. Studies regarding the *K. pneumoniae* identification of virulence markers and high-risk clones are critical for the development of novel diagnostic methods and new therapeutic strategies.

Objectives

The aim of this study was the identification of virulence markers and characterization of the clonal relationship among multidrug resistant *Klebsiella pneumoniae* isolates producing KPC-3 carbapenemases since 2009, in Portugal.

Methods

This study included 27 representative clinical isolates of *K.pneumoniae* KPC-3 producers collected in a tertiary hospital centre in Lisboa, Portugal, between 2009 and 2013. Antimicrobial susceptibility testing was performed by disk diffusion and the results were interpreted according to CLSI and EUCAST guidelines. Genes encoding other β-lactamases including OXA, NDM, CTX-M, TEM, SHV, DHA, FOX, and CMY were screened by PCR and confirmed by sequencing. The isolates were also screened for gene markers of virulence factors: *K2A, fimH, mrkD$_{V1}$, mrkD$_{V2-4}$, khe, rmpA, magA,* and *iucC* by PCR amplification.The clonal relationship was evaluated by M13 fingerprinting and multilocus sequence typing (MLST).

Conclusions

We firstly report an uncommon and concerning overlapping of multidrug-resistance and accumulation of virulence genes in the prevalent (>80%) ST-14 clone identified. The combination of the KPC-3 gene with virulence genes as K2 capsular serotype, fimbrial adhesins, haemolysin, and aerobactin - a bacterial iron chelating agent, can constitute a serious threat, especially for vulnerable populations and may further exacerbate infections caused by this pathogen.

RIBOSWITCH REGULATION OF METHIONINE METABOLISM AND VITAMIN B12 UPTAKE IN MYCOBACTERIA – A ROLE IN PATHOGENESIS?

T. Kipkorir[1], G. Mashabela[1], V. Mizrahi[1], D.F. Warner[1]
[1]University of Cape Town, Pathology and Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa

Backgrounds

Mycobacterium tuberculosis (MTB) is thought to recognize fluctuations in specific environmental stimuli within the host, and to respond with corresponding alterations to gene expression and metabolism. Accordingly, the MTB genome contains a large number of regulatory elements which could contribute to this capacity. These include two vitamin B_{12} (B_{12}) riboswitches that have been identified upstream of *metE* – encoding a B_{12}-independent methionine synthase, and *ppe2* – the first gene in a putative operon with the B_{12} biosynthetic genes, *cobQ1* and *cobU*. We showed previously that disruption of the alternative, B_{12}-dependent methionine synthase, MetH, rendered MTB sensitive to B_{12}, presumably via methionine auxotrophy owing to B_{12} riboswitch-dependent suppression of MetE levels.

Objectives

Unlike MTB, MSM is a constitutive B_{12} producer under standard conditions *in vitro*. Therefore, we hypothesized that MetH would be essential in MSM, and that deletion of *metH* would be possible only by *metE* riboswitch inactivation or in a B_{12} deficient background.

Methods

Targeted knock-out of *metH* proved facile in a MSM Δ*cobK* mutant in which *de novo* B_{12} biosynthesis is disrupted. Curiously, however, the double Δ*metH* Δ*cobK* deletion mutant was not sensitive to exogenous B_{12}. Comparative genomic analyses identified additional B_{12} riboswitches controlling two separate BtuFCD-type B_{12} transporters that are present in MSM but not MTB.

Conclusions

These findings suggest that B_{12}-dependent metabolism in MSM is regulated both at the level of cofactor transport and enzymatic function, thus identifying B_{12} uptake as one potential point of departure in the evolution of the pathogenic MTB from the most recent common mycobacterial ancestor.

CANDIDA ALBICANS IS ABLE TO ALTER ENTEROCYTE TIGHT JUNCTIONS THAT ENHANCES ITS TRANSLOCATION THROUGH THE GUT BARRIER

A. Loiselet[1,2], F. Bon[1], A. Ducreux[1], C. d'Enfert[3], B. Hube[4,5], F. Dalle[1,2]
[1]UMR A PAM Univ Bourgogne-Franche-Comte, UFR Sciences de Santé- Bât B3, Dijon, France
[2]Centre Hospitalier Universitaire, Service de Parasitologie Mycologie, Dijon, France
[3]Institut Pasteur- INRA, Unité Biologie et Pathogénicité Fongiques, Paris, France
[4]Leibniz Institute for Natural Product Research and Infection Biology—Hans Knoell Institute, Department of Microbial Pathogenicity Mechanisms, Jena, Germany
[5]University Hospital Jena, Center for Sepsis Control and Care, Jena, Germany

Backgrounds

C.albicans is commensal yeast of the mucosa in healthy humans that can be responsible for disseminated candidiasis, mainly originating from the gut. Deciphering the cellular and molecular mechanisms of the interaction of *C.albicans* with enterocytes is necessary to better understand the basis of commensalism and pathogenicity of the yeast and to improve the management of disseminated candidiasis. Different routes of tissue invasion by *C.albicans* are reported, partly due to differences in the structure of the epithelial layer. The intestinal epithelium consists in a monolayer of enterocytes where adjacent cells are jointed each other through cell junctions. Among those, tight junctions (TJ) ensure integrity and impermeability of the intestinal barrier, limiting invasion of the gut by *C.albicans.*

Objectives

The aim of our work is to investigate the impact of *C. albicans* interaction upon the integrity of the intestinal barrier.

Methods

Permeability of the intestinal barrier is investigated measuring the transepithelial electrical resistance of Caco-2 cell monolayers interacting with *C. albicans*. The organization of the TJ protein complex is studied by (i) monitoring their cellular localization using microscopy and (ii) their cellular distribution by using western blotting and Nano-HPLC. Molecules of the fungus responsible for these cellular alterations are currently under investigation.

Conclusions

Candida albicans is able to disorganize the TJ protein complex, altering the integrity of the intestinal barrier. As a consequence, *C. albicans* enhances its translocation through the gut barrier. Better understanding the first steps of *Candida* invasion will help to find target molecules to prevent its dissemination during severe candidiasis.

SCREENING DISRUPTORS OF THE TOXIN–ANTITOXIN COMPLEX IN STAPHYLOCOCCUS AUREUS

Y. Ota[1], T. Miyamoto[1], A. Yokota[2], S. Tsuneda[1], N. Noda[2]
[1]Waseda University, Department of life science and medical bioscience, Tokyo, Japan
[2]National Institute of Advanced Industrial Science and Technology, Biomedical research institute, Tsukuba, Japan

Backgrounds

Toxin–antitoxin (TA) modules, which are implicated in microbial cell growth and survival, are widespread in prokaryotic cells. These modules comprise toxins, which are harmful to the host cell and antitoxins, which commonly neutralize the cognate toxins by forming these TA complexes. Therefore, TA complexes are considered promising targets for the development of novel antimicrobial agents to combat the rapid spread of antibiotic resistance in major human pathogens such as *Staphylococcus aureus*.

Objectives

Herein, we aimed to identify new antimicrobial peptides directly targeting the MazEF module, a typical TA module, in *S. aureus* by using a high-throughput screening method combining the phage display technique, massively parallel sequencing, and a continuous fluorometric assay.

Methods

We enriched candidate peptides with a high affinity for the MazF toxin by using phage display technology involving repetitive biopanning. The peptide amino acid sequences were comprehensively determined using massively parallel sequencing. Thereafter, we utilized a continuous fluorometric assay to assess the ability of the peptides to liberate the MazF toxin in the presence of the MazE antitoxin.

Conclusions

Using biopanning followed by massively parallel sequencing, we identified several peptides that specifically bind to the MazF toxin, and subsequently, using a continuous fluorometric assay, we revealed that some peptides overcome the inhibitory effect of the MazE antitoxin on the MazF toxin *in vitro*. Our method can be readily applied in the discovery of disruptors of other TA systems using direct binding mechanisms.

SALMONELLA TYPHIMURIUM REQUIRES SOPB AND SIFA TO SURVIVE INTRACELLULARLY IN A SCV-LIKE COMPARTMENT IN DICTYOSTELIUM DISCOIDEUM

C. Valenzuela[1], *A. Sabag*[1], *Í.M. Urrutia*[1], *M. Varas*[2], *C.A. Santiviago*[1]
[1]*Universidad de Chile, Facultad de Ciencias Químicas y Farmacéuticas, Santiago, Chile*
[2]*Universidad de Chile, Facultad de Ciencias, Santiago, Chile*

Backgrounds

Salmonella survival within eukaryotic cells is explained, in part, by its ability to establish an intracellular compartment known as the *Salmonella* containing vacuole (SCV). To this end, *Salmonella* exploits several effector proteins secreted by type-three secretion systems $T3SS_{SPI-1}$ and $T3SS_{SPI-2}$. We recently reported a role for effector proteins SopB and SifA in the survival of *Salmonella* Typhimurium in *Dictyostelium discoideum*, and the presence of wild-type bacteria in a vacuolar compartment within this amoeba.

Objectives

We evaluated whether the defect in intracellular survival of Δ*sopB* and Δ*sifA* mutants is explained by their inability to survive within SCV-like vacuoles.

Methods

We performed infections of *D. discoideum* expressing a VatM-GFP fusion using bacterial strains expressing the red fluorescent protein mCherry, and analyzed infected cells by confocal laser microscopy. VatM is a vacuolar ATPase used as marker of SCV membranes in other host cells.

Conclusions

According to our results, viable wild-type bacteria were detected laying within VatM-GFP positive vacuoles up to 6 h of infection. In the case of Δ*sopB* and Δ*sifA* mutants, only a few bacteria were detected within VatM-GFP positive vacuoles at 3 h of infection, and most *D. discoideum* cells contained remnants of killed bacteria. Altogether, our results suggest that *S.* Typhimurium resides in a SCV-like compartment in *D. discoideum* and requires effectors SopB and SifA to avoid degradation by this amoeba. We are currently characterizing the composition of the SCV-like compartment in *D. discoideum*.

Supported by FONDECYT grants 1140754 and 1171814, and CONICYT fellowships 21140615, 22140758 and 21150005.

PSEUDOMONAS PROTEGENS AND PSEUDOMONAS CHLORORAPHIS: SWITCH BETWEEN ROOT- AND INSECT-ASSOCIATED LIFESTYLES

P. Vesga[1], P. Flury[1], M. Péchy-Tarr[2], C. Keel[2], M. Maurhofer[1]
[1]Institute of Integrative Biology- Federal Institute of Technology Zurich ETHZ, Plant Pathology, Zurich, Switzerland
[2]University of Lausanne, Fundamental Microbiology, Lausanne, Switzerland

Backgrounds

Insect pests are a major agricultural problem and very difficult to control. Root-colonizing fluorescent pseudomonads are known for their ability to promote plant growth and to protect plants against soilborne fungal pathogens, but some of them belonging to the species *Pseudomonas protegens* and *P. chlororaphis* additionally have insecticidal activity. They can colonize the gut of insect larvae and invade the hemocoel causing systemic infection and death. These bacteria produce an insect toxin termed Fit, which contributes to insecticidal activity.

Objectives

To answer the question whether *P. protegens* and *P. chlororaphis*, which were so far thought to be mostly associated with plants and soil, are naturally associated with insects.

Methods

In order to answer this question, bacteria were isolated from insects collected from the field. Isolates were assessed for presence of the Fit insect toxin gene and insecticidal activity and were phylogenetically characterized. So far, we found that Fit-harbouring pseudomonads are common in different insect species, which indicates that insects are an additional ecological niche for *P. protegens* and *P. chlororaphis*. Currently, we are performing a RNA-sequencing analysis with *P. protegens* CHA0 to determine the genes it needs to switch between a root- and an insect-associated lifestyle. In addition, we have demonstrated, in insect backgrounds, the expression of known insecticidal factors as well as factors involved in suppression of plant pathogens and competition.

Conclusions

Altogether, this knowledge will contribute to a better understanding of *Pseudomonas*-insect interactions and to develop future biocontrol strategies for insects on top of diseases.

EVOLUTIONARY HISTORY OF FUNGAL VERSATILE-LIPASES FROM THE ORDER AGARICALES

J. Barriuso[1], *M.J. Martínez*[1]
[1]*Centro de Investigaciones Biológicas CIB-CSIC, Environmental Biology, Madrid, Spain*

Backgrounds

Lipases (EC 3.1.1.3) and sterol esterases (EC 3.1.1.13) are thoroughly used in industrial applications. Among fungi some extracellular proteins combine properties of both enzymes, and there are known as “Versatile carboxylic ester hydrolases” (abH03.01). Agaricales is the largest clade of mushroom-forming fungi and one of the most ancient orders, comprising wood saprophytes with biotechnological interest. On the other hand, the *in silico* mining of fungal genomes and metagenomes has been shown as an alternative for searching novel lipases, while exploring the evolutionary history and resurrecting intermediate ancestral forms of enzymes can help to explain the mechanistic basis of enzymes function and disclose new functionalities.

Objectives

In this work we explored the presence of genes encoding putative “Versatile lipases” from the order Agaricales. We reconstructed the molecular evolution of these enzymes and inferred the sequence of their ancestral intermediate forms. The potential properties of the candidates are discussed on the basis of their three-dimensional (3D) model structure, the presence and hydrophobicity of the lid, and the substrate binding tunnel.

Methods

We used conserved motifs, sequence and phylogenetic analyses, and three-dimensional modeling to look for candidate genes in public fungal genomes. Moreover, we reconstructed the molecular evolution of these enzymes using novel phylogenetic approaches (PAML4.8).

Conclusions

The evolutionary history of the putative lipases revealed an increase on the length and hydrophobicity of the lid region, as well as in the size of the substrate binding pocket, during evolution time. These facts suggest the enzymes’ specialization towards certain substrates and their subsequent loss of promiscuity.

LESS IS MORE: HYDROLYSIS OF POLYESTERS IS ENHANCED BY A TRUNCATION OF AN ESTERASE

A. Biundo[1], R. Doris[2,3], G. Steinkellner[4], K. Gruber[5]
[1]Polymer and Environmental Biotechnology, Austrian Centre of Industrial Biotechnology, Tulln, Austria
[2]Institute for Environmental Biotechnology, Department of Agrobiotechnology- IFA-Tulln, Tulln, Austria
[3]Polymers and Environmental Biotechnology, Austrian Centre for Industrial Biotechnology, Tulln, Austria
[4]Austrian Centre of Industrial Biotechnology, Austrian Centre of Industrial Biotechnology, Graz, Austria
[5]Institute of Molecular Bioscience, University of Graz, Graz, Austria

Backgrounds

Polymers frequently used for one-way applications like packaging are preferably biodegradable, albeit non-biodegradable polyesters are mostly used. Biodegradability of the aliphatic/aromatic copolyester poly(butylene adipate-*co*-terephthalate) (PBAT) has been investigated, showing biological decomposability under composting conditions. However, little is known about its anaerobic hydrolysis while large amount of food packaging ends up in biogas plants. The enzyme EstA from *Clostridium botulinum* (Cbotu_EstA) actively hydrolyzed PBAT while it failed to act on polyethylene terephthalate (PET). Yet, enzymes would allow mild decomposition of widely used PET enabling recycling of the monomeric building blocks.

Objectives

The enhancement of the hydrolase activity with regard to polyester hydrolysis was carried out by fusion of hydrophobic domains, improving the biocatalyst adsorption on the hydrophobic polymer surface, or by substitution of specific residues, enlarging the active site of the enzyme. The deletion of the Cbotu_EstA N-terminal domain can satisfactory combine both approaches.

Methods

The 3D structure analysis of Cbotu_EstA revealed the presence of an N-terminal domain covering the lid structure and a hydrophobic patch. Chemoluminescence and HPLC analysis determined the adsorption onto hydrophobic surfaces and the hydrolyzing activity of the enzyme, respectively. Furthermore, analysis of the kinetic constants made the catalytic activity investigation of the two forms of the enzyme possible.

Conclusions

Surface engineering successfully produced a highly active Cbotu_EstA variant which was able to hydrolyze PET. Truncation of the N-terminal domain of Cbotu_EstA improved the adsorption of the enzyme on hydrophobic polyester surfaces and enhanced their hydrolysis eight times more compared to the wild-type enzyme, based on released monomers quantification.

CARBOXYLATE PLATFORM CHEMICALS AND BIOFUELS FROM BIOWASTE

E. Hakalehto[1,2], S. Schwede[3], R. Laatikainen[4], E. den Boer[5], L. Piiroinen[1]
[1]Finnoflag Oy, P.O. Box 262, 70101 Kuopio, Finland
[2]Department of Agricultural Sciences, University of Helsinki, Helsinki, Finland
[3]School of Business, Society and Engineering, Mälardalen University, Västerås, Sweden
[4]School of Pharmacy, University of Eastern Finland, Kuopio, Finland
[5]Wrocław University of Science and Technology,
Department of Environmental Protection Engineering, Wroclaw, Poland

Backgrounds

A significant share of the fuels and chemicals used in the economy could be replaced by substances produced from biomass sources. Recent international and European development strategies attribute high priority to the growth of bioeconomy sector. A radical change of production, consumption, processing, storage, recycling and disposal of biological resources is needed, in order to cope with an increasing global population, rapid depletion of many resources, increasing environmental pressures and climate change.

Objectives

Micro-organisms provide tools for circulating the substances in the industrial ecosystems. This paper focuses on the production of carboxylic platform chemicals from industrial and municipal kitchen biowaste using non-aceptic conditions. Verification of this technology has been done based on pilot tests in 3 regions – in Finland, Poland and Sweden.

Methods

The biorefinery technology was implemented in a pilot scale with effective reactor volumes of 200-300 L under anaerobic and microaerobic conditions. The production organisms belonged to the genera *Clostridium* and *Klebsiella*. Selected biowaste streams were subjected to enzymatic pretreatment prior to the inoculation.

Conclusions

The results showed high conversion rates achieved from mixed substrates. The dominating end products were volatile fatty acids (VFAs), ethanol and CO_2. Lower levels of other gases, such as H_2, CH_4 and H_2S, were formed. The conversion rates of glucose to the main fermentation products reached up to 0.81 mol/mol. Valeric acid was one of the main VFA products from the potato waste carbohydrates, whereas in trials on chicken litter, the valerate derived mostly from the amino acids of the biowaste proteins.

[3]University of Huelva, Department of Chemical engineering-
Physical Chemistry and Materials Science, Huelva, Spain
[4]University of Huelva,
Department of Chemical engineering- Physical Chemistry and Materials Science, Huelva, Spain

Backgrounds

Lignin is an aromatic biopolymer traditionally considered a waste product in industrial processes and agricultural practices causing serious pollution problems. At present, lignin is considered a renewable biopolymer for biotechnological applications. The suitability of *Streptomyces* to solubilize lignin from grasses residues, instead of to mineralize this polymer, could be a good strategy for biotechnological purposes.

Objectives

The aim of this work is to set up the optimal conditions to solubilize lignin from agricultural residues using selected *Streptomyces* strains to be applied for oleogels elaboration.

Methods

Different *Streptomyces* strains were cultured for 7 days under Solid-State Fermentation conditions (SSF) on agricultural residues. Transformed substrates were extracted with water or 0.1 M NaOH and extracts were acidified with HCl. Finally, water or alkali-extracted lignin were gravimetrically estimated. Moreover, xylanase, mannanase and laccase activities were determined along the time course of growth. Selected strains were also cultured under SSF conditions supplemented with radicals promoting agents such as quinones and Fe^{3+}-EDTA. Prior to this, the Fe^{3+} content of substrates (60 ± 3 µg g^{-1}) were determined by Atomic Absorption Spectrophotometry. For oleogels preparation alkali-lignin was modified with 1,6-hexamethylene diisocyanate.

Conclusions

An increase in 10-20% of alkali-lignin yield was achieved with selected strains compared to that obtained from uninoculated substrates.

Under radical producing conditions, the colonization ability of strains was not affected being the yield of water-extracted lignin 20 % higher than that obtained in non-supplemented cultures with radical production promoters.

Preliminary assays carried out with oleogels elaborated with alkali-lignin showed suitable thermal resistance and rheological characteristics.

CONSTRUCTION AND CHARACTERIZATION OF MICROBIAL CONSORTIA FOR KERATIN DEGRADATION

D. Kang[1], S. Jacquiod[2], J. Herschend[1], S.J. Sørensen[1]
[1]University of Copenhagen, Department of Biology, Copenhagen, Denmark
[2]INRA, UMR 1347 Agroécologie, Dijon, France

Backgrounds

Europe, especially Denmark, heavily relies on import of soy protein for feed in its animal production. Keratins refer to a group of insoluble, tough and recalcitrant protein material generated in large quantities as a waste-product in commercial slaughterhouses, originating from bristles and hooves. Utilization of microbial consortia can play a crucial role as natural biodegradation process for keratin. It can be transformed into more valuable feedstock through the release of small peptides and amino acids by microbial degradation.

Objectives

Identify microbial communities for keratin degradation and construction of stable microbial consortia for industrial applications.

Methods

A soil-born microbial consortium was enriched on keratin as the sole carbon source in sequential batch cultivations at room temperature and characterized by application of next generation sequencing and specific keratin degradation assays.

Conclusions

During six enrichment cycles, the procedure selected for stable and efficient keratin degrading microbial consortia, mainly constituted by members of bacteroidetes and proteobacteria phyla. For the sake of industrial applications, we used a dilution-based method to reduce the diversity and isolate key component strains involved in efficient keratin degradation, while excluding potential cheaters and ease of controllable outputs. The consortia were structurally stable with the co-existence of four major microbes, comprising aerobic bacterial genera *Chryseobacterium*, *Stenotrophomonas*, *Pseudochrobactrum, Acinetobacter*. Residual substrates proportion is similar when comparing with using the microbial consortium without dilution and approximate 20% after five days. This work has potential applications for a vast range of areas including food and feed, fisheries, biotechnologies and agriculture.

OPTIMIZATION OF A FAST AFFINITY ADSORPTION PURIFICATION METHOD OF FUNCTIONAL LPMOS

S. Valenzuela[1], *G. Ferreres*[1], *G. Margalef*[1], *M. Rodríguez-Astigarraga*[1], *F.I.J. Pastor*[1]
[1]*University of Barcelona, Department of Genetics- Microbiology and Statistics, Barcelona, Spain*

Backgrounds

The recently discovered LPMOs are crucial enzymes for the deconstruction of recalcitrant macromolecules, including lignocellulosic and chitin polymers, thus represent a promising component of industrial cocktail enzymes for degrading biomass. The LPMOs are metalloenzymes that oxidize glycosidic bonds and the catalysis requires the binding of an active oxygen molecule to the copper atom of the enzyme for the oxidative depolymerization of the substrate. Depending on the type of LPMO, the products released are gluco-oligosaccharides that are oxidized either at the reducing (C1) or in both, the reducing (C1) and the non-reducing (C4) end (3).

Objectives

To develop a simple and low-cost method for recombinant LPMOs purification.

Methods

We have cloned two orfs encoding for putatives LPMOs from *Streptomyces ambofaciens*, which is a soil bacterium industrially exploited for the production of antibacterial chemicals. We established a purification method for these enzymes based on the ability of the recombinant LPMOs to bind polysaccharides. In addition, one of the produced LPMOs, named SamAA10C was tested against a variety of cellulosic substrates, including for the first time for an LPMO, bleached pulps used in the paper industry.

Conclusions

We developed a simple and fast method to purify LPMOs in a single step without using any chromatographic column or periplasmic preparation, considerably reducing time used in others studies for the purification step. The purification method introduced for the LPMOs could be a cheap solution, to use these enzymes in industrial applications, and the activity of SamAA10C show the potential of LPMOs in biomass upgrading.

FROM GRASS TO GAS: MICROBIOME DYNAMICS OF GRASS BIOMASS ACIDIFICATION UNDER MESOPHILIC AND THERMOPHILIC TEMPERATURES

C. Abendroth[1], C. Simeonov[2], J. Peretó[1], O. Antúnez[3], R. Gavidia[3], O. Luschnig[4], M. Porcar[1]
[1]Institute for Integrative Systems Biology I2SysBio- University of Valencia-CSIC, Biotechnology, València, Spain
[2]Robert Boyle Institut e.V., Anaerobic Digestion, Jena, Germany
[3]Universitat de València, Servicio Central de Soporte a la Investigación Experimental, València, Spain
[4]Bio H2 Umwelt GmbH, Anaerobic Digestion, Jena, Germany

Backgrounds

Separating acidification and methanogenic steps in anaerobic digestion processes can help to optimize the process and contribute to producing valuable sub-products such as methane, hydrogen and organic acids. However, the full potential of this technology has not been fully explored yet.

Objectives

The aim of this work was to finely characterize the acidification as one of the most important phases of the biogas production process.

Methods

To assess the underlying fermentation process in more detail, we applied for the first time a combination of high throughput sequencing and proteomics on the acidification step of plant material (grass) at both mesophilic and thermophilic temperatures (37 ºC and 55 ºC, respectively).

Conclusions

High strength liquor from acidificated grass biomass exhibited a low biodiversity and was proved very different depending on the temperature. It was dominated by Bacteroidetes and Firmicutes at 37 ºC, and by Firmicutes and Proteobacteria at 55 ºC.

In the methane stage, *Methanosaeta*, *Methanomicrobium* and *Methanosarcina* proved very sensitive to environmental changes as their abundance in the seed sludges dropped drastically after transferring the seed sludges from the respective reactors into the experimental set up. Further, an increase in Actinobacteria coincided with reduced biogas production in the end of the experiment.

Temperature proved a key parameter affecting both taxonomic and proteomic profiles, which were strikingly diverse at 37 ºC and at 55 ºC. Our results suggest that screening approaches targeting *Methanosaeta, Methanomicrobium* and *Methanosarcina* could be useful diagnosis tools as indicators of environmental changes as for example temperature or oxidative stress.

GENOME-SCALE METABOLIC RECONSTRUCTION OF ARTHROSPIRA PLATENSIS PCC9108 AS A TOOL TO IMPROVE ITS TECHNOLOGICAL AND NUTRITIONAL PROPERTIES

L. Agudo[1], *J.L. García*[1], *J. Nogales*[1]
[1]*Centro de Investigaciones Biológicas CIB-CSIC, Environmental Microbiology, Madrid, Spain*

Backgrounds

Arthrospira (Spirulina) *platensis* is one of the most valuable cyanobacteria and widely used as source of added-value compounds, and as feeding due its nutraceutical properties. Elusive so far to genetic manipulation, the improvement of its natural properties by metabolic engineering approaches is challenging. Nonetheless, the increasing development of the metabolic reconstruction field allows the systematically analysing of bacterial metabolic capabilities, at genome-scale. Hence, system biology will becomes a powerful tool to identify new rational ways of improving the biotechnological properties of Spirulina.

Objectives

Analyzing the metabolic properties of *Arthrospira platensis* PCC9108 through Systems Biology approaches.

Methods

We sequenced and annotated the genome of *Arthrospira platensis* PCC9108 using PacBio and RAST server, respectively. Furthermore, we reconstructed a manually curated, full compartmentalized, and mass and charge balanced genome-scale metabolic reconstruction, based on well-known procedures (Nogales, 2014). Finally, we analyze the metabolic features of Spirulina, emphasizing on light's metabolism by means of Constraint-Based Reconstruction and Analysis (COBRA) approach (Lewis et al., 2012).

Conclusions

Based on the genome annotation and metabolic knowledge available, we have constructed one of the most complete cyanobacterial genome-scale metabolic models (*i*LA649). *i*LA649 includes 649 genes, 788 reactions and 749 metabolites. In addition *i*LA649 accounts for a detailed modelling of the light-harvesting as well as a large array of condition-specific biomass objective functions. The potential of *i*LA649 as computational tool for Spirulina based photoenginiering endeavours will be discuss.

NEW GLYCOSIDES FROM A STREPTOMYCES SP. DISCOVERED BY A COMBINATION OF BIOASSAY AND CHEMICAL SCREENING

J.S. Ahn[1], S. Son[1], J. Mina[1], S.K. Ko[1], J.H. Jang[1]
[1]Korea Research Institute of Bioscience and Biotechnology, Anticancer Agent Reseach Center, Cheongju, Republic of Korea

Backgrounds

A number of bacterial metabolites are currently used as pharmaceutically important compounds, and they continue to capture a significant part of new molecular entities of FDAs-approved drugs, demonstrating a continuous search for novel bacterial metabolites is still valuable.

Objectives

In that context, we have screened new bioactive small molecules produced by actinomycetes strains isolated from the soil samples collected from Ulleung Island, a small volcanic island in the Korean East Sea, contains richly diverse microorganisms.

Methods

The cultured extracts of isolated actinomycetes were screened through dereplication strategy based on the results from *in vitro* indoleamine 2,3-dioxygenase (IDO) inhibition assay and HPLC-PDA-MS analysis.The chemical structures were elucidated by detailed NMR and MS spectroscopic analyses. And absolute configurations of the sugar units were determined by the magnitudes of the coupling constants, NOESY correlations, chemical derivatization, and optical rotation measurements.

Conclusions

In the course of screening, we could isolate six secondary metabolites including three new rare glycosides inhibiting IDO enzyme activity from *Streptomyces* sp. KCB13F030. The isolated compounds showed anti-proliferative activities against cancer cell lines and effects on autophagy by observing GFP-LC3 puncta formation in GFP-RFP-LC3 stably expressing HeLa cells. Feeding experiments using resveratrol as a substrate afforded two new mono-glycosylated resveratrols, suggesting the talosylation potential of the strain.

FERMANTATION OF WHEY POWDER TO BIOETHANOL BY VITREOSCILLA HEMOGLOBIN EXPRESSING E. COLI

M.Y. Akbas[1], *T. Sar*[1], *G. Seker*[1], *A.G. Erman*[1]
[1]*Gebze Technical University, Molecular Biology and Genetics, Gebze-Kocaeli, Turkey*

Backgrounds

Bioethanol is the most widely used biofuel for transportation because it is nontoxic and renewable. Cheese whey an inexpensive and abudant food processing waste, could be a promising feedstock for bioethanol production. *Vitreoscilla* Hemoglobin (VHb), the best characterized prokaryotic hemoglobin, enhances respiration under microaerobic conditions. Engineering of bacteria to express VHb has resulted in increased production of many industrially important products.

Objectives

The possible enhancement of ethanol production from whey powder containing media by using *Vitreoscilla* hemoglobin expressing E.coli strains was investigated.

Methods

Ethanol production from whey powder was investigated by using free and immobilized ethanologenic *E. coli* strain FBR5 and bacterial hemoglobin (*Vitreoscilla* hemoglobin, VHb) expressing strain TS3 in different concentrations of whey powder containing fermentation media.

Conclusions

The highest ethanol production was determined by combination of VHB with immobilization by using a medium with an intermediate concentration of lactose. Immobilization of VHb-expressing ethanologenic *E. coli* was found to be a useful approach for ethanol production from whey powder.

PYROLYZED BACTERIAL CELLULOSE AS AN ANODE MATERIAL IN LITHIUM-ION BATTERIES

M.Y. Akbas[1], T. Sar[1], B. Dursun[2], G. Seker[1], A.G. Erman[1], R. Demir-Cakan[3]
[1]Gebze Technical University, Molecular Biology and Genetics, Gebze-Kocaeli, Turkey
[2]Gebze Technical University, Material Science and Engineering, Gebze-Kocaeli, Turkey
[3]Gebze Technical University, Chemical Engineering, Gebze-Kocaeli, Turkey

Backgrounds

There is an increasing demand for a flexible, non-toxic and facile production method for rechargeable batteries used in portable electronic devices. Lithium-ion batteries are one of the appropriate rechargeable batteries due to their higher energy density.

Graphite is widely used as an anode material in lithium-ion batteries. However, graphite anodes have low charge / discharge current density and relatively low capacity. Thus, to find alternative high capacity anode materials at low cost have attracted great attention. Biological materials can be served as attractive carbon materials for energy storage. Among the biological materials, bacterial cellulose (BC) is produced by a bacterium *G.xylinus*. BC which is porous, economic and easy to produce material in large amounts.

Objectives

The potential use of pyrolyzed bacterial cellulose was investigated as an anode material in lithium-ion batteries.

Methods

BC samples were produced and pyrolyzed to yield carbonaceous material under Ar atmosphere at different temperatures. The electrochemical performances of pyrolyzed BCs were evaluated over the 300 cycles.

Conclusions

Pyrolyzed BCs samples showed stable discharge capacities. BC could be used as a potential anode material in Lithium-ion batteries.
This work was supported by the Scientific and Technological Research Council of Turkey (TUBITAK, 115M390).

EFFECT OF CONTACT-DEPENDENT GROWTH INHIBITION (CDI) ON BIOFILM FORMATION OF E.COLI 25922

M.H. Akyıl[1], N. Cihangir[1], S. Genç[1], M. Sayın[1]
[1]Hacettepe University, Biology, Ankara, Turkey

Backgrounds

Contact-dependent growth inhibition CDI is a mechanism of inter-bacterial competition, it has been firstly observed in *E.coli* isolate EC93. CDI is mediated by the CdiB/CdiA two partner secretion proteins. The CdiA effector extends from the surface of CDI(+) inhibitor cells, binds to receptors on neighbouring bacteria and delivers a toxin domain derived from its C-terminal region (CdiA-CT). The C-terminal domain typically possesses toxic nuclease activity, whereas the N-terminal domain appears to control toxin transport into target bacteria. Biofilm is an assemblage of microbial cells that is irreversibly associated with a surface and enclosed in a matrix of primarily polysaccharide material. In previus studies it was shown that disruption of the cdi locus abrogates biofilm formation.

Objectives

We aimed that compare biofilm formation *E.coli* 25922 (CDI^+)with *E.coli* 25922 ΔcdiA (CDI^-).

Methods

In silico analysis of *E.coli* 25922 genome revealed that the WP_038429283 loci contain characteristic features of a CDI locus. Datsenko-Wanner's "One step inactivation" protocol were used to obtain *E.coli* 25922 ΔcdiA. Biofilm formation assays were performed following a previously described method (Danese et al. 2000) with few modifications.

Conclusions

We determined that there are positive correlation between CDI gene and biofilm formation. It is estimated that on adhesion step, CDI has an effective rol. Consequently CDI gene can be considered as a control mechanism that induces biofilm.

ANTI-BIOFILM ACTIVITY OF THE METABOLITES OF STREPTOMYCES ISOLATES AGAINST ENTEROBACTERIACEAE

M.H. Akyıl[1], *N. Cihangir*[1]
[1]*Hacettepe University, Biology, Ankara, Turkey*

Backgrounds

More than 70% of naturally occurring antibiotics have been isolated from different genus of Actinomycetes. As with the other Actinobacteria, Streptomycees are Gram-positive, and have genomes with high GC content. Streptomyces produce complex secondary metabolites. These metabolites are very efficient and useful for the treatment of bacterial disease, cancer and biofilm formation. The Enterobacteriaceae are a large family of Gram-negative bacteria that includes many pathogens, *Salmonella, Escherichia coli, Yersinia pestis, Klebsiella*, and *Shigella.*

Objectives

The main purpose of this study is to investigate the antibiofilm effect of metabolites that isolated from various Streptomyces aganist; *E.coli* ATCC® 25922, *Salmonella bongori* ATCC® 43975, *Shigella flexneri* ATCC® 12022, *Klebsiella pneumoniae* ATCC® 700603.

Methods

We produced various metabolites from Streptomyces that we isolated from soil. 20 different Streptomyces was used for this research. Initially we investigated animicrobial effects of these metablites against determined microorganisms. Finally we studied the effects of these metabolites on *E.coli* ATCC® 25922, *Salmonella bongori* ATCC® 43975, *Shigella flexneri* ATCC® 12022, *Klebsiella pneumoniae* ATCC® 700603 biofilm formation. The antibacterial activity of pure isolates was determined by cross-streak method on Mueller Hinton Agar (MHA). Biofilm formation assays were performed following a previously described method (Danese et al. 2000) with few modifications.

Conclusions

We determined that same metabolites has antimicrobial quality and also antibiofilm activity but some of them is ineffective on biofilm formation. We estimated that this result is because of the metabolites mechanism of actions or because of biofilm formation speed.

EFFICACY OF BCG PASTEUR AND MTBVAC IN IMMUNOTHERAPY OF BLADDER CANCER: IN VITRO AND IN VIVO MODEL

S. Alvarez-Arguedas[1], *C. Martín*[1], *N. Aguiló*[1]
[1]*Mycobacterial Genetic Group,*
Department of Microbiology- Preventive Medicine and Public Health. Universidad de Zaragoza, Zaragoza, Spain

Backgrounds

In 2012, there were globally reported around 430,000 new cases and 165,000 deaths due to bladder cancer. The most commonly used bladder cancer immunotherapy is the current vaccine against tuberculosis called bacillus Calmette-Guerin (BCG) (Brandau, Biom. & Pharm., 2007). In the development of a new tuberculosis vaccine for replacing BCG (Arbués, Vaccine, 2013), we studied the effect of our candidate vaccine MTBVAC on the treatment of bladder cancer.

Objectives

1) Comparison of *in vitro* interaction of MTBVAC and BCG with human established bladder cancer cell lines. 2) Efficacy of MTBVAC and BCG in a murine model of bladder cancer.

Methods

In vitro cultures of established cell lines T24 and J82 (human origin) at different multiplicities of infection (MOI) with BCG Pasteur-GFP or MTBVAC-GFP (these strains constitutively express the GFP). The percentage of infection, cell death and internalization mechanism were studied by Flow Cytometry and Confocal Microscopy. Additionally, we use a murine model of bladder cancer based in MB49-luc (this strain expresses the luciferase enzyme) to compare the survival differences between the treatment with BCG or MTBVAC.

Conclusions

MTBVAC showed a significantly higher capacity of infection at 4 and 7 days compared to BCG Pasteur. Accordingly, MTBVAC also produced a higher cell death of tumor cells than BCG Pasteur. On the other hand, both vaccine strains enter into the tumor cells by macropinocytosis but the organelles that contain them have different pH values. Finally, the survival rate of the mice treated with MTBVAC are significantly higher than those with BCG.

A POLY-EXTREMOPHILIC PEROXIDASE FROM A HALOTOLERANT BACTERIUM, KOCURIA PALUSTRIS STRAIN BW

M.A. Amoozegar[1], *M. Siroosi*[1], *K. Khajeh*[2]
[1]*University of Tehran - Tehran - Iran, Biology, Tehran, Iran*
[2]*Tarbiat Modares University, Biology, Tehran, Iran*

Backgrounds

Dye-decolorizing peroxidase is a new superfamily of haem-peroxidases isolated from fungi and bacteria. Dye-decolorizing peroxidases, as a new group of peroxidases, are potent biocatalysts to decolorize various dyes which makes them appropriate options for bioremediation of wastewaters contaminated with dyes

Objectives

In the present work, the peroxidase from a halotolerant bacterium, *Kocuria palustris* strain BW isolated from Badab Sourt spring in northern Iran was partially purified and then, characterized. Also, decolorization activity of the peroxidase was tested on two different dyes, aniline blue and toluidine blue.

Methods

Ammonium sulfate precipitation and thermal treatment methods were used to partial purification of the enzyme. In order to assay peroxidase activity spectrophotometrically, H2O2 was added to the enzymatic reaction mixture contained 50 mM citrate-phosphate buffer (pH 3), 4.5 M NaCl, appropriate amount of enzyme, and 0.5 mM ABTS at 90 °C and the increase in the absorbance at wavelength of 420 nm was followed.

Conclusions

Among 100 different bacterial strains screened for peroxidase activity on a solid culture medium supplemented with guaiacol, one bacterial strain showed reddish-brown color around its colony, the sign of peroxidase activity. According to 16S rRNA gene sequence, the strain showed 100 % similarity to *K. palustris* DSM 11925. The partially purified peroxidase showed poly-extremophilic nature and its optimum activity was at 90 ºC, pH 2.2-3, and 4.5 M NaCl. Decolorization study showed that the peroxidase decolorized both dyes up to 50% at optimum pH of 2.2. The study is the first report on poly-extremophilic peroxidases isolated from a halotolerant bacterium.

THE ORPHAN RESPONSE REGULATOR AOR1 FROM STREPTOMYCES COELICOLOR IS A NEW PIECE IN THE PUZZLE OF THE REGULATION NETWORK OF ANTIBIOTIC PRODUCTION

S. Antoraz[1], S. Rico[1], H. Rodriguez[2], M. Díaz[1], R. Santamaría[1]
[1]Salamanca University, Instituto de Biología Funcional y Genómica IBFG, SALAMANCA, Spain
[2]CIC bioGUNE, Molecular recognition and Host-Pathogen interactions, Bizkaia, Spain

Backgrounds

Antibiotic production in *Streptomyces coelicolor* responds to different environmental signals, both physicals (pH, temperature...) and chemicals (nutrients, activators...), through a complex signalling network. Recognisance of these stimuli is performed mainly through Two Component Systems (TCS). Usually, TCSs are composed by a histidine kinase (HK) and a response regulator (RR), forming a single operon in the genome, but also exist HKs and RRs without its partner, the so-called orphans. Presence of orphan genes may serve as a way of increasing the response capacity in the cell, expanding regulatory network's complexity.

Objectives

In this work we try to elucidate the role of one of these orphan regulators, Aor1 (Antibiotic Orphan Regulator), that apparently has great importance in antibiotic production in *S. coelicolor* and differentiation.

Methods

We have obtained the deletion mutant (Δ*SCO2281*) in S. *coelicolor* that allowed us to demonstrate that this orphan RR is involved in the positive regulation of antibiotic production and differentiation. This mutant is drastically affected in endogenous antibiotic biosynthesis of actinorhodin, undecilprodigiosin and calcium dependent antibiotic. We have also evidence that shows a possible relation between this RR and the TCS AbrC. On the other hand, we have demonstrated, by q-RT-PCR, that gene *aor1* is part of a four gene operon (*SCO2279-2282*).

Conclusions

RR Aor1 seems to have an important role in antibiotic production in *S. coelicolor*, and its study adds significant information about this main piece in the puzzle that could serve for unveiling the complex antibiotic regulatory network in *Streptomyces.*

ANAEROBACULUM HYDROGENIFORMANS ESTERASE (AHEST): A NEW THERMOSTABLE ESTERASE FOR BIOTECHNOLOGICAL APPLICATIONS

R. Gutierrez[1], J.M. Martins[1], P.S. Kumagai[1], A.M. Castro[2], J.L. Lopes[3], A.P. Araujo[1]
[1]University of São Paulo, Physics Institute of Sao Carlos, Sao Carlos, Brazil
[2]Petrobras, CENPES - Petrobras Research & Development Center, Rio de Janeiro, Brazil
[3]University of São Paulo, Physics Institute, Sao Paulo, Brazil

Backgrounds

Enzymes produced by thermophiles are of interest for biocatalysis because they are stable and active at high temperatures. Additionally, enzymes that are functional in the presence of organic solvents are highly required as biocatalysts, particularly where substrate solubility is limited. Searching for esterases with these attributes, we have identified *in silico* AhEst, a potential esterase from Anaerobaculum hydrogeniformans. The enzyme was produced as a recombinant protein in *E. coli* and used in biochemical and biophysical characterization studies.

Objectives

This study was focused on the evaluation of enzymatic activity and structural stability of the esterase AhEst, in the presence of organic solvents and under increasing temperatures.

Methods

The protein was purified and used for activity assays in the absence or presence of 10% and 20% of ethanol or isopropanol at 25, 45 and 65°C. The activity was measured by the release of *p*-nitrophenol hydrolyzed from the *p*-nitrophenylacetate. Synchroton Radiation Circular Dichroism measurements (SRCD) were used to evaluate the structural stability of AhEst in the same organic solvents described above.

Conclusions

Our results shown that in the presence of ethanol 10% there was no change on enzymatic activity. In isopropanol 10% we observed a significant increase (>20%) in the esterase activity and in 20% of ethanol or isopropanol, AhEst still preserved a high esterase activity (80 to 100%) in all temperatures. SRCD spectra of AhEst showed a high structural and thermal stability in all conditions, agreeing with activity findings. Concluding, AhEst is now available to be used in biocatalytic processes that require extreme conditions.

EXPANDING THE GENE REGULATORY NETWORK IN RESPONSE TO OSMOTIC STRESS IN THE HALOPHILE CHROMOHALOBACTER SALEXIGENS

M. Argandoña[1], R. Garcia-Valero[1], A. Tahrioui[1], J.J. Nieto[1], C. Vargas[1]
[1]University of Sevilla, Microbiology and Parasitology, Sevilla, Spain

Backgrounds

Chromohalobacter salexigens is a broad-growing halophilic bacterium considered as a biological model to study osmoadaptation and a cell factory for the production of ectoines, biostabilizing compatible solutes which have many biotechnological applications. To design new metabolic engineering strategies to obtain improved ectoines production strains of *C. salexigens,* a preliminary transcriptional regulatory network (TRN) core was reconstructed by using an integrative approach that combined RNAseq data from wild type strain and different *in silico* analyses. This core network, constituted by 598 genes and 1192 regulatory interactions, was used to analyse molecular regulation events involved in metabolic osmotic stress response and ectoines metabolism

Objectives

To expand the preliminary osmoregulatory network core involving RNA-seq data analysis of two global regulators knockouts: EupR, a response regulator of a two component system that controls both central an ectoines metabolism, and RpoS, a sigma factor involved in central metabolism and osmoadaptation.

Methods

eupR^{-} and *rpoS*$^{-}$ strains were grown at 0.6 and 2.5 M of NaCl (low and high ectoines production conditions respectively). Three replicates of cells were processed for RNA-seq. After analysis of differential gene expression, metabolic and regulatory genes were selected and included in the previous transcriptional regulatory network core.

Conclusions

Subnetwork analysis pointed TFs that were involved in metabolic salinity-dependent response and/or controlled by EupR or RpoS. These results will be used for further development of a hybrid model to connect the metabolic network of *C. salexigens* with its TRN by using a Systems Biology approach

VERSATILITY OF THE ALKALINE LACCASE PRODUCED BY STREPTOMYCES IPOMOEAE CECT 3341 FOR BIOTECHNOLOGICAL AND ENVIRONMENTAL APPLICATIONS

M.E. Arias[1], A. Blánquez[1], J. Rodríguez[1], M.E. Eugenio[2], R. Martín-Sampedro[2], M. Hernández[1]
[1]University of Acalá, Department of Biomedicine and Biotechnology, Alcalá de Henares, Spain
[2]Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria INIA-CIFOR, Departamento de Productos Forestales, Madrid, Spain

Backgrounds

Laccases (E.C. 1.10.3.2) are considered appropriated tools for biotechnological purposes. In our group, lacasse produced by *Streptomyces ipomoeae* CECT 3341 (SilA) have been fully characterized. The most remarkable features of this bacterial enzyme are the halotolerance and the activity and stability at alkaline pHs. Based on these characteristics the enzyme can be considered as an eco-friendly strategy to solve environmental and technological problems.

Objectives

The aim of this study was to show up the efficiency of SilA laccase for the following purposes:

i) decolourization and detoxification of textile azo-dyes; *ii*) degradation and detoxification of quinolone based antimicrobials and, *iii*) biobleaching of eucalyptus kraft pulp.

Methods

Recombinant SilA laccase was used in the presence or absence of phenolic compounds as mediators. The suitability of laccase-mediator systems (LMS) for decolourization of azo-dyes (Tartrazine and Orange II) and degradation of Ciprofloxacin and Norfloxacin was screened by HPLC-DAD. The detoxification assays were carried out using Algaltoxkit. In addition, the effect of SilA-acetosyringone system on the biobleaching of eucalyptus kraft pulp was studied measuring kappa number, viscosity and CIE l*a*b coordinates.

Conclusions

SilA-acetosyringone system produced azo-dyes decolourization and fluoroquinolones degradation with an 80-90 % efficiency. Moreover, this system was able to detoxify most of assayed pollutants although no direct correlation between degradation and detoxification was observed for Ciprofloxacin. Finally, biobleached pulps with LMS showed a kappa number decrease and a brightness increase without decreasing the viscosity values. CIE *L*a*b** color coordinates demonstrated that biobleached pulps presented the best optical properties even after an accelerated ageing process was applied.

MORPHOLOGICAL AND PHYSIOLOGICAL CHANGES OF CLOSTRIDIUM BEIJERINCKII NCIMB 8052 DURING BATCH BUTANOL PRODUCTION

I. Paredes[1], K. Guerrero[1], J. Quintero[1], R. Gallardo[1], G. Aroca[1], J.C. Gentina[1], R. Conejeros[1]
[1]Pontificia Universidad Católica de Valparaíso, Escuela de Ingeniería Bioquímica, Valparaiso, Chile

Backgrounds

The main characteristic of solvent production by *Clostridium sp*. is that the fermentation typically proceeds in two phases, acids are formed first, followed by solvents production. Both acids and solvents present in the broth influence the physiological state of the population, and in the case of acids, it is believed that they contribute to the initiation of sporulation. However, these two phases have been only distinguished in *C. acetobutylicum*. In some cases, these phases are not clearly separable but currently these kinds of systems are not well studied. The relationship between transition from acidogenic to solventogenic and sporulation are still unclear.

Objectives

To assess the morphological and physiological changes of *Clostridium beijerinckii* NCIMB 8052 during batch ABE fermentation and to associate these changes with cell growth and acids and solvents production.

Methods

Clostridium beijerinckii was grown in a 2 L laboratory fermentor at 300 rpm, 37°C and controlled pH. Samples were analyzed by spectrophotometry for biomass, HPLC for dextrose and acids, and GC for butanol, ethanol and acetone. The morphological changes were followed by flow cytometry, staining and fluorescence microscopy.

Conclusions

The morphological and physiological changes of *C. beijerinckii* during batch cultivation are not synchronized for the whole population, but rather a heterogeneous distribution of morphologies can be found at different times. The staining methodology allowed to differentiate morphological forms of the *C. bejerinckii* cells during the fermentation. Due to the evident changes in the cell-wall during the evolution of the fermentation, different interaction with the Syto-9 and PI dyes were observed.

Biotechnology / Synthetic Biology / Systems Biology

COMBINATORIAL BIOSYNTHESIS OF NATURAL AND NON-NATURAL PLANT-DERIVED PHENOLS IN MICROORGANISMS

J. Aschenbrenner[1], *J. Marienhagen*[1], *M. Bott*[1]
[1]*Forschungszentrum Jülich, Institute of Bio- and Geosciences IBG-1: Biotechnology, Jülich, Germany*

Backgrounds

The group of plant (poly)phenols comprises a larger number of secondary metabolites with a huge potential for applications in food and pharmaceutical industries (e.g. as flavours, colourants, therapeutic agents, antibiotics, etc.). Enzymes related to the phenylpropanoid metabolism are believed to have a rather broad substrate spectrum and thus might be able to accept a variety of different substrates.

Objectives

An *Escherichia coli* strain harbouring a synthetic pathway for phenylpropanoid synthesis will be constructed and evaluated for the possibility to convert chemically synthesized precursors to the respective monolignols. These alcohols will serve as building blocks for the (microbial) synthesis of larger compounds of pharmacological interest.

Methods

E. coli BL21 (DE3) was engineered for the plasmid-based expression of four genes encoding for four enzymes of the complete phenylpropanoid pathway starting from aromatic amino acids. The genes are organized as a synthetic operon under the control of an inducible T7-promoter. The constructed strain was then evaluated for the microbial monolignol production from various natural and non-natural precursors. Experiments were performed in shake flasks and the compounds were determined by HPLC and LC/MS.

Conclusions

Due to relaxed substrate specificity of studied enzymes of the synthetic monolignol pathway, which was successfully established in *E. coli*, this strain appears to be suitable for the microbial production of numerous natural and non-natural monolignols. The versatility of this single strain will provide access to the synthesis of more complex compounds such as flavonoids, stilbenes or lignans with interesting properties.

INJECTION OF NANOBODIES INTO TUMOR CELLS USING A SYNTHETIC INJECTOR E. COLI (SIEC) STRAIN

A. Asensio[1], *B. Álvarez*[1], *D. Ruano-Gallego*[2], *L.Á. Fernández*[1]
[1]*Centro Nacional de Biotecnología CNB-CSIC, Microbial Biotechnology, Madrid, Spain*
[2]*Imperial College, Life Sciences, London, United Kingdom*

Backgrounds

Type 3 secretion systems (T3SS) assemble supramolecular needle-like protein complexes, called injectisomes, able to translocate protein effectors into host cells. One attractive application of T3SS is the injection of therapeutic proteins, such as antibodies, into human cells (e.g. tumor cells). To avoid the use of pathogenic strains carrying T3SS, we engineered the commensal *Escherichia coli* K-12 strain to express injectisomes from the enteropathogenic *E. coli* (EPEC) strain. The resulting strain, named Synthetic Injector *E. coli* (SIEC), was able to translocate EPEC effectors (e.g. Tir) into human tumor cells.

Objectives

The main objective is to develop an expression system that allows the efficient translocation of single domain antibody fragments (nanobodies) into tumor cells using SIEC bacteria.

Methods

We assessed the controlled expression in SIEC of nanobodies fused to various T3-secretion signals and in the presence of different T3-chaperones. We evaluated and quantified the translocation levels of these gene constructs into tumor cell lines using β-lactamase as a reporter, both from high-copy plasmid vectors and single-copy gene integrations in SIEC chromosome. These experiments allowed us to select an optimal promoter, T3-signal and chaperone for controlled and efficient nanobody translocation.

Conclusions

We engineered SIEC strain to deliver nanobodies into the cytosol of tumor cells in a controlled manner both from plasmid and single-copy chromosomal expression. The developed system could be also of application for other therapeutic proteins.

BACTERIOPHAGE FUNCTIONALIZED POLYPYRROLE FOR DETECTION OF CLOFIBRIC ACID USING A MICROBALANCE SENSOR SYSTEM

I.H. Baek[1,2], V. Helms[2], Y. Kim[1]
[1]Kist europe, Environment safety group, Saarbrücken, Germany
[2]Saarland University, Center for Bioinformatics, Saarbrücken, Germany

Backgrounds

Molecularly imprinted polymer (MIP) is a central part of chemical removals or biosensors that depend on functionalized noncovalent recognition cavities. The recognition elements in biosensors usually consist of antibodies, enzymes or other biological receptors that are immobilized on the sensor surface. Filamentous bacteriophages are a member of the family *Inoviridae.* These are various used for material science, drug delivery, tissue engineering, energy and biosensor. Genetically modified bacteriophages can give to various binding recognition cavities including ionic interactions. clofibric acid (CA) is one of the metabolite form of fibrate drugs. These are commonly used in prescription drugs to treat diseases related to the lipid lowering symptom in the blood of both human and domestic animals.

Objectives

Multi-functionalized molecularly imprinted polymer, using genetically engineered filamentous bacteriophage was used for detection of acidic pharmaceutics (CA)

Methods

E. coli were used for plasmid and phage amplification respectively. Phage preparation was performed by PEG/NaCl precipitation. Cyclic voltammetry were performed using an electrochemical flow module of QCM-D, which consists of a working electrode.

Conclusions

A novel MIP combined with filamentous bacteriophages was shown to bind specifically to the substrate CA due to specific noncovalent interactions. Also, we described the use of functionalized phage pyrrole MIP for the real time monitoring of CA. The functionalized phage conductive polymer can be used for efficient on/off sensing of targets. The new method appears to be a promising unique and versatile method with high and efficient reproducibility that should have many applications in the field of sensors, electronics as well as biomedical engineering.

HYDROGEN OVERPRODUCING NITROGENASES OBTAINED BY RANDOM MUTAGENESIS AND HIGH-THROUGHPUT SCREENING

E. Barahona[1], E. Jiménez-Vicente[2], I. Álvarez- Melcón[1], L.M. Rubio[1]
[1]Centro de Biotecnología y Genómica de Plantas. Universidad Politécnica de Madrid UPM - Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria INIA. Campus Montegancedo UPM. 282 23-Pozuelo de Alarcón Madrid- Spain., Biotecnología, Pozuelo de Alarcón, Spain
[2]Virginia Tech, Biochemistry, Blacksburg, USA

Backgrounds

The great interest for hydrogen (H_2) as energy vector underlies research programs aimed to improving its sustainable biological production. During the process of biological nitrogen fixation the enzyme nitrogenase generates a minimum of one molecule of H_2 per turnover. We present a method for the high-throughput selection of nitrogenase variants with enhanced H_2 production. A *Rhodobacter capsulatus* strain has been re-engineered to generate a fluorescent signal in response to nitrogenase-produced H_2. A combination of random mutagenesis and fluorescence-activated cell sorting (FACS) is then used to select H_2-overproducing mutants of *R. capsulatus*.

Objectives

To develop optimized biocatalysts for hydrogen production and to design a biotechnological tool for the detection of H_2-overproducing bacteria.

Methods

The biotechnological tool consists of a library of (10^5-10^6) random nitrogenase variants and a biological H_2 sensor, which is based on the sensing hydrogenase of *R. capsulatus* and in the engineered state produces fluorescent signals. High-throughput selection was achieved by coupling this tool to FACS cytometry.

Conclusions

We have re-engineered the natural H_2 sensing system of *R. capsulatus* and combined it with FACS for the high-throughput selection of nitrogenase variants with enhanced H_2 production that might independently retain their N_2 fixation activity. This technology possesses great potential to identify nitrogenase amino acid substitutions leading to H_2-overproducing variants that could be mimicked in nitrogenases from other microorganisms, expanding the impact of the findings. This tool was also used to perform a genome-wide screening of mutations leading to enhanced H_2 production in *R. capsulatus*.

MOROCCAN BIOACTIVE ACTINOBACTERIA ISOLATES PRODUCING EFFLUX PUMPS INHIBITORS OF RESISTANT BACTERIA

A. Azmani[1], A. Nafis[1], L. Hassani[1], J. Wink[2], M. Barakate[1]
[1]Laboratory of Biology and Biotechnlogy of Microorganisms .Department of Biology, Faculty of Sciences Semlalia Cadi Ayyad University. P.Box.: 2390 Marrakech 40000, Morocco
[2]Helmholtz Center for infection research. Microbial Agents (MWIS) Research Group leader Microbial Strain Collection (MISG) Braunschweig.Germany

Background:

Traditional antimicrobials antibiotics are increasingly suffering from the emergence of multidrug resistance among pathogenic microorganisms. Among the antibiotic resistance mechanisms, efflux pumps have recently received a particular attention. Hence, there is an acute need for new active agents.

Objectives:

Reducing the rate of emergence of antibiotic-resistant is our objective by studying the ability of Moroccan actinobacteria isolates to produce natural efflux pumps inhibitors (EPI) of medical interest.

Methods:

210 actinobacteria isolates were screened for their ability to produce efflux pumps inhibitors using agar diffusion method. As test strains we have used in this study the wild type strain *Escherichia coli* AG100 and its mutant AG100A with non- functional pump efflux system and the two clinical strains of *Staphylococcus.aureus*: the sensitive one SA-1199 and its mutant SA1199B. Phe-Arg-β-naphtylamide (PAβN) which inhibits the efflux system of many bacteria was used as control. The extraction and purification of bioactive compound produced by the most promising isolate were conducted from large scale fermentation on the Bennett medium after extraction by ethyl acetate and purification by HPLC. The structure elucidation was determined after spectroscopic and spectrometric analyses. Taxonomic study to genus and species level of the producing isolate was conducted using morphological, physiological, chemotaxonomic and molecular studies.

Results:

Our screening program showed that among the 210 screened actinobacteria isolates, 9% were able to produce EPI with 7% and 3% respectively against Gram negative and Gram-positive bacteria. The highest EPI activity was produced by the strain Z332 which produce a derivative new compound. This strain could be a new strain of the genus *Streptomyces* as it is most closely related to *S. bellus* NBRC 12844 and *S. coerulescens* CSSP046 species on the basis of 16rDNA sequence while significant differences were obtained on the comparison of the morphological and physiological characteristics of the strain with those of the two nearest species.

Conclusion

Screening only a subsection of our natural product library led to purify a specific EPI capable of sensitizing the Gram-negative bacteria to antibiotics to which they are ordinarily intrinsically resistant. This result demonstrates the great potential of this approach in expanding antibiotic effectiveness regarding the growing challenge of resistance.

MURAMIDASE ACTVITY IN A A 110-KDA MEMBRANE PROTEIN PRODUCED FOR PEDIOCOCCUS ACIDILACTICI ATCC 8042

P.A. Barbosa-González[1], I. García-Cano[1], A. Farrés[1]
[1]Universidad Nacional Autónoma de México, Departamento de Alimentos y Biotecnología, Mexico City, Mexico

Backgrounds

Pediococcus acidilactici ATCC 8042 has been used as starter culture in meat products and exerts a biopreservative effect. This working group hads reported this strain produced a 110- kDa protein with antibacterial activity (García Cano *et al*., 2011). Its gene was sequenced and proved to have homology with a protein with unknown function which contained dominions both for a lytic phage protein and an ABC transporter.

Objectives

The antimicrobial effect of 110-kDa protein represents an enigma because its sequence is not similar to known antibacterials. This research intends to gain insight into its mode of action

Methods

To analyze the individual antimicrobial activity of the 110-kDa protein the gene for its expression was cloned using the vector pET19 and *E. coli* BL 21 as a host, resulting in a recombinant protein with observable antimicrobial activity against important pathogens (*S. aureus, L. monocytogenes, S. pyogenes, E.coli, and S. typhimurium*) . The activity was detected both in zymograms and in growth inhibition tests. Enzymatic activities that may have an effect on cell wall lysis were assayed with spectrophotometric methods and synthetic substrates and the 110-kDa recombinant protein showed muramidase activity. This would not be a canonical muramidase as it does not present homology to any reported peptidoglycan hydrolase. More details into its action mechanism need to be analyzed, as its probably effect on the permeability of bacteria.

Conclusions

The 110-kDa membrane protein is a muramidase and it may be used as an option to reduce and avoid microbial spoilage and contamination

PROWOOD: PROTECTION OF WOOD BY NOVEL BIO-BASED SOLUTIONS

K. Kosalková[1], A. Sola-Landa[2], L. García-Calvo[1], R. Pérez-Redondo[2], C. Sánchez-Orejas[3], M. Calonge[3], C. Barreiro[4,5]
[1]INBIOTEC Instituto de Biotecnología de León, Fungal Biotechnology, Leon, Spain
[2]INBIOTEC Instituto de Biotecnología de León, Actinobacteria, Leon, Spain
[3]INBIOTEC Instituto de Biotecnología de León, Toxicology, Leon, Spain
[4]INBIOTEC Instituto de Biotecnología de León, Proteomics, Leon, Spain
[5]Universidad de León, Área Microbiología. Biología Molecular., León, Spain

Backgrounds

The European Union (EU27) woodworking industry consists today of more than 380,000 companies and employs more than 2.1 million workers. The European industrial interest on wood decay processes is both to accelerate (biorefinery) and to prevent wood degradation (decay). While the hydrolytic degradation processes are extensively studied and improved for biofuels production, the prevention of wood degradation has received less attention, even though, the preservation of wood structures against decomposition is an old challenge.

Objectives

New protective bio-coatings are the core of the ProWood Consortium in order to develop bio-coating solutions based on three alternate sources of novel eco-friendly anti-wood decay agents all combined with three novel, specially developed, coatings.

Methods

Methods for isolation and characterization of anti-microbial or antagonist compounds, as well as, microorganism involved in metal corrosion (biofouling) will be transferred to wood decay characterization.

Conclusions

ProWood is a well-balanced interdisciplinary cluster of outstanding molecular biologists, (bio)chemical engineers joined to economic and social-relevant industrial partners selected for their know-how in biotechnology, bio-coating development, wood handling and validation processes. The Consortium is resulting in innovative bio-coatings to reach an industrially demanded product to cover societal needs in wood protection in a less polluting manner.

BIOTYPES ANALYSIS OF CORYNEBACTERIUM GLUTAMICUM DEMONSTRATES THE EXISTENCE OF INTRA-SPECIES VARIATIONS

F. Pérez-García[1], M.F. Vasco-Cárdenas[1,2], A. del Árbol[1], A.M. Ibañez[1], C. Barreiro[1,2]
[1]INBIOTEC Instituto de Biotecnología de León, Proteomics, Leon, Spain
[2]Universidad de León, Área de Microbología. Biología Molecular., León, Spain

Backgrounds

Mutagenesis with chemical methods, irradiation or genetic manipulation have been the traditional ways to enhance the yield of industrial microbial products or improve relevant strains. Insufficient studies have been developed on final product resistance improvement and even fewer on the naturally-generated biotypes, which could decrease the artificial mutagenesis ratios. This is a capital fact in the case of GRAS microorganisms involved in food, feed and cosmetics production as *Corynebacterium glutamicum*.

Objectives

The analysis of four biotypes of *C. glutamicum* involved in the dicarboxylic acid production are the core of the presented work. Specifically, the proteome analysis of these biotypes growing in an industrial relevant amount of itaconic acid are the proof of concept.

Methods

Cells were cultured in the defined medium CGXII with and without itaconic aid. 2D-DIGE analysis of the intra-cellular proteome were performed and proteins were subsequently identified by means of a MALDI-TOF/TOF mass spectrophotometer. Metabolic pathway analysis was carried out by using the BioCyc web server, which allowed the identification of pathways involved in the itaconic acid resistance among the biotypes.

Conclusions

The relevance of a preliminary biotype screening is demonstrated along the present analysis as a platform for strain production improvement using a proper selection of resistant biotypes facing metabolite toxicity. Besides, an analysed biotype, which presents a more active central metabolism, an optimized nutrient uptake and better protection against osmotic stress and acidification, is presented an excellent candidate for itaconic acid production.

DISCOVERY AND ENGINEERING OF NOVEL DEFENSIN-LIKE ANTIMICROBIAL PEPTIDES TO COMBAT FOOD SPOILAGE

M. Beckett[1], J. Kraszewska[1], T. James[1], U. Bond[1]
[1]Trinity College Dublin, Microbiology, Dublin, Ireland

Backgrounds

Antimicrobial peptides offer potential as novel therapeutics to combat food-spoilage bacteria. Our previous studies identified the peptide human beta-defensin 3, HBD3, as a potent antimicrobial agent for a wide range of food-spoiling bacteria. Thus, HBD3 is an excellent candidate to prevent food spoilage.

Objectives

To identify other peptides with antimicrobial activity similar to HBD3 and engineer peptides with increased activity.

Methods

We carried out an *in silico* screen using HBD3 as the comparative molecule, focusing on peptides of plant origin. We compared the antimicrobial activity of nine defensin-like peptides to the activity of HBD3, against the food-spoiling bacterium *Lactobacillus brevis*. Two of the peptides, Fabatin-2 and Cp-Thionin-2, displayed antimicrobial activity in the same concentration range as HBD3 under high ionic strength conditions. Several of the other peptides displayed antimicrobial activity under low ionic strength conditions. Further analysis revealed a direct correlation between activity and net positive charge of the peptide. A rational design approach was undertaken to increase the antimicrobial activity of a “low activity” peptide, Mungbean defensin PDF-1. First the structure of PDF-1 was compared to the tertiary structure of active peptides. We identified 3 regions of negative charge which were altered to increase the cationic charge of the peptide.

Conclusions

Subsequent testing showed this analogue to have greater activity than the oringianl PDF-1 peptide and any of the previously identified “high activity”peptides. Thus rational design, based on structural and physiochemical properties of short peptides can be used to engineer antimicrobial peptides which are effective at controlling food spoilage bacteria.

NEW ASPECTS OF REGULATION OF AN ANGUCYCLINE ANTIBIOTIC AURICIN IN STREPTOMYCES AUREOFACIENS CCM 34239

C. Bekeova[1], L. Feckova[1], R. Novakova[1], E. Mingyar[1], D. Homerova[1], J. Kormanec[1]
[1]Institute of Molecular Biology Slovak Academy of Sciences, Gene expression, Bratislava, Slovak Republic

Backgrounds

Streptomycetes are characterised by a complex morphological differentiation and production of secondary metabolites, including the majority of known antibiotics. The biosynthesis of secondary metabolites is strictly regulated, involving at least two different levels: a lower pathway-specific level using cluster-situated regulators and a higher one involving various global regulators [1]. We previously identified a gene cluster *aur1* in *Streptomyces aureofaciens* CCM 3239 responsible for production of a unique angucycline antibiotic auricin. Its biosynthesis is regulated by at least four pathway-specific regulators, including response regulator homologue Aur1P, TetR family regulator Aur1R, and two SARP family regulators Aur1PR3 and Aur1PR4 [2].

Objectives

Characterization of new putative regulatory gene *aur1O* and its involvement in regulation of auricin biosynthesis.

Methods

Growth of *S. aureofaciens* CCM3239 and analysis of auricin production was done as described in [3]. Disruption of the genes in *S. aureofaciens* CCM3239 was done as described in [3]. Bacterial two hybrid system was done as described in [4].

Conclusions

1, Deletion of the *aur1O* gene affected production of auricin, indicating its role in regulation of its biosynthesis.

2, The auricin biosynthetic promoter *aur1Ap* had decreased activity in the absence of *aur1O* gene, indicating the role of Aur1O in its activation.

3, Aur1O has been found to interact with the auricin pathway-specific regulator Aur1P, indicating the role of Aur1O as an co-activator of the *aur1Ap* promoter.

SCREENING OF FEEDING STRATEGIES BASED ON TRIGGER EVENTS IN A 24-MICRO BIOREACTOR PLATFORM

C. Bernal Martinez[1], *C. Santos Fernandez*[1]
[1]*Applikon Biotechnology BV, Product Management, Delft, The Netherlands*

Backgrounds

Several bioprocesses exploit feeding strategies such as the minimization of acetate production in microbial cell culture (Johnson *et al*., 2002, Kim *et a*l., 2004, Andersen *et al.*, 2001). Some of these feeding strategies use values for pH or dissolved oxygen (dO2) as a trigger point.

.

Objectives

The objetive was to test the event (trigger point) based control using micro-scale fermentation. The availability of a platform able to perform this approach on a micro-scale cultivation is essential for strain optimization strategy.

Methods

The micro-Matrix has been used to run 24 fermentations using *E.coli (*Chen *et al*., 1997). Applikon's micro-Matrix product is a platform that holds 24 micro bioreactors (working volume 2-5 mL) with individual control of pH, dO2 and temperature. The micro-Matrix is able to program event-based control whereby the control strategy is based on a triggered event

Conclusions

In the present work, two different feeding strategies in an *E.coli* cultivation have been applied based on i) pH above 7.1 and ii) dO2 above 50%, using the work of Chen *et al*., 1997 as a reference. The results demonstrate that the micro-Matrix can be successfully used for the screening of different feeding strategies.

ASSESSMENT OF ANTIFUNGAL AND ANTI-AFLATOXIGENIC EFFECT OF PROBIOTICS: A NOVEL STRATEGIES FOR REDUCING MYCOTOXIN LEVELS IN PEANUTS

S. Bhutada[1]
[1]*Sanjivani Arts - Commerce and Science College, Department of Microbiology, Ahmednagar, India*

Backgrounds

Contamination of peanuts with mycotoxins, particularly aflatoxins, is a worldwide problem that affects both food safety and agricultural economies. Aflatoxins are carcinogenic mycotoxin, produced by *Aspergillus* species. These molds infect food crops in warm humid conditions causing economic losses and affecting the consumers' health adversely.

Objectives

Due to the ubiquitous occurrence of aflatoxins, preventive and remediative measures are necessary including detoxification techniques. The objectives of the present study are to determine the antifungal and anti-aflatoxigenic activity of probiotics for reducing the mycotoxin levels in Peanuts.

Methods

In this study, antifungal activity and Anti-aflatoxigenic effect of Nine probiotic strains against *Aspergillus flavus* and *Aspergillus parasiticus* were studied. The aflatoxin secreted was analyzed and quantified by both UV spectrophotometer and HPLC.

Conclusions

It was found that *Lactobacillus plantarum* showed antifungal (65.89% reduction) and anti-aflatoxigenic (94.56% reduction) activity against *A. flavus* whereas *A. parasiticus* was inhibited by *Lactobacillus plantarum* with the antifungal reduction of 64.75% and anti-aflatoxigenic reduction of 91.32%. The research outcome concluded that *Lactobacillus plantarum* may be used as potential probiotic for reducing the aflatoxin content in Peanuts. Use of Probiotics should be encouraged for use as a bio-detoxification agent for aflatoxins.

UNDERSTANDING COXIELLA VACUOLE BIOGENESIS USING MULTI-PARAMETRIC HIGH-CONTENT SCREENING

M. Bonazzi[1], K. Lambou[1]
[1]Centre d'études d'agents Pathogènes et Biotechnologies pour la Santé, Cell Biology of Bacterial Infections, Montpellier, France

Background

Coxiella burnetii is an obligate intracellular bacterium responsible of severe outbreaks of the zoonosis Q fever. The primary targets of *Coxiella* are alveolar macrophages, however bacteria can invade phagocytic and non-phagocytic cells and disseminate to other tissues and organs, such as the liver and heart, giving rise to hepatitis and endocarditis. Due to its remarkable infectivity and its environmental stability, *Coxiella* is considered a category B biothreat. Upon internalisation by both phagocytic and non-phagocytic cells, bacteria remain confined within *Coxiella*-containing vacuoles (CCVs), tight fitting compartments that mature along the endocytic pathway. Key to the successful colonisation of host cells is the translocation of bacterial effectors translocation by a Dot/Icm type IVb secretion system.

Objectives

Bioinformatics analysis identified over 300 *Coxiella* candidate effectors, a third of which have been validated for secretion. Many *Coxiella* effectors remain completely uncharacterised, it is clear however that several of these are encoded by eukaryotic-like genes (EUGENs), suggesting an interaction with host cell proteins and pathways.

Methods

Using transposon mutagenesis coupled to multi-parametric high-content screening, we have investigated the role of Dot/Icm core protein during *Coxiella* infections, defined the impact of known effectors in different steps of the infectious cycle and identified novel candidate effectors.

Conclusions

Coxiella Vacuolar Proteins (Cvps) seem to be directly implicated in vacuole biogenesis via the manipulation of host vesicular trafficking, allowing CCVs to intercept and recruit membranes, proteins and lipids from the endocytic, autophagy and recycling pathways. We have recently reported that CvpB associates to CCVs by interacting with host phosphoinositides and modulates PI(3)P levels to facilitate homotypic fusion between CCVs. Transposon insertions in *cvpB* lead to a multivacuolar phenotype, *Coxiella* replicating in multiple, isolated CCVs. Interestingly, despite the intracellular replication of *cvpB* mutants remain unaffected, defective CCVs development as *in vivo* relevance as demonstrated using the insect model *Galleria mellonella*.

USE OF RECOMBINANT MULTIEPITOPE PROTEINS AS A STRATEGY TO AID IN THE DIAGNOSIS OF CRYPTOCOCCOSIS AND IN THE IDENTIFICATION OF ENDEMIC AREAS

R. Brandão[1], A. Faria[2], H. Andrade[2], L. Martins[1], A. Silva[1], S. Monte[1]
[1]Federal University of Piaui, Laboratório de Imunogenética e Biologia Molecular LIB, Teresina, Brazil
[2]Federal University of Minas Gerais, Departament of Parasitolgy, Belo Horizonte, Brazil

Backgrounds

Cryptococcosis is a worldwide life-threatening systemic disease caused by *Cryptococcus neoformans* (Genotype VNI-VNIV, VNV) and *Cryptococcus gattii* (Genotype VGI-VGIV). Despite major advances in the search for a rapid test with the goal of an early diagnosis, estimations are that almost one million cases of cryptococcal meningitis in HIV-infected subjects occur annually, causing more than 600,000 deaths. This shows that early diagnosis of cryptococcosis remains a challenge that science and the health system need to address. As important as the early diagnosis is the identification of endemic areas and control of the fungus spreading.

Objectives

To test recombinant multiepitope proteins for the development of a rapid test or epidemiological tool aiming at the identification of endemic regions of cryptococcosis.

Methods

Previously, proteomics and bioinformatics methods were combined and potential antigenic targets were recognized by anti-Cryptococcus antibodies. Here, it was designed and synthesized 4 recombinant multiepitope proteins (A, B, C and D), constructed with the combination of potential peptides, and crossed them with sera from cryptococcosis patients and controls.

Conclusions

The recombinant multiepitope proteins A, B and C showed sensitivity between 57.14 to 88.57%, specificity of 90% and AUC between 0.71 and 0.91. The chimeric D protein presented better results, with sensitivity of 88.57%, specificity of 100% and AUC of 0.97. The results suggest that the recombinant multiepitope proteins in combination with lateral flow assay may increase the ability in diagnosing patients with cryptococcosis and may be useful as an epidemiological tool to identify endemic areas.

ALTERING THE SACCHAROMYCES CEREVISIAE POLY(A) BINDING PROTEIN (PAB1) FOR LEVERAGING CELLULAR ROBUSTNESS

P. Branduardi[1], *M. Brambilla*[1], *F. Martani*[1], *A. Mento*[1], *S. Bertacchi*[1], *D. Porro*[1]
[1]*University of Milano Bicocca, Department of Biotechnology and Biosciences, Milano, Italy*

Backgrounds

When exploited as cell factories, microbial cells are exposed to harsh conditions impairing titer, yield and productivity of the fermentative processes. The development of robust strains therefore represents a pivotal but not easy task to accomplish for the implementation of cost-effective bioprocesses.

Objectives

In our laboratory, we explored the possibility to leverage *S. cerevisiae* potential in terms of cellular robustness through the modulation of a “hub” element involved in post-transcription events. In fact, although transcription shapes the adaptive response to stress, the mechanisms regulating the fate of newly synthesized mRNAs are crucial for tuning the final effect of eukaryotic gene expression.

Methods

The poly(A) binding protein Pab1, as stress granules component, was chosen as the target for obtaining widespread alterations in mRNA metabolism and for selecting stress tolerant phenotypes. Here we will show how either the modulation of Pab1 levels as well as the selection of specific variants through a screening protocol allowed to retrieve strains ameliorated against different stressors; these strains demonstrated better performances under industrially relevant conditions, when compared with controls. Furthermore, the construction of Pab1 chimeras is offering the possibility to further study the contribution of the different parts of the protein in the assembly and clearance of stress granules, with consequences on cellular robustness.

Conclusions

These findings pave the way for a novel approach to unlock industrially promising phenotypes through the modulation and/or the synthetic reconstruction of a post-transcriptional regulatory element.

RELATIONSHIP BETWEEN SPORULATION AND SOLVENT PRODUCTION IN CLOSTRIDIUM BEIJERINCKII NRRL B-598

B. Branská[1], J. Kolek[1], M. Drahokoupil[1], M. Vasylkivska[1], P. Patakova[1]
[1]University of Chemistry and Technology - Prague, Department of Biotechnolohy, Prague 6, Czech Republic

Backgrounds

Although industrial bio-solvent production using genus *Clostridium* had 100 year anniversary last year, it is still in the spotlight, with many not fully revealed mechanisms and regulations. One of such uncovered mechanism is a relationship between sporulation and solvent production. In *C. acetobutylicum,* the most studied representative of solventogenic Clostridia, sporulation and the onset of solvents formation seems to be directly interconnected, however this may not apply for other industrially relevant Clostridia.

Objectives

The objective of this study was to find relations between production parameters and particular stages of sporulation cycle in *C. beijerinckii* NRRL B-598 (formerly *C. pasteurianum* NRRL B-598).

Methods

Spores formation together with solvent production and culture viability were monitored during a whole production and sporulation cycle under specific conditions (supporting/repressing sporulation). A high throughput flow cytometric method based on a combination of light scatter and fluorescence characteristics was employed for spores, live and dead cells enumeration.

Conclusions

Morphological changes typical for spores formation could be observed at the onset of solvent formation, similarly to *C. acetobutylicum*. However, it was proved that it does not apply vice versa, meaning that for *C. beijerinckii* NRRL B-598 solvent production can be undisturbed when sporulation is limited or is not observed at all.

Acknowledgement

This work has been supported by grant project GACR 17-00551S.

FROM GREENHOUSE GASES TO BIOFUEL: CARBON CAPTURE TO N-BUTANOL BY CLOSTRIDIUM BEIJERINCKII

W.J. Sandoval-Espinola[1], M. Chinn[2], M. Thon[3], J.M. Bruno-Barcena[1]
[1]North Carolina State University, Plant and Microbial Biology, Raleigh, USA
[2]North Carolina State University, Agricultural and Biological Engineering, Raleigh, USA
[3]Universidad de Salamanca, Department of Microbiology and Genetics, Villamayor, Spain

Backgrounds

Recent efforts to combat increasing greenhouse gases emissions include their capture into advanced biofuels, such as butanol. However, butanol research has traditionally been centered solely on its generation from sugars, because solventogenic *Clostridiums*, such as *C. beijerinckii* are considered heterotrophic organisms.

Objectives

To monitor in-line the endogenous fermentation gases by *Clostridium beijerinckii* and to assess its capability to assimilate syngas (CO + CO2 + H2) into fermentation products.

Methods

We performed chemostat (D = 0.135 h-1) fermentations while continuously flowing syngas (CO + CO2 + H2) at increasing steady-state concentrations, while analyzing mass balances. We also performed batch experiments with C-13 labeled CO2 to confirm its assimilation into products. We further performed genome- and transcriptome-wide analysis, focusing on autotrophy-related genes.

Conclusions

Our results show the mixotrophic CO_2 and H_2 re-assimilation by n-butanol-producer *C. beijerinckii*. This was detected as synchronous CO_2/H_2 oscillations by direct (real-time) monitoring of the fermentation gasses. Additional functional analysis demonstrated syngas (H_2, CO_2 and CO) assimilation, increasing total carbon recovery above typical heterotrophic values. This was also confirmed by C-13-labeled CO_2 recovered into products. Further genome- and transcriptome-wide analysis, revealed the transcription of key Wood-Ljungdahl pathway and other autotrophy-related genes. Therefore, this report provides genetic and physiological evidence of inorganic carbon-capture by *C. beijerinckii.*

ENGINEERING OF SUGAR TRANSPORT CAPABILITIES OF CORYNEBACTERIUM GLUTAMICUM FOR IMPROVED GROWTH ON D-XYLOSE

C. Brüsseler[1], A. Radek[1], K. Krumbach[1], J. Gätgens[1], T. Polen[1], N. Tenhaef[1], S. Noack[1], J. Marienhagen[1]
[1]Forschungszentrum Juelich GmbH, IBG-1, Juelich, Germany

Backgrounds

Naturally, *Corynebacterium glutamicum* cannot utilize the D-xylose. We have successfully engineered this organism to solely grow on this pentose by functional integration of the Weimberg pathway originally discovered in *Caulobacter crescentus*.

Objectives

Improvement of growth of *C. glutamicum* in D-xylose-containing defined medium.

Methods

C. glutamicum was subjected to an adaptive laboratory evolution (ALE) experiment for improved growth on D-xylose-containing defined medium. Resulting strains were characterized in cultivations in the shake-flask and microtiter plate format and additional genome sequenced. An LC-MS-based method for the quantification of D-xylose was developed and used for the detailed characterization of selected strains with regard to D-xylose consumption.

Conclusions

The ALE yielded several strain variants showing improved growth on D-xylose-containing medium. Conducted genome sequencing helped to identify a frame shift mutation in the gene encoding a transcriptional repressor. Through deletion of this repressor we were able to verify this effect on overall cell-growth in the wild-type background. In addition, we could functionally integrate all genes of the Weimberg pathway into the chromosome of this *C. glutamicum* strain. To our best knowledge this is the first plasmid-free *C. glutamicum* strain being able to grow solely on D-xylose employing the Weimberg pathway.

CHIMERIC LEADERS: TOOLS OF SYNTHETIC BIOLOGY FOR DIFFERENT DIRECTED PEPTIDE MODIFICATIONS

A. Buivydas[1], S.W. Fuchs[2], J. Piel[2], O.P. Kuipers[1]
[1]University of Groningen, Molecular Genetics, Groningen, The Netherlands
[2]ETH Zürich- Institute of Microbiology, Department of Biology, Zürich, Switzerland

Backgrounds

Posttranslationally modified antimicrobial peptides exhibit a potent antimicrobial activity, stability and high target specificity. Some of the peptides are more active even than some antibiotics. All the characteristics are endorsed by posttranslational modifications introduced during biosynthesis steps by dedicated enzymes. Maturation of a peptide begins with a propeptide which is guided by specific modification events due to a leader peptide (an amino acid sequence recognized by particular modification biomodule). The leader peptide is proteolitically removed in the last steps of peptide maturation rendering the modified peptide active.

Objectives

To design plug-and-play biomodules for production of novel peptides containing simultaneous posttranslational modifications of different origins.

Methods

We used synthetic biology approaches to design and implement biomodules for biosynthesis of a peptide with combinatorial modifications of choice. Codon-optimized synthetic genes of designed model peptides to be modified were employed together with dedicated modification machineries.

Conclusions

This is a unique case where posttranslational modifications from two different peptide classes are fused together into a single peptide chain *in vivo*. Here we also show the possibilities of employing chimeric leader peptides for substrate recognition and processing by particular posttranslational modification machineries.

COMPOSTING OF SEWAGE SLUDGE WITH SEMIPERMEABLE FILM TECHNOLOGY: MICROBIAL DIVERSITY AND ENZYMATIC ACTIVITIES THROUGHOUT THE STAGES OF THE PROCESS

C. Calvo[1], T. Robledo-Mahón[1], A. Rodríguez-Calvo[1], M. Manzanera[1], J. González-López[1], E. Aranda[1]
[1]Universidad de Granada, Microbiology- Institute of Water Research, Granada, Spain

Backgrounds

Composting is a bio-active process in which a large number of microorganisms are involved. Among these microorganisms, fungi and bacteria have diverse enzymatic activities that help to the stabilization of the organic matter and allow obtaining the compost, a final product which is safe and useful as an agricultural soil amendment. The starting products and the operational conditions have a high influence in the microbial diversity and will determine the process characteristics

Objectives

The main objectives were to investigate, in a full-scale real composting pile, the evolution of the diversity of bacteria and fungi during the composting process and to correlate the predominant groups and the enzymatic activities of the pile

Methods

The pile was built in real-scale mixing sewage sludge with vegetal pruning wastes as bulking agent. The composting phase was performed under Gore-Tex® semipermeable cover and the maturation phase was developed in an opened windrow system. Analysis of bacterial and fungi communities was performed by Illumina Miseq sequencing. Enzymatic activities: dehydrogenase, protease, phosphatase, β-glucosidase and arylsulphatase activities were determined at each composting phase

Conclusions

Actinomycetales and *Bacilalles* (bacteria) and *Eurotiales* and *Sordariales* (fungi) were the major taxa at the beginning of composting and during the maduration stage, while the highest diversity was detected between 15 and 30 days of composting. Protease, dehydrogenase, β-glucosidase and arylsulfatase activities were higher during the composting phase under Gore-Tex® cover, whereas acid and alkaline phosphatase activities decreased in the maturation stage.

CELLULASE-PRODUCING BACTERIA ISOLATED FROM PERUVIAN SALTERNS USING SUGAR BEET PULP AS SUBSTRATE

C.N. Flores-Fernández[1], A.I. Zavaleta[1], P.E. Canales[1], M. Cárdenas-Fernández[2], J.M. Ward[2], G.J. Lye[2]
[1]Laboratorio de Biología Molecular - Facultad de Farmacia y Bioquímica, Universidad Nacional Mayor de San Marcos, Lima, Peru
[2]Deparment of Biochemical Engineering, University College London, London, United Kingdom

Backgrounds

Sugar beet is an important crop for sugar production in various parts of the world, and the pulp is the main by-product from sugar processing that contains high concentration of cellulose (25%). Halophilic bacteria are recognized for simple nutritional requirements and activity under harsh conditions.

Objectives

To isolate cellulase-producing bacteria from Peruvian salterns using sugar beet pulp as substrate.

Methods

Soil samples were collected from Peruvian salterns and cultured in a medium supplemented with 0.2% yeast extract, 5% NaCl and 10% sugar beet pulp and incubated at 40 °C for 72 h. Subsequent cultures were done in liquid and solid media until isolation of colonies. Screening for cellulase-producing bacteria was carried out on nutrient agar plates containing 1% carboxymethyl cellulose. Selected isolates were characterized based on morphological and physiological characteristics. A total of 26 bacterial strains were isolated, and 34 % were identified as cellulase producers. Diameters of clearing zones (cellulose hydrolysis) around colonies presented more than 20 mm. Moreover, 54 % of these isolates grew up to 25 % NaCl and 77 % fermented glucose. Additionally, 39 % of the strains grew up to 45 °C, 19 % of strains to pH 3, and 77 % of strains to pH 10.

Conclusions

Sugar beet pulp can be used as a selective substrate for the isolation of versatile bacteria producing highly active cellulases, which could have potential industrial applications

CONTINUOUS ABATEMENT OF METHANE COUPLED WITH ECTOINE PRODUCTION BY METHYLOMICROBIUM ALCALIPHILUM 20Z: A STEP FURTHER TOWARDS GHG BIOREFINERIES.

S. Cantera[1]
[1]*University of Valladolid, Chemical engineering and Environmental Technology, Valladolid, Spain*

Backgrounds

The implementation of environmentally friendly CH_4 abatement biotechnologies is not cost-efficient when applied to dilute off-gas emissions such as those from landfills or coal mines. In this sense, the production of high-added value products during CH_4 abatement can become a profitable approach to mitigate climate change.

Objectives

The research here presented investigated for the first time the valorization of dilute CH_4 emissions coupled with the production of ectoine, a microbial molecule with a high retail value in the cosmetic industry (approximately \$1300 kg^{-1}).

Methods

In this context, on a first attempt, the influence of Cu^{2+}, NaCl and CH_4 concentration, as well as temperature, on ectoine production by *Methylomicrobium alcaliphilum 20Z* was evaluated batchwise in gas-tight bioreactors. The results obtained showed that high concentrations of NaCl and CH_4 resulted in increased intra-cellular ectoine yields and high Cu^{2+} concentrations (50 µM) unexpectedly promoted the excretion of ectoine to the culture broth, despite this methanotroph has not been previously classified as an ectoine-excreting strain. The continuous abatement of CH_4 combined with the production of extra and intra-cellular ectoine was further evaluated in 6 stirred tank reactors.

Conclusions

The results obtained in these studies supported the technical viability of a new generation of GHG biorefineries and confirmed that high concentrations of NaCl resulted in higher steady state intra-cellular ectoine yields. In addition, an increase in Cu^{2+} concentration enhanced CH_4 abatement by a factor of 2 and promoted the excretion to the cultivation broth of 20 % of the total ectoine synthesized under continuous operation.

AZOARCUS SP. CIB AS A BIOREACTOR FOR PRODUCTION OF METALLIC NANOPARTICLES

M. Carmona[1], *H. Fernández-Llamosas*[1], *L. Castro*[2], *M.L. Blázquez*[2], *E. Díaz*[1]
[1]*Centro de Investigaciones Biológicas-CSIC, Environmental Biology, Madrid, Spain*
[2]*Facultad de Químicas- Universidad Complutense de Madrid,*
Material Science and Metallurgical Engineering Department, Madrid, Spain

Backgrounds

The β-Proteobacterium *Azoarcus* sp. CIB displays several features of great environmental interest. Thus, the strain CIB has the ability to degrade toxic aromatic compounds, e.g., toluene and *m*-xylene, and to live as an endophyte of rice (1). Recently, *Azoarcus* sp. CIB was shown to tolerate high concentrations of selenite and produce nanoparticles of selenium (2).

Objectives

Here we show that the metal resistance ability of strain CIB extends to other metalloids such as the oxyanion tellurite. The resistance mechanism appears to be the combination of at least three different processes that are interconnected along the cell growth, i.e., an active transport system, the methylation to volatile forms, and the reduction of the oxyanion to elemental metalloid.

Methods

Using different techniques such as TEM, SEM and EDX analyses, we have demonstrated that strain CIB transforms tellurite to less toxic nanorods of tellurium whose size ranges between 50-250 nm long and 5-10 nm width.

Conclusions

These results display the potential of the CIB strain as a suitable biocatalyst for bioremediation of toxic aromatic compounds and heavy metals and metalloids, and as a green biofactory for the production of metallic nanoparticles with biotechnological interest.

THE SOS-RESPONSE CONTROLS INTRINSIC CEPHALOSPSRIN RESISTANCE IN ENTERORCOCCI

L. Carrilero[1], S. Matrat[1], D. Thomas- Lopez[1], B. González-Zorn[1]
[1]Universidad Complutense de Madrid, Animal Health, MAdrid, Spain

Backgrounds

Enterococcus faecalis is a bacterium well known for causing multidrug resistant nosocomial infections. This pathogen exhibits intrinsic resistance to cephalosporins, which, despite all efforts, has not been fully understood. Clinically this is very significant, because cephalosporin treatment constitutes a risk factor for subsequent enterococcal infections.

Objectives

As the SOS response has been shown to be involved in both antimicrobial resistance and virulence of different bacteria we intend to investigate its implication on the resistance profile of *E*. *faecalis*, with special interest on cephalosporin resistance.

Methods

Several mutants in the SOS response in two different genetic backgrounds, JH2-2 and V583, were constructed. Further, a transposon mutant library in order to identify the genetic determinants involved in the phenomenon. MICs were determined using EUCAST methodology.

Conclusions

We discovered that *E. faecalis* has a functional SOS response and assessed its involvement in the sensitization of *E. faecalis* to methoxyiminocephalosporins. Within our transposon mutant library, we identified two glutamine transporters and the *cop* operon as components possibly implicated in decreasing the MIC of *E. faecalis* to cephalosporins. One of the glutamine transporters identified in our library is under the regulation of CroR/S, which has been previously described to play a role in cephalosporin resistance. Additionally, we found that the presence of copper further completely sensitizes *E. faecalis* to cephalosporins. Unraveling the mechanism of intrinsic resistance to cephalosporins in *E faecalis* paves the way for future novel treatment options against this important nosocomial pathogen.

FUEL FROM RUBBISH: ETHANOL PRODUCTION FROM ORGANIC MUNICIPAL SOLID WASTE USING A NOVEL ENRICHED MICROBIAL COMMUNITY

P. Carrillo-Barragan[1], *N.D. Gray*[1]
[1]*Newcastle University, Civil Engineering and Geosciences, Newcastle, United Kingdom*

Backgrounds

Lignocellulosic ethanol (EtOH) is a sustainable alternative to fossil transport fuels. Research has been focused on genetically engineering single microorganisms to fully convert lignocellulosic substrates into EtOH. This approach faces instability, narrow operational conditions and is susceptible to inhibition by contaminants such as those found in waste substrates.

Objectives

We propose the assembly of a robust microbial community from natural environments to transform Organic Municipal Solid Waste (OMSW) into EtOH with the manipulation of physical variables as a means to direct this process.

Methods

Environments where lignocellulose degradation occurs were sampled and used as inocula in microcosms with acid/steam pre-treated OMSW as substrate, cultured at a range of conditions (aerobic vs anaerobic, 4-7 pH values) at 20°C. The fermentation products were monitored using GC-FID and IC. Bacterial DNA was extracted at different time points and Ion torrent was used to sequence the 16Sr RNA amplicon libraries. Pipeline analyses were done using Mothur and Qiime software.

Conclusions

EtOH was the major product in rumen and sludge inoculated systems, both generating their highest EtOH concentrations (~35mM EtOH) when growing at different pH values (7 and 5, respectively) at both initial aerobic and anaerobic conditions. Microcosms inoculated with the combination of both inocula, generated EtOH as the major fermentation product under the range of pH 5 to 7. In the combined community, *Pseudomonas* sp. and *Clostridium sp.* were the most abundant species. Ongoing test are aimed to unravel the mechanisms behind the new community EtOH production to help understand and optimize this process by manipulating physical conditions.

COMPARATIVE ANALYSIS OF EXTRA VERSUS INTRACELLULAR HYDROLYSIS ON CELLOBIOSE FERMENTATION BY SACCHAROMYCES CEREVISIAE

M. Casa Villegas[1], *J. Marín-Navarro*[1], *J. Polaina*[1]
[1]*Instituto de Agroquímica y Tecnología de Alimentos, Biotecnología de alimentos, Paterna, Spain*

Backgrounds

Cellobiose is, besides glucose, a final product of cellulolytic enzyme complexes and therefore a key sugar for the production of second generation bioethanol and other fermentation products from cellulosic material. To overcome the inability of *Saccharomyces cerevisiae* to utilize cellobiose, two main approaches have been used: i) expression in the yeast of a secreted β-glucosidase that hydrolyzes cellobiose extracellularly; ii) cellobiose transport and concomitant intracellular hydrolysis, mediated by combined expression of a cellobiose permease and an intracellular β-glucosidase.

Objectives

Our aim is to compare the efficiency of the two approaches used for cellobiose fermentation by *S. cerevisiae* and predict conditions at which the use of one or the other method could be more practical.

Methods

We have cloned, expressed in *S. cerevisiae* and characterized the function of different heterologous genes encoding intracellular β-glucosidases and cellobiose permeases, to find out pairwise hydrolase/permease associations that enable efficient cellobiose fermentation by the host yeast strain. The performance of these strains was compared with a previously described *S. cerevisiae* strain that ferments cellobiose very efficiently (comparable to glucose) due to the expression of an extracellular β-glucosidase from *Saccharomycopsis fibuligera*.

Conclusions

The yeast strain expressing extracellular β-glucosidase, in medium with cellobiose as the carbon source, showed better growth and fermentation (ethanol production) than any strain that carried intracellular hydrolysis of the disaccharide. The only scenario that we envision where the use of the last approach would be advantageous is simultaneous saccharification and fermentation by cocultures of the fermenting yeast with a cellulolytic microorganism.

NUMERICAL OPTIMIZATION OF LIPASE PRODUCTION BY SOLID-STATE FERMENTATION WITH ASPERGILLUS FUMIGATUS

G.L. Castiglioni[1], R. Pérez Torrado[2], L. Alberto Oliveira Rocha[3], J. Alberto Vieira Costa[4]
[1]Universidade Federal de Goiás, Food Engineering, Goiania, Brazil
[2]Instituto de Agroquímica y Tecnología de Alimentos, Molecular biology, Valencia, Spain
[3]Universidade Federal do Rio Grande do Sul, Departamento de Engenharia Mecânica, Porto Alegre, Brazil
[4]Universidade Federal do Rio Grande, Escola de Química e Alimentos, Rio Grande, Brazil

Backgrounds

Capes

Objectives

The aim of this study was to model and numerically optimize lipase production through solid-state fermentation with filamentous fungus *Aspergillus fumigatus* using rice industry byproducts as substrate under different aeration conditions.

Methods

Strain of filamentous fungus *Aspergillus fumigatus* was used in experiments.
Cultivations were conducted in system described by Castiglioni et all [13]. The growth medium was composed of nutrient solution, rice hulls and defatted rice bran.
Soybean or diesel oils were added in separate experiments at a ratio of 1% (w/w), as an additional carbon source, for further comparison with experiments without their addition. Besides cultures without air supply, aerations of 40, 60, 120 and 200 $mL_{air}.g_{medium}^{-1}.h^{-1}$ were evaluated, aiming to study a wide range of this variable.
Preliminary tests were carried out using different mathematical functions, which were reparameterized for different equations. For optimum adjustments, determination coefficients were calculated. The coefficients of equations were numerically calculated by the method of least squares, and experimental and predicted results were statistically analyzed using univariate variance for significant differences.
Optimal lipase activity values, obtained by the model, were collected for each aeration condition studied. The results have been maximized in relation to aeration to determine the conditions that showed the best lipase production results. The model was validated by performing a new experiment, but under conditions different from those used to construct the model. The condition chosen for the model validation was 90 $mL_{air}.g_{medium}^{-1}.h^{-1}$.

Conclusions

The results of the model developed follow the trends of experimental results, showing similar lipolytic activities. The result of lipase production optimization was 107.56 $U.g^{-1}$ using 83 $mL_{air}.g_{medium}^{-1}.h^{-1}$ during 102 h of fermentation. The validation of mathematical model showed no significant differences from the predicted results, which ensures reliability as a new alternative to optimize the solid-state fermentation process with *Aspergillus fumigatus* using rice byproducts.

CRUDE LIPID EXTRACTS OBTAIN FOR IDENTIFICATION OF MYCOBACTERIA'S PHENOLIC GLYCOLIPID

B. Chavarro-Portillo[1,2], *Z. Rivera-Monroy*[2], *C.Y. Soto*[2], *M.I. Guerrero*[1]
[1]*Hospital Universitario Centro Dermatológico Federico Lleras Acosta E.S.E, Línea Hansen, Bogotá, Colombia*
[2]*Universidad Nacional de Colombia, Departamento de Química- Facultad de Ciencias, Bogotá, Colombia*

Backgrounds

M. leprae possesses the specific-antigenic known as phenolic glycolipid-1 (PGL-1) that mediates the interaction between *M. leprae* and Schwann cells. We previously developed a ***Bio-Nano-technological tool*** for PGL-1 detection, which will be used to detect antibodies against PGL from other skin disease-producing mycobacteria, such as *M. tuberculosis, M. marinum* and *M. ulcerans.* For this goal, PGL patterns from these mycobacteria should be identified and isolated.

Objectives

To design a methodological approach for the identification and purification of PGL from *M. tuberculosis, M. marinum* and *M. ulcerans,* by reverse-phase HPLC.

Methods

Mycobacteria were grown in Middlebrook 7H9 broth for 28 days at 37 °C, and crude-lipid extracts were obtained by extraction using the solvent system CH_3OH: H_2O. PGL was then separated by reverse phase HPLC, using a C18 column to bind the phenol group of the PGL structure, and two mobile phases (acetonitrile: water and methanol: water) were evaluated.

Conclusions

The mobile phase acetonitrile: water solvent systems, from 5:95 to 100: 0 in 40 min, allowed better peak resolution retention times (from 6.9 to 34.3 minutes) compared to those obtained using the mobile phase methanol: water. This is a highly sensitive and specific method that can be applied for PGL detection and purification from mycobacterial species of clinical interest, which produces enough amounts of PGL for detecting anti-PGL antibodies in clinical samples.

USING COMPUTATIONAL SYSTEMS BIOLOGY TO UNDERSTAND THE IMPACT OF GENOMIC DIVERSITY IN THE MYCOBACTERIUM TUBERCULOSIS COMPLEX

A. Chiner-Oms[1], F. Gonzalez-Candelas[1], I. Comas[2]
[1]FISABIO-Universitat de Valencia, Unidad Mixta Infección y Salud Pública, Valencia, Spain
[2]Biomedicine Institute of Valencia, Tuberculosis Genomics Unit, Valencia, Spain

Backgrounds

Species of the *Mycobacterium tuberculosis* complex (MTBC) kill more people every year than any other infectious disease. Because of its global distribution and parallel evolution with the human host, the bacteria is not genetically homogeneous. The observed genetic heterogeneity has relevance at different phenotypic levels, including epidemiological dynamics. However, current datasets have focused in the laboratory reference strain H37Rv.

Objectives

Our main objective is to define how the genetic variability identified in a global collection of isolates affect the biological networks derived from H37Rv experimental data.

Methods

First, we have constructed computational models to grab the expression dynamics of H37Rv genes. We have found that many of those transcription factors are deleted or likely dysfunctional across the MTBC. In accordance, we failed to predict expression changes in strains with a different genetic background when compared with experimental data.
Second, we have mapped about 200000 polymorphisms extracted from 9000 clinical strains on the interactome of the bacteria. We observed that the core of the interactome is more conserved than the periphery. A higher proportion of high impact mutations are in clusters of proteins located on the rim of the interactome than those in the center. The pattern of these mutations impacting the interactome is different for each lineage.

Conclusions

The biological networks of the pathogen are not fully conserved and there is variability among the different lineages. In order to obtain reliable models with which to make predictions there is a need of experimental data from representative samples comprising the natural diversity of the MTBC.

TUNING SYNTHETIC GENE EXPRESSION FOR ENHANCED PRODUCTION OF HETEROLOGOUS MEVALONATE IN ESCHERICHIA COLI

B.H. Choi[1], S.J. Kwon[1], H.J. Kang[1], P.C. Lee[1]
[1]Ajou University, Molecular Science and Technology, Suwon, Republic of Korea

Backgrounds

Isopentenyl diphosphate (IPP) is building block for isoprenoids, which are one of the most abundant natural secondary metabolite, including carotenoids and terpenoids. Most prokaryotes synthesize IPP by 2-C-methyl-D-erythritol 4-phosphate (MEP) pathway, while most plants, eukaryotes and some Gram-positive bacteria synthesize by mevalonate (MVA) pathway.

Objectives

Here we report cloning and reconstruction of three upstream mevalonate (MVA) pathway genes of novel bacterium *Enterococcus Kingsejongenesis*, which was isolated from a South Polar Brown Skua, in *Escherichia coli* for the production of MVA.

Methods

Each gene encoding the three upstream MVA pathway enzymes, HMG-CoA synthase (*mvaS*) and Thiolase/HMG-CoA reductase (*mvaE*), was modularized as an individual synthetic expression unit, and then was functionally expressed with a single or assembled module in *E.coli*. For balanced and fine-turned protein expression in metabolic pathway, expression levels of *mvaS* and *mvaE* were regulated by synthetic expression cassette (SEC) library. Randomizing promoter strength and ribosome binding site (RBS), simultaneously, was employed to diversify expression of mvaS and mvaE protein specifically in *E.coli*.

Conclusions

In this study, functional expression module of MVA pathway was constructed by modularization of each gene. The MVA pathway module from *E.kingsejongenesis* produced 1.6-fold higher mevalonate compared with *Enterococcus faecalis* in *E.coli*. Furthermore, fed-batch fermentation of the recombinant *E.coli* under the newly designed promoter and RBS module resulted in the 1.5-fold enhanced MVA production than that obtained by MVA pathway module from *E.kingsejongenesis* using *lac* promoter. The *E.coli* strain engineered in this study can serve as the basis for creating an alternative way for production of MVA.

CHEMICALLY INDUCED BACTERIAL GHOSTS AS AN SAFE AND EFFICIENT NON-VIRAL DNA DELIVERY VEHICLE IN VITRO

C.W. Choi[1], H.B. Noh[1], N. Vinod[1], S. Oh[1], S. Ji[1], S. Kim[1], H.J. Park[1]
[1]Paichai University, Department of Biology & Medicinal Science, Daejeon, Republic of Korea

Backgrounds

Gene therapy represents promising method to treat diseases by delivering a therapeutic gene within the target cell. To deliver DNA into target cell, a carrier is required. Bacterial ghosts (BGs) are novel and non-living empty bacterial cell envelopes mainly derived from Gram-negative bacteria. The plasmid DNA immobilized in BG system has been shown to be a safe and promising technology for gene delivery and indicating alternative to current viral and bacterial gene delivery system.

Objectives

In this study, we used chemically induced BGs from *Salmonella typhimurium* for the first time as a delivery carrier for green fluorescent protein (GFP) gene to murine macrophages.

Methods

The S. typhimurium ghosts (STGs) were produced using the MIC of NaOH and loaded with minicircle DNA containing GFP gene by diffusion method. Real time PCR analysis confirmed that BGs loaded with minicircle plasmid carrying the GFP gene. *In vitro* studies after transfection showed that the STGs more efficiently delivered the minicircle plasmid within the macrophages. The expression of GFP gene was determined by RT-PCR and qPCR. Moreover, we examined uptake of the STGs loaded with minicircle DNA by confocal laser scanning microscopy.

Conclusions

We have shown that BGs loaded with minicircle DNA efficiently delivered and taken up by macrophages. When compared to minicircle DNA alone, STGs loaded with minicircle DNA was increased transgene expression level. These studies demonstrate for the first time potential of chemically-induced BGs could be used as a novel delivery vehicle and targeting carriers for gene therapy.

PROTECTIVE IMMUNITY AGAINST LISTERIOSIS IN RATS, PROVIDED BY CHEMICALLY-INDUCED LISTERIA MONOCYTOGENES BACTERIAL GHOSTS (LMGS)

C.W. Choi[1], S. Ji[1], S. Oh[1], H.B. Noh[1], K. Seongdae[1], H.J. Park[1], N. Vinod[1]
[1]Paichai University, Department of Biology & Medicinal Science, Daejeon, Republic of Korea

Backgrounds

Listeriosis, caused by the gram-positive, facultative intracellular bacterium, is one of the leading causes of food borne infections in the industrialized world and an etiologic agent of listeriosis to humans with a high mortality rate. Most common clinical feature includes meningitis or septicemia in children and the elderly. Therefore, The development of Listeria vector candidates by attenuation of its virulence is needed for safety considerations.

Objectives

To investigate the LMGs as a potential vaccine candidate, mice were divided into three groups; non-vaccinated control group and subcutaneously immunized groups with HCl-induced LMGs and NaOH-induced LMGs, Most importantly, bacterial loads in both of LMGs-immunized groups were significantly lower than non-immunized control group after virulent *Lm* challenge. These results suggest that immunization with LMGs induces both humoral and cell-mediated immune responses and provides protection against virulent *Lm*.

Methods

Listeria monocytogenes bacterial ghosts (LMGs) were generated by chemically induced lysis and the method is based on minimum inhibitiory concentration of HCl and NaOH. Among LMGs samples, To investigate the LMGs as a potential vaccine candidate, mice were divided into three groups; non-vaccinated control group and subcutaneously immunized groups with HCl-induced LMGs and NaOH-induced LMGs, respectively.

Conclusions

Non-living LMGs has been successfully generated by MICs and the approach is rapid and cost-effective when compared to other known methods. Interestingly, the present strategy may open the door produce BGs from Gram-positive bacteria. Most importantly, we have shown that immunization with LMGs induced significant humoral and cellular immune responses and provided strong protection against virulent challenge in BALB/c mice.

[3]University Duisburg-Essen, Aquatic Biotechnology, Essen, Germany
[4]Ruhr University Bochum, Plant Biochemistry, Bochum, Germany
[5]Università della Svizzera Italiana, Institute of Computational Science, Lugano, Switzerland
[6]Donghua University, College of Environmental Science and Engineering, Shanghai, China
[7]Plymouth University, School of Biomedical and Healthcare Sciences, Plymouth, United Kingdom

Backgrounds

In recent decades, bioleaching of sulfidic ores has been firmly established as an environmentally sustainable alternative to conventional metal extraction methods such as roasting and smelting. By using this technique, environmental pollution is kept at a minimum, as only acidophilic organisms catalyze the dissolution of the sulfide mineral, releasing the incorporated metals. Among the microorganisms in bioleaching heaps, the autotrophic iron oxidizer *Leptospirillum ferriphilum* is one of the most abundant.

Objectives

Despite its importance in biomining and other metal rich and low pH environments, no complete genome sequence of this model species' type strain has been available. However, for further study of the organism and its role in bioleaching communities, a full genome is essential as a reference for proteomic and transcriptomic investigation.

Methods

In this study, Pacific Bioscience (PacBio) single molecule real time sequencing was utilized to provide a closed, circular *L. ferriphilum*^{T} DSM14647 genome of high quality for future use as a publicly available reference. Concurrently, continuous cultivation of axenic *L. ferriphilum*^{T}, grown on its sole substrate ferrous iron, was performed to establish a proteome baseline, and sequence a transcriptome baseline via Illumina HiSeq sequencing technology. Likewise, cells were incubated in batch cultures containing chalcopyrite ($CuFeS_2$; the world's most abundant copper mineral) as a substrate, to investigate *L. ferriphilum*'s resistance to low pH, elevated levels of copper, and oxidative stress caused by the mineral and released heavy metals.

Conclusions

The data made available by this project will serve as a point of reference in future studies on *L. ferriphilum*^{T} and its role in environment and biotechnology.

ELECTROSPUN OF SILK FIBROIN IMMERSED ANOECTOCHILUS ROXBURGHII EXTRACTIONS (CUST903) FROM PLANT FACTORY SYSTEM FOR ANTIOXIDANT AND ANTIBACTERIAL WOUND DRESSING

J.T. Kuo[1], Y.C. Chang[1], Y.C. Chung[1]
[1]China University of Science and Technology, Department of Biological Science and Technology, Taipei city, Taiwan R.O.C.

Backgrounds

CUST903 was extracted by ethanol from *Anoectochilus roxburghii* from Plant Factory production system. In the study, silk fibroin (SF) mat was prepared by electrospinning technique, followed by immersing in solution of CUST903 to evaluate the feasibility of these mats for wound dressing. SF nanofibers provided a better level of equilibrium water content (EWC) and water vapor transmission rate (WVTR).

Objectives

Antioxidant activity of CUST03-loaded SF mats was measured by the DPPH assay and increasing with its concentrations. They exhibited strong antioxidant DPPH radical scavenging activity with IC50 value of 9.8 and 23.6 μg/ml for ascorbic acid and alcoholic leaves extract respectively. The absorbance for reducing power was found to be 0.0410, 0.0932 for ascorbic acid and alcoholic leaves extract respectively. In additions, Cytotoxicity of CUST03-loaded SF mat was evaluated using L929 and A375-S2 fibroblasts through the MTT assay. The antibacterial activity of CUST903-loaded SF mat was evaluated against *E coli* and *S. aureus only 0.13ug/ml*.

Methods

Silkworm cocoons were boiled in an aqueous solution of 0.02M Na2CO3 for 30 min to remove the sericin and then rinsed thoroughly with distilled water. The degummed silk fibroin was then dissolved in a mixture of CaCl2 : C2H5OH : H2O (molar ratio = 1:2:8) at 70°C for 6 h and dialyzed against distilled water for 3 days with successive water changes to remove salt. The Anoectochilus roxburghii was made by plant Factory system which was controlled by light source, temperature and humidity conditions.

Conclusions

Through characterization of physical properties, stability testing, and biocompatibility, the CUST903-loaded SF mat exhibited potential for Antioxidant and antibacterial wound dressing applications.

POLYMORPHISM IN THE REGULATORY REGION OF THE CGYPS1 AND CYYPS7 GENES ENCODING FOR YAPSINS OF CANDIDA GLABRATA

E. Cortés-Acosta[1], J.A. Ibarra-García[1], H.C. Ramírez-Saad[2], M.L. Villa-Tanaca[1], C.H. Hernández-Rodríguez[1]
[1]Instituto Politécnico Nacional-ENCB, Microbiología, Mexico City, Mexico
[2]Universidad Autónoma Metropolitana-UAM-X, Sistemas Biológicos, Mexico City, Mexico

Backgrounds

Candida glabrata is an opportunistic fungus infecting mainly immunocompromised people. Their adherence capacity and exoenzymes contribute to damage to host cell. Particularly, the yapsins are a family of aspartyl proteases involved in maturation of proteins, cell wall function, and etcetera. Yapsin 1 and 7, encoded by *CgYPS1* and *CgYPS7* genes respectively, are a potential virulence factors.

Objectives

In this study, the diversity of regulatory regions and expression profiles of the both genes from *C. glabrata* clinical strains were compared.

Methods

The polymorphism in regulatory regions of both yapsin genes were recognized by DGGE (Denaturing Gradient Gel Electrophoresis) migration profiles. The sequence analysis of regulatory regions revealed that the distribution of Transcription Factor Binding Sites (TFBS) were similar, although some TFBS were not universally distributed. The quantitative expression of *CgYPS7* genes of different *C. glabrata* strains in rich and poor media was estimated by RT-qPCR.

Conclusions

The CGL8 strain, which contains TFBS for a carbon source-responsive element, had a high expression of *CgYPS7* gene in YPD medium. However, the expression levels in YNB medium without nitrogen source of most the strains were, a result coherent with the presence of F$YMAT, a TFBS associated to nitrogen starvation conditions. Also, the CGL33 strain exhibited high expression levels of the *CgYPS7* gene in YNB without carbon source. The primary sequences of *CgYPS7* genes of *C. glabrata* strains are highly conserved among different strains, however the regulatory regions are polymorphic, harbor different TFBS arrays, and showed differential expression profiles.

"IN VITRO" ANTIMICROBIAL ACTIVITY OF THE HYDROALCOHOLIC EXTRACT OF LAFOENSIA PACARI

A.K.M. Santos[1], M.B.P.C. Camara[1], F. Costa Rosa[2], C. Nadine Cunha[3], M. Francyelle Costa[2], C.F. Antonio José[1], M. Georgiana Eurides de Carvalho[1], C. Fernando José Costa[1]
[1]IFMA, Química, São Luís, Brazil
[2]Faculdade Estácio de São Luís, Enfermagem, São Luís, Brazil
[3]LABCENTER, Controle de qualidade, Palmas, Brazil

Backgrounds

Crude extracts or isolated plant coumpounds used in popular medicine can be the source of research for new antimicrobials. Among these plants, there is *Lafoensia pacari*, popularly known as "mangaba brava", easily found in the brazilian "Cerrado" (tropical savannah ecoregion) area. Traditionally, it is used by popular medicine in the form of infusions and leaf and bark maceration for treating diseases

Objectives

To verify the "in vitro" antimicrobial activity of the hydroalcooholic extract of *L. pacari.*

Methods

The vegetal species *Lafoensia pacari* was collected in the village of Contrato, in the city of Morros-MA, under the localization S 02° 54' 47,6" e W 043° 55' 30,1". The barks were dried and posteriorly the extract was obtained using the extracting solvent hydroalcoholic 70% in the proportion of 1:3 (m/v). Afterwards, the extract was submitted to the rotative evaporator under reduced pression, with the temperature controlled up to 50°C, obtaining the final concentraion of 2,9mg/mL. In order to verify the antimicrobial activity, the techniques of agar diffusion and microdilution with the following standard strains: *Staphylococcus aureus* (ATCC 25923), *Escherichia coli* (ATCC 25922), *Salmonella typhi* (ATCC 14028), *Pseudomonas aeruginosa* (ATCC 27853), *Candida albicans* (ATCC 14053)*, Candida krusei* (ATCC 6258) *e Candida parapsilosis* (ATCC 22019).

Conclusions

The extract of *L. pacari* presented only the bacteriostatic effect over the evaluated strains. However, concerning its antifungal activity, we observed the fungicide capacity on all the *Candida* gender strains, presenting the following MFC: 0,36 mg/mL, 0,18 mg/mL e 0,09 mg/mL to *C. krusei, C. albicans* e *C. parapsilosis*,

ANTIMICROBIAL POTENTIAL OF ETHYL ACETATE FRACTION OF LUEHEA CANDICANS AGAINST BACTERIA AND FUNGI

M. Bispo Pinheiro Camara[1], A.J. Cantanhede Filho[1], F.J. Costa Carneiro[1], T. Daniele Val Lima[2], F. Costa Rosa[3], F. Costa Moraes[3], G. Eurides de Carvalho Marques[1]
[1]IFMA, Química, São Luís, Brazil
[2]Faculdade Estácio de São Luís, Química, São Luís, Brazil
[3]Faculdade Estácio de São Luís, Enfermagem, São Luís, Brazil

Backgrounds

Popular medicine empirically diffuses the use of plants's leaves of the genus *Luehea* to treat various diseases. Among the species, stands out the *Luehea candicans*, a brazilian native plant with few reports in the literature about your antimicrobial potential.

Objectives

To inquire the antimicrobial potential of the ethyl acetate fraction of *Luehea candicans* against bacteria and fungi.

Methods

Luehea candicans (Titulaceae) was collected in the Contrato's Village in the city of Morros/MA, under the location S 020 55 '21.0' 'and W 0430 55' 34.7 ''. The botanical identification of the species was registered under the number 4586 that is deposited in the Herbarium of the State University of Maranhão. The weeds were dried and then the crude extract was extracted using 70% hydroalcoholic solvent in the ratio of 1: 3 (m / v). From the ethyl acetate phase, it was parted with dichloromethane again, gaining a ethyl acetate fraction at a concentration of 9.77 mg/mL. The antimicrobial potential was verified in the agar drilling and microdilution techniques using the following species: *Staphylococcus aureus* (ATCC 25923), *Escherichia coli* (ATCC 25922), *Salmonella typhi* (ATCC 14028), *Pseudomonas aeruginosa* (ATCC 27853), *Candida albicans* (ATCC 14053), *C. krusei* (ATCC 6258), *C. parapsilosis* (ATCC 22019) and clinical samples of *C. glabrata* and *C. albicans.*

Conclusions

Only in the microdilution technique was it possible to verify the intense antimicrobial potential of fraction evaluated, highlighting just 1.22 mg/mL CFM and 2.44 mg / mL for clinical samples of *C. glabrata* and *C. albicans* respectively. In the bacteria only inhibitory effect was observed.

COMBINATION OF FOOD WASTES FOR AN EFFICIENT PRODUCTION OF NISIN IN REALKALIZED FED-BATCH CULTURES

M. Costas Malvido[1], *E. Alonso González*[1], *N. Pérez Guerra*[1]
[1]*Universidad de Vigo, Department of Analytical and Food Chemistry, Vigo, Spain*

Backgrounds

Nisin is a bacteriocin produced by *Lactococcus lactis* strains, with a broad spectrum of antibacterial activity against undesirable spoilage bacteria and food-borne pathogens including *Listeria monocytogenes*, *Staphylococcus aureus*, *Bacillus cereus* and *Clostridium botulinum*. This bacteriocin is innocuous, stable to heat at low pH levels and sensitive to the gastric proteinases. For these characteristics, nisin is used as a safe preservative for different foods in many countries. However, considerably higher productions of nisin have been obtained in fed-batch cultures in comparison to the batch mode.

Objectives

To obtain increased nisin production by *L. lactis* CECT 539 at low production cost

Methods

Realkalized fed-batch cultures in diluted whey (DW). The first and third cultures were fed with mixtures of whey (W, 51.35 g of lactose/L) and a 400 g/L concentrated glucose (CG), or with a concentrated mussel processing waste (CMPW, 101.72 g of glucose/L) and CG, respectively. The second and fourth cultures were respectively performed under the same conditions as in the first and third fermentations. However, these cultures were supplemented with W plus a 2 % (w/v) yeast extract (WYE2) and CG (second culture), or with CMPW plus a 2 % (w/v) yeast extract (CMPWYE2) (fourth culture) after sample extractions at 132 and 168 h, respectively. From these times, each culture was fed with mixtures of WYE2 and CG, or CMPWYE2 and CG, respectively

Conclusions

The third (223.98 BU/mL) and fourth (350.61 BU/mL) cultures provided higher nisin concentrations than the first (108.00 BU/mL) and second (158.53 BU/mL) fermentations

ACTIVATION OF SILENT GENE CLUSTERS IN FUNGI AS A TOOL FOR ANTIBIOTIC DRUG DISCOVERY

L. Cubilla Rios[1], *M.M. Aguilar-Pérez*[2]
[1]*Universidad de Panama, Química Orgánica, Panama, Panama*
[2]*Universidad de Panama, Laboratorio de Bioorgánica Tropical, Panama, Panama*

Backgrounds

The indiscriminate use of the current antimicrobials, the microbial capability to develop resistance and the existence of fewer effective antibiotics against certain infections make the discovery of new antibiotics an urgent priority. Endophytic fungi are capable of producing secondary metabolites with antibacterial activity as well as reacting to changes in culture conditions that could activate silent gene clusters. Thus, the ability to enhance the chemical diversity produced by the fungi will increase the possibility of uncovering new antibacterial activities.

Objectives

This research pursues the activation of silent gene clusters to increase the antibacterial spectrum of two fungal strains, *Pestalotiopsis mangiferae* and *P. microspora.*

Methods

In the first phase, strains were grown in five different **media** (e.g. PDA, MEA); second step a **chemical agent** (e.g. Arginine, $CuSO_4$) prior to inoculation onto the selected media. In the third phase, changes in **pH** were used as elicitors, with buffers being used to stabilize the pH (4.0, 4.6, and 5.6) of the media. Finally, changes in the incubation **temperatures** (e.g. 24 and 30 °C) were used as an elictor. An organic extract was obtained from each culture. The antibacterial activity was determined through a susceptibility test against 20 species.

Conclusions

Pestalotiopsis mangiferae produced the greatest inhibition spectrum, 11 bacteria, when MEA was used as a nutrient, $CuSO_4$ as chemical agent, the pH was 4.0, and the temperature 24 °C. In total 18 bacteria were inhibited by all the extracts obtained from the culture of this species. By *Pestalotiopsis microspora* in total 12 bacteria were inhibited. The antibacterial spectrum, in each case, has been clearly improved by using specific culture conditions.

STUDIES ON ANTI-NEOPLASTIC ENZYME - L-ASPARAGINASE ISOLATED FROM BACILLUS SPECIES

S. Dahikar[1]
[1]*Sanjivani Arts - Commerce and Science College - Kopargaon, Department of Microbiology, Kopargaon, India*

Backgrounds

L- asparaginase is enzyme acting on L- asparagine and is widely used as anticancer agent. The reason it is preferred for the purpose is it is biodegradable, non-toxic and can be administered at the local site quite easily.

Objectives

At present various microorganisms are used for production of L-asparginase. The main objectives of this study were to determine anti-neoplastic activity of enzyme - L-asparaginase from Bacillus species from soil.

Methods

In the present study, a total of five soil samples were collected from various places near to Kopargaon, from these soil samples 12 isolates were identified as *Bacillus licheniformis* (5)*, Bacillus alvei* (2), *Bacillus megaterium* (1), *Bacillus cereus* (1), *Bacillus circulans* (1) and *Bacillus subtilis* (2). The optimization study for the process parameters was given useful information about the production of the enzyme maximally. Potential L-asparginase producer isolates were showed the maximum activity at pH 7 and temperature at 37°C. After that the isolates were exposed to the UV treatment for 5, 10 and 15 min for strain improvement and among them Asp11 *(Bacillus subtilis)* was found useful strain for the commercial production of the L-Asparaginase. The purified enzyme of Asp11 was used for protein profile.

Conclusions

This highly potential species can be used for the commercial production of the enzyme which is having immense medical applications as it is one of the promising treatments for the threatening disease called as cancer.

ADJUSTMENTS IN THE LIPID PROFILE OF RHODOCOCCUS UNDER STRESSFUL CONDITIONS MAY BE USED TO IMPROVE BIOTECHNOLOGICAL PROCESSES

C.C. C. R. de Carvalho[1]
[1]*Instituto Superior Técnico, Department of Bioengineering- iBB-Institute for Bioengineering and Biosciences, Lisbon, Portugal*

Backgrounds

When bacterial cells are exposed to stressful conditions, such as the presence of organic compounds, antibiotics, salt or the lack of nutrients, they use a series of adaptive mechanisms to survive. Among these are modifications in the fatty acid (FA) composition of the cellular envelope.

Objectives

The studies aimed at improving biotechnological processes by application of bacterial adaptive mechanisms at the lipid level.

Methods

To determine the cell composition in FAs, after exposure to stress, total lipids were extracted, methylated and the resulting FA methyl esters were analyzed by gas chromatography (GC). Cell membrane composition was determined after chromatographically separating total lipids into neutral lipids, glycolipids and phospholipids. Biocatalysis and bioremediation of model compounds using adapted cells was followed by GC.

Conclusions

R.erythropolis cells changed their FA composition during adaptation to values of temperature, pH, salt and copper concentrations far from the optimum values for cell growth [1]. Following exposure to salt, high percentage of polyunsaturated FA were unexpectedly produced [2]. Alterations in the cell wall and membrane compositions and properties allowed these cells to tolerate compounds usually toxic to other bacterial strains such as terpenes used in biocatalysis, and hydrocarbons and aromatic compounds used in bioremediation [1,3]. The specific adaptive mechanisms also helped the cells to respond to fast environmental changes, and the establishment of the most tolerant cells in populations used in biotechnological processes.

IMPACT OF DIETARY FAT CONTENT ON HOST SUSCEPTIBILITY TO LISTERIA MONOCYTOGENES INFECTION

V. de Las Heras[1], K. Govindarajan[1], S. Joyce[2], P. Casey[3], R. Rubio[4], P. Cotter[4], C. Hill[1], C. Gahan[1]
[1]University College Cork, School of Microbiology- APC Microbiome Institute, Cork, Ireland
[2]University College Cork, School of Biochemistry and Cell Biology- APC Microbiome Institute, Cork, Ireland
[3]University College Cork, APC Microbiome institute, Cork, Ireland
[4]APC Microbiome Institute, Moorepark Food Research Center- Teagasc, Fermoy- Cork, Ireland

Backgrounds

Currently the world is facing an escalation in cases of obesity, influenced by an increase in consumption of elevated levels of saturated fats and sugar, the so-called Western-diet. However the impact of these dietary changes on host susceptibility to foodborne pathogens such as *Listeria monocytogenes* is currently unclear.

Objectives

In this project, using an *in vivo* systems biology approach, we explore the host response to oral *Listeria monocytogenes* infection following murine exposure to defined rodent diets that mimic low-fat or high-fat (Western) diets.

Methods

Mice were fed a control chow diet, a low-fat diet (10% of caloric intake from fat) or a high-fat diet (45% of caloric intake from fat) throughout the experiment. The total bacterial load from the organs at 3 days post-infection was used to characterize *L. monocytogenes* infection. Microbiota analysis (16S DNA sequencing) and host transcriptome analysis were performed to explore the impact of the dietary fat content on the host.

Conclusions

Total bacterial loads from the organs harvested 3 days post-infection show an increased susceptibility to *L. monocytogenes* in mice receiving a high fat diet. This increased susceptibility to infection was associated with significant changes to the composition of the gut microbiota, physiological changes in the gut barrier and immune suppression caused by increased dietary fat content. The findings indicate that diet mediates physiological changes to the host, that can significantly influence susceptibility to infection with *L. monocytogenes*, suggesting that diet should be considered as an important factor in future models of *L. monocytogenes* pathogenesis.

UTILIZATION OF SACCHAROMYCES CEREVISIAE FOR BIOETHANOL PRODUCTION FROM TURNIP JUICE DISCARDS

E. Demiray[1], S. Ertuğrul Karatay[1], G. Dönmez[1]
[1]Ankara University, Biology, Ankara, Turkey

Backgrounds

Widespread usage of fossil fuels cause rapid depletion and there is several environmental consequences which triggers the researches for finding alternative sources. Among these sources bioethanol is one of the most important one because of its renewable and environmentally friendly properties. Because feedstock costs are the major part of bioethanol production, considerable work has been performed toward production of bioethanol using various kinds of feedstocks such as starch or lignocellulose.

Objectives

Turnip juice is made from black carrot and turnip. After turnip juice production; black carrots and turnips are not used and are disposed as a waste. In this study, we examined bioethanol production of turnip juice discards by *S. cerevisiae*. Some important parameters such as initial biomass loading, fermentation time and pretratment conditions were optimized.

Methods

Turnip juice discards were obtained from Kilikya Şalgam Co. and dried in the oven at the 70 ^{0}C. To obtain fermentable sugars; discards hydrolysed in the 1% H_2SO_4 (v/v). Yeast growth, initial and consumed sugar concentrations were monitored periodically. Bioethanol concentration was determinated by using gas chromotography.

Conclusions

Among the tested pretreatment methods the most effective one was acid hydrolysis with autoclaving. It was found in the study that the yeast consumed 2.31±0.06 g/L sugar when the ethanol concentration was 0.4 ±0.06 g/L at the end of 24 hours incubation time at pH 5 in the presence of 50 g/L biomass loading. In the present study we showed that bioethanol production from biomass of turnip juice discards can be increased by appropriate pretreatments.

USAGE OF CARROT POMACE FOR BIOETHANOL PRODUCTION BY KLUYVEROMYCES SP.

E. Demiray[1], *S. Ertuğrul Karatay*[1], *G. Dönmez*[1]
[1]*Ankara University, Biology, Ankara, Turkey*

Backgrounds

In today's world the widespread use of fossil fuels cause rapid depletion and several environmental consequences which triggers the researches for finding alternative fuels. Bioethanol is one the most important renewable source. Bioethanol as a renewable and clean energy source is getting more attractive. The ethanol also reduces carbon dioxide emissions of the vehicles up to 90% when it blended with gasoline. Hence investigation of more effective bioethanol production ways are important.

Objectives

Several different biotechnological applications have been investigated with *Kluyveromyces* sp. For this purpose in our current study we isolated novel osmotolerant yeast strains from biscuit factory wastes and they were used for bioethanol production. Among them *Kluyveromyces* sp. coded as isolate 8 had higher ethanol production capacity than the other isolates in the media containing carrot pomace as carbon source.

Methods

Carrot pomaces were supplied from BELSO Co. Ankara/Turkey. Pomaces were hydrolysed in 1% H_2SO_4 (v/v). Microbial growth, sugar consumption and bioethanol amounts were monitored periodically.

Conclusions

The highest bioethanol production was observed at pH 5 at the end of 12 hours incubation time. Furthermore there were significant amounts of ethanol production was seen at 24 hours incubation time for all tested pH values (4, 5, 6, 7). 8.13 g/L bioethanol was achieved at the end of 24 hours at pH 5.

In this study we showed carrot pomaces are suitable feedstocks for bioethanol production. Fermentation capacity of the *Kluyveromyces sp.* can be increased with different ways such as metabolic or evolutionary engineering.

CARBON MONOXIDE AS A COMPETITIVE INHIBITOR INDUCING REVERSIBLE INACTIVATION OF FE-FE HYDROGENASES BY NON-DISRUPTIVE BINDING AT ACTIVE SITE

K. Dixit[1], S. Singh[2], V. Kannaujiya[3], A. Rahman[1], A.K. Srivastava[1], S. Singh[1], R. Ettrich[4], S. Sundaram[1]
[1]University of Allahabad, Centre of Biotechnology, Allahabad, India
[2]BITS Hyderabad, Biological Sciences, Hyderabad, India
[3]Banaras Hindu University, Botany, Varanasi, India
[4]Institute of Microbiology Academy of Sciences, Center for Nanobiology and Structural Biology, Czechia, Czech Republic

Backgrounds

Hydrogenases efficiently catalyze the production and cleavage of molecular hydrogen. Their use in biotechnological applications is anticipated to make a remarkable contribution to future renewable fuel production. There are three types of hydrogenases: Fe-Fe, Ni-Fe and Fe-only hydrogenases.

Objectives

In this study, the Fe-Fe hydrogenases are majorly focused. The Fe-Fe hydrogenases of green algae (Chlorophytes) are also called “Chlorophyta type” hydrogenases and do not contain F-cluster. The presence of H-cluster at the active site is the main attribute of chlorophyte’s hydrogenase. Carbon monoxide (CO) is an effective inhibitor of Fe-Fe hydrogenases and so is oxygen (O_2).

Methods

The enzyme kinetics was studied for oxygen, carbon monoxide and CrHydA1 and K_m was calculated by Hyper32 software. K_m value 50μM, 22μM and 28 μM were recorded respectively for the inhibitors and the substrate suggesting CO as a potent non-destructive inhibitor, which can protect against oxygen damage.

Conclusions

Oxygen irreversibly destroys the enzyme active site causing potential loss of function. CrHydA1 is a substrate for hydrogenase enzyme and is important functionally for efficient enzyme activity. CO, being a competitive inhibitor of CrHydA1, binds to the iron atom of the 2Fe-H domain and is ordinarily, non-destructive, securing the Fe-S clusters to remain intact in the enzyme. CO has nearly two folds higher affinity for the active site of hydrogenase as compared to oxygen protecting the enzyme against damage from O_2.Here, we present a study of the mechanism by which O_2 irreversibly attacks the H-cluster, by in-silico techniques with the reversible inhibitor CO as a complementary binding substrate.

CHARACTERIZATION OF RESISTANCE GENES AGAINST VANCOMYCIN AND AMPICILLIN IN THE GUT MICROBIOTA OF BLATTELLA GERMANICA

R. Domínguez-Santos[1], I. Talón[1], C. García-Ferris[1], A. Artacho[2], A. Latorre[1]
[1]Institute for Integrative Systems Biology I2SysBio, University of Valencia, Paterna, Spain
[2]FISABIO Foundation, Centre for Advanced Research in Public Health, Valencia, Spain

Backgrounds

The research for new antibiotics against bacterial pathogens is an urgent priority of modern medicine, which has found that the number of bacteria resistant to multiple antibiotics is growing steadily, and therefore antibiotic resistance is recognized as one of the major challenges in public health. *Blattella germanica* is an omnivorous insect that harbour a rich and complex gut microbiota, similar in some characteristics to human gut microbiota, and may contain bacteria with many antibiotic-resistance genes that can be a reservoir to be transferred to humans.

Objectives

To study the composition of the gut microbiota and characterization of resistance genes against vancomycin and ampicillin.

Methods

We have worked with three synchronized adult populations of *B. germanica*. Two of them were treated with antibiotic (vancomycin or ampicillin, respectively) supplied *ad libitum* with water at 0.02% (w/v). The third population was used as a control.

Conclusions

The microbiota in the hindgut of *B. germanica* consists of a very large community of bacteria, and it varies considerably depending on the antibiotic supplied. In general, vancomycin increased the abundance of gram-negative bacteria, as in the phyla Proteobacteria, Fusobacteria and Planctomycetes and reduced the presence of gram-positive bacteria, as in the phylum Firmicutes. Furthermore, ampicillin increased representatives of Bacteroidetes and reduced the phylum Firmicutes. Vancomycin and ampicillin resistance genes encoding multidrug efflux pumps were detected mainly in the phylum Proteobacteria, while specific ampicillin resistance genes were identified in Firmicutes (Bacillales and Staphylococaceae) and Bacteroidetes. These results show that the microbiota of *B. germanica* responds to the effects of antibiotics.

LEVAN AND LEVANSUCRASES: THE ENZYME AND THE PRODUCING MICROORGANISMS, AN UPDATE.

A. Dominguez[1], Á. González-Garcinuño[2], A. Tabernero[3], M.A. Galan[2], E. Martin del Valle[2]
[1]Universidad de Salamanca, Microbiology and Geneticas, Salamanca, Spain
[2]Universidad de Salamanca, Department of Chemical Engineering, Salamanca, Spain
[3]Universidad de Salamanca, 1Department of Chemical Engineering, Salamanca, Spain

Backgrounds

Levansucrases have been studied only in a few microorganisms. The availability of cheaper and new methods of sequencing have allowed the detection new levansucrases in many bacteria

Objectives

Nowadays, levan synthesis and its biocatalysis is claiming attention due to its promising uses in biomedical field. The objective of our work is the analysis of the bacteria producing levansucrases.

Methods

Overall protein sequences obtained by BlastP comparisons against the database of non-redundant protein sequences (http://blast.ncbi.nlm.nih.gov/Blast.cgi) with the well characterized levansucrases of B. subtilis and Z. mobilis and based on high levels of similarity and/or a large functional homogeneity of the hits, we have detected the 685 strains of bacteria, The alignment of proteins was generated by using the Clustal Omega Program (http://www.ebi.ac.uk/services)

Conclusions

In this work we have analyzed the microbial levansucrases of sequenced bacteria concerning sequence homology, signal peptide, metal binding, etc. More than 650 different levansucrase sequences were studied and results were obtained such as phylogenetic trees and conserved residues that could be essential for biocatalysis machinery.

Authors want to acknowledge Spanish Ministry of Economy and Competitiveness for funding support (Project Code: CTQ2016-78988-R). Álvaro González-Garcinuño also acknowledges his PhD grant (F.P.U.) from the Spanish Ministry of Education, Culture and Sport (Ref. FPU14/04914).

DEVELOPMENT OF A MUCOSAL VACCINE AGAINST HIV BASED ON GENETICALLY-ENGINEERED SACCHAROMYCES CEREVISIAE PROBIOTIC STRAINS

B. Douradinha[1]
[1]*Fondazione RiMED, Medicina Rigenerativa e Tecnologie Biomediche, Palermo, Italy*

Backgrounds

A vaccine against HIV must not only elicit both cellular and humoral arms of the immune system, but also induce a mucosal immunity. Sexually transmitted HIV uses mucosal ports of entry, and a mucosal immune response would both prevent a new infection and its further spreading. Genetically engineered *Saccharomyces cerevisiae* strains expressing HIV antigens have shown promising pre-clinical results, as their can stimulate a T cell response but tend to induce a poor mucosal immune response.

Objectives

In this work, we propose the use of probiotic *S. cerevisiae* strains which have been genetically manipulated to express on their surface the HIV Gag antigen. Probiotic *S. cerevisiae* strains are known to naturally induce an immune response in the colon and to be resistant to the gastrointestinal harsh environments, such as acidic gastric juice and bile salts.

Methods

Probiotic *S. cerevisiae* strains were transformed with the bicistronic plasmid pCEV-G1-Km (pCEV) in its simple form or with the HIV *gag* gene (pJRP). We observed that this genetic modification did not impair neither phagocytosis by human dendritic cells (DCs) from healthy donors *in vitro* nor resistance to simulated gastrointestinal stresses. Based on the cell surface markers and cytokines secreted by healthy donors DCs following genetically engineered yeasts, we assume these immune cells polarize in a type 1 response. To measure a specific HIV Gag response, we matured DCs derived from an HIV+ patient with transformed yeasts and incubated them with autologous T cells from the same patient. Only DCs which have been in contact with pJRP-transformed probiotic *S. cerevisiae* strains were able to efficiently perform HIV Gag antigen presentation to T cells, as observed by clonal expansion of the former when later incubated with a Gag peptide pool.

Conclusions

Our results show that genetically engineered probiotic strains of *S. cerevisiae* are promising vaccination strategies against HIV.

ACTINOBACTERIAL GENOME MINING FOR NOVEL ANTIMICROBIAL PEPTIDE DISCOVERY

K. Durrell[1], M. Le Roes-Hill[1], L. Dicks[2]
[1]Institute of Biomedical and Microbial Biotechnology,
Biocatalysis and Technical Biology Research Group, Cape Town, South Africa
[2]Stellenbosch University- Faculty of Science, Microbiology, Cape Town, South Africa

Backgrounds

The emergence of new mechanisms of resistance among a number of organisms has decreased the effectiveness of current antimicrobial agents. The discovery of new classes of antimicrobial compounds based on targets identified from bacterial genomics is historically invaluable as a source of antimicrobial drugs. Genome sequencing has revealed that 35-40% of the biosynthetic genes in actinobacterial genomes encode for novel compounds. These organisms therefore represent a vast resource of novel bio-active compounds and will be exploited in this study.

Objectives

To analyse the genome sequences of selected actinobacterial strains for the presence of novel secondary metabolite biosynthetic gene clusters (smBGCs) and to preliminarily determine their potential to produce novel bio-active compounds.

Methods

The genome sequences of five actinobacterial strains were analysed for the presence of novel ribosomally synthesized and post-translationally modified peptide (RiPP) smBGCs using the online predictive tool antiSMASH. The strains were cultivated on a solid basal salts medium supplemented with various carbon sources for optimal antimicrobial production, bio-active compounds extracted, and the antimicrobial activities of the extracts were preliminarily determined.

Conclusions

It is predicted that the five actinobacterial strains have 8 to 55 smBGCs, of which at least 40% represent novel compounds. Extracts prepared from the strains exhibited activity against a methicillin-resistant *Staphylococcus aureus* ATCC 33591, *Mycobacterium aurum* A+ and *Candida albicans* ATCC 90028. In future, in order to access the full biosynthetic potential of the actinobacterial strains, standard drug discovery techniques and more modern genome-based coupled with culture-based drug discovery techniques will be performed in parallel.

EFFECT OF ADDITIVE LACTOBACILLUS PLANTARUM ON AMMONIUM PRODUCTION IN WHOLE PLANT CORN SILAGE DURING PROLONGED STORAGE

M. Duvnjak[1], *M. Čuklić*[1], *K. Gazić*[1], *J. Pintar*[1], *D. Grbeša*[1]
[1]*University of Zagreb Faculty of Agriculture, Department of Animal Nutrition, Zagreb, Croatia*

Backgrounds

Ensiling is a method for moist forage preservation based on natural fermentation of sugars to acids, mainly lactic acid. *Lactobacillus plantarum* is often used as additive during ensiling to promote optimal fermentation resulting in rapid lactic acid production and pH drop thus improving dominant nutrients preservation. Ammonium production is simple indicator of protein degradation and deamination in silages. Literature states proteolysis is active primarily during first few weeks of silage production. Excess proteolysis in silages is connected with multiple negative effects on silage quality and animal performance.

Objectives

In the present study, the application of *Lactobacillus plantarum* on ammonium production in WPCS during prolonged storage of silage was investigated.

Methods

Yellow corn hybrid (Bc 462) was ensiled in five replications in laboratory scale silos without and with *Lactobacillus plantarum* additive (300000 CFU/g fresh material). Silages were sampled at the beginning and on 15th, 48th, 98th, 182th, 274th and 364th day of ensiling when contents of ammonium (g/kg of CP), crude protein (CP) and DM were monitored. Effects of time, silage additive and their interactions on silages were tested using the PROC MIXED procedure in SAS 9.3.

Conclusions

The analyses showed that the ammonium contents increased in silages during whole period of prolonged storage ($P<0,05$) and were under influence of silage additive ($P<0,05$) and defined interactions ($P<0,05$). Control silages had higher ammonium contents, except on the 182th day when silages with *Lactobacillus plantarum* had higher values. We conclude that application of additive reduced negative deamination activity that was undoubtedly present during whole storage period.

RE-FACTORING PSEUDOMONAS PUTIDA FOR VALORIZATION OF LIGNOCELLULOSE-DERIVED SUGARS

P. Dvořák[1], V. de Lorenzo[1]
[1]Centro Nacional de Biotecnología CNB-CSIC, Systems and Synthetic Biology Program, Madrid, Spain

Backgrounds

Sugars and aromatic compounds derived from lignocellulosic waste can serve as cheap substrates for biotechnological production of value-added chemicals. However, well-defined microbial platforms that could efficiently perform such task are scarce. Pseudomonas putida KT2440 is a GRAS-certified, robust soil bacterium with versatile metabolism and high stress tolerance, a host well suited for biotechnological operations. P. putida KT2440 has been employed for production of fine chemicals from glucose and for processing lignin-derived aromatics. But its potential for valorization of other products of lignocellulose decomposition is limited due to the lack of metabolic traits.

Objectives

The objective of this study was to empower P. putida with novel biocatalytic functions that would pave the way towards its application in biotechnological recycling of lignocellulosic waste.

Methods

To meet this goal, we have adopted as a cellular chassis an in-house derivative of P. putida KT2440, strain P. putida EM42 with streamlined genome and superior physiological properties. The native and heterologous pathways for D-xylose utilization and valorization were successfully tested in our chassis. Functional screening of cellulases from distinct sources revealed enzymes enabling rapid growth of EM42 on products of cellulose decomposition and parallel accumulation of valuable biopolymers within the cell.

Conclusions

The obtention of a P. putida strain capable of efficient utilization of cellulose and hemicellulose-derived sugars for biomass formation and production of desirable chemicals provides a showcase of how rational orchestration of the metabolic properties of P. putida expands the catalytic scope of this bacterium towards industrial applications.

Biotechnology / Synthetic Biology / Systems Biology

BIOACTIVE COMPOUNDS FROM CYANOBACTERIA

C. Edwards[1], *L. Lawton*[1]
[1]*Robert Gordon University, Pharmacy & Life Sciences, Aberdeen, United Kingdom*

Backgrounds

Algae are an essential component of global ecosystems using light and carbon dioxide to produce organic carbon and oxygen. Consequently they are found in diverse habitats including terrestrial and aquatic habitats, hot springs to Antarctic mats. The ecological diversity has resulted in chemical diversity and they increasingly investigated as sources of new chemical entities in drug discovery programs, in particular anti-cancer.

Objectives

Production of a wide array of peptides for research/commercial use.

Methods

Algae (400-500 L per month) were grown in parallel batch cultures. Cells were harvested and extracted using methanol, cleaned up by automated flash chromatography with final polish by preparative high performance liquid chromatography (HPLC). Throughout the process quality and quantity of compounds in extracts/fractions were tracked by ultra performance liquid chromatography – photodiode array-mass spectrometry (UPLC-PDA-MS) to ensure high purity is achieved. Due to the highly toxic nature of the compounds, extreme precautions were exercised throughout processing, with frequent review. In addition, packing and shipping strategies were developed as the peptides are classified as extremely dangerous according to transport regulations so the usual couriers such as FedEx will not take them. In addition, as they are considered as potential weapons of mass destruction, export licence and control is essential.

Conclusions

Despite all the challenges a wide array of bioactive peptides were produced underpinning research projects and providing revenue (£420 K GBP).

YEAST-BASED BIODIESEL PRODUCTION FROM INDUSTRIAL WASTES

K. Erkan Türkmen[1], E.D. Ulusman[1], N. Aksöz[1]
[1]Hacettepe University Faculty Of Science, Biology, Ankara, Turkey

Backgrounds

In recent years, alternative energy sources have been sought for fossil fuels. Biodiesel is a cheap and renewable alternative that has the most potential to advance. Yeasts are more preferred than other microorganisms due to their rapid growth and high amount of oil production. For these reasons, these microorganisms are remarkable candidate for biodiesel production.

Objectives

In this study, we aimed to produce biodiesel from yeasts that were isolated from soil. Besides, industrial wastes were used as growth medium to reduce the cost and reuse industrial wastes properly.

Methods

Microorganisms were isolated from various soil samples. Antibiotic(Gentamycin) was added into isolation medium to eliminate bacterial growth. Subsequently microorganisms were inoculated into several media to improve oil production. For separating oil from yeast, Folch Method was carried out on each yeast isolate. Converting biodiesel was provided by transesterification process. As a result of GC-MS analysis, species identification of the highest biodiesel potential isolates were determined by 18s rRNA analysis.

Conclusions

According to results, this study confirmed our opinion about yeast based biodiesel production. Production of yeast based biodiesel using industrial wastes were successfully managed. Therefore, Yeast-Based Biodiesel can be considered an alternative energy sources to fossil fuel and further way of recycling industrial wastes.

BACTEROIDES THETAIOTAOMICRON ENDO-LEVANASE IN ACTION: DEGRADATION OF BACTERIAL AND PLANT LEVANS

K. Ernits[1], *T. Visnapuu*[1], *K. Viigand*[1], *T. Alamäe*[1]
[1]*University of Tartu, Genetics, Tartu, Estonia*

Backgrounds

Gut microbiota plays a huge role in human well-being by participating in food digestion, energy harvest, mineral absorption and inhibition of pathogenic bacteria. Growth of beneficial (probiotic) bacteria in the gut can be specifically promoted by prebiotic food ingredients such as inulin and inulin-type fructooligosaccharides (β-2,1 linked fructans) that are fermented by bifidobacteria and lactobacilli.

Objectives

Novel prebiotics have attracted interest of food scientists. Our workgroup is focusing on synthesis of novel β-2,6 linked prebiotic fructans – polymeric levans and oligomeric levan-type fructooligosaccharides (FOS). Prebiotic potential of these substrates on fecal consortia will be further assayed.

Methods

1) Levan and levan-type FOS are synthesized from sucrose using a highly active and stable levansucrase Lsc3 of *Pseudomonas syringae*.

2) Levan is degraded into FOS using the endo-levanase of *Bacteroides thetaiotaomicron*.

Conclusions

Lsc3 produces from sucrose FOS and levan. Levan is easily precipitated from the media with ethanol. Purification of FOS is laborious as a huge amount of glucose arising from the reaction must be removed.

We have cloned, overexpressed, purified and characterized the endo-levanase BT1760 of human gut commensal *Bacteroides thetaiotaomicron*. We showed that BT1760 produces FOS from various levans, including those of very high molecular weight. Importantly, the BT1760 also cleaves a plant levan (from timothy), whereas plant inulin was not degraded. Compared to few other studied bacterial endo-levanases, the BT1760 is the most active and can be regarded as a feasible catalyst for the production of FOS from levans.

BIOCHEMICAL AND EVOLUTIVE INSIGHTS OF OLEATO-DERIVED OXYLIPIN PRODUCTION IN PSEUDOMONAS AERUGINOSA

M. Estupiñán[1,2], *P. Diaz*[2], *M.À. Manresa*[1]
[1]*University of Barcelona, Biology- Health and Environment, Barcelona, Spain*
[2]*University of Barcelona, Genetics- Microbiology and Statistics, Barcelona, Spain*

Backgrounds

Pseudomonas aeruginosa displays the ability to convert oleic acid into a class of hydroxylated fatty acids known as oxylipins, whose biotechnological applications have extensively been studied, constituting important emulsifying agents in food and cosmetics industries, acting as antibacterial or antifungal substances, or as intermediate compounds for fine chemistry. A diol synthase (DS) activity is responsible for such a conversion, which proceeds through the dioxygenation of oleic acid to release hydroperoxide 10-H(P)OME ((10*S*)-hydroxy-(8*E*)-octadecenoic acid), followed by conversion of the hydroperoxide intermediate into 7,10-DiHOME ((7*S*,10*S*)-dihydroxy-(8*E*)-octadecenoic acid).

Objectives

Identification of the gene/s involved in DS activity for functional and phylogenetic characterization of the encoded enzymes.

Methods

Gene identification was performed through genome mining. Functional characterization of the enzymes was done by mutant complementation, site-directed mutagenesis, and expression analysis. Bioinformatic approaches were used for phylogenetic and structural studies.

Conclusions

The genes responsible for the two enzymatic activities were identified: a dioxygenase (10*S*-DOX) encoded by *PA2077* catalyses the first step of the reaction, whereas the diol-synthase (7,10-DS) encoded by *PA2078* converts the hydroperoxide into 7,10-DiHOME.
Both genes constitute an operon, although they preserve their individual activities when cloned separately in *E. coli*, indicating that no heterocomplex formation is required. No orthologues of these genes were found in other species, being unique for *P. aeruginosa*. *In silico* analysis suggest that the two enzymes were originated by a gene duplication event, constituting a separate cluster among cytochrome c peroxidases, being thus the first characterized members of a new subfamily of bacterial peroxidases designated as Fatty acid-di-heme Cytochrome c peroxidases (FadCcp).

ANCIENT VOLCANIC SOILS AS A SOURCE OF BACTERIAL THERMOPHILIC LIPASES

M. Estupiñán Romero[1,2], *C. Buruaga*[1], *J. Ribera*[1], *A. Fillat*[1], *J. Martínez*[1], *P. Diaz*[1]
[1]*University of Barcelona, Genetics- Microbiology and Statistics, Barcelona, Spain*
[2]*University of Barcelona, Health- Biology and Environment, Barcelona, Spain*

Backgrounds

Bio-inspired processes have a low environmental impact, reduce the amount of waste material and minimize costs. Thermophilic enzymes provide natural tools for application in biotechnological processes requiring high temperature conditions and insights into evolutionary mechanisms of the current biosphere selective pressure.

Objectives

Isolation and characterization of bacterial thermophilic enzymes from ancient volcanic soils.

Methods

Microorganisms of samples from laurisilva soils in El Hierro (Canary Islands) were isolated and various enzymatic activities at temperature ranges between 20 and 60°C were tested. Strain JR3 was selected as highly lipolytic and identified by 16S rDNA sequencing. Degenerated primers were designed and lipase LipJ was cloned and characterized using *p*-NP-derivative substrates. Evolutionary divergence of LipJ has been studied both, *in silico* and by site-directed mutagenesis.

Conclusions

The isolated JR3 strain showed high lipase activity at temperatures above 60°C, and was selected for identification and study. Strain JR3 was assigned to the genus *Bacillus*, showing a 98% identity with *Bacillus cereus*. Analysis of the extracellular lipolytic activity of JR3 showed high tolerance to temperatures even higher than 80°C, maintaining the highest levels of activity when tested at 100°C. However, analysis of activity of the cloned lipase (LipJ) showed optimum activity at 30°C. When the 3D model of the cloned lipase was obtained, the typical structure of thermophilic lipases was observed, suggesting that this enzyme derives most likely from a thermophilic ancestor. Site-directed mutagenesis over the recognized thermophilic regions expands LipJ activity to higher temperatures (80°C) and on longer chain substrates, confirming the hypothesis of evolutionary drift.

NEW TAILORING BIOSYNTHETIC PROTEINS OF POLYKETIDE ANTIBIOTIC AURICIN IN STREPTOMYCES AUREOFACIENS CCM 3239

L. Feckova[1], C. Bekeova[1], R. Novakova[1], E. Mingyar[1], D. Homerova[1], J. Kormanec[1]
[1]Institute of Molecular Biology Slovak Academy of Sciences, gene expression, Bratislava, Slovak Republic

Backgrounds

The soil bacteria of the genus *Streptomyces* produce various secondary metabolites including many medicinally important antibiotics. Aromatic polyketides comprise a large group of structurally diverse secondary metabolites, which are produced by type II PKSs, which comprise three essential subunits (KS, CLF, ACP) and further subunits (KR, ARO, CYC) involved in modification of the nascent polyketide chain. Various tailoring reactions catalyzed by diverse oxygenases, reductases, methylases, and glycosyltranferases produce a final bioactive polyketide [1]. We previously identified polyketide cluster *aur1* in *Streptomyces aureofaciens* CCM 3239 responsible for production of a unique angucycline antibiotic auricin. It is produced during a narrow time period following entry into stationary phase. This unusual phenomenon likely arises from a complex regulation of auricin biosynthesis [2].

Objectives

Characterization of tailoring biosynthetic genes involved in the biosynthesis of auricin.

Methods

Growth of *S. aureofaciens* CCM3239 and analysis of secondary metabolite production was done as described in [3]. Disruption of the genes in *S. aureofaciens* CCM3239 was done as described in [3]. Transcription was determined by S1-nuclease mapping using RNA isolated from different growth phases as described in [3].

Conclusions

1, We characterized an operon *sa13, sa12, sa11, sa10*, encoding genes involved in biosynthesis of auricin in *S. aureofaciens* CCM 3239.

2, We identified promoter directing expression of the *sa13, sa12, sa11, sa10* operon and found its differential dependence upon two auricin-specific positive regulators, Aur1PR3 and Aur1PR4.

ISOLATION OF AN EFFICIENT BACTERIAL CELLULOSE PRODUCER

J. Fernández[1], *G. Morena*[1], *R. Reina*[1], *J. Pastor*[1], *J. Martinez*[1]
[1]*University of Barcelona, Department of Genetics- Microbiology and Statistics, Barcelona, Spain*

Backgrounds

Bacterial cellulose (BC) is produced by some microorganisms. BC displays exceptional physicochemical properties: high crystallinity, high tensile strength, high hydrophilicity, and biocompatibility. These unique properties enable many successful applications and make BC a multifunctional biomaterial. An issue that restrains commercial production and extended application of BC is the low yield of the producing strains. Strains with higher yields would reduce costs in mass production.

Objectives

The aim of this study was to isolate new strains with a high yield of bacterial cellulose production and to characterise the obtained cellulose.

Methods

Samples of commercial wine vinegar were screened to isolate cellulose producing strains. Hestrin Schramm broth (HS) was used as an enrichment and production media. After incubation of the bacteria in liquid culture in static conditions, a cellulosic pellicle is obtained on the air-liquid interface. Cellulose production yield was compared with that from *Komagataeibacter xylinus*, a well-studied bacterial cellulose synthesizer. The most productive isolate was further investigated.

Conclusions

The most productive isolate, JF2, was subjected to 16S rRNA sequence analysis and identified as a putative *Komagataeibacter obodiens* strain. JF2 showed a higher efficiency than the control strain. Growing on HS medium supplemented with mannitol, JF2 produced 200% more cellulose than *K.xylinus*. Cellulose production curves over time showed that JF2 reached the maximum production at 5 days, while *K.xylinus* needed 7 days. SEM analysis of the pellicles showed homogeneous structure of cellulose ribbons. These results suggest that JF2 has potential as bacterial cellulose producer with industrial application.

[2]*Instituto Cavanilles de Biodiversidad y Biología Evolutiva, Botánica, Paterna, Spain*
[3]*Universitat de València, Botánica, Burjassot, Spain*

Backgrounds

Recently, the concept of lichen symbiosis has been expanded to include bacterial communities as integral components. In fact, lichens are currently recognized as associations of multiple species in which bacterial communities could contribute with different roles, such as stimulating lichen thalli growth and/or protecting them by the production of biofilm and pigments. However, some of these activities attributed to these bacteria have been based on culture-independent methods or hardly studied, being also of biotechnological interest.

Objectives

The objective was to evaluate the ability of a collection of culturable bacteria isolated from the Mediterranean lichen *Ramalina farinacea* to produce phytohormones, biofilms and pigments.

Methods

Phytohormones production was evaluated through the detection of auxins and the enzyme ACC-deaminase, biofilm formation in microtiter plates and bacterial pigments on conventional culture media. Selected strains were identified by partial *16S rRNA* gene sequencing.

Conclusions

A high percentage of bacterial strains produced phytohormones, mostly the auxin IAA and the ACC-deaminase enzyme being detected in minor proportion. Biofilm production was observed in more than 90% of the strains and around 70% of them produced pigments, being mostly yellow, pink, orange and white. These activities could favor lichens colonization and adaptation to a wide variety of environmental conditions, by offering protection against biotic and abiotic factors and/or promoting growth within the lichen thallus. Further, their potential applications could be in agriculture and pharmaceutical and textile industries, among others. Finally, selected bacterial strains were ascribed to diverse taxa. (PROMETEOII/2013/021; VALi+d fellowship; UV-Research Support to BACPLANT).

[4]Medical University of Wroclaw, Department of Pharmaceutical Microbiology and Parasitology, Wrocław, Poland
[5]Wroclaw University of Technology, Centre for Advanced Manufacturing Technologies, Szczecin, Poland

Backgrounds

Bacterial cellulose (BC) is a natural polymer produced by bacteria *Gluconacetobacter xylinus*. The application of the magnetic field is a promising alternative to the conventional BC production methods.

Objectives

The main aim of the presented study was to evaluate the impact of rotating magnetic field (RMF) on BC synthetized by *G. xylinus* in regard to its production rate and quality parameters.

Methods

The cultures of *G. xylinus* were exposed to RMF of frequency equals 50 Hz and magnetic induction 34 mT for various time periods at different stages of *G. xylinus* cultivation, in the customized RMF exposure system. The obtained BC samples were analyzed using a set of analytical methods including ATR-FTIR, XRD, SEM, degree of polymerization, dry weight and water related properties assessment.

Conclusions

It was found, that the application of RMF, regardless of the exposure mode applied, significantly increased the cellulose thickness, weight and capacity of swelling in water in comparison to the unexposed controls. The changes of water-related properties were reflected by the degree of BC porosity and its fibril arrangement. Another significant observation, found in the synchronus 2D correlation of ATR-FTIR spectra was the impact of RMF on the dynamics of the formation of BC microfibers crystallinity. Therefore, it can be concluded, that the use of RMF may provide a novel technique for altering BC biogenesis and when fully developed, may find application in the multiple biotechnological applications.

[8]Wrocław Medical University, Department of Pharmaceutical Microbiology and Parasitology, Wrocław, Poland

Backgrounds

Bacterial cellulose (BC) is a natural polymer produced by bacteria *Glucanacetobacter xylinus*. BC exhibits superior purity when compared with plant cellulose, so treatment is not required to remove unwanted polymers and contaminants (e.g. lignin, hemicellulose). However, BC obtained after fermentation always contains impurities like bacterial cells and culture media components. The application of BC (especially for medical purposes) requires removal of media residues and bacterial cells containing toxins like lipopolysaccharide.

Objectives

The study aimed at evaluation of various types of alkali rinsing with regard to their efficacy in terms of removal, not only of bacteria but also bacterial metabolites, from cellulose matrices formed by *G. xylinus* strains. Moreover, we tested the type of alkali rinsing on membrane cytotoxicity *in vitro* and we compared matrices' ability to induce oxidative stress in macrophages.

Methods

For the production of cellulose, three reference *G. xylinus* strains were used of. In order to remove bacterial cells and media components the BC samples were purified using 3 different concentrations of NaOH solution. For one group of BC samples, the purification procedure using a particular NaOH concentration was repeated two times and for another group, four times.

Conclusions

Our results indicated that the type of alkali rinsing should be adjusted to specific *G. xylinus* strains that are used as cellulose producers to obtain safe biomaterials in the context of low cytotoxicity and macrophage induction.

This study was supported by the National Centre for Research and Development in Poland (Grant No. LIDER/011/221/L-5/13/NCBR/2014).

SINGLE NUCLEOTIDE MUTATIONS LEAD TO IMPROVED FUNCTIONALITY OF SFGFP IN BIOTECHNOLOGICALLY IMPORTANT THERMOPHILIC CHASSIS

E. Frenzel[1], *R. van Kranenburg*[2], *O.P. Kuipers*[1]
[1]*University of Groningen, Department of Molecular Genetics, Groningen, The Netherlands*
[2]*Wageningen University, Laboratory of Microbiology, Wageningen, The Netherlands*

Backgrounds

Fluorescent reporter proteins (FP) have become an indispensable tool for the optimization of microbial cell factories and in synthetic biology *per se*. Their applicability is, however, constrained by species-dependent performance and misfolding at elevated temperatures.

Objectives

Flow cytometry-based benchmarking of a set of GFPs, sfGFPs and species-specific codon-optimized variants revealed that none of the proteins was satisfyingly detectable in *Parageobacillus thermoglucosidans*. This indicates that rational engineering does not necessarily lead to an optimized expression.

Methods

We employed an undirected mutagenesis approach coupled to fluorescence-activated cell sorting in order to isolate sfGFP variants active in the chassis background at 60°C.

Conclusions

Unexpectedly, a few nucleotide substitutions, including silent mutations, significantly improved the functionality in *P. thermoglucosidans*. This underpins the strong codon-dependence of FP performance, which might be connected to modulation of the translation and folding speed, especially at higher temperatures.

The novel sfGFP variants were active in other industrially relevant thermophilic spore formers, thus proving their broad applicability. The sfGFP variants were furthermore used as output elements to explore the transcriptomic landscape of *P. thermoglucosidans* grown under a broad set of conditions. This enabled us to study the architecture of promoters and regulons, as well as the heterogeneity of gene expression on the single-cell level.

Results from ongoing studies will be presented and hypotheses on the impact of single nucleotide mutations leading to synonymous amino acid substitutions and temperature stability of sfGFP will be discussed.

CHARACTERIZATION OF A NEW THERMOPHILIC B GLUCOSIDASE FROM DYCTIOGLOMUS TURGIDUM

F. Fusco[1], R. Ronca[1], G. Fiorentino[1], P. Contursi[1], S. Bartolucci[1], D. Limauro[1]
[1]University of Naples Federico II, Biology, Naples, Italy

Backgrounds

Biomass is an alternative source of renewable energy and can represent a new source for feedstock and chemical production; cellulose, the major component of biomass, is a linear polymer of glucose linked by β-1,4-glycosidic bonds. It is hydrolyzed to glucose by synergic action of endoglucanase, exoglucanase and b-glucosidase that complete the final step cleaving cellobiose in glucose. The improvement of enzymatic performance is strongly requested in bioprocesses; for this reason, thermozymes are often explored because they not only are stable at high temperature but are unusually resistant in organic solvents and detergents.

Objectives

This study is focused on the characterization of a new thermophilic b-glucosidase of the hyperthermophilic bacterium *Dyctioglomus turgidum*. Synthetic gene *Dtubglu* (Dtur_0462) from *D. turgidum* genome was constructed exploiting *Escherichia coli* codon usage. *Dtu*bGlu, expressed in *E. coli*, was purified and biochemically characterized.

Methods

Enzyme purification was performed by heat treatment and affinity chromatography on a His-Trap connected to an AKTA Explorer system (GE Healthcare); β-Glucosidase was assayed using p-nitrophenyl- β-Dglucopyranoside (pNPG) in microplate reader (Synergy H4, Biotek).

Conclusions

A new promising hyperthermophilic b-glucosidase, *Dtu*bGlu of *D. turgidum* was identified. Enzymatic activity was assayed on different substrates and kinetically characterized on pNPG showing a K_M value of 0.53 mM. The optimal pH (pH 5.4) and temperature (80°C) were determined. *Dtu*bGlu shows stability at high temperature (100% of activity after 3 h at 80°C). These features make this enzyme an excellent candidate for technological applications.

METAGENOMIC AND PROTEOMIC ANALYSIS OF LAB-SCALE, MESOPHILIC ANMBR AND THERMOPHILIC CSTR BIOGAS REACTORS RECEIVING MICROALGAL BIOMASS FEEDSTOCK FROM A PHOTOBIOREACTOR RECOVERING WASTEWATER EFFLUENT NUTRIENTS

J. Gaby[1], S. Greses-Huerta[2], M. Arntzen[1], D. Aguado[3], J. Ferrer[3], A. Seco[2], S. Horn[1]
[1]Norwegian University of Life Sciences NMBU,
Faculty of Chemistry- Biotechnology and Food Science IKBM, Ås, Norway
[2]Universty of Valencia, Department of Chemical Engineering, Valencia, Spain
[3]Polytechnic University of Valencia, Institute of Hydraulic and Environmental Engineering, Valencia, Spain

Backgrounds

Effluent from sewage treatment plants can contain high amounts of nitrogen and phosphorus which could eutrophicate water bodies. As an alternative to release or further costly treatment, wastewater treatment effluent may be used as a source of nutrients to grow *Scenedesmus* spp. microalgae in a membrane photobioreactor (MPBR), and the microalgal biomass may be subsequently fed to a biogas reactor.

Objectives

Recover genomes of taxa involved in the anaerobic digestion of microalgal biomass and examine the expression of pathways for cellulose, hemicellulose, lignin and protein hydrolysis.

Methods

Microalgal biomass was harvested from a MPBR as feedstock for a mesophilic (35°C) anaerobic membrane bioreactor (AnMBR) and a thermophilic (55 °C) continuous stirred tank reactor (CSTR) for production of biogas. We studied the reactor and feedstock microbial communities through 16S amplicon sequencing, shotgun metagenomics, and metaproteomics.

Conclusions

From 47 gigabases of shotgun metagenomic data we recovered 313 genome bins including 13 that were >95% complete. In the thermophilic CSTR, *Coprothermobacter*, a potential protein degrader, and the candidatus EM3 phylum comprised approximately 1/3 each of the microbial community. We are using metagenomics to infer the characteristics that allow EM3 bacteria to decompose microalgal biomass. The mesophilic AnMBR community was more diverse and included the dominant taxa W22 (20%), a sugar fermenter, and T78 (15%), a carbohydrate and lignocellulosic degrader. Through proteomics analysis, we determined the abundance of 2936 proteins of which only 17% had hypothetical gene annotations. The most abundant proteins encoded diverse cellular processes including methanogenesis and nutrient acquisition.

Biotechnology / Synthetic Biology / Systems Biology

AN ESCHERICHIA COLI STRAIN REFERENCE PANEL FOR GENOTYPE-TO-PHENOTYPE ANALYSIS

M. Galardini[1], C.L. Herrera[2], A. Koumoutsi[2], J.A. Cordero Varela[1], A. Telzerow[2], A. Typas[2], P. Beltrao[1]
[1]EMBL-EBI, EBI, Cambridge, United Kingdom
[2]EMBL, Genome Biology, Heidelberg, Germany

Backgrounds

Understanding how genetic variants, across individuals of the same species, contribute to variability in phenotypes is a central question in genetics. However, we currently lack models that can describe how genetic variability impacts on different molecular layers (e.g. protein stability and function) and how the ensemble of these effects manifests to cellular phenotypes.

Objectives

.

Methods

To address this problem, we collected a panel of ~1000 *Escherichia coli* strains (natural isolates and evolved strains) that were genotyped and phenotyped across ~200 chemical and environmental conditions in order to develop and test predictive phenotypic models. Molecular and cellular knowledge of *E. coli* K12 was used to model the consequence of mutations across a subset of ~730 fully sequenced strains.

Conclusions

We observed that deleterious mutations in conditionally important genes in *E. coli* K12 are often but not always associated with poor growth in the respective condition in other strains. This suggests that conditional essentiality is not strictly conserved across strains. We also observed that both non-synonymous substitutions and gene content variability have the same importance in determining the phenotype, highlighting the importance of recombination in bacteria.
Collectively, our dataset of genotypes and phenotypes constitutes a resource for the development of predictive phenotypic models and highlights the evolutionary plasticity of conditional essentiality in *E. coli*. We anticipate that this strain reference panel will become a community resource to tackle the various facets of the genotype-to-phenotype problem.

IMPROVED PRODUCTION OF THE ANTIBIOTIC ACTINORHODIN IN STREPTOMYCES COELICOLOR IMMOBILIZED-MYCELIAL CELL CULTIVATIONS

A. Sutera[1], F. Lopresti[2], R. Dolcemascolo[1], R.M. Fontana[1], L. Botta[2], A.M. Puglia[1], G. Gallo[1], R. Scaffaro[2]
[1]University of Palermo, STEBICEF, Palermo, Italy
[2]University of Palermo, DICAM, Palermo, Italy

Backgrounds

Actinomycetes, Gram-positive filamentous bacteria, are the most prolific source of industrially important bioproducts, like antibiotics and enzymes. *Streptomyces coelicolor*, producing different antibiotics including the blue pigmented actinorhodin (ACT), is a model organism for antibiotic production. During actinomycete liquid cultivations, one of the major causes negatively affecting bioproductivity is the growth of a pellet-shaped biomass.

Objectives

i) Evaluation of ACT production in *Streptomyces coelicolor* M145 mycelial cells immobilized on polycaprolactone (PCL) and polylactic acid (PLA) nanofiber membranes, modified or not by an O_2-plasma treatment.
ii) Identification of gene products associated with the improvement of ACT production.

Methods

- Scanning electron microscope (SEM) analysis.
- Determination of total protein content.
- Determination of ACT amount.
- Differential proteomic analysis based on 2-D Fluorescence Difference Gel Electrophoresis (2D-DIGE) and mass spectrometry (MS) procedures.

Conclusions

Starting from spore suspensions, *S. coelicolor* immobilized-mycelial cells were obtained in liquid cultivations using modified or unmodified PCL and PLA membranes. All the immobilized-mycelial cell cultivations showed an increment of ACT yield in comparison to free-mycelial cells, with O_2-plasma treated PLA membranes the most effective ones. Differential protein patterns of immobilized- and free-cell cultivations were revealed by a preliminary SDS-PAGE analysis. Therefore, a differential proteome analysis, based on 2D-DIGE and MS procedures, is being carried out to highlight molecular processes and metabolic pathways differentially regulated in immobilized- and free-cell cultivations.

[4]INBIOTEC- Instituto de Biotecnología de León, Biopharmacy and Biomedicine Department, León, Spain
[5]INBIOTEC- Instituto de Biotecnología de León, Proteomics, León, Spain
[6]Área de Microbiología, Departamento de Biología Molecular, León, Spain

Backgrounds

The woodworking industry is an essential economic sector which encompasses over 280,000 companies in the European Union. In this context, wood decay processes are of prominent interest, considering both their industrial applications in biorefinery and their importance in the prevention of wood degradation.

Fungi are known as active degraders of lignocellulosic materials in nature.

Objectives

Alternaria sp. is a fungal genus which includes endophytic, saprobic and plant pathogenic species. The aim of this study was to analyse the secretome from *Alternaria tenuissima*, given its potential as a phytopathogenic mold able to colonise and survive on wood.

Methods

The *Alternaria tenuissima* strain used in the studies was grown in presence of different lignocellulosic substrates and the enzymatic extract secreted to the culture medium was obtained at several time points. Two-dimensional gel electrophoresis of proteins was performed and proteins were subsequently identified by means of a MALDI-TOF/TOF mass spectrophotometer.

Conclusions

The analysis of the results showed a total of 80 identified proteins, 37 of which were isoforms. Out of the total number of 80, 33 proteins were successfully assigned to a KOG functional category (*Eukaryotic Clusters of Orthologous Groups,* contained in the COG database). 76% of the determined proteins belonged to the G category (proteins related with carbohydrate metabolism and transport) and, the remaining, to categories K, O and M.

These results are congruent with the expected secretome in the analysed conditions, and they confirm *Alternaria tenuissima* as an interesting species in the wood decay processes.

PROTEOME RESPONSE OF THE PENICILLIN-PRODUCING MOLD PENICILLIUM CHRYSOGENUM TO CASEIN PHOSPHOPEPTIDES AND CACL2

R. Domínguez-Santos[1,2], K. Kosalková[1], C. Barreiro[2,3], L. García-Calvo[4], J.F. Martín[2], A. Ibáñez[5], A. Morales[3], C. García-Estrada[1]
[1]INBIOTEC- Instituto de Biotecnología de León, Biopharmacy and Biomedicine Department, León, Spain
[2]Área de Microbiología, Departamento de Biología Molecular, León, Spain
[3]INBIOTEC- Instituto de Biotecnología de León, Proteomics, León, Spain
[4]INBIOTEC- Instituto de Biotecnología de León, Environment Department, León, Spain
[5]Instituto de Investigación de la Viña y el Vino, Universidad de León, León, Spain

Backgrounds

Penicillin biosynthesis in *Penicillium chrysogenum* is one of the best characterized secondary metabolism processes. However, the mechanism by which penicillin is secreted still remains to be elucidated. Calcium (Ca^{2+}) plays an important role in the metabolism of filamentous fungi, and casein phosphopeptides (CPP) are involved in Ca^{2+} internalization.

Objectives

Taking into account the role played by Ca^{2+} and CPP in the secretory pathway and considering the positive effect that Ca^{2+} exerts on penicillin production, the analysis of global protein changes produced after CPP/$CaCl_2$ addition is very helpful to decipher the processes related to the biosynthesis and secretion of penicillin.

Methods

A wide proteome comparative analysis using 2D-DIGE was carried out to characterize the mechanisms triggered by CPP/$CaCl_2$.

Conclusions

The most interesting proteins that were overrepresented after CPP/$CaCl_2$ addition were a peroxisomal catalase, three proteins of the methylcitrate cycle, two aminotransferases and cystationine β-synthase, which are directly or indirectly related to the formation of penicillin amino acid precursors. Importantly, two of the enzymes of the penicillin pathway (isopenicillin N synthase and isopenicillin N acyltransferase) are clearly induced after CPP/$CaCl_2$ addition. Most of these overrepresented proteins are either authentic peroxisomal proteins or microbody-associated proteins. This evidence suggests that addition of CPP/$CaCl_2$ promotes the formation of penicillin precursors and the penicillin biosynthetic enzymes and stimulates the formation of peroxisomes and microbodies, which may be involved in transport of penicillin biosynthetic intermediates and finally in penicillin secretion.

IMPACT OF DIETARY NITROGEN DEPRIVATION ON BLATTABACTERIUM ENDOSYMBIONT AND HINDGUT MICROBIOTA IN BLATTELLA GERMANICA

C. García-Ferris[1], R. Domínguez[1], B. Pérez-Rocher[1], J.A. Castro[2], J. Baixeras[3], A. Moya[1], A. Latorre[1]
[1]Institute for Integrative Systems Biology I2SysBio, University of Valencia, Paterna, Spain
[2]Department of Biology- Faculty of Science, University of the Balearic Islands, Palma, Spain
[3]Cavanilles Institute of Biodiversity and Evolutionary Biology ICBiBE, University of Valencia, Paterna, Spain

Backgrounds

German cockroach, *Blattella germanica*, harbors two levels of symbiotic interactions. One is set around a single bacterial endosymbiont, *Blattabacterium*, located inside specialized fat body cells called bacteriocytes. Another, more complex, is the consequence of a highly diverse bacterial microbiota, inhabiting the luminal surface of the hindgut. This is one of the few known examples of an insect that keeps both gut microbiota and an endosymbiont. *Blattabacterium* plays a central role in the host nitrogen metabolism allowing the mobilization and recycling of urate deposits, in which excess of dietary nitrogen is stored, by contributing the urease activity that degrades urea to ammonia which is then recycled by the host into glutamine, needed for essential amino acids biosynthesis by *Blattabacterium*. In contrast, the function of the bacterial microbiome located in the *B. germanica* hindgut is presently far from being completely understood.

Objectives

The main objective is to assess whether the microbiome also collaborates in the host nitrogen metabolism once urate deposits depleted.

Methods

B. germanica adults were fed with an artificial diet free of N-protein to trigger urate mobilization and, after 9 weeks of treatment, fat body and hindgut were dissected. *Blattabacterium* and bacteriocyte populations were followed using QPCR and microscopy of fat body, and the bacterial composition of hindgut microbiome was determined using a metagenomic analysis.

Conclusions

We have evaluated whether a nitrogen-deprived diet induces changes in diazotrophic bacteria in the microbiota that could fix nitrogen supplying organically bound nitrogen to the host, thus complementing *Blattabacterium* in the nitrogen metabolism of the insect.

BIOTECHNOLOGIC POTENTIAL OF BACTERIAL STRAINS ISOLATED FROM A FOREST PEST (BARK BEETLES)

A. Fabryová[1], M. Kostovčík[1], A. Díez-Méndez[2], A. Jiménez-Gómez[2], L. Celador-Lera[2], Z. Saati-Santamaría[2], E. Menéndez[3], M. Kolařik[1], P. García-Fraile[1]
[1]Institute of Microbiology, Laboratory of fungal genetics and metabolism, Prague, Czech Republic
[2]University of Salamanca, Microbiology and Genetics Department, Salamanca, Spain
[3]University of Evora, Institute of Mediterranean Agricultural and Environmental Sciences ICAAM, Evora, Portugal

Backgrounds

Bark beetles establish symbiosis with several microbial strains which play different roles within the beetle holobiont, aiding for instance the beetle to hydrolyze the tree host with the production of hydrolytic enzymes to degrade the ingested bark and wood.

Objectives

In the present study, we aimed the isolation of bark beetle bacterial endosymbionts producing lignocellulolytic enzymes, as cellulases, xylanases and laccases, with potential applications in production of biofuels from biomass and capability for colorant degradation, with potential applications in the textile industry and for wastewater treatment.

Methods

We isolated and identified several bacterial strains from bark beetle species *Cryphalus piceae, Ips typographus* and *Pithophtorus pithophtorus,* collected in the Czech Republic from pine, spruces and fir trees, respectively. Strains were classified according to their 16S sequence as belonging to the genera *Erwinia*, *Pantoea*, *Curtobacterium*, *Yersinia*, *Pseudomonas, Staphylococcus* and *Rahnella*. Several plate screening methods were applied in order to detect lignocellulolytic enzymes and colorant degradation. Moreover, genome sequence of selected strains was obtained and analyzed looking for cellulases, xylanases, amylases and laccases.

Conclusions

Those strains are capable of colorants and plant cell compounds degradation. All isolates of the study showed capability of hydrolyzing several of the tested compounds. Besides, genome sequences revealed the presence of enzymatic machinery required for biomass hydrolysis

GENOME ANALYSIS BACTERIAL STRAINS ISOLATED FROM BARK BEETLES REVEALS THE PRESENCE OF GENES INVOLVED IN THE BIOSYNTHESIS OF ANTIBIOTICS AND OTHER MICROBIAL SECONDARY METABOLITES

P. García-Fraile[1], M. Kostovčík[1], Z. Saati-Santamaría[2], R. Martínez-García[2], I. Chapado-Pinto[2], R. Rivas[2], M. Kolařik[1]
[1]Academy of Science of the Czech Republic, Institute of Microbiology, Prague, Czech Republic
[2]University of Salamanca, Microbiology and Genetics, Salamanca, Spain

Backgrounds

Bark beetles establish symbiosis with several microbial strains which play different roles within the beetle holobiont. It has been described how some of these bacterial associates protect the bark beetle holobiont by producing substances which inhibit the growth of bark beetles' antagonists and therefore, those strains can be of great interest in pharmaceutical industry.

Objectives

The aim of this work was the detection of the genetic machinery for the synthesis of bioactive secondary metabolites with potential interest in biomedicine within the genome sequences of bacterial isolates from several bark beetle species.

Methods

Thus, we isolated bacterial associates from Ips cembre, Xylocleptes bispinus, Ips acuminatus and Pytogenes bidentatus adults and from Ips typographus larvae. The insect individuals had been collected from their tree hosts in different locations within the Czech Republic. Then, we tested the allelopathic interactions between our isolates and different pathogenic bacterial and fungal species. Those strains with greater capability to inhibit the pathogenic ones were selected to obtain their genome sequence, which was analyzed in order to find the genes potentially implicated in the synthesis of bioactive secondary metabolites.

Conclusions

Bioinformatic analysis of the genome sequence of bark beetles' bacterial associates revealed the capability of those strains to synthesize bioactive compounds with potential uses in pharmaceutical and biomedical industries.

PHENOTYPIC AND MOLECULAR CHARACTERIZATION OF SACCHAROMYCES STRAINS FROM DIFFERENT ENVIRONMENTAL NICHES AS A FUNCTION OF THE TEMPERATURE

E. García-Ríos[1], *A. Querol*[1], *J.M. Guillamón*[1]
[1]*Instituto de Agroquímica y Tecnología de los Alimentos, Biotecnología, Paterna, Spain*

Backgrounds

Production of useful products through microbial fermentation is a core activity of industrial biotechnology, and yeasts are one of the most widely used microorganisms in industrial biotechnology. This industry spends a huge amount of energy cooling or heating these processes, to fine-tune temperature as close as possible to the optimum growth temperature of the fermentative strains. The adaptation and tolerance of yeast strains towards temperatures outside the optimum range is crucial for economic and eco-efficient production processes for new and traditional fermentations.

Objectives

We evaluated the growth capacity of a collection of *Saccharomyces* strains belonging to different environments in order to improve some of these strains in terms of thermotolerance by using different genetic and metabolic engineering techniques.

Methods

To carry out this objective, experimental evolution and inter- and intraspecific hybridization experiments were performed to generated non-GMO improved strains. A multi-omic approach was also performed in strains with divergent phenotype at low and high temperatures. The better knowledge about yeast thermotolerance, provided by this systematic global approach, will be used to design new strategies of adaptive evolution.

Conclusions

Sulfur assimilation, nitrogen uptake, maintenance of the membrane asymmetry and oxidative stress response proved to be crucial mechanisms for the better thermotolerant capacity and they have been deeply analyzed by using different biochemical approaches.

GENOME-SCALE METABOLIC RECONSTRUCTION AND ANALYSIS OF SPHINGOPYXIS GRANULI STRAIN TFA

I. García-Romero[1], J. Nogales[2], E. Santero[1], B. Floriano[1]
[1]Andalusian Center for Developmental Biology,
Pablo de Olavide University and Department of Molecular Biology and Biochemistry Engineering, Sevilla, Spain
[2]Centro de Investigaciones Biológicas CIB, 2Environmental Biology Department, Madrid, Spain

Backgrounds

Sphingopyxis granuli strain TFA is a Gram-negative bacterium belonging to *Sphingomonadaceae* family whose most studied metabolic feature is its ability to use the aromatic organic solvent tetralin as the sole carbon and energy source. Regarding other metabolism aspects, this bacterium is able to accumulate poly-hydroxybutyrate (PHB) as carbon reservoir and, recently, it has been described as the first *Sphyngopyxis* representative able of growing anaerobically using nitrate as final electron acceptor. As several oligotrophic bacteria have been assigned to this genus, it is interesting to study other features of its metabolism that remain poorly or not characterized at all.

Objectives

The main objective of this work is to know better and deeply the TFA metabolic capabilities through the construction of a metabolic model at a genome scale.

Methods

Initially, two models of TFA were constructed based on *Escherichia coli* and *Pseudomonas putida* models, using the MrBac server. They were merged to obtain the first draft in which each reaction was manually reviewed. In order to complete the model, missing reactions were incorporated to fill the gaps in metabolic pathways thanks to the TFA genome annotation and metabolic/biochemical databases such as KEGG, BRENDA, MetaCyc and BiGG or by similarity search in Uniprot/SwissProt and the *Pseudomonas* Database.

Conclusions

The constructed model of TFA metabolism, *i*IG738, consist of 738 genes, 1392 reactions and 1107 metabolites classified in 95 metabolic subsystems. The reconstruction has highlighted diverse new carbon sources that TFA can use, which have been validated *in vivo*. Overall, *i*IG738 constitutes a powefull computational tool to evaluate, at system level, the metabolic traits of the oligotrophic bacterium TFA under a large array of environmental conditions.

CLONING AND EXPRESSION OF SCFV ANTIBODY FRAGMENT AGAINST PCRV PROTEIN OF PSEUDOMONAS AERUGINOSA IN E. COLI

E. Bayat[1], S. Hosseini[2], F. Barkhordari[2], R. Moazzami[2], H. Jahandar[3], F. Davami[2], L. Nematollahi[2], Y. Garoosi[2]
[1]Pharmaceutical Sceinces Branch- Islamic Azad University,
Faculty of Advanced Sceinces & Technology- Department of Molecular and cellular Sceinces, Tehran, Iran
[2]Pasteur Institute of Iran, Biotechnology Research Center, Tehran, Iran
[3]Pharmaceutical Sceinces Branch- Islamic Azad University,
Faculty of Advanced Sceinces & Technology- Department of Biotechnology, Tehran, Iran

Backgrounds

Pseudomonas aeruginosa is a major cause of hospital-acquired infections, particularly in mechanically ventilated patients. It is also a leading cause of death in cystic fibrosis patients. A key virulence factor associated with the disease severity of *P. aeruginosa* is its type III secretion system (T3SS) which injects bacterial toxins directly into the cytoplasm of host cells. PcrV is an important structural protein of the TTSS. An engineered human antibody Fab fragment that binds to the *P. aeruginosa* PcrV protein with high affinity has been identified which has potent in vitro neutralization activity against the TTSS.

Objectives

In this study an antibody molecule in the form of recombinant single chain variable fragment antibody (scFv) has been designed against PcrV protein in order to be expressed in *Escherichia coli* expressing strain, BL21.

Methods

cDNA molecule encoding the antibody fragment was cloned in pET28a expression vector. Cloning procedure was confirmed by sequencing and restriction digestion analysis. The expression vector was transformed into *E. coli* cells and the expression of recombinant protein was then induced by IPTG (0.5mM). SDS-PAGE was used to detect the expression of the desired protein. Western blotting using anti His-6 antibody was performed to confirm the expressed recombinant protein.

A 1175bp DNA fragment encoding the designed scFv antibody was cloned in pET28a plasmid and restriction digestion with NcoI/XhoI enzymes confirmed the gene. SDS-PAGE and western blot analysis confirmed presence of an induced 43kDa protein.

Conclusions

The results showed that E. coli BL21 can be a suitable strain for high level expression of anti PcrV-scFv protein. Purification, refolding and in vitro assays will be performed in next steps.

Biotechnology / Synthetic Biology / Systems Biology

FROM DETECTION TO ACTION: PRODUCTION AND CHARACTERIZATION OF THE HIGHLY ACTIVE ANTIFUNGAL PROTEIN AFPB FROM THE CITRUS POSTHARVEST PATHOGEN PENICILLIUM DIGITATUM

S. Garrigues[1], *M. Gandía*[1], *F. Marx*[2], *J.F. Marcos*[1], *P. Manzanares*[1]
[1]*Instituto de Agroquímica y Tecnología de Alimentos IATA - CSIC, Department of Food Biotechnology, Paterna, Spain*
[2]*Medical University of Innsbruck, Division of Molecular Biology, Innsbruck, Austria*

Backgrounds

Antifungal proteins (AFPs) are small, cationic, cysteine-rich proteins that are secreted in large amounts by filamentous ascomycetes. Phylogenetic analyses suggested the grouping of AFPs in classes A, B and C. AFPs from class A have been widely studied, including the protein PAF from *Penicillium chrysogenum.* Previous attempts to detect the unique AfpB in the citrus postharvest pathogen *Penicillium digitatum* were not successful, despite high gene expression. PAF and AfpB show limited sequence identity.

Objectives

To use a *P. chrysogenum*-based expression system to produce and purify AfpB, and subsequently characterize its antifungal activity and properties.

Methods

A *P. chrysogenum*-based expression cassette consisting of *paf* 5´and 3´regulatory regions was used to direct the *afpB* gene expression in *P. digitatum*. AfpB was purified using cation-exchange chromatography. Antimicrobial assays were performed in 96-well plates.

Conclusions

The use of the *paf* gene promoter and terminator resulted in the efficient production and secretion of AfpB by *P. digitatum*, with no deleterious effect on the growth or virulence of the fungus, and the subsequent purification in high yields. AfpB has extreme thermal stability and resistance against proteolysis. AfpB showed potent antifungal activity against a range of filamentous fungi, with completely inhibitory concentrations around one micromolar, and was surprisingly active against *P. digitatum*. The AfpB structure was modeled and used to design synthetic peptides that allowed the mapping of fungal domains in the protein. AfpB is a very promising biomolecule for the development of novel antifungal agents.

COMPARATIVE GENOMICS TO DETERMINE PROBIOTIC PROPERTIES OF ENTEROCOCCUS FAECIUM 17OM39

V. Ghattargi[1], M. Gaikwad[1], S. Pandit[1], Y. Nimonkar[1], B. Meti[2], Y. Shouche[1], O. prakesh[1], D. Dhotre[1], S. pawar[1]
[1]National Centre for Cell Science, Microbial Culture Collection, pune, India
[2]Basaveshwar Engineering College, biotechnology, bagalkot, India

Backgrounds

The *Enterococcus faecium* 17OM39 was isolated from the gut of healthy Indian and an integrated approach of experimental evidence and genomic analysis was used to know its potential as probiotic. For numerous questions, the safety of probiotic strains should be carefully evaluated. It is therefore suggested that when considering an *Enterococcus* strain for use as a starter or probiotic culture, it is imperative that each particular strain should be carefully evaluated for the presence of all known virulence factors and antibiotic resistance.

Objectives

Whole genome comparison of Enterococcus faecium 17OM39 with other probiotic as well as pathogenic and non-pathogenic strains of same species

Knowing Pan, Core genome and Unique features

Identifying genes imparting probiotic properties, virulence factors and antibiotic resistance

Genome differences based on ecological niche

Methods

Whole genomes of ten strains were downloaded from the NCBI genomes. Bacterial pan genome annotations pipeline other bioinformatic tools are used to find the pan, core and unique genes. A list of fifty-three genes responsible for probiotic properties were screened within the genomes by performing BLASTX. The Comprehensive Antibiotic Resistance and Virulence Factors of Bacterial Pathogens databases were used to find the antibiotic resistance and virulence genes associated within the genomes.

Conclusions

Comparing the genomes of different strains of *Enterococcus faecium* isolated from a different source with our stain has improve the understanding of location and function of genes imparting probiotic features, antibiotic resistance, virulence and mobile elements. These insights have also help in understanding the genome differences based on ecological niche and the commensal and inherent probiotic properties of *Enterococcus faecium* 17OM39.

EMPLOYING COMPUTATIONAL APPROACH FOR SELECTION OF A POTENTIAL PROBIOTIC CANDIDATE

V. Ghattargi[1], M. Gaikwad[1], S. Pandit[1], Y. Shouche[1], B. Meti[2], D. Davaray[1], D. Dhotre[1], S. Pawar[3]
[1]National Centre for Cell Science, Microbial Culture Collection, pune, India
[2]Basaveshwar Engineering College, Biotechnology, Bagalkot, India
[3]NCCS, Microbial Culture Collection, pune, India

Backgrounds

The conventional methods for performing *in-vitro* cell culture-based assays and experiments are used by researchers to discover probiotic candidate. Computational genome analysis can be a cost-effective solution for the primary screening of potential probiotic candidate.

Objectives

Knowing the signature genes present in the genome of probiotic organisms

Methods

Ten bacterial genera containing species commonly used as probiotics for human consumption were compared based on publicly available complete genome sequences. The analysis included complete genome of *Lactobacillus* (93), *Lactococcus* (17), *Bifidobacterium* (65), *Leuconostoc* (15), *Saccharomyces* (2) as well as a selection of *Bacillus* (93), *Enterococcus* (28) *Streptococcus* (25), *Clostridium* (10) and *Escherichia* (21) genomes. The latter five genera included genomes from probiotic, commensal as well as pathogenic organisms to investigate if their non-pathogenic members shared more genes with the other probiotic genomes. List of known genes associated with probiotic properties, antibiotic resistance and virulence were screened from the literature and searched in all the genomes. Bioinformatic analysis was carried out using various available softwares and *in house* PERL and R scripts.

Conclusions

This study illustrates how over 369 genomes and 220 plasmids can be broadly compared using simple bioinformatic tools, and gain insights into the signature genes present in genomes of a probiotic candidate. These signature genes can be used for bio-prospecting of novel probiotic bacteria. We also believe the data presented here can assist in understanding the commensal and probiotic relationship of bacteria with their human host.

Biotechnology / Synthetic Biology / Systems Biology - Part II

RE-ENGINEERING SLOW SAND FILTRATION AFFECTS THE TOTAL EUKARYOTIC COMMUNITY, BUT A KEYSTONE FUNCTIONAL FOOD-WEB IS RESPONSIBLE FOR PATHOGEN REMOVAL ACROSS ALTERNATIVE CONFIGURATIONS

J. Gibbs[1], *E. Porca Belio*[1], *G. Collins*[1]
[1]*National University of Ireland- Galway, Microbiology, Galway, Ireland*

Backgrounds

Slow Sand Filtration (SSF) is a low-energy, low-technology, chemical-free, simple-to-use approach for tertiary municipal wastewater treatment. The biologically-driven removal of potentially pathogenic bacteria is a key aspect of this technology, making it a suitable option when the treated effluent is being released into recreational, aquacultural or irrigation waterbodies.

Previous SSF studies have focused on the structure, and microbiology, of the bacterial community whilst the roles of eukaryotic microorganisms have been overlooked.

Objectives

Two distinct – a (i) traditional and (ii) modified, back-washed – SSF configurations were investigated at laboratory-scale to determine the composition of the microbial community in spatio-temporal biofilm samples.

Methods

Q-PCR, T-RFLP gene fingerprinting, and high-throughput sequencing of 16S and 18S rRNA genes were collectively deployed to characterise the total microbial community of the SSFs. A targeted approach based on DNA-stable isotope probing and rRNA sequencing was used to trace the functional community implicated in ^{13}C-labelled pathogenic *E. coli* retention in the differently-configured SSFs.

Conclusions

Depth (position in the SSF sand bed) and the configuration design more significantly affected changes to the eukaryotic community structure, diversity and species richness than to the bacterial community. Eukaryotes were also stronger, and more frequent, indicator organisms of configuration and depth. Tracing ^{13}C-labelled *E. coli* revealed a diverse web of eukaryotic bacteriovores implicated in pathogen retention and inactivation by the SSFs. Species responsible for greatest up-take of labelled biomass across the time-series used – namely Cercozoans, Oligohymenophorea (and other Cilliates) and Variosea amoebozoans – were identified as the predominant predators across both SSF configurations.

LOOKING FOR A FLEXIBLE BIOCATALYST: THE ROLE OF THE ACTIVE POCKET IN THE PRODUCT SPECIFICITY OF THE B-FRUCTOFURANOSIDASE FROM XANTHOPHYLLOMYCES DENDRORHOUS

M. Gimeno-Pérez[1], Z. Merdzo[1], C. Martín de las Hijas[1], L. Lutter[1], N. Míguez[2], M. Ramírez-Escudero[3], F.J. Plou[2], J. Sanz-Aparicio[3], M. Fernández-Lobato[1]
[1]Centro de Biología Molecular Severo Ochoa, Departamento de Biología Molecular, Madrid, Spain
[2]Instituto de Catálisis y Petroleoquímica, Grupo de Biocatálisis Aplicada, Madrid, Spain
[3]Instituto de Química Física Rocasolano, Departamento de Cristalografía y Biología Estructural, Madrid, Spain

Backgrounds

Promoting health through functional food consumption is a current target in food industry that demands the development of new products including bioactive compounds as prebiotics. In this context, some β-fructofuranosidases are biotechnologically interesting enzymes able to transfer fructose moieties to sucrose generating fructooligosaccharides (FOS). Among them, *Xanthophyllomyces dendrorhous* β-fructofuranosidase (Xd-INV) has the ability to transfer a fructose unit to D-glucose of sucrose through a β(2-6) linkage, forming the FOS neokestose and neonystose as main products. Structural analysis of this enzyme reveals an active high glycosylated dimer, of which monomers show the typical bimodular arrangement from the GH32 family with a long C-terminal extension and a flexible loop (Glu334 – His343) surrounding the catalytic pocket that accommodates substrates together with Trp105.

Objectives

Analysis of the role of relevant residues in the flexible loop and Trp105 that could modulate transfructosylating specificity of the enzyme.

Methods

Site-directed mutagenesis of Xd-INV (Trp105, Glu334, Gln341, Asn342, His343 residues) and heterologous expression of the mutant proteins in *Pichia pastoris* was developed. Kinetic behavior of Xd-INV variants were assessed using HPLC and the involved structural determinants enlightened.

Conclusions

In this study, we have obtained and analyzed diverse mutants of Xd-INV involved in the enzyme specificity and assigned a functional role to the peculiar flexible loop Glu334-His343 and Trp105 residue of this protein.

Biotechnology / Synthetic Biology / Systems Biology - Part II

ANTIMICROBIAL POTENTIAL AND MECHANISM OF ACTION OF THYMOQUINONE AGAINST GRAM-POSITIVE AND GRAM-NEGATIVE BACTERIA

S. Goel[1], *P. Mishra*[1]
[1]*Indian Institute of Technology, Biochemical Engineering and Biotechnology, NEW DELHI, India*

Backgrounds

Antimicrobials of plant origin have been proved to be of paramount importance in combating the antibiotic resistance developed in pathogenic bacteria. One such phytochemical is Thymoquinone, extracted from *Nigella sativa*, which has shown potential antibacterial activity.

Objectives

To study Antibacterial potency and Anti-biofilm activity of thymoquinone and its underlying mechanism of action.

Methods

The antibacterial activity of Thymoquinone was quantified by calculating its MIC (Minimum Inhibitory Concentration) and MBC (Minimum Bactericidal Concentration), Bactericidal kinetics (time required to kill bacteria) and Post-antibiotic effect (post treatment efficiency of inhibiting bacterial growth). Cytotoxicity of thymoquinone on HaCaT (keratinocytes) cell line was also studied. Also, the bactericidal activity of thymoquinone was visually studied by SEM and LIVE/DEAD fluorescent imaging.

Conclusions

Thymoquinone was found to be a very promising bactericidal and biofilm inhibiting agent against gram negative *(E. coli* and *P. aeruginosa*) and gram positive bacteria (*B. subtilis* and *S. aureus*). MIC and MBC values of thymoquinone were found to be very less and comparable to that of kanamycin and chloramphenicol.

SEM imaging showed cell wall surface irregularities and cell lysis with cellular content release. LIVE/DEAD imaging using acridine orange (AO) and ethidium dibromide (EtBr) confirmed the bactericidal activity as treated bacteria showed selective uptake of EtBr over AO.

We find that Thymoquinone acts by ROS induction in cells, as shown by H_2DCF-DA assay.

In addition, Thymoquinone, at MIC, was found to be nontoxic to human keratinocytes (except for MIC value of *E.coli*) demonstrating its efficacy as a promising antibacterial agent.

FEMS7-1842
Biotechnology / Synthetic Biology / Systems Biology - Part II

DECIPHERING LIGNIN METABOLISM IN PSEUDOMONAS PUTIDA

H. Gomez-Alvarez[1], *Z. Martin-Moldes*[1], *J. Nogales*[1], *E. Diaz*[1]
[1]*Centro de Investigaciones Biologicas-CSIC, Department of Environmental Biology, Madrid, Spain*

Backgrounds

Lignin is discarded in paper manufacturing and biofuel production processes in spite of its peerless potential as a renewable source of aromatics for the biochemical industry. The undeniable bottleneck for its utilization relies on the development of an efficient depolymerising strategy that translates lignin molecular complexity into monoaromatics. A few bacteria are so far regarded as potential *whole-package chassis* for lignin valorisation given their ligninolytic capacities, metabolic versatility and ease to be engineered[1,2]. *Pseudomonas putida* KT2440 is one of them, and its potential as a lignin-based biochemical producer has already been described[3]. Nonetheless, an indisputable lack of knowledge regarding lignin depolymerisation by bacteria hampers proper lignin exploitation and stresses the need for further studies on bacterial lignin metabolism.

1 http://dx.doi.org/10.1016/j.cbpa.2015.06.009

2 http://dx.doi.org/10.1016/j.copbio.2016.02.030

3 http://dx.doi.org/10.1073/pnas.1410657111

Objectives

To achieve a systems biology view of the lignin metabolism in *Pseudomonas putida* KT2440 as basis for engineering future lignin valorisation processes.

Methods

A systems biology workflow including transcriptomics, genetic engineering, and biochemical analytical methods combined with metabolic reconstruction is applied to develop a lignin-specific metabolic model of *P. putida* KT2440. The metabolic model is then employed to better identify and overcome limitations in lignin utilization.

Conclusions

The lignin-specific metabolism of *Pseudomonas putida* KT2440 will be described, with special emphasis in those pathways likely involved in high-molecular-weight lignin depolymerisation. Model-driven metabolic engineering strategies for optimal lignin metabolism will also be presented. In overall, this work illustrates the metabolic capacities of *Pseudomonas putida* KT2440 towards lignin utilization and paves the way for future valorisation processes.

FEMS7-1945
Biotechnology / Synthetic Biology / Systems Biology - Part II

INNOVATION IN BACTERIOPHAGE-BASED BIOCONTROL OF THE PLANT PATHOGEN RALSTONIA SOLANACEARUM THROUGH IRRIGATION WATER

E. G Biosca[1], *B. Álvarez*[1,2], *M.M. López*[2]
[1]*Universitat de Valencia, Microbiología y Ecología, Burjassot, Spain*
[2]*Instituto Valenciano de Investigaciones Agrarias IVIA, Bacteriología, Moncada, Spain*

Backgrounds

Ralstonia solanacearum is a soil- and water-borne plant pathogen responsible for bacterial wilt, one of the most devastating bacterial diseases of solanaceous crops. This pathogen has a quarantine status in the European Union (EU) where it has been frequently detected in waterways, and associated with several water-borne outbreaks. This poses a problem for growers because the use of *R. solanacearum* contaminated water for irrigation is prohibited in the EU, where water scarcity is increasing, particularly in Mediterranean countries.

Objectives

The objective was to develop an innovative biocontrol procedure based on the lytic action of *R. solanacearum* specific bacteriophages for bacterial wilt disease management through irrigation water.

Methods

Lytic bacteriophages of *R. solanacearum* were isolated from environmental water and selected according to their specificity, stability and lytic activity under different environmental conditions. Morphology, and molecular and genomic characteristics were also determined. Biocontrol ability was assessed in irrigation water and host plants watered with the pathogen alone or with different combinations of the bacteriophages, also after their production at pilot scale.

Conclusions

The innovative technology developed, which is patent pending (priority number P201530730), reduces bacterial wilt incidence in all cases, with disease absence in most of them. It offers a natural, efficient and easily applicable strategy for bacterial wilt prevention and/or control, with less legal restrictions and environmental impact than chemical treatments. It can also be incorporated into integrated management programs against bacterial wilt. (CPI_14_244_Valoritza i transfereix_VLC/CAMPUS_UVEG & IVIA).

ANTIMICROBIAL ACTIVITIES AND ANALYSIS OF THE SECONDARY METABOLITES PRODUCED BY TWO AMYCOLATOPSIS STRAINS ISOLATED FROM LICHENS.

I. Gonzalez Martinez[1], F. Román[1], M. Estévez[1], F. Muñoz[2], C. Justicia[2], M. de la Cruz[3], P. Sánchez[3], L. Rodríguez[3], B. Cautain[3], J. Martín[2], J. Tormo[2], O. Genilloud[1]
[1]Fundacion MEDINA, Microbiology, Granada, Spain
[2]Fundacion MEDINA, Chemistry, Granada, Spain
[3]Fundacion MEDINA, Screening, Granada, Spain

Backgrounds

Microbes are the leading producers of useful natural products. For decades, microbial natural products have been one of the major sources of novel drugs for pharmaceutical companies, and today there still are novel molecules waiting to be discovered from these natural sources, especially from actinomycetes.

Objectives

Analysis of the secondary metabolites with antimicrobial activity produced by two *Amycolatopsis* strains. Fermentation of the strains in two different formats and in 8 media. Test crude extracts against a panel of Gram-positive and Gram-negative bacteria and two fungi. Bioassay guided fractionation by HPLC of the active extracts. Identification of the active compounds by LCMS analysis.

Methods

We fermented two *Amycolatopsis* strains in two fermentation formats, and we studied their antimicrobial, antibacterial and antifungal activities and cytotoxicity. The strains were fermented in eight media from which we selected the medium FRM for scale-up since the strains produced more secondary metabolites with activity against Gram-negative bacteria. The scale-up extract was fractionated by HPLC, and tested to confirm the original activity. The active fractions were analyzed by LC-MS.

Conclusions

One of the strains produced a family of novel antibiotics with activity against Gram-negative bacteria and structurally related to macrolides, which did not have any coincidence to any entry in the Dictionary of Natural Products,. Another novel chlorinated compound was detected by LC-MS, which could have a role in the activity on some of the microbes of the panel.

ENHANCED PRODUCTION OF CERULENIN BY A NEW FUNGAL SPECIES OF PHOMA FOLLOWING IMPROVED FERMENTATION CONDITIONS

V. Gonzalez-Menendez[1], *G. Crespo*[2], *C. Toro*[1], *F. Muñoz*[2], *J. Martin*[2], *F. Reyes*[2], *O. Genilloud*[1], *J.R. Tormo*[2]
[1]*Fundacion MEDINA, Microbiology, Granada, Spain*
[2]*Fundacion MEDINA, Chemistry, Granada, Spain*

Backgrounds

As result of an antimicrobial Natural Products Screening campaign an endophytic fungal strain of *Phoma* sp. isolated from the endemic plant *Arthrocnemun macrostachyum* from the saltmarsh of Cabo de Gata (Almeria) was shown to produce cerulenin as determined by LC/MS dereplication. Cerulenin is a commercial inhibitor of the fatty acid and polyketide synthases with known antimicrobial properties. This antibiotic had only been reported previously as produced by the rice pathogen *Sarocladium oryzae* from which all efforts in trying to improve production and increase cerulenin fermentation titers in this strain had limited success.

Objectives

Evaluate and improve the production of cerulenin in a new producing strain following an OSMAC approach to enhance the metabolite production.

Methods

Test the use of adsorptive polymeric resins and small-molecule epigenetic elicitors in an OSMAC approach to enhance cerulenin production by the new *Phoma* sp. strain.

Conclusions

The use of epigenetic modifiers did not increase titers of the target compound, but induced the production of three different dendrolides in the presence of 5-azacitidine and valproic acid. On the contrary, the addition of XAD-16 resin did result in a 5-fold increase in the production of cerulenin compared to the best previous production conditions described (the original producer strain in a zeolite based fermentation with an ion trapped agent). The production of cerulenin by this new producer strain, offers an alternative solution for the production of cerulenin with better yields.

A NOVEL COMPUTATIONAL METHOD TO IMPROVE BIOTECHNOLOGICAL PROCESSES BASED ON MICROBIAL COMMUNITIES

A. Sorokin[4], A. Orakov[1,5], N. Sakenova[1,5], I. Goryanin[1,2,3]
[1]OIST, Biological Systems Unit, Onna, Japan
[2]University of Edinburgh, School of Informatics, Edinburgh, United Kingdom
[3]Tianjin Institue of Industrial Biotechnology, Biodesign centre, Tianjin, China
[4]Institute of Cell Biophysics RAS, Mechanism of Cell Genome Functioning Laboratory, Pushchino, Russia
[5]School of Science and Technology, Nazarbayev University, Astana, Kazakhstan

Background
There is a great potential for the use of bacterial communities for bioremediation and waste treatment. Systems metabolic engineering for microbial community redesign is a promising approach. The successful development of synthetic microbial communities is essential to add value to the main challenges for sustainable development. Some of these challenges could be addressed by advances in computational tools and modelling. However, current tools only provide separate taxonomic and functional analyses.

Objectives
A number of experimental and in silico tools have been produced, but they need to be further improved. The challenge is to create effective integrated functional, taxonomic and metabolic analyses.

Methods
Our post-annotation analysis and visualization tool uses data integration algorithm to merge taxonomic and functional data annotated at read level. The resulting 3D dataset with axes of Functions, Taxonomy and Metagenome samples is visualized via three heatmaps of each axis versus two others (F&T, F&M, T&M). Additionally, KEGG pathway enrichment sorting/heatmap and its map visualization are implemented.

Conclusions
Advantages of the tool are: 1) Integrated functional and taxonomic analysis; 2) Comparative analysis of KEGG pathway enrichments; 3) KEGG pathway maps; 4) Both DNA and RNA analyses. We have applied our method to analyze metagenomic data from Microbial Fuel Cell communities which are used for wastewater treatment. We have identified set of genes which should be knocked down or overexpressed to improve treatment performance. We are going to test our predictions to improve real waste treatment from awamori (sake) plants and swine farms in Okinawa.

IDENTIFICATION OF WILD YEASTS IN ECUADORIAN CHICHAS

N.J. Grijalva Vallejos[1], E. Matallana[1], A. Aranda[2]
[1]Universitat de Valencia, Biochemistry and Molecular Biology, Valencia- Burjassot, Spain
[2]Instituto de Agroquímica y Tecnología de Alimentos CSIC,
Departamento de Biotecnología de Alimentos, Valencia, Spain

Backgrounds

Ecuadorian *chichas* are a variety of homemade beverages with a low alcoholic content, derived from the spontaneous fermentation of cereals (mainly maize) and/or fruits. These substrates are important habitats for bacteria and wild yeast populations that have not been fully characterized. Some of them may be related with specific organoleptic characteristics of the final product.

Objectives

The aim of this study was to identify different species of yeast with fermentative potential, present in the natural microbiota of four Ecuadorian *chichas* of rice, oats, grape and *yamor* (traditional indigenous beverage which is brewed using seven varieties of corn. It is known as the drink of Wisdom).

Methods

Samples of the four types of Ecuadorian *chichas,* prepared under controlled conditions, were taken at three time-points of fermentation: initial (day 3), tumultuous (day 7) and final (day 14). A total of 254 yeast isolates were identified by conventional microbiological analysis and by polymerase chain reaction – restriction fragment length polymorfism (PCR – RFLP) of ITS1-5.8S rDNA – ITS2; results were confirmed by sequencing. Interdelta analysis for *Saccharomyces cerevisiae* strain characterization was also performed.

Conclusions

Twelve yeast genera were isolated from Ecuadorian *chichas* samples. The most representative yeast species were: *Hanseniaspora guillermondii*, *Hanseniaspora opuntiae, Saccharomyces cerevisiae, Torulaspora delbruecky, Pichia kluyveri, Candida sp.* and *Rhodotorula mucilaginosa. Hanseniaspora* species were dominant at the beginning of fermentation in all the analyzed beverages. *Saccharomyces cerevisiae* isolates were abundant in rice *chicha* and *Torulaspora delbruecky* isolates dominates in grape *chicha*. In further investigations we will study the potential industrial applications of these new yeast strains.

CRISPR-CAS9 TARGETING OF THE E. COLI CHROMOSOME REVEALS LARGE-SCALE SENSITIVITY PATTERNS

B. Gutierrez[1], *L. Cui*[1], *A. Bernheim*[1], *D. Bikard*[1]
[1]*Institut Pasteur, Microbiology, Paris, France*

Backgrounds

The CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats) loci and their Cas (CRISPR associated) proteins have been shown to provide an adaptive immunity in bacteria. They are able to capture DNA fragments of plasmids, phages and other invading elements and use this information to destroy homologous genetic elements. When programmed to target the bacterial chromosome, CRISPR-Cas9 was shown to kill the cell, and this property could be optimized to engineer sequence-specific antimicrobials. Nevertheless, the efficiency with which Cas9 can find and cleave its target is not always the same but likely depends on the target sequence and position along the genome.

Objectives

The goal of this study is to elucidate which are the genetic requirements for efficient CRISPR-Cas9 targeting in the bacterial chromosome.

Methods

We have performed a high-throughput screening with a CRISPR library that we constructed including 10^5 different guide RNAs targeting the chromosome of *Escherichia coli*. This library was introduced in *E. coli* and the expression of Cas9 was induced. In order to determine the efficiency with which each guide RNA can kill *E. coli,* next generation sequencing of the library was performed before and after induction.

Conclusions

According to our results, there are efficient guide RNAs, which are rapidly depleted from the library, while weak guide RNAs, are still present several hours after Cas9 induction. This experiment revealed a large-scale pattern in which large regions of the chromosome are more susceptible to the Cas9-mediated killing.

E. COLI CHASSIS VARIANTS WITH ENHANCED TRANSLATIONAL CAPACITY: MANIPULATION OF THE GENOMIC COPY NUMBER OF RRNA AND TRNA GENES

Z. Gyorfy[1], Z. Lipinszki[1], V. Vernyik[1], G. Draskovits[1], K. Urmos[1], T. Sari[1], F. Blattner[2], G. Posfai[1]
[1]Biological Research Center, Institute of Biochemistry, Szeged, Hungary
[2]Scarab Genomics, LLC, Madison, USA

Backgrounds

Translation of recombinant proteins in a prokaryotic host is often limited by the capacity of the translational apparatus of the host. By adjusting the abundance of key components (rRNA operons, tRNA genes) of the host, we sought to enhance the expression of recombinant proteins in *E. coli*.

Objectives

First, we investigated the effect of changing the wt number of rRNA operons. Testing for GFP production, we found that increased rRNA operon copy number resulted in increased amount of GFP per cell. On the population level, however, lower copy numbers were beneficial. We showed that while higher GFP production per cell in high copy number variants was due to increased cell size, slower growth (due to fewer rRNA operon copies) allowed for higher GFP/total protein ratio. Next, we doubled the copies of six rare tRNA genes for expression of recombinant proteins with suboptimal codon composition. The novelty of the approach was to insert the tRNA genes into rRNA operons. This arrangement ensures that extra tRNA is supplied on demand (depending on growth rate), minimizing interference with normal cell physiology. Insertion of the tRNA genes resulted in increased expression of GFP variants carrying runs of rare codons, and demonstrated the advantage of the approach over traditional, plasmid-based tRNA abundance adjustments.

Methods

Genomes with various numbers of rRNA operons and tRNA genes were constructed by homologous recombination-based procedures.

Conclusions

E. coli variants with adjusted numbers of rRNA operons and tRNA genes may be useful alternatives for enhanced recombinant protein production.

DEVELOPMENT OF SELF-HEALING TECHNIQUE FOR CONCRETE CRACKING BY USING GLYCOCALYX SLIME-PRODUCING AND AUTOTROPHIC BACTERIA

E.S. Ha[1], K.H. Yang[2], S.S. Lee[1]
[1]Kyonggi University, Life Science, Suwon, Republic of Korea
[2]Kyonggi University, Plant-Architectural Engineering, Suwon, Republic of Korea

Backgrounds

Development of self-healing concrete is required for recover concrete-cracking because the technique can solve the problems in economic aspect.

Objectives

This study is to develop a self-healing concrete technique for cracking during the long term by using, which can be tolerance to strong alkali environment. Moreover, we searched the optimal adsorption condition.

Methods

Glycocalyx slime producing and autotrophic bacteria were identified as *Rhodobacter capsulatus*, *Rhodopseudomonas palustris, Rhodobacter blasticus, Rhodospirillum rubrum, Rhodobacter sphaeroids* with 1ml of each strain and 9ml of each culture. Glycocalyx slime producing was confirmed by incubation of strains with five kinds of carbon source (succinate, fructose, glucose, lactate, malate) at 25℃ under light.

The bacterial growth was confirmed in OD_{600} and glycocalyx slime was extracted and quantified in weight. The amount of slime produced in malic acid - treated culture medium was the highest in Rhodobacter blasticus strains (1.47 ± 0.08 g / L) except for Rhodospirillum rubrum. It was recommended as an optimal strain by showing a film formation efficiency considerably higher than the first target (0.5 g / L). Meanwhile, bacteria adsorbed four materials such as powder-formed high absorbent resin, bead formed high absorbent resin, expanded vermiculite and phyllite. Form SEM analysis, we confirmed cation exchange capacity and absorption of bacteria on the materials. Bacterial growth adsorbed on expanded vermiculite was optimal in 120 ~ 150 meq / 100 g and pH in range of 5.5 ~ 7.5. The optimal material is the magnesia phosphate potassium in determination of various phosphate sources with magnesia. The water to binder for material is 40%. Magnesia molar phosphate potassium complex is 3.4. As Molar magnesia phosphate has decreased, TruByte-K increased and the pore structure tended to become dense.

Conclusions

The technique could be applied to develop self-healing concrete in the civil engineering or plant-architecture engineering field.

SYSTEMS ANALYSIS AND GENOME SCALE METABOLIC NETWORK RECONSTRUCTION IN PSEUDOMONAS VERONII 1YDBTEX2 FOR INTEGRATION OF GENOME-WIDE EXPRESSION DATA AND PHYSIOLOGY INTERPRETATION

N. Hadadi[1], A. Chiappino Pepe[1], V. Pandey[1], M. Morales[2], M. Dubey[2], J.R. van der Meer[2], V. Hatzimanikatis[1]
[1]Ecole Polytechnique Fédérale de Lausane, Chemistry and Chemical Engineering, Lausanne, Switzerland
[2]University of Lausanne, Department of Fundamental Microbiology, Lausanne, Switzerland

Backgrounds

Pseudomonas veronii is a motile bacterium capable of degrading a variety of aromatic hydrocarbons such as benzene, toluene, ethylbenzene and *m*- and *p*-xylene (BTEX). Additionally, the strain *P. veronii* 1YdBTEX2 can survive on a minimal growth medium that contains an aromatic compound as a single carbon source. The growth of the bacterium in contaminated environments makes it a promising natural tool for bioremediation of contaminated soils.

Objectives

In this study, we investigated the metabolic flexibility and versatility of *P. veronii* 1YdBTEX2 at system level through the reconstruction and analysis of its genome-scale metabolic model (GEM). GEMs serve as platforms to integrate context specific data (i.e., omics data), to predict strain-specific phenotypes, and ultimately allow for better understanding of genotype-phenotype relationships.

Methods

We used the RAVEN Toolbox to reconstruct *itPvr*, the first genome-scale metabolic model of *P. veronii*.

Conclusions

itPvr accounts for 1243 genes, 1738 reactions, and 1795 metabolites. We performed extensive and manually curated gap-filling and quality control to reconcile experimental data such as growth measurements on different media and genome-wide expression data obtained under various exposures.

We further performed bioenergetics analysis to investigate the effect of thermodynamics constraints on the feasibility of reactions and on the metabolic capabilities.

We demonstrate how *itPvr* can serve as a platform for predicting cellular responses to environmental or genetic perturbations. *itPvr* provides a holistic overview of the metabolic needs and capacities of *P. veronii* and can guide experimental strategies to enhance the biodegradation capabilities of *P. veronii* to be ultimately used for bioremediation of contaminated soils.

SUNLIGHT MEDIATED SYNTHESIS OF SILVER NANOPARTICLES BY YARROWIA LIPOLYTICA NBRC 1658 AND SACCHAROMYCES CEREVISIAE AND DETERMINATION OF ANTIMICROBIAL ACTIVITY

H. hammamchi[1], *G. Koşarsoy Ağçeli*[1], *N. Cihangir*[1]
[1]*Hacettepe, Biology, Ankara, Turkey*

Backgrounds

Biological methods can be used to synthesize silver nanoparticles without the use of any harsh, toxic and expensive chemical substances. Silver nanoparticles have potential to be using in several biological applications.

Objectives

Silver nanoparticles used in this present study were synthesized by standard published procedures with little modifications. Therefore, we focused on the biological synthesis silver nanoparticles from *Yarrowia lipolytica* NBRC 1658 and *Saccharomyces cerevisiae*.

Methods

Yeast cultures were grown in yeast extract broth and centrifuged at 72,000 × g for 20 minutes. Supernatant was mixed with 1 mM $AgNO_3$ solution for the synthesis of AgNPs and incubated at room temperature sunlight conditions. The different parameters were optimized for the synthesis of AgNPs including concentration of silver nitrate, concentration of yeast extract and silver nitrate, time, temperature and pH which had been identified as factors which affect the productivity of AgNPs. Silver nanoparticles were analysed using UV–Vis spectrophotometer and Fourier Transform Infrared Spectroscopy (FTIR), SEM, XRD. There antibacterial activites checked by disc diffusion method. The antimicrobial index compared with other antibiotics.

Conclusions

The obtained results clearly suggest that microorganisms have potential to synthesis of eco-freindly Silver nanoparticles and using in several application.

FEMS7-2101
Biotechnology / Synthetic Biology / Systems Biology - Part II

EXTRACELLULAR SYNTHESIS OF SILVER NANOPARTICLES BY MONASCUS SP. AND ITS BIOMEDICAL APPLICATIONS

H. hamideh[1], G. Koşarsoy Ağçeli[1], N. Cihangir[1]
[1]hacettepe, biology, ankara, Turkey

Backgrounds

Nanotechnology is rapidly growing field and deals with synthesis and control the materials with nano size ranges from 1 to 100 nm. Microorganisms have potential to be using in several biological applications, such as enzyme production, nanopartical synthesis.

Objectives

The main object of the work was biological synthesis silver nanoparticles by a fungus, Monascus sp.

Methods

In this work fungal cultures were grown in malt extract broth, and incubated at 30^{o}C. The different parameters were optimized for the synthesis of SNPs including concentration of silver nitrate, concentration ratio of fungal extract and silver nitrate, time, temperature and pH which had been identified as factors which affect the productivity of SNPs. The biomass was harvested by using Whatman filter paper No. 1 and washed twice with sterile double distilled water to remove any medium component from the biomass. The filtrate was challenged with 1mM of $AgNO_3$ and incubated at 25^{o}C under dark and light room condition. The color of the solution slowly turned black-dark yellow indicating the reduction of silver ions and the formation of the AgNPs. The AgNPs were characterized using UV–Visible spectroscopy, SEM, FTIR, XRD, AFM. The activity of biologically synthesised silver nanoparticles (AgNPs) was checked by disc diffusion method for using antibacterial ageint.

Conclusions

In conclusion, we have reported biological synthesis of AgNPs using Monascus sp. as a green, reusable, nontoxicand inexpensive heterogeneous catalyst. Thesynthesized AgNPs were characterized by using UV–vis,XRD, FTIR, AFM and SEM and the bacterial biosynthesis of the titaniumdioxide provides a fast, purest form of producing nanoparticles.

X-RAY STRUCTURE OF LINALOOL DEHYDRATASE/ISOMERASE REVEALS ENZYMATIC ALKENE SYNTHESIS- AN ENZYME FOR THE BIOTECHNOLOGICAL PRODUCTION OF BUTADIENE?

J. Harder[1], *R. Marmulla*[1], *S. Weidenweber*[2], *U. Ermler*[2]
[1]*Max-Planck-Institute for Marine Microbiology, Microbiology, Bremen, Germany*
[2]*Max-Planck-Institute of Biophysics, Molecular Membrane Biology, Frankfurt, Germany*

Backgrounds

Linalool dehydratase/isomerase (Ldi), an enzyme of terpene degradation in *Castellaniella defragrans*, isomerizes the primary monoterpene alcohol geraniol into the tertiary alcohol (S)-linalool and dehydrates (S)-linalool to the alkene b-myrcene. Future biotechnological applications of Ldi are in particular the industrial butadiene and isoprene production from renewable sources. Over twenty patents have reported the potential use of the enzyme for such a biotechnological application which may lead to nylon and other polymers as well as to octane and other biofuels.

Objectives

Here we report on the crystal structures of Ldi with and without terpene substrates, revealing a cofactor-free homopentameric enzyme. The substrates were embedded inside a hydrophobic channel between two monomers of the (alpha,alpha)6 barrel fold class and flanked by three clusters of polar residues involved in acid-base catalysis.

Methods

The enzyme was purified after expression in *Escherichia coli* and crystalized for structure determination. Amino acid mutants were constructed and tested for activity.

Conclusions

The presented structural data of Ldi revealed the terpene binding site between two monomers inside a hydrophobic channel, unprecedentedly for (alpha,alpha)6 barrel proteins, and three catalytic clusters involved in catalysis. This knowledge provides a rational basis for expanding the substrate specificity of the enzyme and for increasing its turnover rate. From the new platform more targeted biotechnological avenues can be explored.

FUNGALBRAID: A GOLDENBRAID-BASED MODULAR CLONING PLATFORM FOR THE ASSEMBLY AND EXCHANGE OF DNA ELEMENTS TAILORED TO FUNGAL BIOTECHNOLOGY

M. Hernanz-Koers[1], M. Gandía[1], G. Sandra[1], M. Paloma[1], L. Yenush[2], D. Orzáez[3], J.F. Marcos[1]
[1]Instituto de Agroquímica y Tecnología de los Alimentos IATA-CSIC, Department of Food Biotechnology, Paterna, Spain
[2]Instituto de Biología Molecular y Celular de Plantas IBMCP, Mecanismos de la Respuesta al Estrés en Plantas, Valencia, Spain
[3]Instituto de Biología Molecular y Celular de Plantas IBMCP, Biotecnología y Mejora Vegetal de Especies Cultivadas, Valencia, Spain

Backgrounds

Challenges ahead in the study and exploitation of filamentous fungi are the optimization of DNA cloning and fungal genetic transformation, the exchange of standardized genetic elements, and the availability of synthetic biology tools.

Objectives

In this context, we propose the adaptation of the plant bio-design platform GoldenBraid 3.0 (GB) to fungi through: (i) the expansion of the GB toolbox with the domestication of fungal-specific genetic elements; (ii) the design of specific GB structures; and (iii) the *Agrobacterium*-mediated genetic transformation (ATMT) and gene disruption of the plant pathogen *Penicillium digitatum* as proof of concept.

Methods

Genetic elements domesticated into the GB entry vector pUPD2 were: the promoters P*trpC* and P*gpdA* from *A. nidulans*, and P*paf* from *P. chrysogenum*; the positive selection marker *nat1* for Nou^R; the negative marker HSV*tk* for $F2dU^s$; and the terminators T*trpC* from *A. nidulans*, T*tub* from *N. crassa* and P*paf* from *P. chrysogenum*. Other GB elements can be directly used in fungi, such as the markers *hph* for Hyg^R or *nptII* for $G418^R$, fluorescent protein reporters or epitope tags. Modular assembly of elements generates an increasing number of diverse transcriptional units in the pDGBα3/pDGBΩ3 destination vectors. The GB grammar was adapted to design specific GB structures for gene disruption through homologous recombination and dual selection. Furthermore, universal primers were designed for the analysis of transformants. ATMT of *P. digitatum* resulted in positive transformants.

Conclusions

The GoldenBraid technology has been successfully adapted for the ATMT of filamentous fungi. We propose the name of FungalBraid (FB) for this new branch of GB.

STRUCTURAL DESIGN OF A CHIMERIC MULTIVALENT NEISSERIA MENINGITIDIS VACCINE

S. Hollingshead[1], I. Jongerius[2], S. Johnson[1], R. Exley[1], S. Lea[1], C. Tang[1]
[1]University of Oxford, Sir William Dunn School of Pathology, Oxford, United Kingdom
[2]UMC Utrecht, Bacterial Infections and Immunity, Utecht, The Netherlands

Backgrounds

Serogroup B *Neisseria meningitidis* is the predominant cause of meningococcal disease in the Western hemisphere. A polysaccharide vaccine for this serogroup is not feasible due to its poor immunogenicity. Therefore alternative approaches are required to generate a serogroup B meningococcal vaccine.

Objectives

We used structure based design to construct a chimeric vaccine composed of the meningococcal antigens fHbp and PorA.

Methods

fHbp was used as a molecular scaffold to display the immunogenic VR2 loop of PorA. We successfully generated several fHbp-PorA chimeras that retained both the fHbp and PorA antigenic epitopes and induced an immune response against both antigens. Our biochemical analyses and fHbp-PorA structures, demonstrate the fHbp-PorA chimeras are thermally stable, elicit bactericidal antibodies directed against fHbp and PorA, and the PorA epitope folds in a conformation recognised by a bactericidal antibody.

Conclusions

The work provides the proof in principle that fHbp can be used as a molecular scaffold upon which surface exposed regions of any immunogenic membrane protein, such as PorA, can be displayed. Similar approaches could be adopted for other pathogens.

Biotechnology / Synthetic Biology / Systems Biology - Part II

RAISING BUTANOL PRODUCTION FROM AROMATIC COMPOUNDS WITH METABOLIC MODIFICATION IN RHODOCOCCUS JOSTII RHA1

B.S. Hsieh[1], H.M. Yang[1], G.H. Lin[2]
[1]Tzu Chi University, Master Program in Microbiology and Immunology, Hualien, Taiwan R.O.C.
[2]Tzu Chi University, Department of Microbiology- School of Medicine, Hualien, Taiwan R.O.C.

Backgrounds

The problem of aromatic compounds pollution and shortage of petroleum arise with the industrial development. *Rhodococcus jostii* RHA1 is able to degrade aromatic compounds due to lots of oxygenases in it. No existing microorganism has been reported to remove the toxic substances and synthesize the biofuel simultaneously.

Objectives

The aim of this study is to produce the butanol from the consumption of the aromatic compounds and elevate the butanol production with metabolic engineering in *R. jostii* RHA1.

Methods

R. jostii RHA1BuOH was construct by overexpression of heterologous KIVD(Alpha-ketoisovalerate decarboxylase from *Lactobacillus lactis*) and ADH2(alcohol dehydrogenase2 from *Saccharomyces cerevisiae*) in *R. jostii* RHA1,.and *R. jostii* RHA1$P_{ro04166}$TFBS BuOH was construct by replacing the promoter with the native promoter $P_{ro04166\ TF\ BS}$ in *R. jostii* RHA1, The butanol production from both strains is optimization by metabolic modification in keto-acid pathways with markerless mutagenesis. The produced alcohol compounds were quantified by a gas chromatograph.

Conclusions

The results suggested that the butanol was produced by using environmental contaminants and lignocellulose with *R. jostii* RHA1$P_{ro04166}$TFBSBuOH. The modified strain, *R. jostii* RHA1BuOH*1,* was construct, but the quantity of alcohols compounds have not been determined by a gas chromatograph.

Biotechnology / Synthetic Biology / Systems Biology - Part II

PSEUDOMONAS PUTIDA WSP COMPLEX AND PSEUDOMONAS AERUGINOSA PELA PROMOTER AS THE COMPONENTS OF A CONTACT DEPENDENT SURFACE SWITCH

A. Hueso-Gil[1], V. de Lorenzo[1]
[1]Centro Nacional de Biotecnología, Systems Biology, Madrid, Spain

Backgrounds

As many other microorganisms, *Pseudomonas putida* senses surfaces and changes its lifestyle from planktonic to biofilms mainly through a whole of physiological changes orchestrated by the endogenous secondary messenger c-di-GMP.

Objectives

This state of affairs opens the possibility to construct a surface-responsive device where contact sensing by the bacteria is connected to a desired output through the effect of c-di-GMP.

Methods

We have characterized a surface protein complex, Wsp, homologous to the counterpart in the *P. putida* relative, *P. aeruginosa* (Hickman *et al*., 2005) in terms of colony morphology, c-di-GMP quantification, biofilm formation.... We have also developed a c-di-GMP reporter that can sense variations in c-di-GMP using the promoter of the *pelA* gene of *P. aeruginosa* (Baraquet *et al*., 2012), the first gene of the *pel* operon. This promoter has been engineered upstream of *lacZ*

Conclusions

Similarly to the species where it was first found, the Wsp system of *P. putida* is composed of several structural components and two main proteins: WspR, which encodes the domains GGDEF and EAL (responsible of cycling or esterifying c-di-GMP, respectively), and WspF, the protein which regulates WspR activity due to its methylesterase activity (Huangyutitham *et al*., 2013). Regarding to the promoter, In *P. putida,* P_{pelA} is regulated mainly through repression of the native FleQ regulator protein, while FleN has only a minor role. This is in contrast to the functioning of the pair FleQ-FleN that regulates expression of *pelA* gene in *P. aeruginosa* by both repression and activation.

FEMS7-1426
Biotechnology / Synthetic Biology / Systems Biology - Part II

MICROBIAL FUEL CELL OPERATING WITH THIOSULFATE AND AN ACIDOPHILIC MIXED CULTURE

J. Hurtado[1], S. Jibaja[1], J. Medina[2], J. Begazo[1], A. Berastain[1]
[1]Universidad Peruana Cayetano Heredia, Ciencias celulares y moleculares, Lima, Peru
[2]Universidad Peruana Cayetano Heredia, Ciencias Exactas, Lima, Peru

Backgrounds

Microbial fuel cells (MFC´s) have been demonstrated using a variety of microorganisms including acidophilic microorganisms. Bacterial leaching often realease metlas and and inorganic sulfur compounds as tetrathionate and thiosulfate to the mining process and waste waters. The untreated acidic metal-rich water may harm the environment. It has been reported generation of electricity in microbial fuel cells using tetrathionate, but not using thiosulfate. Here, we investigate the use of thiosulfate in microbial fuel cells using an acidophilic mixed culture.

Objectives

Demonstrate the use of thiosulfate in microbial fuel cell using and acidophilic mixed culture

Methods

The fuel cell used in this study was a two-chamber camera with anode and cathode chambers separated by a Naflon 117 membrane. The electrodes were Graphite felt. The anolyte was thiosulfate at pH 3.6 and the catholyte was water. A mixed culture of anaerobic acidophilic bacteria growing in thiosulfate, developed from copper sulfides was used as inoculum. The maximum cell voltage obtained was 18 mV.

Conclusions

This study demonstrated that thiosulfate generate electricity using a acidophilic bacterial cell culture.

ISOLATION AND CHARACTERIZATION OF SULFUR-OXYDIZING BACTERIA (SOB)

A. Ibáñez[1], R. Cobos[1], A. Diez[1], S. González-García[1], J.M. Álvarez-Pérez[1], C. Barreiro[2], E. Garzón-Jimeno[1], J.J.R. Coque[1]
[1]Universidad de León, Instituto de Investigación de la Viña y el Vino, León, Spain
[2]INBIOTEC- Instituto de Biotecnología de León, Proteomics, León, Spain

Backgrounds

Phosphorous is the second most important key element as a mineral source in plant nutrition. Nevertheless, P is not easily available because it occurs mostly in insoluble forms, therefore large amounts of soluble forms of P are applied to soils as fertilizers. Furthermore, they are dependent on P, derived from phosphate rock, which is a finite resource, and based on its current rate of use, it has been estimated that the global worldwide known reserves of P rock may be depleted in approximately 100 years. The development of profitable eco-friendly technologies by using SOB (Sulphur-Oxidizing Bacteria), which oxidize sulphur to produce sulphuric acid creating an acidic leaching environment for phosphate solubilisation could contribute to the recovery of soluble phosphorous from phosphate rock.

Objectives

The isolation and characterization of SOB, and the analysis of their ability to obtain soluble phosphate from landfill schlams.

Methods

The SOB were isolated from different samples by using 4 different media: 9K-Fe, 9K-$Na_2S_2O_3$, *Acidithiobacillus thiooxidans* medium and *Leptospirillum* medium. Isolates were placed on *Thiobacillus* agar plates supplemented with bromocresol green as pH indicator and identified by amplification and sequencing of the 16S rDNA. The phosphate solubilized in a mini-real dump was simulated and measured with green malachite.

Conclusions

As a result of the experiments, the possibility of extracting the residual phosphorous of schlams in the long term by using SOB strains was determined. In the future, it will be advisable to find a sulphur mineral source in order to monetize the process.

DESIGN OF SCAR-TYPE MARKERS FOR DETECTION OF ACTINOBACTERIA WITH BIOCONTROL ACTIVITY AGAINST FUNGAL PATHOGENS BY QPCR

S. González-García[1], J.M. Álvarez-Pérez[1], A.M. Ibáñez Sánchez[1], R. Cobos[2], M.Á. Olego[1], A. Diez[2], E. Garzón-Jimeno[1], J.J.R. Coque[1]
[1]Universidad de León, Instituto de Investigación de la Viña y el Vino, León, Spain
[2]RGA Bio-investigación S.L., I+D, León, Spain

Backgrounds

Decline symptoms in young vineyards is one of the biggest problems worldwide in the wine industry, being responsible of significant economic losses. These symptoms are caused by fungal pathogens causing grapevine trunk diseases.

To contribute to reduce this problem, our laboratory have isolated and characterised a selection of endophytic and rhizospheric actinobacteria from the root system of young grapevines. These actinobacteria have a potential activity as biocontrol agents (BCAs), being able to reduce fungal infection levels in young pre-treated grapevines. Three selected actinobacteria have been applied in field assays on grafted vines.

Objectives

The main objective of this work is to develop SCAR markers, specific for each selected actinobacteria, in order to detect and quantified their capability to colonize both the rhizosphere and the root system of the treated plants.

Methods

DNA of the selected actinobacteria has been amplified with only one degenerated primer obtaining characteristics electrophoresis band patterns. Unique bands in these polymorphisms were cloned and sequenced. These sequences were subsequently used to look for intergenic regions that are not evolutionarily conserved. Inside this non-conserved regions, a pair of SCAR primers were designed to identify by qPCR each relevant strain.

Conclusions

Specific primers designed allow us an unequivocally detection of the three corresponding BCAs in vine plants. Moreover, the use of this methodology shows a high reliability for the detection of a particular actinobacteria in a complex population of microorganisms.

NOVOSPHINGOBIUM TARDAUGENS NBRC 16725 AS A NOVEL BIOCATALYST FOR STEROID BIOTRANSFORMATIONS

J. Ibero[1], *D. Sanz*[1], *B. Galán*[1], *E. Diaz*[1], *J.L. García*[1]
[1]*CIB-CSIC, Environmental Biology, Madrid, Spain*

Backgrounds

Several Gram-positive bacteria, mainly actinobacteria, have been described as efficient tools for developing industrial steroid biotransformation processes whereas the use of Gram-negative bacteria in this matter is very limited. Using Gram-negative bacteria would largely facilitate existing bioprocesses due to its easier handling. *Novosphingobium tardaugens* NBRC 16725 (described as strain ARI-1) is a Gram-negative aerobic bacteria isolated from activated sludge in a wastewater treatment plant using 17β-estradiol (an environmentally relevant endocrine disruptor) as sole source of carbon and energy[1]. Recently our group has used this bacterium to unravel the degradation pathway of the 17β-estradiol androgen and to study the metabolic versatility of the strain in steroid biotransformations.

Objectives

To assess the metabolic capabilities of strain NBRC 16725 in order to develop a new bacterial platform for steroid biotransformations.

Methods

A comparative *in silico* analysis was carried out to annotate the genes of strain NBRC 16725 putatively involved in steroid catabolism. Gene expression experiments combined with directed mutagenesis studies were performed to assign specific functions to those genes previously identified. LCMS technique served to characterize intermediate metabolites detected.

Conclusions

The data presented enabled us to expand our knowledge on the metabolic pathways and biotransformation capabilities of a Gram-negative bacterium that becomes a new model system in the steroid field. Moreover, *N. tardaugens* NBRC 16725 might cover a wide spectrum of steroid biotransformation reactions and its improvement as an efficient biocatalyst may lead to promising alternative biotechnological processes.

Department of Bioscience Engineering, Antwerpen, Belgium

Backgrounds

Food and water supply in both short and long-term space exploration missions is restricted by technical and economic constraints. The mass requirements in a Life Support System without recycling is estimated between 5500 and12800 kg per person per year, with a resupply cost of $12600 per kilo.

In order to enable long-term space exploration missions or permanent space habitation, the MELiSSA concept was developed by the European Space Agency (ESA): a bio-regenerative life support system for the complete recycling of gas, liquid and solid waste. The urine production represents a major flux of nutrients in such a life support system but requires further processing in order to make the nutrients available for food production.

Objectives

The Urine NItrification ConsortiUM (UNICUM) is a urine nitrification system designed to produce a nitrate rich fertilizer stream.

Methods

Given the space requirements of biosafety, stability and controllability, all the microorganisms involved in the biological treatment of urine must be known and characterized. As a result, a synthetic approach was favored and *de novo* synthetic communities with different combination of the nitrifying strains *Nitrosomonas ureae* Nm10, *Nitrosomonas europaea* ATCC 19718, *Nitrobacter winogradskyi* Nb-255 and *Nitrobacter vulgaris* Z were assembled. Ureolysis, nitritation and nitratation activity of the different consortia were elucidated in batch. The combinations of *Ns. europaea* and *Nb. winogradskyi* showed a higher metabolic activity, and was selected to evaluate the synergistic interactions by means of proteomic analysis under salinity stress.

Conclusions

Our results demonstrates the feasibility of nitrogen recovery with synthetic communities for future space missions.

EXPLORING THE ROLE OF RESIDUES INVOLVED IN THE OXYANION HOLE OF RHODOCOCCUS SP. CR53 LIPR BY RATIONAL EVOLUTION LIPASES VARIANTS

B. Infanzón[1], *J. Martínez*[1], *F.I.J. Pastor*[1], *P. Diaz*[1]
[1]*University of Barcelona, Department of Genetics- Microbiology and Statistics, Barcelona, Spain*

Backgrounds

Rhodococcus sp CR-53 LipR constitute the first characterized member of the new bacteria lipase family X (Bassegoda A, 2012), and displays an uncommon Y-type class of oxyanion hole shared by members of *C. antartica*, all fungal-lipases (Widmann P, 2010).

Objectives

We aimed to understand the role of residues involved in the oxyanion hole of LipR by the performance of two residues modifications.

Methods

Saturation mutagenesis was used to generate enzyme variants of the specific residues Tyr^{110} and Asp^{111}, previously described for CAL-A as the most relevant amino acids, involved in stabilization of the tetrahedral intermediate. 3D model analysis and *in silico* docking studies were created.

Conclusions

No variants with activity were obtained. However, the LipR D111G variant showed a shift towards longer fatty acid chain-length acyglycerol esters. In addition, in silico models showed that the substitution of Asp by a Gly produces a wider entrance tunnel that could allow for a better and tight accommodation of larger substrates.

GENETIC ENGINEERING OF SACCHAROMYCES CEREVISIAE FOR HYALURONIC ACID PRODUCTION

P. Jeeva[1], G. Jayaraman[1], M. Toivari[2], O. Koivistoinen[2], L. Ruohonen[3]
[1]Indian Institute of Technology Madras, Biotechnology, Chennai, India
[2]VTT Technical Research Centre of Finland Ltd, Metabolic Engineering, Espoo-02044, Finland
[3]VTT Technical Research Centre of Finland Ltd, Industrial biotechnology and food solutions, Espoo-02044, Finland

Backgrounds

Hyaluronan (HA) is a commercially valuable polysaccharide used for various applications. HA is synthesized by polymerization of two nucleotide sugars UDP-glucuronic acid and UDP-N-acetylglucosamine by the polymerizing enzyme HA synthase (*hasA*). Two major genes required for the formation of HA monomers are *hasB* (UDP-glucose dehydrogenase) and *hasD* (glucosamine-1-phosphate acetyl transferase) respectively.

Saccharomyces cerevisiae, a eukaryote, an attractive host for HA production due to its advantages such as lack of pathogenecity and hyaluronidase. In addition, it does not produce HA or any other polysaccharide that contains glucuronic acid due to absence of *hasA* and *hasB.* This makes it a superior model system to understand HA biosynthesis better. Jeong et.al.,(2014) reported HA production in *Pichia pastoris* using *Xenopus laevis has* genes. Hence, *Xenopus has* genes were chosen to engineer *Saccharomyces* for HA production.

Objectives

To metabolically engineer *Saccharomyces cerevisiae* for HA production

Methods

Recombinants were constructed by *MoClo* and CRISPR CAS9 method. HA production was measured using CTAB assay

Conclusions

Initially, the recombinant *Saccharomyces* was constructed by cloning codon optimized *Xenopus hasA* and *hasB* genes in a custom made vector by *MoClo* method. A reduction in their expression levels was observed in co-transformed clones. This was hypothesized to be due to dual high copy number plasmids. To overcome this issue, chromosomal integration of *hasAB* from *Xenopus* and *hasCD* from *Saccharomyces* using CRISPR CAS9 system was carried out. However, strains with *hasABCD* also showed lower expression as compared to strains with only *hasAB*/*hasCD.*

ENGINEERING SYNTHETIC SCAFFOLD TO CO-LOCALIZE PATHWAY ENZYMES FOR HYALURONIC ACID PRODUCTION IN LACTOCOCCUS LACTIS

A.B. Muthukrishnan[1], P. Jeeva[1], V. Devi[1], G. Jayaraman[1]
[1]Indian Institute of Technology IIT Madras, Biotechnology, Chennai, India

Backgrounds

Hyaluronic acid (HA) is a biopolymer synthesized by certain virulent bacteria. The properties of HA offer several biomedical applications. Hence, HA producing avirulent recombinant organisms are being developed. However, challenges such as low yield and low molecular weight still remain. Recent studies suggest that Synthetic scaffolds can be built to target enzymes into spatial proximity for enabling optimal flow of substrates and products. Here we aim to employ this Scaffolding strategy to improve the yield and molecular weight of HA production in *Lactococcus lactis*.

Objectives

Engineering Synthetic scaffolds of pathway enzymes for enhancing the spatial proximity of the polymer precursors for HA synthesis in *Lactococcus lactis.*

Methods

Based on the computational analysis and experimental studies, we've engineered a pNZ8148 vector based plasmid for the expression of a synthetic scaffold to co-localize the HA-precursor synthesis genes (*hasB* and *hasC*) in different ratio. Also, these enzymes are expressed under two different promoters (P_{lacA} and P_{Zn}) enabling modular control over the metabolic flux. The enzyme catalysing the polymerisation (HasA), being a membrane-bound enzyme is integrated into the *L. lactis* chromosome.

Conclusions

The scaffolding strategy using synthetic biology approach employed in this study might allow co-localization of the pathway enzymes (Has B and Has C) in the *L. lactis* strain. Further molecular and metabolic flux analysis studies of this strain will aid in optimizing the ratio of the precursors and the process strategies for improved HA production in *L. lactis*. Insights from this study will contribute further to our understanding of synthetic engineering for metabolic pathways.

THE ENHANCEMENT OF MICROBIAL SYSTEM STABILITY USING A HELPER MICROORGANISM

S.Y. Jeong[1], *T.G. Kim*[1]
[1]*Pusan National University, Microbiology, Busan, Republic of Korea*

Backgrounds

Methanotrophs (aerobic methane oxidizing bacteria) are a biological resource for various purposes, e.g., removal of contaminants and methane. A number of nonmethanotrophic bacteria, such as *Rhizobium, Sinorhizobium,* and *Mesorhizobium*, have been shown to stimulate the growth of methanotrophs when they grow together.

Objectives

This study investigated effects of the *Hyphomicrobium* sp. NM3 as a nonmethanotroph on growth and activity of *Methylocystis* sp. M6 and *Methylosinus trichosporium* OB3b.

Methods

M6 or OB3b was mixed with NM3, isolated from a methanotrophic consortium, at different mixing ratios (1:4~1:14). The consortia at 1:14 were continuously operated at hydraulic retention times (HRT) of 15 and 10 days.

Conclusions

First of all, we found that NM3 stimulated the methanotrophic activity of both M6 and OB3b, which was density-dependent. When a co-culture of M6 and NM3 was cultivated at a HRT of 15 days, the methane removal rate and cell weight were 30.4 ± 4.3 $\mu mol \cdot L^{-1} \cdot d^{-1}$ and 3.0 ± 0.3 $g \cdot L^{-1}$, respectively, in the co-culture while 16.8 ± 4.5 $\mu mol \cdot L^{-1} \cdot d^{-1}$ and 2.1 ± 0.2 $g \cdot L^{-1}$, respectively, in M6 only. In another experiment, the co-culture was operated at a higher dilution rate (a 10 day HRT) for 30 days, with NM3 being spiked when methane removal rate dropped below 20.0 $\mu mol \cdot L^{-1} \cdot d^{-1}$. NM3 spiking immediately recovered the methanotrophic activity of M6. The methane removal and cell weight were 25.8 ± 7.5 $\mu mol \cdot L^{-1} \cdot d^{-1}$ and 2.2 ± 0.2 $g \cdot L^{-1}$, respectively. To sum up, *Hyphomicrobium* sp. NM3 can be a promising biological agent for methane oxidation enhancement in methanotrophic biotechnological processes.

REVEALING THE IMPACT OF HYALURONAN SYNTHESIS ON CELL GROWTH OF STREPTOCOCCUS EQUI SUBSP. ZOOEPIDEMICUS

L. Franke[1], Z. Černý[1], D. Čožíková[2], J. Kulhánek[2], A. Růžičková[1], V. Velebný[3], J. Jílková[1]
[1]Contipro a.s., Fermentation group, Dolní Dobrouč, Czech Republic
[2]Contipro a.s., Department of Pharmacokinetics, Dolní Dobrouč, Czech Republic
[3]Contipro a.s., R&D, Dolní Dobrouč, Czech Republic

Backgrounds

Hyaluronic acid (HA) is a linear glycosaminoglycan which is applied in cosmetic and pharmaceutical industry. In the last years HA production is predominantly based on *Streptococci* fermentation. Biosynthesis of HA and cell wall components compete for the same precursors (UDP-N-Acetylglucosamin and UDP-glucuronic acid) in hyaluronic acid producing bacterium *Streptococcus equi* subsp. *zooepidemicus* (SEZ). This interconnection can complicate further bioprocess optimization. Therefore, understanding of this issue is essential for efficient development of new production strains.

Objectives

To quantify the impact of HA synthesis on cell growth, energy consumption and by-products formation in SEZ strain with blocked HA synthesis pathway.

Methods

Hyaluronan synthase deletion mutant (SEZ *ΔhasA)* was prepared by site-directed mutagenesis with the use of thermosensitive plasmid pTE10t. Fermentations were carried out in bioreactors Multifors (Infors HT, Switzerland) with working volume of 800ml. High performance liquid chromatography was performed for organic acids and intracellular UDP-sugars determination.

Conclusions

It was proved that hyaluronan biosynthesis in SEZ represents a substantial energy load. Production of major fermentation products was about 17% lower in case of strain SEZ *ΔhasA*. Concentration of intracellular UDP-sugars was significantly higher due to HA synthesis pathway disruption. Only negligible proportion of these precursors was utilized for cell wall synthesis. Obviously the competing processes of cell wall biosynthesis and HA production do not mean a crucial issue in SEZ strain used for HA production.

Biotechnology / Synthetic Biology / Systems Biology - Part II

BACTERIAL BIOFERTILIZERS DESIGN TO IMPROVE VETCH YIELD PRODUCTION IN CEREAL CROPS ROTATION

J.D. Flores-Félix[1], A. Jiménez-Gómez[1], M. Marcos-García[1], P.F. Mateos[1], E. Martínez-Molina[1], E. Velázquez[1], R. Rivas[1]
[1]University of Salamanca, Department of Microbiology and Genetics, Salamanca, Spain

Backgrounds

Legumes-cereals crop rotation is one of the traditional agricultural practices which has been recovered by the new Common Agricultural Policy. In this case, legumes fix nitrogen due to their symbiosis with nitrogen fixing bacteria and part of this assimilable nitrogen remains in the soil, available for the cereals which are used in rotation. Vetch is one of the most used legume crops in this practise. In addition, to the date, there are no relevant research projects that had analysed the most effective bacterial associations with this kind of crop.

Objectives

The principal objectives of this work were the isolation, selection and characterization of specific bacterial strains suitable to design effective biofertilizers capable to establish an efficient vetch-bacterial symbiosis and therefore the vetch and wheat yields in the crop rotation.

Methods

We identified the 86 isolated strains as belonging to the genus *Rhizobium*. All the strains were able to colonize vetch and wheat roots. Fresh weight of the aerial part of inoculated vetch plants was higher than that of the negative control plants, with values between 75% and 97% for the different strain with respect to the control. According to *in vitro* test, the strain VSAT32 was selected to be inoculated in field trials, which showed higher productions in both crops (120% in vetch and 22% in wheat respect to the control).

Conclusions

Our results showed that strain VSAT32 has the ability to colonise vetch and wheat root surfaces and promote plant growth, suggesting that its interaction with theses crops would be beneficial, being a potential candidate as inoculant for legume-cereal crop rotation.

Biotechnology / Synthetic Biology / Systems Biology - Part II

HYPERSENSITIVITY TO YEAST CWI PATHWAY ACTIVATION THROUGH A SYNTHETIC FEEDBACK LOOP CIRCUIT

E. Jiménez-Gutiérrez[1], E. Alonso-Rodríguez[1], M. Molina[1], H. Martín[1]
[1]Universidad Complutense de Madrid, Departamento de Microbiología II, Madrid, Spain

Backgrounds

The cell wall integrity pathway (CWI) in *Saccharomyces cerevisiae*, mediated by the Mitogen-Activated Protein Kinase (MAPK) Slt2, is responsible for the maintenance of the stability of this essential structure. The activation of this pathway is triggered by cell wall alterations, resulting in the phosphorylation of a MAPK cascade that leads to an intense transcriptional response. Therefore, a precise regulation of the pathway to ensure a proper signaling duration and intensity is essential for an adequate physiological output.

Objectives

Our main goal was to explore the consequences of introducing a positive feedback loop in the CWI pathway, and to analyze the potential of this genetic circuit as a tool for the identification of novel stimuli and regulatory components.

Methods

By using synthetic biology approaches, we have generated a genetic circuit named 'IPAC' (Integrity Pathway Activation Circuit) that provides hyperactivation of the pathway under stimulating conditions. To this end, the *MKK1^{S386P}* allele, coding for a constitutively active version of the CWI MAPKK, was placed under the control of the *MLP1* promoter, which is strongly induced under stimulating conditions.

Conclusions

Stimulation of the pathway in cells containing the IPAC circuit leads to a hyperactivation of the CWI MAPK Slt2, which results in cellular lethality. We have found several mutants showing resistance to the IPAC-induced sensitivity to Congo red, zymolyase and SDS, suggesting that the corresponding genes are involved in the regulation of the CWI pathway. We have also identified novel activating compounds, such as neomycin sulfate, EDTA, LiCl or diphenhydramine hydrochloride.

MECHANISM OF PALLADIUM AND GOLD UPTAKE AND TRANSPORT IN E. COLI

N. Joudeh[1]
[1]*University of Oslo, Department of Biosciences, Oslo, Norway*

Backgrounds

Bacteria use certain heavy metals in their systems, such as copper and nickel, which participate in many cellular processes. They have evolved special machineries to take up and transport these elements. Some bacteria were found to take up other precious heavy elements such as gold and palladium, which are toxic and not needed for metabolism. However, the reason for that and the mechanism of uptake/transport of these elements are still unknown.

Objectives

The biological pathway(s) of Pd and Au uptake and transport will be elucidated. Computational modelling will be used to understand these complex pathways. Later, we will study the ability to manipulate this process genetically to make the bacteria take up larger amounts of elements to be used in future application, such as bioremediation.

Methods

The proteins involved in this process will be studied by characterizing transposon mutants found to affect both the uptake and the transport processes. Then, mutations leading to either reduced or increased uptake will be sequenced, and related genes in the same pathway will be assayed for their involvement in this process. Electron microscopy and energy-dispersive X-ray spectroscopy will be used to characterize the changes in subcellular location of elements due to the introduced mutations.

Conclusions

A debate whether this process is biological or not has been going for many years. Our recent results showed that this process is largely biological. Therefore, we can move to the next step and start to find out the proteins and pathways involved.

LOCAL AND SYSTEMIC IMMUNE RESPONSE TRIGGERED BY MYCOBACTERIA IN BLADDER CANCER TREATMENT

E. Noguera-Ortega[1], R.M. Rabanal[2], E. Gómez-Mora[3], C. Cabrera[3], M. Luquin[1], E. Julián[1]
[1]Universitat Autònoma de Barcelona, Dept. Genètica i Microbiologia, Bellaterra, Spain
[2]Universitat Autònoma de Barcelona,
Unitat de Patologia Murina i Comparada- Departament de Medicina i Cirurgia Animals- Facultat de Ve terinària, Bellaterra, Spain
[3]Hospital Germans Trias i Pujol,
Fundació IrsiCaixa- Institut de Recerca en Ciències de la Salut Germans Trias i Pujol IGTP, Badalona- Barcelona, Spain

Backgrounds

A proper activation of the immune system is a clue step for the efficacy of intravesical instillation of *Mycobacterium bovis* BCG in non-muscle invasive bladder cancer patients. The efficacy of this therapy, in terms of safety and/or survival rates, can be improved by using live or gamma-irradiated non-pathogenic mycobacteria such as *Mycobacterium brumae*, and/or by using new delivery vehicles for mycobacteria such as olive-oil-in water emulsions. At present, however, is it not known to what extend these new therapeutic options modify the induced immune response.

Objectives

We aimed to analyse the local and systemic immune response induced by alternative therapeutic options to BCG.:

Methods

Using the orthotopic murine model of bladder cancer different intravesical treatments were carried out: live or gamma-irradiated BCG or *Mycobacterium brumae*, formulated in aqueous solution or in an olive oil-in-water emulsion. In each group of mice the local immune response was measured by analysing the immune cells infiltrated into the bladder cavity using cytometry, and by measuring the presence of cytokines and chemokines in the urine. The systemic immune response generated was measured by evaluating the production of anti-mycobacteria antibodies in mice sera, and by studying the recall response to mycobacteria antigens in splenocytes cultures from treated and non-treated mice,

Conclusions

Taken together our data indicates that all treatments induce an immune response but at different degrees, being mainly significant when live mycobacteria is used and even enhanced when the emulsion formulation is used for intravesical instillation of mycobacteria.

LIGNINOLYTIC MICROORGANISMS ISOLATED FROM COMPOST PILE WITH POTENTIAL FOR THE IMPROVEMENT OF COMPOSTING PROCCESS AND BIOTECHNOLOGICAL APPLICATIONS

M.D.M. Jurado[1], M.J. López[1], F. Suárez-Estrella[1], J.A. López-González[1], J. Moreno[1]
[1]University of Almería, Biology and Geology, Almería, Spain

Backgrounds

The biodegradation of lignin is a key activity during composting due to its involvement in the humification process and the release of nutrients for microorganisms. This polymer binds covalently both to hemicellulose and cellulose making it difficult to biodegrade and**,** therefore**,** it constitutes a limiting stage of composting. Its biodegradation requires an enzymatic system in which several enzymes participate, namely, lignin peroxidase (LiP), laccase, manganese peroxidase (MnP).

Objectives

The aim of this work was to investigate the capacities related to the lignin metabolism from a collection of microorganisms isolated from horticultural plant waste subjected to composting. This was carried out in order to select the more efficient ligninolytic strains that could be applied for composting improvement and in several biotechnological applications as well.

Methods

The selection was performed in two phases. In the first one, 7 qualitative tests related to the metabolism of lignin were applied, since there is currently no single qualitative evidence to conclusively discriminate ligninolytic activity. Accordingly, in the second one, 49 strains (4 bacteria and 45 fungi) were selected and the production of three ligninolytic enzymes: laccase, LiP and MnP were quantified.

Conclusions

As a consequence of these analyses, several strains that could be considered of interest for the improvement of the composting process and for other biotechnological applications were detected. *Rhodotorula glutinis* 4305 was the most efficient strain for the production of laccase and LiP, whereas *Galactomyces geotrichum* 4210 was the maximum producer of MnP.

Biotechnology / Synthetic Biology / Systems Biology - Part II

THE SEARCH FOR SUSTAINABILITY: BIOLOGICAL METHANE UTILIZATION UNCORKED.

M. Kalyuzhnaya[1]
[1]*San Diego State University, Biology, San Diego, USA*

Backgrounds

Climate change consequences pose significant risks to human health, including reductions of freshwater supplies and food. Global warming is driven by the emission of greenhouse gases, mostly CO_2 and methane. Widespread and steady growth of anthropogenic actions (i.e., fossil fuel production, agriculture, landfill use, and municipal wastewater treatment) makes methane not only the major contributor to climate change, but also the primary target for near-term climate regulation.

Objectives

Biological methane conversion is the main mechanism that controls methane emission in nature. However, the concept of using methane-utilizing microbes for improving sustainability of humane-made systems is just beginning to take shape. Our most recent research efforts are focused on developing bio-based approaches to converting scattered sources of methane (stranded natural gas, coal methane and biogas) into value-added chemicals. This presentation will describe a systems-based investigation of central metabolic pathways in *Methylomicrobium alcaliphilum* $20Z^R$, a model methanotroph and a promising microbial system for methane biocatalysis.

Methods

We combined whole-genome flux-balance modeling with systems-biology approaches (i.e. global metabolomics, transcriptomics and quantitative proteomics) and classical enzymology and genetics to both improve the understanding of methane utilization and facilitate metabolic engineering.

Conclusions

A set of novel mechanisms contributing to the central metabolic pathway regulation and key metabolic precursor formation are proposed. Novel traits allowing enhanced production of biodiesel, commercially important organic acids (i.e. succinic, lactic, gluconic and muconic acids) and amino acids (i.e. ectoine and glutamate) were developed. Our results bridge the potential of biological systems with technology development to address affordable, small-scale methane mitigation.

FUNCTIONAL EXPRESSION AND ENZYMATIC CHARACTERIZATION OF ENDO-ARABINANASES FROM BIFIDOBACTERIA UTILIZING ARABINAN

Y. Kang[1], S.L. Jeong[1], G.H. Nam[1], J.M. Lee[1], N.S. Han[1], T.J. Kim[1]
[1]Graduate School of Chungbuk National University,
Division of Animal- Horticultural and Food Sciences, Cheongju 28644, Republic of Korea

Backgrounds

endo-(1,5)-α-L-Arabinanase (ABN; EC 3.2.1.99) is an *endo*-acting hydrolase which cleaves the internal α-(1,5)-L-arabinofuranosidic linkages of arabinan polymers. According to their substrate preferences and modes of action, ABNs can be categorized into two different groups: (1) ABN-A exclusively hydrolyzes debranched arabinan, (2) ABN-B can hydrolyze α-(1,5)-L-arabinofuranosyl backbone of both sugar beet (branched) and debranched arabinans.

Objectives

Novel *endo*-(1,5)-α-L-Arabinanase genes were found from the genomes of *Bifidobacterium dentium* and *Bf. longum*, respectively. On the basis of the enzymatic properties, each enzyme can be categorized and utilized for the branched arabinooligosaccharides.

Methods

Two putative genes encoding BfdABN-B and BflABN-B were cloned from *Bifidobacterium dentium* ATCC 27679 and *Bf. longum* DSM 20211, respectively. Each gene was constitutively expressed in *E. coli*. Their enzymatic properties were determined.

Conclusions

In the present study, At the amino acid sequence level, they share less than 30% of identities with various known ABNs type-B. Each ABN-B gene, which is fused with six-histidines at C-terminus, was constitutively expressed in *Escherichia coli*. Although the debranched (linear) arabinan is the most preferred substrate, BfdABN-B and BflABN-B possess the significant activity towards sugar beet arabinan as well. While they hydrolyze debranched arabinan into arabinobiose and arabinotriose, both ABN-B enzymes can produce a variety of branched arabinooligosaccharides from sugar beet arabinan. These hydrolases can play an important role in arabinan utilization.

PHENOTYPIC SCREENING OF ESCHERICHIA COLI MUTANTS EXHIBITING ALTERED TRANSCRIPTIONAL PROFILES

Z. Kapustina[1], *G. Alzbutas*[1], *A. Lubys*[1]
[1]*Thermo Fisher Scientific, R&D, Vilnius, Lithuania*

Backgrounds

Gene expression patterns are intimately linked to the physiological state of the cell, which is mirrored in global cellular parameters such as growth rate, cell size, abundance of RNA polymerases and ribosomes. Transcriptional analyses revealed that growth environment as well as metabolic stress caused by overproduction of heterologous proteins is associated with substantial changes in global *E. coli* gene expression profile. However, the effect of genome-wide modulation of transcription patterns on physiological state of *E. coli* cells has not been studied in depth; moreover, analyses are often confined to the knockout mutations.

Objectives

Here we will present the results of a genome-wide transposon mutagenesis study designed to not only disrupt the genes at insertion sites but also significantly enhance the transcription of nearby genomic loci. We aim to identify *E. coli* mutants exhibiting elevated growth rates and/or enhanced efficiency of heterologous protein expression.

Methods

Tn5 minitransposon was designed to contain outward-facing strong promoter sequences. *In vivo* mutagenesis strategy based on delivery of transposition system elements on suicide vectors was developed and used for generation of more than 50 000 insertional mutants. HITS (High-throughput Insertion Tracking by deep Sequencing) technology was optimized for Ion Torrent™ sequencing platform and used for high-throughput analysis of transposon insertion sites after phenotypic screening experiments.

Conclusions

Genetic circuits are coupled to the physiological state of the cell. Alterations of global gene expression profile can lead to identification of intriguing *E. coli* traits leading to the construction of novel cloning and gene expression host strains.

Biotechnology / Synthetic Biology / Systems Biology - Part II

ANTIMICROBIAL EFFECT OF COMPONENTS OF ROOT EXTRACT OBTAINED FROM VEXIBIA ALOPECUROIDES

T. Karpenyuk[1], A. Goncharova[1], T. Kustova[1], M. Zavorotnaya[1], A. Platayeva[1], M. Kucherbayeva[1]
[1]al-Farabi Kazakh National university, Research Institute of Issues in Biology and Biotechnology, Almaty, Kazakhstan

Backgrounds

An actual problem of modern medicine and pharmacology is not only the chemical synthesis of antimicrobial agents, but also the search for new sources of natural antibiotics, including plant origin. Antimicrobial activity of plants, extracts isolated from them and individual components is largely caused by the presence of certain chemical groups belonging to different classes of biologically active substances (BAS).

Objectives

We investigated the antimicrobial properties of the total extract of the roots of plants *Vexibia alopecuroides* and identified BAS causing this activity.

Methods

The total extract was obtained by a two-step maceration fractionated by flash chromatography by appliance Biotage Isoler. Identification of components conducted by high performance liquid chromatography-mass spectrometry and nuclear magnetic resonance, the antimicrobial activity was determined by serial dilutions in broth.

Conclusions

The antimicrobial activity against *Staphylococcus aureus, Methicillin-resistant Staphylococcus aureus, Pseudomonas aeruginosa, Candida glabrata, Candida krusei, Candida albicans* was identified for 9 individual compounds belonging to the group of flavonoids. They are identified as the soforaflavon G, leahianon A, alopekuron A, alopekuron B, alopekuron C, alopekuron F, alopekuron D, soforaflavon I and glabrol. For leahianona A, alopekurona A, B and C, the minimum concentration causing 50% of growth inhibition for *Staphylococcus aureus*, methicillin-resistant *Staphylococcus aureus* was <0.8 µg / ml, which is comparable to the minimum concentration of antibiotic Ciprofloxacin, triggering a similar effect.

Biotechnology / Synthetic Biology / Systems Biology - Part II

ISOLATION, PURIFICATION AND ANTIBACTERIAL PROPERTIES OF HUMAN RECOMBINANT LACTOFERRIN FROM TRANSGENIC GOATS

A. Kastsianevich[1], M. Kapustin[1], U. Falkouskaya[1], E. Kolomiets[2], A. Budzevich[3]
[1]Institute of Microbiology of National Academy of Sciences of Belarus, laboratory of protein, Minsk, Belarus
[2]Institute of Microbiology of National Academy of Sciences of Belarus, Laboratory of biological control agents, Minsk, Belarus
[3]Scientific and Practical Center of the National Academy of Sciences of Belarus on Animal husbandry, laboratory of animal biotechnology, Zhodino, Belarus

Backgrounds

Lactoferrin (LF) is iron binding mammalian glycoprotein referred to transferrin family. LF possesses anti-bacterial, anti-oxidant and anti-carcinogenic properties and acts as an iron transfer agent in human body. Due to these reasons, LF is used in a variety of commercial products including functional foods, therapeutic drinks, fermented milk, chewing gum, cosmetics and tooth paste.

Now human LF is substitute by the analog derived from cow milk. It should be noted that protein of animal origin is distinguished from human LF by potential allergenicity and low affinity to human receptors.

Numerous forms of recombinant human lactoferrin (rhLF) have been produced in multiple expression systems, including transgenic plants and animals. Only a few technologies could be scaled up to industrial level. These lactoferrins are rhLF from *Aspergillus awamori*, produced by Agennix (Houston, TX, USA), rhLF from rice and rhLF from goats (Scientific and Practical Center of the National Academy of Sciences of Belarus on Animal husbandry, Belarus)

Objectives

To isolate, purify rhLF from milk of transgenic goats and study its antibacterial properties.

Methods

Centrifugation, spectrometry, SDS-PAGE, ion-exchange chromatography, agar well diffusion method

Conclusions

The lab-scale method of purifying the rhLf from the milk was achieved using ion-exchange chromatography and resulted in 95% purity. The purity of rhLf was determinated by SDS-PAGE.

Strains of Escherichia coli were chosen as test cultures for evalution of antimicrobial activity. Antibiotic kanamycin served as the control. Antimicrobial activity was cheeked via diameter of growth inhibition zones of test cultures. It was found that minimal inhibitory concentration of LF was 50 mg/ml

IRON OXIDIZERS AT HIGH CHLORIDE CONCENTRATIONS: ADAPTATION OF FERRIMICROBIUM ACIDIPHILUM T23T AND ISOLATION OF NOVEL SALT-TOLERANT ALICYCLOBACILLUS STRAINS

M. Kaszuba[1], D. Huynh[1], J. Rivera-Araya[2], S.R. Kaschabek[1], W. Sand[1], G. Levicán[2], M. Schlömann[1]
[1]TU Bergakademie Freiberg, Institute of Biosciences, Freiberg, Germany
[2]Universidad de Santiago de Chile, Departamento de Biología, Santiago de Chile, Chile

Backgrounds

Acidophilic iron oxidizers have been reported to be inhibited by high chloride concentrations. This is problematic for bioleaching operations, since increased chloride concentrations may occur during leaching processes, e.g. the use of sea water or the recycling of the acid solution.

Objectives

Thus, there is a necessity to obtain chloride-tolerant iron oxidizers and a better understanding of biochemical mechanisms enabling them to tolerate high chloride concentrations.

Methods

Ferrimicrobium acidiphilum $T23^T$ was exposed to different chloride concentrations, cultivated in modified DSMZ medium 1190 with 10 mM $FeSO_4$ and 5 mM citric acid in weekly cycles at 30°C, 130 rpm. Adaptation was conducted stepwise with elevated NaCl concentrations. Results showed that *F. acidiphilium* $T23^T$ tolerates ≤ 200 mM NaCl and reproducible subcultivation is achieved in the presence of 100-150 mM NaCl. Reactive oxygen species (ROS) measurements with dichloro-dihydro-fluorescein diacetate exhibited that addition of >100 mM NaCl may cause oxidative stress in bacterial cells. Interestingly, the addition of an osmoprotectant, e.g. 1 mM of trehalose, could lower ROS production and thus reduce oxidative stress. To obtain highly chloride-tolerant bacteria, in addition to those from adaptation studies, bacteria were enriched and isolated from marine tailing samples from Spain on solid medium containing 340 mM NaCl. Acidophiles could successfully be isolated and assigned to the genus *Alicyclobacillus.* The isolates could oxidize ferrous iron in the presence of up to 850 mM NaCl, with iron oxidation capacities being NaCl and temperature dependent.

Conclusions

These findings may be of biotechnological relevance to establish bioleaching of metals at high chloride concentrations.

[4]Universidad de Sevilla, Genética, Sevilla, Spain

Backgrounds

Chitooligosaccharides (COS) are β-(1,4)-linked oligomers of N-acetyl-glucosamine (GlcNAc) and glucosamine (GlcN) formed by chemical or enzymatic hydrolysis of chitosan or chitin. The growing biotechnological interest of COS in fields such as food or health increases the demand of the producing enzymes as well as their characterization and functional improvement.

Objectives

Express a chitinase of 42 kDa from *Trichoderma harzianum* in a heterologous system, obtain protein levels compatible with its crystallization for the future protein structural resolution and evaluate the ability of the recombinant protein to produce COS.

Methods

The chitinase *gene* cDNA from *T. harzianum* was expressed in *Pichia pastoris* using a restriction-free cloning strategy, production of heterologous protein was analysed and escalated up to a 5 L fermenter level. Recombinant protein was purified and some crystals were obtained which allows undertake the protein structural resolution. Synthesis of oligosaccharides from different substrates were evaluated and optimized using the recombinant enzyme. HPAEC-PAD on a Dionex ICS3000 system and Mass Spectrometry were used in the reaction studies and product characterization.

Conclusions

A chitinase of 42 kDa from *T. harzianum* was overexpressed in *P. pastoris*, the recombinant protein was purified, characterized and crystallized for the protein structural resolution. Production of COS mediated by this enzyme was evaluated and some of the molecules formed were characterized.

STRUCTURAL STABILITY, THERMODYNAMICS AND APPLICATIONS OF A-AMYLASES OF THERMOPHILIC BACTERIA FROM HOT SPRING RESERVOIR IN TULSI SHYAM, GUJARAT (INDIA)

B. Kikani[1], *S. Singh*[2]
[1]*PD Patel Institute of Applied Sciences, Department of Biological Sciences, Changa, India*
[2]*Saurashtra University Campus, UGC-CAS Department of Biosciences, Rajkot, India*

Backgrounds

Thermostable enzymes are industrially very significant, as they possess various benefits over the enzymes of mesophiles. Our research group in India is involved with the distribution, molecular diversity and biocatalytic potentials of thermophilic bacteria and actinomycetes.

Objectives

In the present report, we describe the thermostable α-amylases of thermophilic bacteria. The research mainly dealt with the inherent stability of the amylases.

Methods

The enzymes were purified by a single step purification technique, using hydrophobic interaction chromatography on Phenyl Sepharose 6FF. The α-amylases were characterized with respect to substrate kinetics, stability and structural attributes. Various thermodynamics parameters; ΔS^*, ΔH^*, E and ΔG^* were computed and analyzed to establish the stability of the enzyme-substrate reaction. The changes in the secondary structure of the enzyme under various physicochemical conditions were followed by the Circular Dichroism (CD) spectroscopy. The starch hydrolysis efficiency of the purified enzyme was detected in terms of the dextrose equivalence value.

Conclusions

The overall findings highlighted on the easy and cost effective method of the purification, the intrinsic stability of the amylase as elucidated the CD Spectroscopy and thermodynamic analysis. The calcium independent nature and resistance against chemical and solvent denaturation suggested potential for the commercial applications.

COMPARATIVE GENOME ANALYSES OF BACILLUS STRAINS PRODUCING GAMMA-GLUTAMYLTRANSPEPTIDASE

J.M. Lee[1], J. Lee[1,2], S.L. Jeong[1], Y. Kang[1], S.W. Lee[2], B.S. Hurh[2], T.J. Kim[1]
[1]Graduate School of Chungbuk National University,
Division of Animal- Horticultural and Food Sciences, Cheongju 28644, Republic of Korea
[2]Sempio Foods Company Research Center, -, Cheongju 28156, Republic of Korea

Backgrounds

γ-Glutamyltranspeptidase (GGT) catalyzes the cleavage of γ-glutamyl compounds and the transfer of γ-glutamyl moiety to water, or to amino acid/peptide acceptors. GGT can be utilized for the generation of γ-glutamyl peptides or glutamic acid, which are used as food taste enhancers.

Objectives

In the present study, genome sequence of various *Bacillus* spp. were comparatively analyzed and their enzymatic properties were characterized. These enzymes can enhance the taste of fermented food.

Methods

In the present study, *Bacillus amyloliquefaciens* SMB469 with high GGT activity was isolated from *Doenjang*, a traditional fermented soy food of Korea. The gene encoding GGT from *B. amyloliquefaciens* SMB469 (BaGGT469) was cloned from the isolate, and heterologously expressed in *E. coli* and *B. subtilis*. For comparison, three additional GGT genes were cloned from *B. subtilis* 168, *B. licheniformis* DSM 13, and *B. amyloliquefaciens* FZB42.

Conclusions

The BaGGT469 protein was composed of 591 amino acids. The final protein comprises two separate polypeptide chains of 45.7 and 19.7 kDa, generated via autocatalytic cleavage. It shares about 83.8% and 67.8% of amino acid sequence identities with those from *B. subtilis* and *B. licheniformis*, respectively. These results suggest that BaGGT469 can be utilized for the enzymatic production of various γ-glutamyl compounds. The relationships between their primary structures and enzymatic activities were comparatively investigated on the basis of the genome analyses.

OPTIMISATION OF EXTRACELLULAR LIPASE PRODUCTION BY CRYPTOCOCCUS DIFFLUENS D44

A. Koca[1], S. Durmaz Sam[1], B. Sariyar Akbulut[1]
[1]Marmara University- Faculty of Engineering, Dept. of Bioengineering, ISTANBUL, Turkey

Backgrounds

Lipases don't only catalyse the hydrolysis of triglycerides but also esterification, transesterification, alcoholysis, acidolysis reactions. They are widely used in the food, detergent, and pharmaceutical industry. A wide range of microorganisms produce lipases with remarkably different properties. Increasing the yield of microbial lipases will help diminish production and downstream processing costs. *Cryptococcus diffluen*s D44 is a yeast strain isolated from a petroleum refinery environment with an ability to secrete extracellular lipase enzyme.

Objectives

Medium composition is an important factor that controls the biosynthesis and secretion of lipases. The influence of several edible oils (including olive, sunflower, corn, and sesame oils) as sole carbon sources in the presence and absence of an emulsifying agent (Tween® 80) on the growth and lipase expression of *C. diffluens* D44 cells was investigated in this study.

Methods

Each oil (sterilised by dry heat) was added to sterile growth medium at a concentration of 2.0% (v/v) before inoculation. Growth was monitored via absorbance measurements at 600 nm at pre-determined time intervals. Lipase in the supernatant obtained after centrifugation (at 12,000 rpm for 15 min) was used in enzymatic assays. Lipase activity was determined spectrophotometrically using p-nitrophenyl palmitate as the substrate. Protein measurements were carried out applying Bradford method in which bovine serum albumin was the protein standard.

Conclusions

Depending on our preliminary studies, lipase production increased regularly after lag phase and summitted at the early stationary phase for all oils studied. The highest specific growth rate, biomass production and lipase activity were attained when sunflower oil was the inducer.

DETERMINATION OF NANOPARTICLE BY EXTRACELLULAR SYNTHESIS OF TIO2 BIO-NPS FROM MICROORGANISMS AND ITS BIOLOGICAL ACTIVITY

S.P. Kodal[1], G. Koşarsoy Ağçeli[2], H. Hammamchi[2], N. Cihangir[2], Z. Aksu[1]
[1]Hacettepe University, Chemical Engineering Department, Ankara, Turkey
[2]Hacettepe University, Department of Biology, Ankara, Turkey

Backgrounds

TiO_2 bio-NPs is well known to attack a wide range of microbes by altering the cell membrane structure and its functions. Therefore, nanoparticles have been widely used for the development of many biological and pharmaceutical products.

Objectives

In the present work we report a simple, fast, cost-effective and nonpolluting approach for synthesis of TiO_2 bio-NPs using microorganism species.

Methods

Microorganisms were freshly inoculated in medium and incubated. 25 ml of it was taken and diluted by adding 75 ml of sterile distilled water containing nutrients and allowed to grow for another 24 h, 20 ml of 0.025 M titanium sulfate solution was added to the culture solution and it was heated on steam bath up to 60°C until white deposition starts to appear at the bottom of the flask. After 24 h, the culture solution was observed to have distinctly markable coalescent white clusters deposited at the bottom of the flask. Precipitate obtained was centrifuged and the condensed precipitate was washed with distilled water to obtain neutral pH. The precipitate was calcined at 500°C for 3 h for the removal of biomass organic contents to get TiO_2 NPs. The different parameters were optimized for the synthesized. Characteristics of the synthesized TiO_2 NPs were analyzed using UV–Vis spectrophotometer, SEM, FTIR, XRD, AFM. The efficiency of biologically synthesized TiO_2 NPs was checked for its antibacterial and antibiofilm activity.

Conclusions

The obtained results clearly suggest that microorganisms have potential to synthesis of TiO2 bio-nanoparticles.

BIOSYNTHESIS OF ZIRCONIA NANOPARTICLES BY MICROORGANISMS

S.P. Kodal[1], H. Hammamchi[2], G. Koşarsoy Ağçeli[2], N. Cihangir[2], Z. Aksu[1]
[1]Hacettepe University, Chemical Enginnering Department, Ankara, Turkey
[2]Hacettepe University, Department of Biology, Ankara, Turkey

Backgrounds

Zirconia is an important ceramic with a wide range of applications including electrochemical devices, structural ceramics and catalytic systems. Zirconium oxide nanoparticles powder has been selected to improve the properties, as a bio-compatible material that possesses high fracture resistance, and to improve fracture toughness of ceramics by developing a new generation of ceramic-matrix composites.

Objectives

Biological methods can be used to synthesize zirconia NPs without the use of any harsh, toxic and expensive chemical substances. The aim of this work is to produce zirconia nanoparticles by microorganism which isolated from soil.

Methods

The bacteria were cultured as described elsewhere. After incubation, the culture was centrifuged at 72,000 × g for 20 minutes and washed thoroughly under sterile conditions. The bacterial biomass was then resuspended in 100 ml of a 10^{-3} M aqueous solution of K_2ZrF_6 (pH 3.6) in a 500 ml erlenmeyer flask and kept on a shaker (200 rpm) at 37 ^{o}C. The reaction between the bacterial biomass and ZrF_6^{-2} ions was carried out for a period of 24 h and centrifuged at 72,000 × g for 20 minutes. The characteristics of the synthesized zirconia nanoparticles were analyzed using TEM, FTIR and XRD. The efficiency of biologically synthesized zirconia nanoparticles was evaluated for their antibacterial activity by agar well diffusion method against different pathogenic bacteria as previously described.

Conclusions

Nanoparticles are being synthesized using chemical and physical methods, however the adverse effects of these methods sought for the discovery of novel sustainable methods.

AN EFFICIENT PROCEDURE FOR MARKERLESS DELETIONS OF ANTIBIOTIC CLUSTERS IN ENGINEERED STREPTOMYCES LIVIDANS TK24 STRAIN FOR HETEROLOGOUS EXPRESSION OF SECONDARY METABOLITE GENE CLUSTERS

J. Kormanec[1], *D. Homerova*[1], *R. Novakova*[1], *R. Knirschova*[1], *L. Feckova*[1], *B. Rezuchova*[1], *B. Sevcikova*[1]
[1]*Institute of Molecular Biology Slovak Academy of Sciences, Gene Expression, Bratislava, Slovak Republic*

Backgrounds

The members of the soil bacteria of the genus *Streptomyces* play critical roles in soil ecology and produce various secondary metabolites including many medicinally important antibiotics. *Streptomyces* genomes contain numerous cryptic secondary metabolite gene clusters of unknown functions. An strategy to access these compounds comprises their heterologous expression in engineered well-characterised *Streptomyces* host strains [1]. We set out to develop *Streptomyces lividans* TK24 strain as a host for the expression of heterologous gene clusters using previously developed efficient deletion system based on the positive selection of double crossover events with blue pigment producing gene *bpsA* [2].

Objectives

Optimization of the deletion system based on the *bpsA* gene for successive deletions of dominant antibiotic gene clusters in *S. lividans* T24, followed by removing of antibiotic resistance cassette genes.

Methods

Deletions of antibiotic gene clusters in *S. lividans* TK24 was done as described in [2].

Conclusions

1, We optimized deletion system based on the *bpsA* gene. Using the system several gene clusters were successively deleted in *S. lividans* TK24 strain.

2, Production of mithramycin was substantially increased in the engineered *S. lividans* strain after heterologous expression of mithramycin gene cluster.

CONSTRUCTION OF A UNIQUE AND INNOVATIVE PLATFORM FOR PRODUCTION OF PROTEINS BASED ON PSYCHROTOLERANT YEAST DEBARYOMYCES MACQUARIENSIS

E. Krajewska[1], M. Wicka-Grochocka[2], M. Wanarska[2], H. Cieśliński[2]
[1]Gdansk University of Technology, Molecular Biotechnology and Microbiology, Gdansk, Poland
[2]Gdansk University of Technology- Faculty of Chemistry, Molecular Biotechnology and Microbiology, Gdansk, Poland

Backgrounds

The increasing demand for proteins showing high activity at low temperatures, entails the development of technologies for their efficient production and purification. Despite the fact, that many expression systems have been developed by now, they are based mainly on mesophilic or thermotolerant bacteria and yeast. Due to high thermolability of cold-active proteins, these systems are not optimal for their efficient production. The expression system based on psychrotolerant yeast as expression host is potentially the best system for the efficient production of enzymes derived from cold-adapted organisms. Yeast combine the advantages of prokaryotic and eukaryotic expression systems such as fast-growing biomass and efficient secretion of proteins outside the cell, thus allowing a pre-purified preparations of the protein. In addition, yeast as an eukaryotic cells are capable of performing posttranslational modifications, and hence it is possible to obtain correctly folded proteins.

Objectives

The aim of this study was the construction of new platform for the production of proteins, based on pre-selected psychrotolerant yeast cells of *Debaryomyces macquariensis* which were transformed with series of expression vectors. In addition, to test the functionality of the new expression system recombinant plasmids containing the gene encoding β-galactosidase active at low temperature were also constructed, enabling the production of this protein in the yeast *Pichia pastoris* and *Debaryomyces macquariensis*.

Methods

Methods included PCR, cloning of DNA fragments, transformation and the gene expression.

Conclusions

Recombinant *D. macquariensis* strains were able to produce cold-active β-galactosidase from *Paracoccus* sp. 32d. The new expression system was constructed and compared to *Pichia pastoris* system.

EXPLORING BIOLOGICAL POTENTIAL OF CYANOBACTERIA FOR BIOFUEL PRODUCTION

G. Kufryk[1]
[1]*Grand Canyon University, CSET, Phoenix, USA*

Backgrounds

Cyanobacteria are a group of photosynthetic prokaryotes that are capable of oxygenic photosynthesis. Some cyanobacteria are naturally capable of producing compounds that can be used as the source of biofuels: hydrogen, isoprene, C-16 and C-18 lipids, ethanol, etc. Many of them can be genetically engineered to improve the yield of bioproducts, and as photoautotrophic organisms, they can be grown quickly and inexpensively which makes this group particularly suitable for bioengineering.

Objectives

Our goal was genetic engineering of cyanobacterial strains for the purpose of increasing the yield of biohydrogen that was generated in their cultures.

Methods

To this end, the native bidirectional hydrogenase was genetically engineered and overexpressed in several strains of cyanobacteria using a series of alternative promoters. Hydrogen producing activity of bioengineered hydrogenase was tested in vitro. Hydrogen production was recorded and evaluated in the cultures of the cyanobacterial mutants.

Conclusions

Genetic engineering of cyanobacteria allowed us to significantly increase their hydrogen-producing capacity without compromising the stability of the mutant strains. A combination of site directed mutagenesis and overexpression of *hoxE* gene in cyanobacteria resulted in 6 to 8 - fold increase of hydrogen evolution, depending upon the choice of parental strain and growth conditions. As the details of molecular regulation of hydrogen production in the cell become increasingly available, new steps are being taken to improve the level of hydrogen production by cyanobacteria. Due to a photoautotrophic nature and low maintenance cost of these microorganisms, they represent the most economical system for biological hydrogen production with a potential for commercial application.

Biotechnology / Synthetic Biology / Systems Biology - Part II

STUDYING THE ROLE OF PENTOSE PHOSPHATE PATHWAY IN XYLOSE METABOLISM AND FERMENTATION IN THE YEAST OGATAEA POLYMORPHA

O. Kurylenko[1], R. Vasylyshyn[1], J. Ruchala[2], K. Dmytruk[1], A. Sibirny[1]
[1]Institute of Cell Biology- NAS of Ukraine, Department of Molecular Genetics and Biotechnology, Lviv, Ukraine
[2]University of Rzeszow, Department of Biotechnology and Microbiology, Rzeszow, Poland

Backgrounds

The pentose-sugar xylose is the second-most abundant monosaccharide in hydrolysates released from lignocellulosic biomass. *Ogataea polymorpha* is one of the most thermotolerant xylose-fermenting yeast species, however, with low efficiency of xylose alcoholic fermentation in the wild-type strains. The functional role of two key enzymes involved in the non-oxidative part of pentose phosphate pathway, namely transketolase and transaldolase, in xylose metabolism and alcoholic fermentation in *O. polymorpha* remained unclear.

Objectives

Screening of a new targets for improvement of xylose utilization during high-temperature xylose alcoholic fermentation in the yeast *O. polymorpha.*

Methods

Standard methods of yeast molecular genetics and biochemistry were used.

Conclusions

O. polymorpha contains both cytosolic transaldolase (*TAL1*) and transketolase (*TKL1*) and their peroxisomal counterparts (genes *DAS1* and *TAL2*, respectively). The deficiency or overexpression of these genes was examined regarding their roles in xylose utilization and fermentation. The *tal1*Δ, *tal2*Δ and *das1*Δ mutants were constructed by gene disruption technique. The conditionally knockout *tkl1*Δ mutant was constructed by replacing the endogenous promoter of *TKL1* gene by regulated *YNR1* promoter of nitrate reductase, repressed by ammonium sulfate as nitrogen source. A significant decrease in xylose-fermenting ability and totally blocked growth on xylose was observed in *tkl1*Δ and *tal1*Δ mutants. Overexpression of *DAS1* gene in *tkl1*Δ mutant led to restoration of growth on xylose, however, only after prolonged lag phase. The ability of xylose utilization in *tal1*Δ strain was easily restored by overexpression of *TAL2* gene. Moreover, overexpression of each of the mentioned genes resulted in improvement of ethanol production from xylose.

CARYOLAN-1-O1, AN ANTIFUNGAL VOLATILE PRODUCED BY STREPTOMYCES SPP., INHIBITED ENDOMEMBRANE SYSTEM OF FUNGI

S.W. Hong[1], G. Cho[2], Y.S. Kwak[1]
[1]Gyeongsang National University, Applied Life Science, Jinju, Republic of Korea
[2]Gyeongsang National University, Plant Medicine, Jinju, Republic of Korea

Backgrounds

Streptomyces spp. has the ability to produce various secondary metabolites that interact with the environment. It also has potential for its role in the discovery of new antibiotics. Some secondary metabolites have been reported as having antibacterial properties.

Objectives

This study attempted to discover new antifungal volatiles from the genus *Streptomyces* in order to understand how it works as an antifungal compound. To date the biological activity of caryolan-1-ol has not yet been investigated.

Methods

To observe the antifungal activity, a mixture of the main components caryolan-1-ol and the unknown sesquiterpene were collected from *Streptomyces* sp. S4-7. The mixture could act as an antifungal agent and had a dose-dependent character. Furthermore, synthetic caryolan-1-ol also inhibited the dose-dependent growth of the fungus. To understand the mode of action of caryolan-1-ol, chemical-genomics profiling assays were performed.

Conclusions

The results *Streptomyces* produced caryolan-1-ol that affected the endomembrane system by working on sphingolipid synthesis, function of the vesicle and served as the key location for antifungal activity.

Biotechnology / Synthetic Biology / Systems Biology - Part II

INDUSTRIAL PRODUCTION OF PSEUDOMONAS CHLORORAPHIS

E. Lagendijk[1], N. van Biezen[1], C. Blad[1], S. de Weert[1]
[1]Koppert BV, R&D Microbiology, Berkel en Rodenrijs, The Netherlands

Backgrounds

Every year approximately 25 % of the worlds crop yield is lost, mainly due to diseases caused by phytopathogenic fungi. Products on the market to fight these diseases are mostly chemicals, harmful for the health of people and the environment. Biological control of plant diseases by beneficial microbes forms an interesting alternative. These so called beneficial bacteria can be used for sustainable crop protection.

Objectives

The rhizosphere bacterium, *Pseudomonas chlororaphis,* is a good root colonizer and produces a wide variety of secondary metabolites with antifungal activity which makes it an interesting potential for biological crop protection.

Methods

To develop a commercial Plant Protection Product (PPP) that can be used in agricultural applications, it is of important to understand the mode of action and growth characteristics of this bacterium. Process and product development starts with the selection of a suitable media and optimized growth conditions in small scale bioreactors. Besides a reasonable biomass yield also metabolites are of importance. During growth a metabolic profile of this strain is gained.

Conclusions

Pseudomonas chlororaphis is a fast growing strain resulting in high yields of approx. 1E10 cells.ml-1 within 24 hrs. During growth the metabolite profile shows at least 4 different antibiotics with antifungal activity.

SINGLE CELL TIME LAPS MICROSCOPY OF ELECTROSTATICALLY MODIFIED SURFACE OF ALIVE BACTERIAL CELLS REVEALS ELECTROSTATIC EFFECTS ON CELL DIVISION AND ADHERENCE

A. Lapanje[1], I. Rybkin[2], T. Rijavec[1], G. Sukhorukov[3], D. Gorin[2]
[1]Jozef Stefan Institute, Department of Environmental Sciences, Ljubljana, Slovenia
[2]Saratov State University, Saratov State University, Saratov, Russia
[3]Queen Mary University of London, Queen Mary University of London, London, United Kingdom

Backgrounds

In general bacterial cells resemble negative surface charge mainly due to the excess of negatively charged moieties of molecules incorporated in membrane and cell wall. Based on our measurement, bacterial cells posses approximately -40mV of surface potential. This can enable deposition of positively charged molecules on their surface resulting reverting surface potential.

Objectives

Such method of surface modification enables using the layer-by-layer method to enclose bacterial cell in a few nanometre thick permeable and strong capsule as well as to modify their surface potential. In the past, this method was applied in many planar and 3D non-living structures. Here we aimed to develop a whole platform of electrostatic modification of surface of alive bacterial cells.

Methods

Tuning the method it enabled us to cover single bacterial cells by different numbers of layers, affecting the surface permeability, or forming aggregates of defined sizes. Using time laps confocal microscopy we observed that we can control growth and division of single bacterial cells as well as the protein expression based on emGFP reporter. Since we can affect surface charge of bacteria we also attached bacteria on inorganic surfaces forming artificial biofilms. Unexpectedly, we observed effects of different mineral surfaces on metabolic activity. The metagenomic analysis shoved modified climax composition of bacterial biofilms after exposure to the environment of surface previously covered by charged bacterial cells.

Conclusions

This approach enables non-genetic modification of bacterial surface and gives a new tool to study cell-cell and cell-surface interaction as well as to develop new carrier based biotechnological processes.

FEMS7-2507
Biotechnology / Synthetic Biology / Systems Biology - Part II

A NEW SYNTHETIC METHOD OF NON-GENETIC MODIFICATION OF ALIVE BACTERIA CELLS FOR REMOTE GUIDING, IMMUNE PROTECTION, GROWTH CONTROL AND MONITORING OF CELLS IN BACTERIAL THERAPIES

A. Lapanje[1], I. Rybkin[2], O. Gusliakova[2], O. Sindeyeva[2], N. Pytayev[2], D. Gorin[2], G. Sukhorukov[3]
[1]Jozef Stefan Institute, Department of Environmental Sciences, Ljubljana, Slovenia
[2]Saratov State University, Saratov State University, Saratov, Russia
[3]Queen Mary University of London, Queen Mary University of London, London, United Kingdom

Backgrounds

Using a top-down engineering approach, the ideal cancer therapy can be envisioned to use tiny programmable 'robot factories' that specifically target tumours, are selectively cytotoxic to cancer cells, are self-propelled, are responsive to external signals, can sense the local environment and are externally detectable. As such by using synthetic biology approach many bacteria can be modified to use them as small robots in treatments. However, there are also many drawbacks amongst the most important can be the host immune response and dangerous therapies due to low control as well as impossible monitoring of bacterial distribution inside the body.

Objectives

To solve these problems we developed non-genetic modification of surface of bacterial cells. The approach was focused to cover epitopes on the cell surfaces and, to incorporate far red fluorescent dies as well as magnetic particles to observe distribution of cells inside the body and guide cells by the magnetic field, respectively.

Methods

The method was based on the electrostatic deposition of polyelectrolytes. Since we can covalently bind far red Cy7 dye to the charged polyelectrolytes and electrostatically attach magnetite nanoparticles we could modify *Escherichia coli* top10 strain to become visible through the body and guided by magnetic fields. We injected these cells in the mouse cardio-vascular system to observe effect of magnetic field on distribution.

Conclusions

Passive distribution of cells resulted in concentration of amount of cells in lungs and livers and use of permanent magnet increased amount of cells in legs. The number of polyelectrolyte layers controlled division time of bacteria.

NOVEL GENETIC TOOLS FOR PSYCHROBACTER SPP.

R. Lasek[1], *M. Krolikowski*[1], *D. Bartosik*[1]
[1]*University of Warsaw- Faculty of Biology, Department of Bacterial Genetics, Warsaw, Poland*

Backgrounds

The study of cold-adapted bacteria is a promising branch of microbiology, especially given their huge biotechnological potential. However, the research on psychrophiles is hindered by the lack of specific genetic tools for this group of prokaryotes. Having studied in detail a pool of Arctic strains of the genus *Psychrobacter*, we decided to use selected genetic modules of their native plasmids in the construction of novel *Psychrobacter*-specific vectors.

Objectives

We aimed to create a series of new genetic tools functional in DAB_AL43B, a well-characterized *Psychrobacter* strain with a completely sequenced genome. It includes (i) a protein expression vector (pExPsy), (ii) a vector for testing promoter activity in vivo (pRSPsy), and (iii) a two-plasmid system for introducing markerless deletions in the DAB_AL43B genome (pLOL/pROFL).

Methods

Standard genetic manipulations were used in the construction of plasmid vectors. The obtained shuttle vectors were introduced into *Psychrobacter* sp. cells via triparental mating. The *E. coli*-derived *lacZ* gene was used as a reporter gene or a counterselection marker.

Conclusions

Several new genetic tools were obtained and verified to be functional in *Psychrobacter* sp. DAB_AL43B. The pExPsy vector carries a strong promoter P_{SLF} induced by sodium dodecyl sulfate and laurylaldehyde, which allows for the inducible expression of His-tagged proteins. The RSPsy vector is used to conduct high throughput LacZ activity assays, whereas in the pLOL/pROFL system the *lacZ* gene serves as a counterselection marker (the product of X-gal hydrolysis being deleterious for DAB_AL43B). We believe that these novel tools will facilitate further studies of *Psychrobacter* spp.

IDENTIFICATION OF PROTEIN-PROTEIN INTERACTIONS PRESENT IN THE ASSEMBLY LINE OF KALIMANTACIN, A SECONDARY METABOLITE ANTIBIOTIC

T. Lathouwers[1], B. Uytterhoeven[1], C. Michiels[2], R. Lavigne[1]
[1]KU Leuven, Biosystems- Lab of Gene Technology, Leuven, Belgium
[2]KU Leuven, Department of Microbial and Molecular Systems - Centre for Food and Microbial Technology, Leuven, Belgium

Backgrounds

Secondary metabolites are natural compounds produced by bacteria. They are not essential for development of their producers, but provide them with a selective advantage, like elimination of environmental competitors by antimicrobial activity. Two classes of secondary metabolites are the polyketides and non-ribosomal peptides. Although chemical diverse, both groups are produced by large assembly lines. Each assembly line consists of modules, which are built up by multiple enzymatic domains. Every module attaches a new building block to the metabolite's backbone, realizing elongation and functional specialization.

Objectives

Natural hybrid pathways exist, combining both polyketide and non-ribosomal peptide modules. This inspired researchers to create new antibiotics by designing hybrid lines, but often production of metabolites was abolished, possibly due to a lack of protein-protein interactions linking the different modules. In this project, protein interactions were identified in the biosynthesis cluster of kalimantacin, a hybrid antistaphylococcal compound produced by *Pseudomonas fluorescens* BCCM_ID9359.

Methods

In this study, 63 fragments, representing the domains and connective regions of the kalimantacin assembly line, were amplified for yeast two-hybrid analysis. The use of an integrated pool-array technique allowed testing of all different combinations, thereby creating a protein interaction map of the entire biosynthesis cluster. In total, 28 interactions were identified, 13 of them could be confirmed further.

Conclusions

Results include a specific interaction between a *trans*-acting enoyl reductase and carrier proteins of the pathway, also an interaction possibly linking two modules. In future, these interactions are examined further and will be a useful basis for hybrid engineering of clusters.

NORINE, FLORINE, S2M : POWERFUL BIOINFORMATICS RESOURCE AND TOOLS TO SCREEN FOR NOVEL NONRIBOSOMAL PEPTIDES, NATURAL METABOLITES WITH VERSATILE ACTIVITIES

Q. Esmaeel[1], Y. Dufresne[2], A. Flissi[2], M. Pupin[2], P. Jacques[1], V. leclere[3]
[1]Univ Lille-Sciences et technologies, Institut Charles Viollette, villeneuve d'ascq, France
[2]Univ Lille-Sciences et technologies, Laboratoire CRIStAL, villeneuve d'ascq, France
[3]Univ Lille - Sciences et technologies, Institut Charles Viollette, villeneuve d'ascq, France

Backgrounds

Secondary metabolites are a huge resource of natural compounds with applications in different area including medicine and agriculture. Many of them, harbouring a peptidic structure are produced through a ribosome-independent pathway represented by multienzymatic modular complexes working as assembly lines, so-called nonribosomal peptides synthetases. The nonribosomal modular synthesis, together with the monomer recruitment mecanism can drive the production of compounds displaying large structural biodiversity leading to attracting biological activities or properties. Indeed, such nonribosomal peptides are marketed as antibiotics (ie penicillin or vancomycin) or are promising sustainable compounds for pesticide replacement as they can be used as biocontrol agent to protect cultures from fungal diseases.

Objectives

The objective of the work was the development of bioinformatics tools for *in silico* genome mining leading to the accelerated discovery of novel nonribosomal peptides. Our work was especially focused on the identification of siderophores and lipopeptides, for their putative applications in biocontrol.

Methods

Specific bioinformatics tools were developed (http://bioinfo.cristal.univ-lille1.fr/NRP/) and related in Florine workflow. The discovery workflow was applied on genome sequences available in public databases.

Conclusions

The availability of increasing number of genome sequences of microorganisms combined with bioinformatic approaches has led to the discovery of a large number of new NRPs. *In silico* analysis on 48 gapless complete genomes of *Burkholderia* revealed at least 161 clusters potentially producing 11 novel products including siderophores and lipopeptides. Some predictions, supported by experimental data, will be presented. The role of these non ribosomal peptide *in vivo* and potential applications will be discussed.

THE WHOLE GENOME ANALYSIS OF ASPERGILLUS SOJAE SMF 134 ISOLATED FROM MEJU, KOREAN TRADITIONAL FERMENTED SOYBEAN BRICK

I. Lee[1], K.M. Kim[1], Y.H. Choi[2], B.S. Hurh[2]
[1]Kookmin University, Bio Fermentation Convergence Technology, Seoul, Republic of Korea
[2]Sempio Foods Company, Sempio Fermentation Research Center, Chungcheongbukdo, Republic of Korea

Backgrounds

Aspergillus sojae may have a great potential as a starter (*koji*) mold for the soybean fermentation due to its high protease and leucine aminopeptidase (LAP) activities.

Objectives

We analyzed the whole genome of *A. sojae* SMF 134 isolated from *meju*, Korean traditional fermented soybean brick with focus on its biochemical abilities and toxigenecity to evaluate its merits as a starter mold at the genomic level.

Methods

The genomic DNA of SMF 134 was sequenced in the PacBio and analyzed using diverse bioinformatics programs.

Conclusions

The genome size was 40.1 Mbp with 13,748 ORFs. The *A. sojae* SMF 134 had more protease genes (151 genes) than *A. oryzae* (134 genes), which verified higher proteolytic activity of *A. sojae* than that of *A. oryzae*. Especially proteases such as aminopeptidase and carboxypeptidase that play important roles in flavor development and debittering during soybean fermentation were more in *A. sojae* than in *A. oryzae*. In toxigenicity analysis, the *A. sojae* SMF 134 had all orthologs of the aflatoxin (AF) biosynthesis genes, however, it appeared to be non-aflatoxigenic because of a termination point mutation in *aflR* and the lack of the polyketide synthase (PKS) gene. In addition, the *A. sojae* SMF 134 could not produce cyclopiazonic acid (CPA) due to the defective genes in the CPA cluster. The genomic data of *A. sojae* SMF 134 will be used to study *A. sojae* genetically for understanding the production of various enzymes that play a key role in soybean fermentation and characteristics of it as a starter mold.

DEVELOPMENT OF WHOLE CELL HEAVY METAL BIOSENSORS BY RECOMBINING T7 TRANSCRIPTIONAL MODULES AND CADC BIOPARTS

H.J. Kim[1], H. Jeong[2], D.W. Lee[3], S.J. Lee[1]
[1]Chung-Ang University, Department of Systems Biotechnology, Anseong, Republic of Korea
[2]Korea Research Institute of Bioscience and Biotechnology, Infectious Disease, Daejeon, Republic of Korea
[3]Kyungpook National University, School of Applied Biosciences, Daegu, Republic of Korea

Backgrounds

Genome sequencing analysis of *Bacillus oceanisediminis* 2691 revealed redundant heavy metal resistance related genes encoding heavy metal-sensing transcriptional regulators (i.e. *cadC*), and heavy metal efflux pumps.

Objectives

In this study, we attempted to develop whole cell heavy metal biosensors using synthetic genetic circuits with T7 transcriptional modules and CadC bioparts.

Methods

In application aspects, these heavy metal sensing genes could be used as synthetic biological parts for the development of heavy metal-specific whole cell biosensors. Six *cadC* genes were transcriptionally fused with *egfp* gene in *E. coli.* We confirmed that cellular fluorescence was generated differentially in response to various heavy metal ions. These results indicated that CadC proteins could be used as sensory modules for specific heavy metal ions in cells. Next, T7 transcription system was combined with CadC bioparts to generate synthetic genetic circuity to amplify intracellular fluorescent signals, and to upgrade the sensitivities of heavy metal biosensors.

Conclusions

This study shows how to screen sensory and regulatory bio-parts, including CadC regulators and *cadO* operators, from the genome of a novel bacterial isolate from ocean sediment, and how to obtain proper bio-parts with distinct specificities from among reiterated paralogous genes. Furthermore, we combined T7 signal amplification modules with CadC to generate CadC-T7 synthetic circuits to detect heavy metals with enhanced specificity and sensitivity.

Biotechnology / Synthetic Biology / Systems Biology - Part II

FUNGAL GROWTH IN A CHEMOSTAT SHOWS POTENTIAL FOR A ROBUST AND SIMPLE PRODUCTION PLATFORM AT 40°C

S. Barig[1], H. Leupold[1], K.P. Stahmann[1]
[1]Brandenburgische Technische Universität Cottbus-Senftenberg, Technische Mikrobiologie, Senftenberg, Germany

Backgrounds

Microorganisms are used for industrial production since a century, e.g. citric acid production by *Aspergillus niger*, or since decades, e.g. microbial riboflavin production from renewables by the fungus *Ashbya gossypii*, as well as the bacterium *Bacillus subtilis* [1, 2].

Objectives

Two drawbacks of microbial systems are addressed: first, a suboptimal cultivation temperature limiting metabolic flux and causing cost-effective cooling equipment, and second, the need of sterile technique.

Methods

A screening of environmental samples was performed using agar plates containing a defined mineral salts medium with nitrate as sole nitrogen, plant oil as sole carbon source and acidic pH excluding sterile technique [3]. Filamentous fungi were isolated at up to 50°C. Colony growth rate on the agar surface was compared. Fungal isolates were identified by ITS sequencing and investigated in chemostat experiments.

Conclusions

Screening revealed hundreds of fungal strains from different environmental sources. Temperature optima of the best strains were found between 39°C and 42°C. Isolate *Aspergillus fumigatus* AR04 showed maximum growth rate of 1,100 µm/h at 40°C on agar plates with full medium, while *A. gossypii* grew 150 µm/h. *A. fumigatus* AR04 grew even faster than reference strains of *A. fumigatus*, *A. niger*, *A. oryzae*. In chemostat cultivations with minimal medium *A. gossypii* showed at dilution rate of 0.32 h^{-1} and 28°C a biomass production of 0.91 g/L [4]. Steady state was still adjustable for AR04 at 40°C at 0.7 h^{-1} and biomass concentration of 1.2 g/L. This behavior fits to the Arrhenius equation and suggests a growth maximum never reported before for a fungus.

IMMUNOGENICITY AND BIOACTIVITY OF A MYCOPLASMA PNEUMONIAE SUBUNIT VACCINE MIXED WITH VARIOUS ADJUVANTS IN BALB/C MICE

Y. Li[1], J. Guo[2], X. Luo[2], Y. Qi[2], S. Li[2], Y. Pan[2], J. Li[2], T. Xu[2], Q. Yin[2], Y. Shao[2], B. Yang[2]
[1]Huadong Research Institute for Medicine and Biotechniques, Nanjing, China
[2]Huadong Research Institute for Medicine and Biotechniques,
Department for Pharmaeutical biotechnology, Nanjing, China

Backgrounds

Mycoplasma pneumoniae (M.pneumoniae)is a human pathogen that colonizes the mucosal surfaces of the respiratory tract.The patients show flu-like sumptoms but characteristically the infection is chronic in onset and recovery.Pneumonia can be followed by extrapulmonary manifestations affecting mainly are skin and the central nervous system.In addition,the cell wall-less bacterium M.pneumoniae is resistant to common-first-line β-lactam antibiotics.Vaccination is a possibility to effectively reduce the incidence of infection due to M.pneumoniae.In this study,we used the recombinant protein P1C-P116N-P30C(MP559)as antigen in combination with different adjuvants for an optimized immunization procedure and evaluated the antibody response as well as celluar response in an accepted animal model.

Objectives

To identify effective adjuvants, immunity dose and procedure for the mycoplasma pneumoniae(MP) subunit vaccine MP559.

Methods

Groups(n=16) of female 6-week-old BALB/c mice (22±2g) were immunized respectively with MP subunit vaccine MP559 alone (5μg or 20μg dose), MP559 with Alum-adjuvant, MP559 with PolyI:C adjuvant , MP559 with CpG adjuvant, MP559 with Alum-PolyI:C adjuvant, MP559 with Alum-CpG adjuvant, MP559 with PolyI:C-CpG adjuvant, MP559 with Alum-PolyI:C-CpG adjuvant by intramuscular injection four times at a 2-week interval. All animals blood was collected via the sinus of eye on the day before each immunization and the second, third and fourth weeks after last immunization, the sera antibody titers were detected by ELISA. After the final immunization, the spleen cells were prepared and then stimulated with 10μg of MP559 for 72h. IL-1, IL-4 and IFN-γ in the supernatant of cultured splenical cell were detected with ELISA Kits.

Conclusions

Immunizing three times with 20μg MP559 with Alum-PolyI:C adjuvant at a 2-week interval could induce the best humoral and cellular immune responses in BALB/c mice. This study laid the foundation for clinical trial of mycoplasma pneumoniae subunit vaccine MP559.

Biotechnology / Synthetic Biology / Systems Biology - Part II

BIOCHEMICAL CHARACTERIZATION OF SERINE PROTEASE-LIKE ENZYME FROM STREPTOMYCES LAURENTII

S.V. Ganesan[1], B.L. Liu[1], M.J. Lee[1], C.A. Chang[1]
[1]Chaoyang University of Technology, Applied Chemistry, Taichung, Taiwan R.O.C.

Backgrounds

Orchids are vulnerable to several disease caused by mechanically transmissible and highly *in vitro* stable plant viruses such as odontoglossum ringspot virus (ORSV) or cymbidium mosaic virus (CymMV). Previous studied have shown that an actinomycetes isolate can secrete a protease-like substance in its culture filtrate that can degrade coat proteins of ORSV and CymMV and abolish their infectivity.

Objectives

The present study attempts to identified this actinomycetes isolate, and the biochemical characterization of a thermoactive and thermostable serine protease-like enzyme from actinomycetes cultivation filtrate were also investigated.

Methods

The 16S rRNA gene sequences to study bacterial phylogeny and taxonomy was used. The cultivation filtrate was partially purified by ammonia sulfate and preliminary enzymological study were engaged. The protease activity was confirmed by zymogram-native PAGE.

Conclusions

The isolate was identified as *Streptomyces laurentii* N74-3 based on their morphological characters and 16S rDNA sequencing by BLASTN and phylogenetic tree analysis. The predicted RNA secondary structure showed the free loop energy score of -286.60, which were characterized by the formation of several helices and showed more structural motifs. Actinomycete was analysed for the production of serine protease-like enzyme on skim milk casein agar and soybean meal mediums. The protease activity was performed in zymogram, which showed the clear band at 35 kDa. The enzyme showed greater activity at the optimum temperature between 70 and 80°C. Enhanced activity was also observed at alkaline pH 10 to 12. The isolated enzymes were strongly inhibited by PMSF, which suggested that the enzyme may belongs to serine protease enzyme family.

COMPARATIVE PROTEOMICS OF A BUTANOL TOLERANT LACTOBACILLUS MUCOSAE ISOLATE DURING GROWTH WITH 2, 3 AND 4% BUTANOL

S. Liu[1]
[1]*NCAUR, Renewable Product Technology, Peoria, USA*

Backgrounds

Butanol can be naturally produced via microbial fermentation by *Clostridium* species. But the current available butanol fermenting microbes are sensitive to increased butanol content.

Objectives

One strategy to overcome butanol toxicity is to modify *Clostridium* species by introducing butanol tolerance related genes.

Methods

Several *Lactobacilli* were found capable of growth in 3-4% butanol after long term adaptation. One particular isolate, *Lactobacillus mucosae* BR0605-3 showed most robust growth in 4% butanol, was used to identify new butanol tolerance genes by 2D gel analyses and proteomics.

Conclusions

A total of 603 spots analyzed showing differences indicating the global and complex nature of cellular responses to increased butanol in the growth medium. Among 30 proteins identified 18 shown increased expression levels and 12 shown reduced expression levels by the presence of 2%, or 3% or 4% butanol. The *Lactobacillus mucosae* butanol tolerance responses involved general stress responses (GroEL, GroES and DnaK), and the shifts from active carbohydrate metabolisms to energy saving modes, plus adaptation of butanol through a balanced redox potential. Pentose phosphate pathway and some amino acid syntheses were slowed down during growth with increased butanol. The ratio of NAD(P)H /$NAD(P)^+$ was likely increased due to reduced activity of D-lactate dehydrogenase and 6-phospohogluconate dehydrogenase.

Biotechnology / Synthetic Biology / Systems Biology - Part II

APPLICATION OF THE RECOMBINANT CUTINASES ANCUT 3 AND ANCUT 4 OF ASPERGILLUS NIDULANS IN DEGRADATION OF POLYESTERS

A. Llanos Reyes[1], K. Rosete Viveros[1], S. Morales García[1], M. Sánchez Sánchez[1], C. Peña Montes[1], A. Farrés González[1]
[1]Universidad Nacional Autónoma de México, Departamento de Alimentos y Biotecnología, Mexico City, Mexico

Backgrounds

Polyesters excessive consumption in daily life has had a negative impact on the environment. To achieve a faster degradation enzymes have been used and among them, cutinases have been employed successfully to hydrolyze a wide variety of polyesters. In our research group, four cutinases from *Aspergillus nidulans* have been identified, isolated, cloned and expressed in *Pichia pastorias* (Vega, 2013, Bermúdez, 2013 and Rosete, 2017). Of these four cloned enzymes, ANCUT 1 and ANCUT 2 have provided effective results in the degradation of polyesters (Sánchez, 2015 and Morales, 2017).

Objectives

The objective of this study is to evaluate the degradation potential against different polyesters using the ANCUT3 and ANCUT4 recombinant cutinases of *Aspergillus nidulans*, due to their close phylogenetic relationship with ANCUT 1 and ANCUT 2 (Castro, 2014), which suggests that they could also carry out this process.

Methods

The ability of these enzymes in the degradation of polyesters was evaluated using polycaprolactone (PCL), polybutylenesuccinate (PBS), polyethylenesuccinate (PES), polylactic acid (PLLA) and polyethyleneterephthalate (PET). Preliminary assessment showed hydrolysis halos in plates. This was followed by the determination of the optimal substrate degradation conditions: temperature, time, pH and influence of the solvent. The degradation degree was determined by weight loss, absolute acidity and scanning electron microscopy.

Conclusions

The results show that the ANCUT3 and ANCUT4 cutinases are an interesting alternative in the enzymatic degradation of this type of polymers, since the results have been favourable. As future work it is intended to test a mixture of the 4 enzymes to obtain a higher polymer degradation.

Biotechnology / Synthetic Biology / Systems Biology - Part II

QUERCITRIN FUNCTIONALIZED NANOSTRUCTURED BONE IMPLANT TITANIUM SURFACES FOR THE MODULATION OF BACTERIAL AND CELLULAR ADHESION

M.A. Llopis-Grimalt[1], M.A. Forteza-Genestra[1], A.M. Amengual-Tugores[1], J.M. Ramis[1], M. Monjo[1]
[1]Grupo Terapia Celular e Ingeniería Tisular- Institut Universitari d'Investigació en Ciències de la Salut- Universitat de les Illes Balears, Instituto de Investigación Sanitaria de Palma, Palma, Spain

Backgrounds

Titanium implants are widely used in modern medicine with several applications such as orthopedic and dental implants. Titanium implants associated infections are the main cause of implant failure and are usually caused by the patient's microbiota. *Staphylococcus epidermidis* is one of the main causative agents of implant-related infections and its ability to form biofilms plays a key role in this process.
There are several strategies for the development of biomaterials with improved integration of the patient's tissues and reduced bacterial adhesion and biofilm formation. One strategy is the formation of nanostructures, such as ordered nanotube structures or nanopores on the implant surface. Another strategy is their functionalization with active biomolecules in order to make virtual bioinert materials become bioactive. Flavonoids are small polyphenolic molecules with a broad range of bioactivities such as antioxidant, antibacterial and anti-inflammatory properties. Among different flavonoids, quercitrin was selected in previous studies as our best candidate for coating surfaces of dental and orthopedic bone implants.

Objectives

The main objective of this research was the development of quercitrin functionalized nanostructured titanium surfaces that reduce biofilm formation and promote osseointegration with potential application in implantable medical devices.

Methods

Functionalized nanostructured titanium surfaces were developed by electrochemical anodization and evaluated for *Staphylococcus epidermidis* CECT4184 adhesion and biofilm formation by scanning electron microscopy, crystal violet and serial dilution agar plating method. In addition, human Bone Marrow Mesenchymal Stem Cells were used to test cell adhesion.

Conclusions

The obtained results have allowed us to establish the best quercitrin functionalized nanostructure for improved bone implants.

DNA TRANSFER AND GENOMIC INTEGRATION IN HUMAN CELLS USING TYPE IV SECRETION SYSTEMS OF HUMAN PATHOGENS

C. González-Prieto[1], R. Gabriel[2], D.L. Guzmán-Herrador[1], S. Steiner[3], C. Roy[3], M. Schmidt[2], M. Llosa[1]
[1]Universidad De Cantabria, IBBTEC, Santander, Spain
[2]National Center for Tumor Diseases, Department of Translational Oncology, Heidelberg, Germany
[3]Yale University, BCMM, New Haven CT, USA

Backgrounds

- Gene therapy strategies require methods to introduce DNA into specific human cell types and to integrate it in the genome for stable expression.

- We have shown that any DNA can be introduced into specific human cell types as a protein-DNA complex through the Type IV Secretion System (T4SS) of *Bartonella henselae* by a mechanism resembling bacterial conjugation.

Objectives

- To extend this DNA delivery system to T4SS from other human pathogens targeting different cell types

- To follow the fate of the delivered DNA and analyze the integration pattern
- To compare the efficiency of different conjugative systems

Methods

- Infection of human cultured cell lines with human pathogens containing mobilizable plasmids with markers for eukaryotic selection and different conjugative systems.
- Evaluation of transient and permanent expression of introduced DNA by measuring GFP positive cells and neomycin resistant colonies, respectively.

- Determination of the integration pattern of the foreign DNA in the human genome by LAM-PCR and high throughput sequencing.

Conclusions

- We can deliver DNA into different human cell types through the T4SS of Bartonella henselae, Legionella pneumophila, and Coxiella burnetii, suggesting DNA delivery can be accomplished by many, if not all, bacterial T4SS.
- The efficiency of transfer depends on the conjugative relaxase
- The relaxase TrwC promotes genomic integration of the incoming DNA

FEMS7-2816
Biotechnology / Synthetic Biology / Systems Biology - Part II

ORAL COLONIZATION AND PH BUFFERING BY STREPTOCOCCUS DENTISANI, A PROBIOTIC BACTERIUM TO PREVENT TOOTH DECAY

A. López-López[1], A. Mira[1], C. Llena[2], T.I. Nicolescu[2], M.D. Ferrer[1]
[1]Centro Superior de Investigación en Salud Pública, Genomics and Health, Valencia, Spain
[2]Facultad de Medicina y Odontología. Universidad de Valencia, Estomatología, Valencia, Spain

Backgrounds

A new bacterial species, named *Streptococcus dentisani*, was isolated from dental plaque of caries-free individuals. It has a double effect that has been proposed to potentially prevent tooth decay: an antimicrobial activity against oral pathogens and a pH buffering capacity through the arginolytic pathway.

Objectives

The aim of this work was to evaluate the colonization efficiency and pH buffering in a pilot clinical study

Methods

Eleven adult volunteers enrolled in the study. The probiotic was applied at a total dose of 10^9 CFUs, administered in a buccoadhesive gel for 5 minutes, either in a single dose or daily for a week. Dental plaque and saliva samples were collected after 15 and 30 days of first application where amounts of *S. dentisani* and pH was measured by qPCR and reflectometry, respectively.

Conclusions

There was a significant increase in *S. dentisani* cells/ng of plaque DNA and in the percentage of *S. dentisani* from total bacterial cells, at day 15 but not at day 30. In addition, there was a significant increase in basal salivary pH both at day 15 ($p=0.024$) and day 30 ($p=0.014$), and in the salivary pH after a sugar rinse at day 30 ($p=0.029$). The results indicate the *S. dentisani* is transiently able to colonize the oral cavity and to buffer oral pH, suggesting a promising probiotic potential, as dental caries is caused by acid-mediated tooth demineralization. Future randomized, placebo-control clinical trials should evaluate the use of *S. dentisani* to prevent tooth decay.

Biotechnology / Synthetic Biology / Systems Biology - Part II

PRODUCTION OF BIOPLASTICS IN DEFINED MIXED CULTURES OF SYNECHOCOCCUS ELONGATUS AND PSEUDOMONAS PUTIDA

H. Löwe[1], K. Pflüger-Grau[1], A. Kremling[1]
[1]Systems Biotechnology, Mechanical Engineering, Garching, Germany

Backgrounds

Cyanobacteria that have been genetically modified to secrete carbohydrates, can even exceed the areal productivity of the traditional crop-based production of sucrose [1]. Compared to conventional feedstocks, cyanobacteria can also be cultivated on non-arable land and can grow in salty or brackish water, making them an interesting alternative and field of research.

Objectives

Our aim is to couple genetically engineered *Synechococcus elongatus* PCC7942 *cscB*, which releases sucrose into the fermentation broth, to *Pseudomonas putida cscAB* that was genetically modified to consume this sugar.

Methods

A common medium based on BG-11 was designed that supported growth of both organisms. Sugar production was then studied in shaking flasks and a 1.8-L photobioreactor yielding up to 3 g/L of sucrose in the culture supernatant after one week. In a first attempt, sucrose containing culture supernatant was successfully used to support the growth of recombinant *P. putida cscAB*. As next step, both organisms were able to grow simultaneously under photosynthetic conditions, allowing *P. putida* to produce polyhydroxyalkanoates up to 0.1 g/L from cyanobacterial sucrose.

Conclusions

Taken together, cyanobacterial carbohydrates were successfully used as a carbon source for the cultivation of *P. putida*, a potential workhorse for industrial biotechnology. This extensible technology thus offers a potentially cheap feedstock for fermentation of plentiful possible products [2] and might be an opportunity to make industrial biotechnology more cost-competitive in the future.

CARBOXYL NANOPARTICLE ADHERENCE TO EXTERIOR OF C. ALBICANS HYPHAE CELL WALL IS MEDIATED BY THE HYPHAL ADHESIN ALS3

A. Lyden[1], L. Lombardi[2], W. Sire[1], J. Simpson[3], G. Butler[2], G. Lee[1]
[1]University College Dublin, School of Chemistry & Chemical Biology, Dublin 4, Ireland
[2]University College Dublin, Conway Institute for Biomolecular & Biomedical Research, Dublin 4, Ireland
[3]University College Dublin, School of Biology & Environmental Science, Dublin 4, Ireland

Backgrounds

Candida albicans is the lead fungal pathogen of nosocomial bloodstream infections in the US and causes 400,000 incidents worldwide annually. Rapid and inexpensive diagnosis and treatment of fungal infections is crucial for prevention of fatalities. Nanoparticles have potential to serve as therapeutics, contrast agents for MRI and a tool for sample preparation.

Objectives

Little is known about how nanoparticles interact with the yeast cell wall, which is crucial to nanoparticle design. We have characterized the interaction of carboxyl-functionalized nanoparticles of various diameters and surface charge with the exterior cell wall of C. albicans hyphae and identified an optimal cell surface target.

Methods

Using laser scanning confocal microscopy and an image analysis protocol, we compared the adsorption of nanoparticles to the hyphal cell wall of mutant strains deficient in expression of certain cell-surface proteins.

Conclusions

A highly significant reduction in particle binding was observed with an Δals3 strain compared to isogenic and clinical isolate strains, suggesting Als3 is the main mediator of carboxyl nanoparticle adhesion. In the absence of Als3, nanoparticles bind to germ tubes in a pattern resembling the localization of Als1. This suggests that Als1 may also play a role in binding. Additionally, we showed that surface charge influences binding – positively charged amine-functionalized nanoparticles fail to bind to the hyphal cell wall unlike negatively charged carboxyl-functionalized nanoparticles. This research suggests Als3 could be a useful target for nanoparticle mediated diagnostics and therapeutics, and provides direction for the optimal size and surface characteristics of nanoparticles for binding to the fungal cell wall.

SELECTION OF AN EFFICIENT PROMOTER AND ITS APPLICATION IN TOYOCAMYCIN PRODUCTION IMPROVEMENT IN STREPTOMYCES DIASTATOCHROMOGENES 1628

Z. Ma[1], *X. Yu*[1]
[1]*China Jiliang University, College of Life Sciences, Hangzhou, China*

Backgrounds

The selection of efficient promoter is usually very crucial for gene expression and metabolic engineering in Streptomycetes.*Streptomyces diastatochromogenes* 1628 was shown to produce the nucleoside antibiotic toyocamycin (TM).However, to our knowledge, promoter engineering in *S. diastatochromogenes* 1628 has not been performed so far.

Objectives

Promoters *kasO*p*,SPL-21 and SPL-57, were shown to be much stronger than *perm*E* in different streptomycetes strains. In this study we investigated whether *kasO*p*, SPL-21 and SPL-57 can be used in *S. diastatochromogenes* 1628.

Methods

Promoter activities were determined by using the β-glucuronidase base assay (GUS-assay).In addition the promoters were used to over-express the gene *toyF* that encodes an adenylosuccinate lyase involved in TM biosynthesis.

Conclusions

Our results indicate that all tested promoters can be used to express genes in *S. diastatochromogenes* 1628. Interesting, promoter SPL-21 showed the strongest transcriptional and expression level and gave rise to a 5.2-fold increase in GUS activity compared with control. In order to improve TM production, the promoters were used to control expression of *toyF*. This gene encodes an adenylosuccinate lyase involved in TM biosynthesis. Among all different recombinant strains, the strain 1628-21F, in which over-expression of *toyF* gene was driven by SPL-21, exhibited the largest increase in TOYF activity and TM production. In a 5-l fermenter this strain produced more than 2 times more TM compared with the wild-type strain.

MICROBIOLOGICAL CONDITION AND ANTIBACTERIAL ACTIVITY OF MEDICINAL SYRUP AND ELIXIRS COMMERCIALIZED IN THE CENTRAL MARKET OF SAO LUIS-MA/BRAZIL

J.R. Sá Melo[1], S.A.M. Alvares Martins[1], S.F. Rocha Constantino[1], W.D. Machado Maciel[1], M. Santos Costa Penha[2], M. Bispo Pinheiro Camara[3], T.D. Val Lima[4], R.D.J. Mendes do Lago Moraes[4], S. Cristina Maia[4], G. Silva Nunes[1], F. Costa Moraes[5]
[1]Faculdade Estácio de São Luís, Biomedicina, São Luís, Brazil
[2]Instituto Florence de Ensino Superior, Farmácia, São Luís, Brazil
[3]IFMA, Química, São Luís, Brazil
[4]Faculdade Estácio de São Luís, Enfermagem, São Luís, Brazil
[5]Faculdade Estácio de São Luís, Enfermagem/Biomedicina, São Luís, Brazil

Backgrounds

In Brazil, the use of medicinal plants to treat various diseases is a widely adopted alternative. Many people resort to home-made preparations such as medicinal syrup and elixirs, medicinal beverages prepared by healers from plants. However, due to the conditions of preparation of these products, there is concern regarding the hygienic and sanitary qualities of it. Nevertheless, researches with medicinal plants are being carried out for the discovery of new antibacterial substances.

Objectives

Evaluate the microbiological quality and the antibacterial activity of medicinal syrup and elixirs commercialized in the central market of São Luís-MA/BRA.

Methods

Were used a honey-based syrup with plants and three root-based elixirs with herbs and leaves, commercialized in the central market of São Luís-MA/BRA. The microbiological parameters were investigated following the Pharmacopoeia methods for the investigation of faecal coliforms, heterotrofic microorganisms and fungi. The antibacterial activity was investigated from the techniques: disk-diffusion, agar drilling and microdilution. Chloramphenicol 0,01mg/mL was used as positive control, and distilled water as negative control. The evaluated microorganisms were: *Staphylococcus aureus* (ATCC 25923), *Escherichia coli* (ATCC 25922), *Salmonella typhi* (ATCC 14028) e *Pseudomonas aeruginosa* (ATCC 27853). All tests were duplicated.

Conclusions

The fungal growth in all evaluated products, and the presence of faecal coliforms in one of the elixirs don't meet the hygienic and sanitary conditions recommended by the current legislation.
Only the syrup presented an inhibitory effect against the evaluated bacteria, except the sample of *P. aeruginosa.* In contrast, the elixirs had no effect on the species tested.

OXYGEN-LIMITED GROWTH OF SCHEFFERSOMYCES (PICHIA) STIPITIS FOLLOWS EGLI'S DUAL NUTRIENT LIMITED GROWTH PATTERN

S. Maitra[1], *A. Narang*[1]
[1]*Indian Institute of Technology, Biochemical Engineering and Biotechnology, New Delhi, India*

Backgrounds

Due to the dwindling reserves of fossil fuels, there is a need for sustainable energy sources. Production of bioethanol from agricultural residues may provide such an alternative. *Pichia stipitis* is one of the very few strains that ferment both hexoses and pentoses to ethanol without by-products. **A major issue that prevents the industrial use of *Pichia stiptis* is its explicit requirement of microaerophilic conditions for fermentation. A systematic study is needed to understand if such microaerophilic conditions can be maintained robustly.**

Objectives

A) Development of a systematic approach towards understanding the optimum conditions of *Pichia stipitis* for fermentation

B) Development of a mechanical model that predicts the steady state characteristics

Methods

Pichia stipitis (CBS 6054) was studied systematically in a **chemostat** for ethanol yield and productivity. The C: O ratio in the feed was varied at fixed dilution rate and $k_l a$. **Medium was optimized to ensure the limitations were entirely controlled by the C: O ratio.**

Conclusions

Three definite growth regimes (as observed for different C: N concentrations (Egli et al., 1986)) were obtained i.e. C-limited, dual limited and O-limited. Ethanol production starts as the system enters dual limitation regime and continues throughout the O-limited regime, hence **ethanol production in *Pichia stipitis* is a robust process.** Using an approach similar to that in Egli et al., 1986, **a model has been developed** that predicts the steady state characteristics at any dilution rate.

ENZYMATIC SYNTHESIS OF THE DIPEPTIDE TRP-HIS USING L-AMINO ACID ESTERASE

K. Maki[1], T. Tanaka[1], K. Takagi[2], M. Wakayama[1]
[1]Ritsumeikan University, Life science, Kusatsu, Japan
[2]Ritsumeikan University, Applied Chemistry, Kusatsu, Japan

Backgrounds

Trp-His is the only vasoactive dipeptide known to regulate intracellular Ca^{2+}concentration and prevent the onset of atherosclerosis in vivo. A peptide chain that is longer than a tri-peptide is not absorbed through the mucous membrane of epithelium cells of the small intestine. To date, few studies on anti-atherosclerotic small peptides, except for the tetra-peptide Lys–Arg–Glu–Ser, have been reported. It has also been reported that Trp-His works as a Ca^{2+} channel blocker.

Objectives

The aim of this study was to investigate efficient enzymatic synthesis of Trp-His from tryptophan methyl ester and histidine using L-amino acid esterase. This enzymatic synthesis is useful for industrial applications because it does not have complicated steps like chemical synthesis.

Methods

In the first step, soil microorganisms exhibiting L-amino acid esterase activity were screened. The ability of the isolates to synthesize Trp-His was qualitatively evaluated by a colorimetric method and quantitatively analyzed by HPLC.

Conclusions

Eight microorganisms exhibiting Trp-His synthetic activity were isolated and identified by analysis of the 16S ribosomal RNA gene sequences. Among these isolates, *Pseudomonas* sp. KM1 showed the highest activity. Optimal reaction conditions for the production of L-amino acid esterase by *Pseudomonas* sp. KM1 have been examined. When *Pseudomonas* sp. KM1 was cultured in a medium containing D-glucose and yeast extract as carbon and nitrogen sources, the highest Trp-His synthetic activity, 0.0171 μmol/min/mg, was obtained under the following reaction conditions: 50 mM tryptophan methyl ester, 250 mM histidine, and the enzyme at 40°C and pH 9.0 for 60 min.

NEW SYNTHETIC TOOLS, BASED ON RECOMBINEERING AND CRISPR/CAS9, TO UPGRADE GENOME EDITING OF THE ENVIRONMENTAL BACTERIUM PSEUDOMONAS PUTIDA KT2440

T. Aparicio[1], V. de Lorenzo[1], E. Martínez-García[1]
[1]Centro Nacional de Biotecnología CSIC, Systems Biology Program, Madrid, Spain

Backgrounds

The advent of Synthetic Biology has brought about the possibility to massively manipulate bacterial genomes to efficiently program complex genetic devices. Among the commonly used organisms in synthetic biology, the soil and non-pathogenic bacterium *Pseudomonas putida* KT2440 offers a remarkably capacity as a chassis due to its metabolic versatility and high resistance to organic solvents. The engineering of environmental bacteria has been eased with the availability of a broad collection of molecular tools gathered into the SEVA collection. However, genome engineering is still a time-consuming process. Recently, the use of oligos combined with its protection, delivered by the Ssr-recombinase, enabled genome editing (Aparicio T., et al. 2016). While promising, this method show low frequencies of modification making the selection of mutants lacking inconspicuous phenotypes laborious.

Objectives

On this background, we aimed at further developing this procedure by combining it with the use of the CRISPR/Cas9 system as an efficient counter-selection method of non-mutated sequences in *P. putida*.

Methods

To this end, we cloned the Cas9 gene and the CRISPR array into different SEVA plasmids. To survey its functional efficiency we selected the *pyrF* gene as deletion target. Then, we combined the use of the Ssr protein together with Cas9 and transformed cells with an oligo-DNA and the CRISPR plasmid harboring the proper guide.

Conclusions

The combination of both technologies worked with high efficiency for entering a suite of mutations in the chromosome of *P. putida.* These results pave the way for automated and multiplexed editing of the genome of this biotechnologically important bacterium.

HEALTH AND DISEASE IMPRINTED IN THE TIME VARIABILITY OF THE HUMAN MICROBIOME

D. Martínez Martínez[1], J.M. Martí Martínez[1,2], T. Rubio Martínez-Abarca[1], A. Latorre Castillo[1,3,4,5], A. Moya Simarro[1,3,4,5], C. Peña Garay[1,2]
[1]Institute for Integrative Systems Biology I2SysBio, Systems Biology, Paterna, Spain
[2]Corpuscular Physics Insitute IFIC, Cosmology, Paterna, Spain
[3]Cavanilles Institute of Biodiversity and Evolutionary Biology, Evolutionary Genetics, Paterna, Spain
[4]CIBER in Epidemiology and Public Health, Epidemiology and Public Health, Madrid, Spain
[5]FISABIO, Genomics and Health, Valencia, Spain

Backgrounds

Human microbiota plays an important role in keeping the physiological status of the host healthy. Factors such as dietary changes, antibiotic intake, age and disease are often related to higher fluctuations in the temporal microbial composition. This implies that a healthy person will have a stable microbiota, which means that it will be less susceptible to external perturbations.

Objectives

The main objective of this work is to model the time variability of the human gut microbiota for characterizing quantitatively its stability and relate it with the health status of the person.

Methods

We analyzed 16S rRNA and shotgun metagenomic sequencing (SMS) published data from the gut microbiota of 99 individuals monitored over time. We modeled the microbial populations over time with the Taylor's law, and then characterized their stability with the Langevin equation as the basis of our mathematical model.

Conclusions

Temporal fluctuations in the microbial composition revealed significant differences in all the scenarios studied. This research shows that a fluctuation scaling law describes the temporal changes in the gut microbiota. This law enables the temporal variability of the microbial population to be estimated and quantitatively characterizes the path toward disease via a noise-induced phase transition. The estimation of the systemic parameters for follow-up studies may have clinical use and, more generally, may also have applications in other fields where it is important to know whether a given community is stable or not.

SIMULATING THE METABOLIC RESPONSE AT HIGH AND LOW SALINITY IN THE EXTREMOPHILE CHROMOHALOBACTER SALEXIGENS BY USING THE IFA762 GEM METABOLIC MODEL

L. Martínez Martínez[1], *F. Piubeli*[1], *M. Salvador*[2], *M. Argandoña*[1], *J.J. Nieto*[1], *C. Vargas*[1]
[1]*University of Sevilla, Microbiology and Parasitology, Sevilla, Spain*
[2]*University of Surrey, Faculty of Health and Medical Sciences, Guildford, United Kingdom*

Backgrounds

The broad salt-growing *C. salexigens* is a natural producer of ectoines. However, its biotechnology exploitation requires a comprehensive understanding of its physiology and genetics. In order to deepen the understanding of the complex metabolism of *C. salexigens* and its adaptation to osmotic stress, as well as their relationship with the production of ectoines, we have developed a genome-scale metabolic model (GEM) (iFA762) with capacity to simulate the metabolic response at high and low salinity (0.6 M vs 2.5 M NaCl).

Objectives

To get insight in the complex metabolism of *C. salexigens* and its adaptation to osmotic stress to be used in the production of ectoines by GEM simulation.

Methods

Uniform random samples were used to calculate flux distributions probability in the central metabolism of iFA762 model at different salinities. A comparison with experimental results was also carried out.

Conclusions

In this assay of random sampling, fluxes distribution of the most relevant reactions of central metabolism and ectoines synthesis were determined and a salinity-dependent distribution was found for some fluxes. However, a non-significant distribution in some of them were also observed. This agrees with previous experimental results that indicated that an overflow is produced due to the non-adaptation of the TCA. These results showed the capacity of the iFA762 model to simulate metabolic response at different salinities and will help us to develop new metabolic engineering strategies for the optimization of ectoines producer strains.

Funding: MINECO/FEDER(BIO2015-63949-R) y Junta de Andalucía(P11-CV1-7293 MO).

D-LACTIC ACID PRODUCTION WITH METABOLIC ENGINEERED ESCHERICHIA COLI FROM SUGARCANE BAGASSE AND CORN STOVER HYDROLYSATES

A. Martinez[1], *A. Vargas-Tah*[1], *J. Utrilla*[1], *B. Trujillo-Martínez*[1], *M.E. Rodríguez-Alegría*[1], *G. Gosset*[1]
[1]*Instituto de Biotecnología - UNAM, Cellular Engineering and Bioacatalyst, Cuernavaca, Mexico*

Backgrounds

D-lactic acid (D-LA) can be used for a wide array of applications including the production of the biodegradable biopolymer Poly-Lactic-Acid. D-LA production from plant hydrolysates is required for low cost production.

Objectives

To develop *Escherichia coli* strains that preferentially produces D-LA from pentoses and hexoses and lignocellulosic hydrolysates.

Methods

A D-lactogenic strain was obtained using metabolic engineering tools and adaptive evolution. This evolved D-lactogenic *E. coli* strain, named JU15, was sequenced and the following genotype was revealed: *ΔpflB, ΔadhE, ΔfrdA, ΔxylFGH, gatC S184L, ΔmidarpA, Δreg 27.3 kb*, being the galactitol mutant (GatC S184L) responsible for efficient xylose transport. The L-lactic and acetic acid production pathways were deleted in JU15, resulting strain AV03 (JU15 Δ*poxB*, Δ*ackA-pta,* Δ*mgsA*).

Conclusions

Results showed that strain JU15 produces D-LA with high yield and productivity in laboratory simulated hydrolysate media and actual sugar cane bagasse hemicellulosic hydrolysate with a minimal nutrient addition in pH controlled batch fermenters. Strain JU15 showed sequential carbon source utilization and acetic acid production. The AV03 strain showed simultaneous consumption of glucose and xylose and no acetic acid production in laboratory simulated hydrolysate and sugar mixtures (pentoses and hexoses) from corn stover hydrolysates. The D-LA yield from hydrolysate sugars was close to 0.95 g/g_{sugars} in all cases and volumetric productivities above 1 g/L h were obtained in batch cultivations from 0.2 to 10-liter fermenter scale.

FEMS7-1533
Biotechnology / Synthetic Biology / Systems Biology - Part II

METABOLIC ENGINEERING OF ESCHERICHIA COLI FOR R-3-HYDROXYBUTYRATE PRODUCTION WITH INCREASED AVAILABILITY OF NADPH

A. Martinez[1], M. García-Benítez[1], L.M. Martínez-Mejía[1], G. Hernández-Chávez[1], G. Gosset[1]
[1]Instituto de Biotecnología - UNAM, Cellular Engineering and Bioacatalyst, Cuernavaca, Mexico

Backgrounds

R-3-hydroxybutyryl-CoA is the biochemical precursor used by several microorganisms to produce polyhydroxybutyrate, a biodegradable bioplastic. Moreover, R-3-hydroxybutyryl-CoA can be enzymatically converted to R-3-hydroxybutyrate (R-3-HB), which is a chemical building block used in the manufacture of antibiotics, biofuels, pharmaceuticals and in the controlled synthesis of several polyhydroxyalkanoates with specific composition and length.

Objectives

In this study, the Gram-positive bacterium *Escherichia coli* was metabolically engineered to produce R-3-HB from glucose in mineral media.

Methods

First, to reduce the formation of fermentation co-products, all the genes encoding carbon competing pathways in the phosphoenolpyruvate, pyruvate and acetyl-CoA nodes were eliminated into the chromosome of *E. coli*. Second, as the biochemical conversion of acetyl-CoA into acetoacetyl-CoA and then into R-3-hydroxybutyryl-CoA requires a reduction step that uses NADPH, a gene encoding a glyceraldehyde-3-P dehydrogenase from *Streptococcus mutans*, that specifically uses NADP, was integrated into the chromosome to promote the formation of NADPH when glyceraldehyde-3-P is metabolized to 1,3-bi-phosphoglycerate. Third, the genes encoding the beta-ceto thiolase and the acetoacetyl-CoA reductase from *Azotobacter vinelandii* were cloned in tandem with the homologous thioesterase of *E coli* in an IPTG inducible vector to promote the conversion of acetyl-CoA into R-3-hydroxybutyrate, and the non-fermentative strain was transformed with this plasmid.

Conclusions

Strain characterization in shake flasks and aerated bioreactors, allowed to produce R-3-HBT with a 59% yield of the maximum theoretical, reaching 9.9 g/L in batch cultures when mineral media and glucose were used. However, unexpected production of high amounts of pyruvate and acetate points to further genetic modifications and to use fed-batch cultivation.

BIOTECHNOLOGICAL APPROACHES FOR OBTAINING OF NEW COMPLEX BIOPREPARATION FOR ORGANIC AGRICULTURE

L. Melkonyan[1], G. Avetisova[1], A. Chakhalyan[1], S. Keleshyan[1], Z. Karapetyan[1], S. Stepanyan[1], A. Toplaghaltsyan[1], A. Saghyan[2]
[1]SPC "Armbiotechnology" of NAS of Armenia, Laboratory of Selection of strain-producers of BAS, Yerevan, Armenia
[2]SPC "Armbiotechnology" of NAS of Armenia, Director, Yerevan, Armenia

Backgrounds

The world community comes across with the problem of increasing exploitation of mineral fertilizers. Mineral fertilizers and many toxic chemicals damage the biosphere. They also contribute to various human diseases by affecting fruits and vegetables that grow in this contaminated soil. In this aspect to remediate soil and enhance its fertility, the minimisation of exploiting rates of ecologically irrational chemicals and their substitution by ecologically safe fertilizers is of crucial importance. One of the ways to solve this problem is the development and manufacturing of biofertilizer.

Objectives

The aim of study was to develop a technology of complex, ecologically safe biofertilizer.

Methods

Strains of different microorganisms with high nitrogen-fixing activities were isolated from various soils of Armenia by methods described previously *(Yegorov N.S., 1995; Zheldakova R.A., 2003)*.

Conclusions

A selected strain allowed to develop “Ecobiofeed+” biopreparation also consisting of natural minerals and raw plant materials. This complex can be used for versatile plant feedings including nitrogen nutrition and all types of soil fertilization. “Ecobiofeed+” biopreparation increased germination, root striking of seedlings and planting stocks, crops of vegetables and melons, industrial, fodder, fruit and berry cultures, plant immunity, environmental purity and quality of vegetables and fruits.The advantages of this biopreparation are its high efficiency (not washed out from the soil), duration of its effect, early ripening of crops, decrease of some plant diseases, reduction of nitrates in agricultural products and soil regeneration.

Biotechnology / Synthetic Biology / Systems Biology - Part II

BGL-3 FROM TALAROMYCES AMESTOLKIAE: A FUNGAL BETA-GLUCOSIDASE PRODUCED UNDER CARBON SOURCE STARVATION, USEFUL FOR 2G AND 3G BIOFUELS PRODUCTION

J.A. Méndez-Líter[1], *L.I. De Eugenio*[1], *M.J. Martínez*[1]
[1]*Centro de Investigaciones Biológicas CIB-CSIC, Environmental Biology, Madrid, Spain*

Backgrounds

Plant biomass represents one of the most abundant and underutilized biological resources, and is a promising source of material for 2G biofuels production. Recently, 3G biofuels, based in algae biomass, have emerged as an alternative and the discovery of enzymes applicable for 2G and 3G processes, represent an interesting alternative for industry.

Objectives

In this work, we describe the production, purification and characterization of a β-glucosidase from *T. amestolkiae* (BGL-3), and its effectiveness in hydrolysis and saccharification of several substrates.

Methods

BGL-3 was produced in Mandels medium induced with several carbon sources, analyzing the expression of the *bgl3* gene by qRT-PCR. The saccharification of wheat straw was carried out with Celluclast 1.5L (Novozymes), as commercial source of cellulases, with or without BGL-3 or N-50010 (Novozymes), as source of β-glucosidase activity, to complement Celluclast 1.5L.

Conclusions

BGL-3 was produced with every inductor tested, suggesting that its production was carbon-source independent. Analysis of *bgl3* expression levels showed that its transcription is triggered under carbon starvation. Purified BGL-3 showed good thermal stability and high efficiency over *p*NPG and cellooligosaccharides. In wheat straw saccharification, BGL-3 worked better than the commercial cocktail N-50010 supplementing Celluclast 1.5L. Besides, its versatility was remarkable, since BGL-3 hydrolyzed the algal polysaccharide laminarin (1,3-β bonded), with higher yields than a commercial laminarinase. It is the first time that such versatility is described in a 1,4-β-glucosidase, which makes BGL-3 outstanding for a potential application for production of 2G and 3G biofuels.

Thanks to MINECO BIO2015-68387-R and CM S2013/MAE-2907 for funding.

BIOLOGICAL CONVERSION OF WASTE LIGNOCELLULOSIC BIOMASS FOR ALCOHOL PRODUCTION

L. Mezule[1], B. Dalecka[1], T. Juhna[1]
[1]Riga Technical University, Water Research Laboratory, Riga, Latvia

Backgrounds

Conversion of lignocellulosic biomass, e.g., grass, agricultural and wood processing waste, into valuable chemical products, e.g., biofuel, is closely linked with the selection of the most efficient pre-treatment and hydrolysis technique to produce fermentable sugars. Biological hydrolysis is regarded as one of the potential approaches over to classically applied chemical treatments, however, it is often linked with high costs of enzymes and long conversion time. At the same time it has been acknowledged that fermentation feed produced via biological hydrolysis has less fermentation inhibitors and is more suitable for alcohol producing microorganisms.

Objectives

In this research laboratory made enzyme products from white rot fungi were tested in a simple pre-treatment/hydrolysis assay to produce fermentable sugars. The suitability of these preparations for yeast and *Clostridium* fermentation processes were further tested in batch and pilot scale.

Methods

The results demonstrated that it is possible to produce fermentable sugar of up to 80% from the theoretical yield from lignocellulosic biomass within 24 hours of hydrolysis. The obtained sugar solutions were applicable for alcohol production and did not showed any significant effect ($p > 0.05$) on microorganism growth properties.

Conclusions

It was possible to design a simple, efficient biological biomass conversion technology to produce alcohols.

BREVIBACILLUS LATEROSPORUS STRAIN BGSS7: ISOLATE FROM SILAGE WITH A BROAD SPECTRUM OF ANTIMICROBIAL ACTIVITY AGAINST GRAM POSITIVE AND GRAM NEGATIVE MULTIRESISTANT PATHOGENS

S. Jovanovic[1], N. Mirkovic[1], M. Miljkovic[1], M. Malesevic[1], J. Lozo[2], B. Jovcic[2], G. Vukotic[2], B. Filipic[3], K. Novovic[1], M. Kojic[1]
[1]Institute of Molecular Genetics and Genetic Engineering- University of Belgrade, Laboratory for Molecular Microbiology, Belgrade, Serbia
[2]Faculty of Biology- University of Belgrade, Biochemistry and Molecular Biology, Belgrade, Serbia
[3]Faculty of Pharmacy- University of Belgrade, Department of Microbiology and Immunology, Belgrade, Serbia

Backgrounds

Antimicrobial peptides are short-sequence peptides with broad spectrum activity against bacteria, fungi and viruses. They are divided into two groups based on biosynthesis: i) non-ribosomally synthesized peptides, which are mostly produced by bacteria and ii) ribosomally synthesized peptides. *Brevibacillus laterosporus,* previously classified as *Bacillus laterosporus*, can produce antimicrobial peptides, such as lolatin A and lactolisperin.

Objectives

The aims of present study was to (i) isolate bacteria from silage, (ii) screen for production of antimicrobial peptides and (iii) identify of bacterial strains with antimicrobial activity against various pathogens.

Methods

For isolation of bacteria, 10 g of silage was re-suspended in 90 mL of peptone water, submitted to serial tenfold dilution and spread on the surface of LB, GM17 and MRS agar plates. After incubation at 37°C for 48h, fifty colonies per plates were randomly selected and transferred in corresponding broth and incubated o/n at 37°C. Agar well diffusion test was used for detection of antimicrobial activity.

Conclusions

Among randomly selected isolates from silage, only one BGSS7 showed strong inhibitory activity against *Staphylococcus aureus*, *Listeria monocytogenes*, *Klebsiella pneumoniae* and *Pseudomonas aeruginosa*, which was identified as *Brevibacillus laterosporus* by 16S rRNA gene sequencing. This is the first report of isolation of *B. laterosporus* from the silage with broad antagonistic potential. In this study, we gave preliminary data about antimicrobial activity of BGSS7 against Gram positive and negative pathogens; however localization of the gene(s) coding for antimicrobial peptide production, as well as determination of structure of the antimicrobial peptide is still in progress.

ANTIFUNGAL ACTIVITY OF VOLATILE ORGANIC COMPOUNDS FROM ENDOPHYTIC GEOTRICHUM CANDIDUM AGAINST RICE PATHOGEN RHIZOCTONIA SOLANI

A. Mookherjee[1], *M. Maiti*[1]
[1]*Indian Institute of Technology- Kharagpur- India, Biotechnology, Kharagpur, India*

Backgrounds

Antimicrobial volatile organic compounds (VOCs) from biological sources have enormous potential as a replacement of chemical fumigants. For the past few decades, scientists were able to discover different microbes with the ability to synthesize antimicrobial VOCs. Endophytic microbes, one of the prospective source, have the capacity to produce vast numbers of bioactive agents due to their presence in a specialized niche.

Objectives

The objective of this study was to detect antimicrobial activity, if any, in a laboratory isolated endophytic fungi with fruity fragrance. Based on the qualitative profile of its VOCs, metabolic engineering experiments were set up for enhancement of its antimicrobial activity.

Methods

The endophytic fungi was identified through phenotypic and molecular characterization. Metabolite profile of the fungal VOCs from GC-MS analysis, facilitated to find out prospective targets of precursor feeding for enhancement of its antimicrobial activity.

Conclusions

The endophytic fungi was successfully identified as *Geotrichum candidum* PF005. *G. candidum* PF005 had significant antifungal activity against rice pathogen *Rhizoctonia solani*. The source of carbon as nutrient was identified to be important factor for the production of antifungal VOCs. Presence of esters, hydrocarbons and alcohols were identified in significant proportion from the volatile fraction of *G. candidum* PF005. Antifungal activity against phytopathogenic *R. solani* got improved by feeding the fungal strain PF005 with precursors of 2-phenylethanol and 3-methyl-1-butanol synthesis pathways. Fruity fragrance and qualified presumption of safety status of *G. candidus* make it much more desirable candidate to utilize it as mycofumigant to control phytopathogen *R. solani* of crop plants.

ASSESSING THE ROLE OF CANDIDATE TRANSPORTERS IN THE METABOLIC COMPLEMENTATION BETWEEN BLATTELLA GERMANICA AND ITS ENDOSYMBIONT BLATTABACTERIUM

M. Muñoz Benavent[1], C. Picazo[2], R. Domínguez-Santos[1], J. Peretó[1], C. García-Ferris[1], A. Latorre[1]
[1]Institute for Integrative Systems Biology I2SysBio, University of Valencia, Paterna, Spain
[2]Institute for Integrative Systems Biology I2SysBio, Univeristy of Valencia, Paterna, Spain

Backgrounds

Symbiosis is a key biological interaction in evolution processes. It is present all over the biological kingdoms and is especially important in insects. It is the case of the german cockroach (*Blattella germanica*), which has an endosymbiont: *Blattabacterium cuenoti*. This is a flavobacterium who lives inside specialised cells called bacteriocytes, located in the fat body of the cockroach. The biological interaction between both organisms has been studied and it has been hypothesised that it is due to a metabolic complementation based on the recycling of nitrogen. The bacterium would complete the uricolityc pathway and produce ammonia from urea, which must be transported into *Blattabacterium*. The ammonium would be organically fixed by the host in the form of glutamine that would be transported into *Blattabacterium* to be used in the biosynthesis of essential amino acids.

Objectives

The objective of this study is to identify some of the molecular elements involved in this complementation, in particular the transporters that allow the flow of molecules through the membranes that separate the cytoplasm of both organisms (*Blattabacterium* / *Blattella* interphase).

Methods

For this we have analyzed the genome of *Blattabacterium* in search of candidate proteins (alt. transporters) in order to express them in yeast and carry out functional complementation tests. These experiments consist of cloning our candidate proteins in yeast mutants for the transport of the molecules involved in the hypothetical metabolic complementation.

Conclusions

Later they will be cultivated in restrictive media that will allow to evaluate their function.

SCREENING AND CHARACTERIZATION OF INDIGENOUS MICROALGAL STRAINS FOR PRODUCTION OF BIOMASS AND CAROTENOIDS UNDER PHOTOAUTOTROPHIC AND MIXOTROPHIC GROWTH CONDITIONS

T. Mutanda[1], *N. Zibula*[1]
[1]*University of KwaZulu-Natal, Microbiology- School of Life Sciences, Durban, South Africa*

Backgrounds

Microalgae are currently gaining considerable attention for biofuels and biochemicals production by the biorefinery approach. Carotenoids are accessory pigments interacting with harmful reactive oxygen species (ROS) thereby acting as free radical quenchers, singlet oxygen scavengers and lipid antioxidants and are reportedly beneficial to human well-being.

Objectives

To screen and characterize microalgae producing carotenoids.

Methods

In this study, 20 unique wild-type indigenous microalgal strains were isolated from diverse aquatic habitats in KwaZulu-Natal Province, South Africa. The axenic microalgal strains were propagated in modified seawater and BG-11 growth media for 15 days in closed bioreactors and screened for carotenoid production by non-destructive chromatographic and spectrophotometric analysis. Two microalgal stains (strain 1 and strain 2) showed potential for β-carotene production and were subsequently subjected to photoautotrophic and mixotrophic growth conditions. Both strains showed robust growth and biomass accumulation under photoautrophic growth conditions. Total β-carotene production was 0.325 and 0.311 mg/mL for strain 1 and strain 2 respectively after 15 days of uninterrupted growth under photoautotrophic growth conditions. Several carbon sources were investigated and strain 1 and strain 2 grew maximally in media supplemented with glycerol and sodium acetate respectively. Microalgal strain 1 and strain 2 achieved highest total β-carotene concentration of 0.372 mg/mL and 0.385 mg/mL respectively, in media supplemented with sodium acetate after 15 days of growth.

Conclusions

Therefore, mixotrophic growth conditions enhanced β-carotene production by the 2 strains as compared to photoautotrophy. This study demonstrated suitable growth conditions for production of biomass and carotenoids by two indigenous microalgal strains with potential for biotechnological applications.

CHARACTERIZATION OF UNEXPLORED QATARI BACILLUS THURINGIENSIS STRAINS FOR IDENTIFYING POTENTIAL BIO-INSECTICIDE PRODUCERS TARGETING DIPTERAN INSECTS

S. Jaoua[1], K. Nair[1]
[1]Qatar University, Department of Biological & Environmental Sciences, Doha, Qatar

Backgrounds

Many fatal human diseases are contributed to the *Dipteran* vectors like mosquitoes. The measures of controlling them are mostly chemical based. Use of these chemical insecticides are considered one of the crucial environmental problems today. One of the sustainable and biological alternative is the use of larvicidal endotoxin proteins produced by the gram-positive soil bacterium, *Bacillus thuringiensis* (*Bt*) in the form of spherical crystals.

Objectives

Our objective is to screen the unexplored Qatari microbial communities to identify *Bacillus thuringiensis* strains that would be a good candidate to produce bio-insecticide.

Methods

We have isolated 700 strains and have found 441 isolates that produce spherical crystals. After intrinsically studying the spherical crystals by Scanning electron microscopy, we have categorized the 441 isolates based on their protein and plasmid patterns. Among these, we have 19 isolates that have molecular and biochemical characteristics indicative of insecticidal activity. We have also evidenced structural instability in the plasmid of these isolates when evaluating the endotoxin genes by PCR (polymerase chain reaction) amplifications.

Conclusions

In conclusion, considering the extreme climatic conditions of Qatar, the microbial community offers unique *Bt* strains and our analyses show that they have the potential to replace the chemical insecticides.

EVOLUTIONARY HISTORY OF FUNGAL VERSATILE-LIPASES FROM THE ORDER AGARICALES

J. Barriuso[1], *M.J. Martínez*[1]
[1]*Centro de Investigaciones Biológicas CIB-CSIC, Environmental Biology, Madrid, Spain*

Backgrounds

Lipases (EC 3.1.1.3) and sterol esterases (EC 3.1.1.13) are thoroughly used in industrial applications. Among fungi some extracellular proteins combine properties of both enzymes, and there are known as “Versatile carboxylic ester hydrolases” (abH03.01). Agaricales is the largest clade of mushroom-forming fungi and one of the most ancient orders, comprising wood saprophytes with biotechnological interest. On the other hand, the *in silico* mining of fungal genomes and metagenomes has been shown as an alternative for searching novel lipases, while exploring the evolutionary history and resurrecting intermediate ancestral forms of enzymes can help to explain the mechanistic basis of enzymes function and disclose new functionalities.

Objectives

In this work we explored the presence of genes encoding putative “Versatile lipases” from the order Agaricales. We reconstructed the molecular evolution of these enzymes and inferred the sequence of their ancestral intermediate forms. The potential properties of the candidates are discussed on the basis of their three-dimensional (3D) model structure, the presence and hydrophobicity of the lid, and the substrate binding tunnel.

Methods

We used conserved motifs, sequence and phylogenetic analyses, and three-dimensional modeling to look for candidate genes in public fungal genomes. Moreover, we reconstructed the molecular evolution of these enzymes using novel phylogenetic approaches (PAML4.8).

Conclusions

The evolutionary history of the putative lipases revealed an increase on the length and hydrophobicity of the lid region, as well as in the size of the substrate binding pocket, during evolution time. These facts suggest the enzymes’ specialization towards certain substrates and their subsequent loss of promiscuity.

LESS IS MORE: HYDROLYSIS OF POLYESTERS IS ENHANCED BY A TRUNCATION OF AN ESTERASE

A. Biundo[1], R. Doris[2,3], G. Steinkellner[4], K. Gruber[5]
[1]Polymer and Environmental Biotechnology, Austrian Centre of Industrial Biotechnology, Tulln, Austria
[2]Institute for Environmental Biotechnology, Department of Agrobiotechnology- IFA-Tulln, Tulln, Austria
[3]Polymers and Environmental Biotechnology, Austrian Centre for Industrial Biotechnology, Tulln, Austria
[4]Austrian Centre of Industrial Biotechnology, Austrian Centre of Industrial Biotechnology, Graz, Austria
[5]Institute of Molecular Bioscience, University of Graz, Graz, Austria

Backgrounds

Polymers frequently used for one-way applications like packaging are preferably biodegradable, albeit non-biodegradable polyesters are mostly used. Biodegradability of the aliphatic/aromatic copolyester poly(butylene adipate-*co*-terephthalate) (PBAT) has been investigated, showing biological decomposability under composting conditions. However, little is known about its anaerobic hydrolysis while large amount of food packaging ends up in biogas plants. The enzyme EstA from *Clostridium botulinum* (Cbotu_EstA) actively hydrolyzed PBAT while it failed to act on polyethylene terephthalate (PET). Yet, enzymes would allow mild decomposition of widely used PET enabling recycling of the monomeric building blocks.

Objectives

The enhancement of the hydrolase activity with regard to polyester hydrolysis was carried out by fusion of hydrophobic domains, improving the biocatalyst adsorption on the hydrophobic polymer surface, or by substitution of specific residues, enlarging the active site of the enzyme. The deletion of the Cbotu_EstA N-terminal domain can satisfactory combine both approaches.

Methods

The 3D structure analysis of Cbotu_EstA revealed the presence of an N-terminal domain covering the lid structure and a hydrophobic patch. Chemoluminescence and HPLC analysis determined the adsorption onto hydrophobic surfaces and the hydrolyzing activity of the enzyme, respectively. Furthermore, analysis of the kinetic constants made the catalytic activity investigation of the two forms of the enzyme possible.

Conclusions

Surface engineering successfully produced a highly active Cbotu_EstA variant which was able to hydrolyze PET. Truncation of the N-terminal domain of Cbotu_EstA improved the adsorption of the enzyme on hydrophobic polyester surfaces and enhanced their hydrolysis eight times more compared to the wild-type enzyme, based on released monomers quantification.

COMPARATIVE GENOMIC ANALYSIS OF NOVEL ACINETOBACTER SYMBIONTS: A COMBINED SYSTEMS BIOLOGY AND GENOMICS APPROACH

V. Gupta[1], *U. Sood*[1], *Y. Singh*[1], *R. Lal*[2]
[1]*University Of Delhi, Lab 112- Department Of Zoology, Delhi, India*
[2]*University Of Delhi, Lab 115- Department Of Zoology, Delhi, India*

Backgrounds

BACKGROUND : The increasing trend of antibiotic resistance in *Acinetobacter* is a matter of global concern as it drastically limits the range of therapeutic agents required to treat multidrug resistant (MDR) infections. To concur these pathogenic bacteria, we planned a network theory based study to identify the regulatory proteins.

Objectives

OBJECTIVES: Comparative genomics analysis was performed in between 3 strains of *Acinetobacter* spp. isolated from sheep and one from the insect gut. Sequencing and annotations were done to gain the details in pathogenicity of *Acinetobacter* spp.

Methods

METHODS: In this study we have applied multi-omics approach to explore system ecology of *Acinetobacter* spp. using genomics and systems biology. Four novel strains of *Acinetobacter* spp. (pathogenic and non-pathogenic) were phylogenetically classified and further used to computationally construct subnetwork/modules using the network theory methods

Conclusions

RESULTS: We identified eight major key regulatory genes (hubs), guaA, rpsB, rpsI, rpsL, rpsE, rpsC, rplM and trmD , which have functional roles demonstrating a hierarchical scale-free fractal protein-protein interaction network. Two unique key hubs, *i.e*., guaA and guaB played an important role in *Acinetobacter* sp. isolated from insect gut. The hub guaA was comparatively more important than guaB as it help in effective module regulation. The rpsI gene was important in all the studied novel strains of *Acinetobacter* spp. The rplM gene was specific only to strains isolated from sheep gut.

CONCLUSIONS: We found that three genes hub, rpsM, rpsB and rpsI, were involved in the regulation of overall network topology across all *Acinetobacter* strains in this study. Combining the multi-omics approach have revealed the system ecology of *Acinetobacter* ecotypes for further investigation of these hubs if they are effective drug target for *Acinetobacter* spp. infections.

CARBOXYLATE PLATFORM CHEMICALS AND BIOFUELS FROM BIOWASTE

E. Hakalehto[1,2], S. Schwede[3], R. Laatikainen[4], E. den Boer[5], L. Piiroinen[1]
[1]Finnoflag Oy, P.O. Box 262, 70101 Kuopio, Finland
[2]Department of Agricultural Sciences, University of Helsinki, Helsinki, Finland
[3]School of Business, Society and Engineering, Mälardalen University, Västerås, Sweden
[4]School of Pharmacy, University of Eastern Finland, Kuopio, Finland
[5]Wrocław University of Science and Technology,
Department of Environmental Protection Engineering, Wroclaw, Poland

Backgrounds

A significant share of the fuels and chemicals used in the economy could be replaced by substances produced from biomass sources. Recent international and European development strategies attribute high priority to the growth of bioeconomy sector. A radical change of production, consumption, processing, storage, recycling and disposal of biological resources is needed, in order to cope with an increasing global population, rapid depletion of many resources, increasing environmental pressures and climate change.

Objectives

Micro-organisms provide tools for circulating the substances in the industrial ecosystems. This paper focuses on the production of carboxylic platform chemicals from industrial and municipal kitchen biowaste using non-aceptic conditions. Verification of this technology has been done based on pilot tests in 3 regions – in Finland, Poland and Sweden.

Methods

The biorefinery technology was implemented in a pilot scale with effective reactor volumes of 200-300 L under anaerobic and microaerobic conditions. The production organisms belonged to the genera *Clostridium* and *Klebsiella*. Selected biowaste streams were subjected to enzymatic pretreatment prior to the inoculation.

Conclusions

The results showed high conversion rates achieved from mixed substrates. The dominating end products were volatile fatty acids (VFAs), ethanol and CO_2. Lower levels of other gases, such as H_2, CH_4 and H_2S, were formed. The conversion rates of glucose to the main fermentation products reached up to 0.81 mol/mol. Valeric acid was one of the main VFA products from the potato waste carbohydrates, whereas in trials on chicken litter, the valerate derived mostly from the amino acids of the biowaste proteins.

[3]University of Huelva, Department of Chemical engineering-
Physical Chemistry and Materials Science, Huelva, Spain
[4]University of Huelva,
Department of Chemical engineering- Physical Chemistry and Materials Science, Huelva, Spain

Backgrounds

Lignin is an aromatic biopolymer traditionally considered a waste product in industrial processes and agricultural practices causing serious pollution problems. At present, lignin is considered a renewable biopolymer for biotechnological applications. The suitability of *Streptomyces* to solubilize lignin from grasses residues, instead of to mineralize this polymer, could be a good strategy for biotechnological purposes.

Objectives

The aim of this work is to set up the optimal conditions to solubilize lignin from agricultural residues using selected *Streptomyces* strains to be applied for oleogels elaboration.

Methods

Different *Streptomyces* strains were cultured for 7 days under Solid-State Fermentation conditions (SSF) on agricultural residues. Transformed substrates were extracted with water or 0.1 M NaOH and extracts were acidified with HCl. Finally, water or alkali-extracted lignin were gravimetrically estimated. Moreover, xylanase, mannanase and laccase activities were determined along the time course of growth. Selected strains were also cultured under SSF conditions supplemented with radicals promoting agents such as quinones and Fe^{3+}-EDTA. Prior to this, the Fe^{3+} content of substrates (60 ± 3 µg g^{-1}) were determined by Atomic Absorption Spectrophotometry. For oleogels preparation alkali-lignin was modified with 1,6-hexamethylene diisocyanate.

Conclusions

An increase in 10-20% of alkali-lignin yield was achieved with selected strains compared to that obtained from uninoculated substrates.

Under radical producing conditions, the colonization ability of strains was not affected being the yield of water-extracted lignin 20 % higher than that obtained in non-supplemented cultures with radical production promoters.

Preliminary assays carried out with oleogels elaborated with alkali-lignin showed suitable thermal resistance and rheological characteristics.

Biotechnology / Synthetic Biology / Systems Biology - Part III

CONSTRUCTION AND CHARACTERIZATION OF MICROBIAL CONSORTIA FOR KERATIN DEGRADATION

D. Kang[1], S. Jacquiod[2], J. Herschend[1], S.J. Sørensen[1]
[1]University of Copenhagen, Department of Biology, Copenhagen, Denmark
[2]INRA, UMR 1347 Agroécologie, Dijon, France

Backgrounds

Europe, especially Denmark, heavily relies on import of soy protein for feed in its animal production. Keratins refer to a group of insoluble, tough and recalcitrant protein material generated in large quantities as a waste-product in commercial slaughterhouses, originating from bristles and hooves. Utilization of microbial consortia can play a crucial role as natural biodegradation process for keratin. It can be transformed into more valuable feedstock through the release of small peptides and amino acids by microbial degradation.

Objectives

Identify microbial communities for keratin degradation and construction of stable microbial consortia for industrial applications.

Methods

A soil-born microbial consortium was enriched on keratin as the sole carbon source in sequential batch cultivations at room temperature and characterized by application of next generation sequencing and specific keratin degradation assays.

Conclusions

During six enrichment cycles, the procedure selected for stable and efficient keratin degrading microbial consortia, mainly constituted by members of bacteroidetes and proteobacteria phyla. For the sake of industrial applications, we used a dilution-based method to reduce the diversity and isolate key component strains involved in efficient keratin degradation, while excluding potential cheaters and ease of controllable outputs. The consortia were structurally stable with the co-existence of four major microbes, comprising aerobic bacterial genera *Chryseobacterium*, *Stenotrophomonas*, *Pseudochrobactrum, Acinetobacter*. Residual substrates proportion is similar when comparing with using the microbial consortium without dilution and approximate 20% after five days. This work has potential applications for a vast range of areas including food and feed, fisheries, biotechnologies and agriculture.

MARINE BACTERIAL COMMUNITY FUNCTIONAL METAGENOMICS AND GENETIC ANALYSIS TO ISOLATE AND CHARACTERISE NOVEL BIOACTIVE COMPOUNDS TOXIC TOWARDS THE NEMATODE CAENORHABDITIS ELEGANS

J. Nappi[1], *F. Ballestriero*[1], *C. Campi*[1], *S. Egan*[1]
[1]*University of New South Wales, School of Biotechnology and Biomolecular Science, Sydney, Australia*

Backgrounds

Due to the rise of microbial resistance to antibiotics, there is an urgent need for the discovery and development of new antimicrobial drugs. Marine environments and in particular host-associated bacteria are proving to be a promising source of novel bioactive metabolites. Moreover modern –omics tools enable researchers to tap into the vast diversity and potential of uncultured microorganisms.

Objectives

The aim of this study was to use a culture independent functional metagenomic approach to identify and characterise new bioactive metabolites isolated from bacterial epiphytes of the seaweed *Ulva australis*.

Methods

We screened an *E. coli metagenomic fosmid* library of the microbial community associated with *U. australis* for activity against the model nematode *Caenorhabditis elegans*. Active clones were further analysed with transposon mutagenesis. The resulting mutant clone library was screened for loss of activity and the mutants sequenced to identify the gene clusters involved in the toxicity towards *C. elegans*.

Conclusions

Our library screening resulted in 150 potential active clones and of those, six were confirmed as being toxic to the nematode. One clone (JJ117) was particularly toxic to *C. elegans* and further analysis revealed that it contains DNA sequence with high identity to an unknown marine alpha-proteobacteria (order *Rhodobacterales)*. Bacterial species within this taxa have previously been shown to be associated with the production of antibacterial compounds. Genetic analysis indicates that this clone produces a novel compound involving the activity of one ATP grasp superfamily protein and an Alpha E superfamily protein. Further studies will involve genetic complementation and chemical analysis of JJ117.

IDENTIFICATION, ACTIVITY AND MOLECULAR SCREENING OF PECTINASE ENZYME IN HALOPHILIC BACTERIA FROM SALT LAKE, IRAN

Z. nasrollahzadeh[1], *E. Salehghamari*[1], *M.A. Amoozegar*[1]
[1]*Science, Biology, Tehran, Iran*

Backgrounds

Pectinase is enzymatic complex including pectin methyl esterase, pectin lyase and polygalactoronase. Finding the microorganisms with ability of synthesis of these enzymes in extreme condition such as different salt concentration could have beneficial application in industry.

Objectives

In this research we screened halophilic bacteria from salt lake of Iran and activity and the genes of coding pectinase were studied.

Methods

Isolated bacteria from Urmia, Inche Boron and Gomishan lakes were cultured on selective medium containing pectin as sole carbon source. The positive isolates were identified by I2/kI qualitative test. The activity of pectin esterase, pectin lyase and polygalactoronase enzymes was measured in positive isolates by spectrophotometry at 620, 235 and 595 nm respectively. The pectate lyase gene was amplified using appropriate degenerated primers, in order to screen the gene. Then the products were cloned and sequenced.

Conclusions

Among the 130 studied strains, 17 positive strains were identified for these enzymes of which 10, 6 and 1 belonged to the Gomishan, Inche Boron and Urmia lakes respectively. The results of spectrophotometer showed that most of the produced pectin esterase, pectin lyase and polygalactoronase enzymes were related to isolated strains from the Inche Boron Lake. Although, R_2S_{25} bacterial strain isolated from Inche Boron Lake showed the highest production of these enzymes.
After sequencing the PCR products from 17 positive samples of halophilic bacteria, the phylogenic tree of pectate lyase gene was established to introduce the evolutionary relationship in different strains. In conclusion, the evolutionary algorithm of pectinase gene was different from *16s rDNA* phylogenetic tree.

CONVERSION OF LIGNOCELLULOSE TO JET FUELS WITH MEMBRANE CONCENTRATION

A. Netrusov[1], V. Teplyakov[2], M. Tsodikov[3]
[1]Lomonosov Moscow State University, Microbiology, Moscow, Russia
[2]Topchiev Institute of Petrochemical Synthesis RAS, Lab. 29, Moscow, Russia
[3]Topchiev Institute of Petrochemical Synthesis RAS, Lab. 14, Moscow, Russia

Backgrounds

Lignocellulose is a most abundant polysaccharide source on the Earth and it is a suitable renewable substrate for the fuel obtaining.

Objectives

Membrane technologies allow to select and to concentrate the liquid fuels (alcohols) from the cultural broths of alcohol and acetone-butanol-ethanol (ABE)-fermentations with lignocellulose enzymatic digests as substrate.

Methods

Lignocelluloses of hard and softwoods as well as grass and topinambur biomass were delignified by environmental-friendly ways, and then subjected to industrial cellulases treatments to obtain C6-sugar's liquors. ABE and bioethanol fermentations were used to produce fuel alcohols which were further concentrated from the broth with membrane technique allowing to get 7-15-times concentrated alcohols with low energy inputs. Resulting concentrated alcohols were used as substrates in the catalytic process for hydrocarbons obtaining (C8-C10) – components of jet fuels:

$2\ ROH + H_2 \rightarrow R–R + 2\ H_2O$, with up to 87% conversion rate.

Viewed drawbacks, restrictions and challenges of the methods exploited will be discussed.

Conclusions

New technology developed to obtain hydrocarbons for jet fuel mixtures manufactured from the renewable natural sources without much damage to the nature in environmentally friendly way without using the fossil resources.

UNFOLDED PROTEIN RESPONSE (UPR) CAN DRIVE INDUCTION OF IFN-B AND ANTIVIRAL RESPONSES USING A SYNTHETIC PATHWAY BYPASS COMPRISED BY A CHIMERIC XBP1-2CARD-RIG-I PROTEIN.

E. Nistal-Villán[1], R. Ferrero[2], A. Coll[2], J. Argemi[2], S. Rius-Rocabert[1], G. González-Aseguinolaza[2], T. Aragon[2]
[1]Universidad San Pablo CEU-Facultad de Farmacia.,
Secciíón de Microbiología. Dep. de Ciencias Farmacéuticas y de la Salud., Boadilla del Monte, Spain
[2]Center for Applied Medical Research CIMA- University of Navarra.,
Gene Therapy and Regulation of Gene Expression Program, Pamplona, Spain

Backgrounds

Deficiencies in the endoplasmic reticulum (ER) protein folding capacity may cause the activation of signaling mechanisms known as the Unfolded Protein Response (UPR) in eukaryotes. IRE1alpha is an ER-resident transmembrane protein activated by the UPR. Under ER physiological and pathological stress conditions, including viral infections, IRE1alpha activation results in the excision of a non-conventional 26-nucleotide intron within the ORF of the mRNA encoding the transcription factor XBP1, generating a new mRNA that yields the expression of XBP1s protein.

In chordate animals, detection of cytoplasmic viral dsRNA during infections triggers the induction of the IFN-β induction pathway. Its relevance in inducing an antiviral response is highlighted by the many different viral antagonistic mechanisms to prevent such induction.

Objectives

To generate recombinant mRNAs where expression of the retinoic acid inducible gene I (RIG-I) 2CARD domain is controlled by the XBP1 splicing mechanism, bypassing dsRNA detection requirement, in order to stimulate IFN-β-dependent immune responses linked to UPR activation.

Methods

Plasmids containing the minimal XBP1 splicing elements fused to the constitutively active 2CARD domain of the dsRNA sensor RIG-I were constructed. IFN-β induction-dependent reporter, qRT-PCR and antiviral response activities were tested in HEK293T and A549 cells in response to different UPR agonistic stimuli, including viruses in order to measure antiviral response.

Conclusions

We have optimized a minimal XBP1-2CARD-RIG-I sequence to reconstitute the IFN-β pathway in an UPR-dependent fashion. Activation of our system by different agonist suggest the possibility to use unconventional alternative pathways in order to reconstitute type-I IFN deficient systems.

[4]Universidade Ceuma, Curso Farmácia, São luis, Brunei
[5]Faculdade Estacio São Luís Maranhão, Curso Nutrição, São luis, Brazil
[6]Faculdade Estacio São Luís Maranhão, Curso Enfermagem, São luis, Brazil

Backgrounds

The research of vegetable extracts is important for the discovery of new compounds with therapeutic properties. Among several vegetable species to be investigated the Manilkara zapota (sapoti) stands out. It is a fruit which skin is used by indigenous natives for treatment of diarrhoea and fever.

Objectives

This work has the objective of investigate the antimicrobial activity of the extract of Manilkara zapota.

Methods

The M. zapota (sapoti) fruits were picked at the Estácio São Luís-MA college, under the location 25°28′63,9 ″ S and 44°29′02,6 ″W. The plant registration was obtained in the Herbarium of the Maranhão Federal University, which exsiccate number is 01352. The fruit peel gone through a drying process followed by the production of the extract where it was used solvent extractor hydro alcoholic at 70 % in the proportion of 1:3 (m/v). Next, the extract was subjected to a rotary evaporator under pressure reduced to the controlled temperature of up to 50 °C when it was obtained the final concentration of 0,71mg/mL. Diffusion techniques in ágar and seriated macrodilution were used to evaluate the antimicrobial activity. The following standard vines-strains were used and were originated from the American Type Culture Collection (ATCC): Staphylococcus aureus (25923), Klebsiella pneumoniae (10031), Escherichia coli (25922), Salmonella typhi (14028), Pseudomonas aeruginosa (27853), Candida albicans (14053), Candida krusei (6258), Candida parapsilosis (22019).

Conclusions

The antimicrobial effect of the above mentioned extract against fronts of all the evaluated vine-strains was observed exclusively in the macro dilution technique. It was noted minimal Bactericidal and fungicides concentrations of only 0,08mg/mL and 1,7 mg/mL against samples of P. aerugionsa and C. parapsilosis, respectively.

CONSTRUCTION OF THE CELL SURFACE DISPLAY SYSTEM USING NEW AUTOTRANSPORTER FROM PSYCHROBACTER CRYOHALOLENTIS K5T

K. Novototskaya-Vlasova[1], L. Petrovskaya[2], A. Zlobinov[2], E. Rivkina[3]
[1]Institute of Physicochemical and Biological Problems in Soil Science- Russian Ac, Cryology of soils laboratory, Puschino, Russia
[2]Shemyakin & Ovchinnikov Institute of Bioorganic Chemistry., Bioengineering Department, Moscow, Russia
[3]Institute of Physicochemical and Biological Problems in Soil Science- Russian Academy of Sciences, Cryology of soils laboratory, Puschino, Russia

Backgrounds

Autotransporter (AT) family includes outer membrane proteins from Gram-negative bacteria which consist of N-terminal passenger and C-terminal translocator domains and utilize Type V secretion for export to the cell surface. Previously, we have cloned the gene coding for a potential AT protein (AT877) from *P. cryohalolentis* $K5^T$ isolated from cryopeg within Siberian permafrost. This protein was overexpressed in *Escherichia coli* cells and the passenger domain with lipase activity was displayed on the cell surface.

Objectives

To evaluate applicability of AT877 for the cell surface display of heterologous passengers, we have constructed hybrid proteins which included α-helical linker and translocator domain of AT877. Cold-active esterase EstPc, scaffold protein ^{10}Fn3 (human fibronectin domain) and fluorescent protein mCherry were used as passenger domains.

Methods

Display of the heterologous passengers at the cell surface was confirmed by the use of cell fractionation studies and esterase activity measurements (for EstPc passenger), whole cell ELISA (for ^{10}Fn3) and confocal microscopy (for ^{10}Fn3 and mCherry).

Conclusions

Obtained results prove that the presence of the AT877 α-helical linker and the translocator domain is sufficient for the targeting of various passenger proteins to the surface of *E. coli* cells. This is a new example of the biotechnologically relevant enzyme from the unique microbial community of permafrost and a potential basis for the construction of a new cell-surface display system.

The work was supported by RFBR grant 16-04-00717 and grant SS-8384.2016.4.

PRODUCTION OF 1,2-PROPANDIOL FROM DEOXYSUGARS BY CALDICLLULOSIRUPTOR SPECIES

J. Orlygsson[1], *S. Scully*[1]
[1]*University of Akureyri, Faculty of Natural Resource Sciences, Akureyri, Iceland*

Backgrounds

As 1,2-propanediol (1,2-PD) has a single stereocenter it can be found in two enantiomeric forms. (S)-1,2-PD can be produced microbially with the fermentation of methylpentoses (L-fucose and L-rhamnose) while the (R)-enantiomer is produced from hexoses and pentoses via the methylglyoxal pathway. Few investigations have been reported on thermophiles producing 1,2-PD from deoxysugars although several species within the genus of *Caldicellulosiruptor* have been reported to do so from L-rhamnose

Objectives

The aim of this work is to examine the deoxysugar metabolisms of the whole genus of *Caldicellulosiruptor*.

Methods

In present investigation all nine strains of *Caldicellulosiruptor* are examined under anaerobic conditions in batch culture using serum bottles on glucose, fucose and rhamnose (all 20 mM).

Conclusions

Fermentation of glucose resulted mainly in the production of acetate, lactate and hydrogen but no 1,2-PD was produced, indicating that active methylglyxoal pathway is not present in any of the nine species within the genus. Rhamnose was used as a carbon and energy source for six of the nine species, with values of 1,2-PD ranging from 0.73 mM (*C. owensis*) to 7.7 mM (*C. hydrothermalis*). Other main products were acetate and hydrogen. Fucose was degraded to a mixture of 1,2-PD, acetate, lactate and hydrogen by three (*C. bescii, C. saccharolyticus, C. hydrothermalis*) of the nine species. *C. bescii* produced 3.2 mM of 1,2 PD and *C. saccharolyticus* and *C. hydrothermalis* 8.0 mM. Our results show that the ability of 1,2-PD-production from deoxysugars is more widespread among the genus *Caldicellulosiruptor* than previously reported.

IDENTIFICATION, CLONING AND HETEROLOGOUS EXPRESSION OF A CRYPTIC RIPP GENE CLUSTER FROM THE MARINE STRAIN STREPTOMYCES CANIFERUS

D. Oves-Costales[1], M. Sanchez-Hidalgo[1], J.R. Tormo[2], O. Genilloud[1]
[1]Fundacion MEDINA, Microbiology, Granada, Spain
[2]Fundacion MEDINA, Chemistry, Granada, Spain

Backgrounds

Microbial natural products continue to play an invaluable role in the discovery and development of the chemotherapeutic arsenal. In the last years much attention has been given to marine microorganisms, which have proven to be a rich source of new natural products with therapeutic potential.[1]

Objectives

During our ongoing research with marine actinobacteria we identified by genome mining an intriguing cryptic gene cluster likely encoding the biosynthesis of up to five ribosomally synthesized and post-translationally modified peptide natural products (RiPPs).[2]

Methods

In order to gain more insight into these cryptic metabolites, the gene cluster (17 Kb) was cloned in the integrative pCAP01 vector employing a TAR-based strategy,[3] and the resulting construct was integrated into the host strains *Streptomyces coelicolor* M1152, M1154 and *Streptomyces albus* J1074. These engineered strains were subjected to an array of fermentation conditions, and the corresponding microbial extracts analyzed by LC-MS comparative metabolite profiling in order to identify any cryptic metabolite absent in control fermentations of the host strains.

Conclusions

A combination of genome mining, cloning and heterologous expression was implemented as a strategy to identify new microbial natural products.

PURIFICATION AND CHARACTERIZATION OF A-AMYLASE FROM BACILLUS AMYLOLIQUIFACIENS

A. Paloyan[1], L. Melkonyan[2], A. Mkhitaryan[1], A. Hambardzumyan[1], A. Saghyan[3]
[1]SPC "Armbiotechnology" of NAS of Armenia, Laboratory of Molecular Biology, Yerevan, Armenia
[2]SPC "Armbiotechnology" of NAS of Armenia, Laboratory of Selection of BAS Strain-producers, Yerevan, Armenia
[3]SPC "Armbiotechnology" of NAS of Armenia, Director, Yerevan, Armenia

Backgrounds

α-Amylase is used in starch-containing raw material processing and constitute the main masses of enzyme preparations used in biotechnology. In the scientific literature there is described microorganisms application in the field of α-amylase production. The rate of hydrolysis of starch by α-amylase depends on many conditions of the process such as temperature, pH, substrate concentration, enzyme concentration, presence of stabilizing agents.

Objectives

The variety of α-amylases application always drives scientists to search a new α-amylases by improved properties.

Methods

Bacillus amyloliquefaciens strains from the Microbial Depository Center of SPC “Armbiotechnology” NAS RA have been studied as α-amylases sources. The optimum temperature for growth and α-amylase production in the starch-containing media was 45°C. The highest yield of α-amylase activity was after 48 hours of fermentation. α-Amylase of *Bacillus amyloliquifaciens* strain MDC1974 was isolated and purified. After fourth stage of purification (chromatography on DEAE Toyopearl and on hydroxyapatite, 100-10 kDa cut off, gel filtration on Toyopearl 55F and concentration) the specific activity of α-amylase increase 50 times reaching to 350 u/mg. Native gel electrophoresis was used to assess the purity of the enzyme. The degree of homogeneity of α-amylase was exceeded 95%. SDS-PAGE electrophoresis results indicate 58.4 kDa for enzyme molecular weight. α-Amylase shows the highest activity at pH 6.5-7 and at 75°C.

Conclusions

According to the obtained results α-amylase of *Bacillus amyloliquifaciens* has valuable properties and after engineering the strain-producer based on *Bacillus amyloliquifaciens* α-amylase gene will get industrial application.

BIOSYNTHESIS OF PALLADIUM NANOPARTICLES BY PURE AND MIXED CULTURES: KEY PARAMETERS AND MECHANISMS

A. Pat-espadas[1], E. Razo-flores[2], R. Rangel-mendez[2], F.J. Cervantes[2]
[1]Geology Institute Unam, Northwest Regional Station, Hermosillo, Mexico
[2]Instituto Potosino De Investigacion Cientifica Y Tecnologica, Environmental Sciences, San Luis Potosi, Mexico

Backgrounds

Nanoparticles are extensively used because they exhibit unique electronic, magnetic, catalytic and optical properties which are different from those of bulk materials. The use of microorganisms for remediation purposes has been applied since years ago; however, the approach of production of nanoparticles is very recent. Biological methods constitute a feasible option that also offer advantages over traditional methods of synthesis.

Objectives

The aim of this work was to study the influence of different parameters such as metal and cells concentration, time and electron donor on the synthesis of palladium nanoparticles by pure and mixed cultures.

Methods

Pure culture of *Geobacter sulfurreducens* strain PCA (DSM 12127; ATCC51573) was routinely cultured anaerobically in acetate:fumarate medium and exposed to concentrations of 25, 50 and 100 mg Pd(II)/L as Na_2PdCl_4.

Anaerobic granular sludge was explored for its ability to reduce Pd(II) to Pd(0). For this six different electron donors were explored. Control assays were carried out in cell-free media. All assays were incubated at 30° C and performed in duplicate. Samples were analyzed at specific time intervals. Analytical techniques such as transmission electron microcopy, FT-IR spectra and X-ray diffraction were used.

Conclusions

The results obtained from this study demonstrated that the biosynthesis of nanoparticles is mainly influenced by: speciation (soluble and solid species), metal and cell concentrations, electron donor and the presence or absence of a redox mediator.

In pure cultures the results obtained demonstrated that NPs synthesis occur by means of two mechanisms: (i) direct contact involving reduction by outer membrane c-type cytochromes; and (ii) indirectly by using an electron shuttle. For mixed cultures the reduction of Pd(II) is strongly dependent on the electron donor used and inhibition occurs at levels as low as 0.96 mg Pd(II)/L. However it is possible to achieve Pd reduction by setting the adequate parameters of synthesis.

BUTANOL TOLERANCE VERSUS BUTANOL PRODUCTION IN MUTANTS AND ADAPTED STRAINS OF CLOSTRIDIUM BEIJERINCKII

P. Patakova[1], M. Vasylkivska[1], J. Kolek[1], M. Drahokoupil[1]
[1]University of Chemistry and Technology Prague, Department of Biotechnology, Prague 6, Czech Republic

Backgrounds

Butanol production is a unique feature of so-called solventogenic clostridia which belong to heterofermentative, Gram-positive, sporulating bacteria performing acetone-butanol-ethanol (ABE) fermentation. Unfortunately, the main bottleneck of the process, which prevents its industrial application, is low final butanol concentration caused by poor butanol tolerance of the production strains.

Objectives

To overcome this problem, different mutation and adaptation techniques were tested to obtain more tolerant strains (in comparison to parent *Clostridium beijerinckii* strain). The strains exhibiting more tolerant phenotype were further used for butanol production.

Methods

For obtaining mutant strains, chemical mutagenesis using ethyl methanesulfonate (EMS) was used. The obtained mutants were grown in media containing increasing butanol concentration using bromcresol purple as growth indicator, because vegetative multiplication of *C.beijerinckii* is associated with acids production. In addition, butanol adapted strains were prepared by repeated re-inoculation of vegetative cells or spores to media with increasing butanol concentration. The strains exhibiting the most tolerant phenotype were further tested for butanol production under substrate non-limiting conditions i.e. in media containing high sugar concentration.

Conclusions

High tolerance and high production features are rarely present together. However mutant and adapted strains showing both these properties will be a subject of further investigation which will be focused on finding the cause of this win-win situation.

NEW COLORIMETRIC ASSAY FOR HYALURONIC ACID DETERMINATION IN COMPLEX SAMPLES

S. Pepeliaev[1], D. Smirnou[1], J. Jana[1], F. Lukáš[1], Č. Zbyněk[1], V. Vladimír[2]
[1]Contipro A.S., Fermentation group, Dolní Dobrouč, Czech Republic
[2]Contipro A.S., CEO, Dolní Dobrouč, Czech Republic

Backgrounds

Hyaluronic acid (HA) is a unique biopolymer widely used in medicine and cosmetics. The knowledge of precise HA concentration is a must in pharmaceutical and cosmetic production as well as in diagnostics. There are several groups of methods routinely used for HA quantification each having its own advantages and drawbacks. The right choice of an appropriate method is based on HA concentration range, complexity of sample and good understanding of principles of the given method.

Objectives

Introduction of a new colorimetric assay for HA determination and its comparison with already existing methods. Selection of the most appropriate method depending on application.

Methods

New enzyme-coupled colorimetric assay with high sensitivity and range based on HA digestion with Streptococcus pneumoniae hyaluronan lyase SpnHl and subsequent colour reaction of unsaturated disaccharides with 3-methyl-2-benzothiazolinone hydrazone. Comparison of the new assay with already known methods based on turbidimetry, colorimetry, immunoprecipitation, gravimetry, high performance liquid chromatography, gel electrophoresis.

Conclusions

Newly presented assay for HA determination offers the highest sensitivity among the known colorimetric methods, is reasonably fast, safe and inexpensive. The assay has modular structure and thus is very flexible: it could be used for a variety of samples detecting HA in range 1-2000 µg/ml. The presented assay could replace other methods in applications not demanding nanogram-scale sensitivity. Such applications are yield control in biotechnological production of HA, quality control of HA-containing pharmaceuticals and cosmetics, HA content determination in skin, joints, vitreous humour and other tissues and organs relatively rich in HA. For nanogram-scale application the ELISA-based assays are recommended.

NOVEL AND UNFORESEEN TRAITS OF THE REGULATORY CIRCUIT MASTERED BY DNTR, THE REGULATOR OF 2,4-DINITROTOLUENE BIODEGRADATION IN BURKHOLDERIA CEPACIA R34

D. Perez-Pantoja[1], P. Nikel[2], M. Chavarria[3], V. de Lorenzo[4]
[1]Universidad Tecnológica Metropolitana, Programa Institucional de Fomento a la I+D+i, Santiago, Chile
[2]Technical University of Denmark, The Novo Nordisk Foundation Center for Biosustainability, Lyngby, Denmark
[3]Universidad de Costa Rica,
Escuela de Química & Centro de Investigaciones en Productos Naturales CIPRONA, San José, Costa Rica
[4]Centro Nacional de Biotecnología CNB-CSIC, Programa de Biología de Sistemas, Madrid, Spain

Backgrounds

B. cepacia R34 mineralizes the xenobiotic compound 2,4-dinitrotoluene (DNT) owing to the dnt genes encoding the Rieske-type (RTDO) DNT dioxygenase (DNTDO) that are transcriptionally controlled by the LysR-type DntR regulator.

Objectives

In this work we addressed for the first time the regulatory network mastered by DntR revealing several traits previously unnoticed in the multiple studies performed in surrogate hosts.

Methods

For an accurate assessment of the regulatory role of substrates and enzymes implied in this system we first evaluated the suitability of naphthalene as a DNTDO substrate and its deleterious effect over host physiology. Experiments of substrate consumption and oxidative stress revealed that naphthalene is a DNTDO substrate as good as DNT but its metabolization is much less stressful for the native host. We accomplished the generation of a dntR mutant derivative and confirmed its role as the exclusive activator of DNTDO-encoding genes in response to salicylate. The detailed description of the regulatory system commanded by DntR was performed by using gfp transcriptional fusions to the PdntA promoter and the previously uncharted PdntR promoter, revealing a striking positive autoregulation by this activator. The utilization of naphthalene in addition to salicylate as inducer revealed the requirement of a DNTDO substrate for full activation of both promoters, thereby counteracting any gratuitous induction. Additionally, a dntAa mutant derivative revealed that a strain harbouring an inactivated DNTDO showed maximal induction by salicylate in both promoters irrespective of naphthalene presence. This suggested that the dioxygenase is able to block the activation by DntR and that the presence of a substrate would release such a repression.

Conclusions

The regulatory circuit described in this work suggests that communication between the activity of RTDO and the system controlling their expression is a key trait that explains the widespread presence of this conspicuous enzymatic family in routes evolved for degradation of xenobiotics.

SYNTHETIC ADHESINS TO TARGET ENGINEERED E. COLI TO HUMAN TUMORS EXPRESSING EGFR

C. Mañas[1], E. Pico[1], L.Á. Fernández-Herrero[1]
[1]Centro Nacional de Biotecnología CNB-CSIC, Biotecnología microbiana, Madrid, Spain

Backgrounds

E. coli and other anaerobic bacteria can colonize solid tumors. We have previously developed a way to improve the colonization ability of *E. coli* to solid tumors by engineering the expression on the bacterial surface of synthetic adhesins (SAs) that bind to specific surface antigens expressed on tumor cells [1]. SAs are based on single domain antibodies (nanobodies) fused to the β-domain of Intimin. This technology was originally tested *in vitro* and *in vivo* using SAs binding GFP, which was expressed on the surface of HeLa tumor cells.

Objectives

Apply the SAs technology into relevant human tumor models naturally expressing a validated surface tumor antigen, such as the epidermal growth factor receptor (EGFR). Bladder and colon cancers are adequate models since EGFR is frequently overexpressed by these tumor cells and these organs represent a good environment for *E. coli*.

Methods

We have generated SAs against EGFR based on our previous selection of nanobodies binding EGFR [2]. SAs of higher affinity and specificity were integrated in the chromosome of *E. coli* and their expression and binding to EGFR was confirmed by flow cytometry analysis. The engineered *E. coli* strains with these SAs bind specifically to bladder and colon carcinoma cell lines expressing EGFR.

Conclusions

We have generated SAs against human EGFR that allow the specific binding of *E. coli* to human bladder and colon carcinoma cells expressing this tumor antigen.

[3]University of Salento, Department of Biological and Environmental Sciences and Technologies, Lecce, Italy
[4]University of Salento,
Laboratory of Analytical and Isotopic Mass Spectrometry- Department of Cultural Heritage, Lecce, Italy

Backgrounds

The metabolic pathways leading to industrially relevant secondary metabolites production, like antibiotics, usually compete for pools of metabolic intermediates common to the biosynthetic processes necessary for bacterial growth. *In silico* modelling and omic-approaches are becoming crucial to provide system level comprehension of bacterial metabolism, enabling the identification of new strategies to obtain industrially relevant engineered strains.

Objectives

In this study we characterized the metabolic landscape of *Streptomyces ambofaciens,* an industrial producer of antibiotics, anti-fungal and iron-chelating compounds, to predict new metabolic engineering targets for their overproduction.

Methods

We took advantage of the recently published *S. ambofaciens* genome sequence and of databases for gene/protein function prediction to reconstruct its metabolic model,manually refining it to improve the accuracy of growth rate predictions and to include antibiotic production pathways. The integration of time-resolved transcriptomic data with Flux Balance Analysis was then adopted to highlight the metabolic adjustments occurring in different growth conditions. At the same time Flux Scanning based on Enforced Objective Flux (FSEOF) analysis was performed to identify new targets for antibiotic production increase.

Conclusions

A metabolic model of *S. ambofaciens,* including 1244 genes and spyramicin, antimycin, stambomycin and congocidine complete pathways, was produced, and it represents a solid platform for the exploitation of *S. ambofaciens* biotechnological potential. Then, through different data integration, we outlined the main effects of gene expression changes on the overall metabolic reprogramming occurring during *S. ambofaciens* growth curve. Moreover, we identified a set of new potential overexpression target candidates for spiramycin over-production and experimentally validated one of them.

ESCHERICHIA COLI GROWTH AND HYDROGEN PRODUCTION USING BREWERY WASTE: OPTIMAL PRETREATMENT AND ROLE OF HYDROGENASES

A. Poladyan[1], *K. Trchounian*[1], *A. Trchounian*[1]
[1]*Yerevan State University, Department of Biochemistry- Microbiology and Biotechnology, Yerevan, Armenia*

Backgrounds

Dihydrogen (H_2) is a clean, renewable energy for the future. Brewery spent grains (BSG), one of the by-products of brewery production, were applied for *Escherichia coli* growth and H_2 production.

Objectives

E. coli BW25113 wild-type and hydrogenase (Hyd) mutants with deletions of genes for key subunits of Hyd1-4 (Δ*hyaB,* Δ*hybC,* Δ*hycE,* Δ*hyfG*), respectively, as well as Δ*hyaB*Δ*hybC* double mutant growth, redox potential kinetics and H_2 production were investigated upon BSGH utilization. After 24 h growth mutants biomass yields were ~0.3 g dry weight L^{-1}, closed to wild type value, and ~1.8 fold less compared with the data of wild type bacteria grown on peptone medium (PM) with glycerol. However, specific growth rates were similar, even ~1.1 fold stimulated upon Δ*hyaB*Δ*hybC* double mutation. Readings of redox Pt electrode dropped up to -400 ±10 mV, with H_2 yield of 0.75 mmol/L at the 3rd h of wild type growth and persisted until 48 h. Whereas, redox Ti-Si electrode readings drop was negligible and kept positive in contrast to glycerol fermentation in PM. H_2 production was not observed with defective Hyd3 and Hyd4, therefore, Hyd3 and Hyd4 are responsible for H_2 production using BSGH, whereas defective Hyd1 and Hyd2 led to up to 2 fold stimulation of H_2 yield.

Methods

The dilute acid and alkali pretreatment methods were used to hydrolyze the lignocellulose structure; and the BSG hydrolysate (BSGH) optimal conditions for bacterial growth and H_2 production were designed.

Conclusions

These findings might be useful for development of H_2 production biotechnology using different organic wastes.

BIOTRANSFORMATION AND VALORIZATION OF RESIDUES AND WASTES BY FUNGAL LIPASES

M. Molina-Gutiérrez[1], N.L.S. Hakalin[1], M.D. Moldovan[1], L. Rodríguez-Sánchez[2], M.J. Martínez[1], A. Prieto[1]
[1]Centro de Investigaciones Biológicas CIB-CSIC, Environmental Biology, Madrid, Spain
[2]Centro de Investigaciones Biológicas CIB-CSIC, Gas Chromatography, Madrid, Spain

Backgrounds

Across the last decade, the use of lignocellulosic wastes for bioethanol production has been promoted, as they constitute a renewable, available and inexpensive feedstock that does not compete with food production. Industrial manufacture of 2G-bioethanol is already a fact, but to yield a profitable process, not only the polysaccharides from plant biomass must be exploited. The lipid fraction of some residues may contain interesting components to be used for industrial purposes upon their appropriate transformation, for example, in esters. These esters are generally produced by chemical catalysis, but most of these reactions can also be performed by clean and soft procedures, using biocatalysts.

Objectives

Commercial preparations with lipase or sterol esterase activities, and the versatile lipase secreted by *Ophiostoma piceae* (OPE), were compared as catalysts of the synthesis of esters of biotechnological interest using industrial residues as lipid sources. The enzymes were immobilized and their effectiveness and recyclability compared.

Methods

Lipid fractions were extracted from biomass and used as substrates for enzymatic conversion by CalA, CalB or OPEr. Reactions were developed at 28 °C in a vertical mixer. The reaction products were analyzed by TLC or GC. Enzymes were covalently immobilized onto silanized magnetic nanoparticles (MNPs) as mCLEAs or by specific linkage to amino-functionalized-MNPs.

Conclusions

Fatty acid-esters of phytosterols, hydroxycinnamic acids, and short-chain alcohols can be synthetized using the assayed fungal lipases, although with different efficiency. Enzyme immobilization onto MNPs allows easy recovery of the catalyst for further recycling.

A NOVEL PROGRESSIVE CLUSTERING APPROACH FOR CREATING ECOLOGICAL NETWORKS REVEALS THE STRUCTURE OF MICROBIAL COMMUNITIES AT DIFFERENT SCALES

F. Puente-Sánchez[1], J. Tamames[1]
[1]Centro Nacional de Biotecnología-CSIC, Systems Biology, Madrid, Spain

Backgrounds

Usual methods for building ecological networks are based on co-occurrences between two taxa. But since microbial communities are probably structured by interactions between multiple partners, these approaches are likely to miss most of the complexity of natural microbiomes.

Objectives

Our main goal was to design a procedure capable to identify aggregations of taxa that can constitute building blocks nucleating the whole community, and characterise them from the ecological and functional point of view.

Methods

We have devised a new method for creating networks, in which a progressive, agglomerative clustering procedure is used to recover modules of co-occurring organisms. The modules have different size, from two taxa to tens of them. We have used the samples in microDB database (http://botero.cnb.csic.es/envDB), comprising more tan 20.000 environmental samples from all kind of environments. The usage of this huge set of information required the development of a new scoring measure adapted to the presence/ausence data characteristic of this database.

Conclusions

We have found specific modules for each environment, but also many that can be shared. These modules act like a nucleating unity to which other taxa can adhere to form progressively bigger communities. We have characterized these paths of aggregation using the genome content of the taxa on them, studying the metabolic similarity or divergence of the newly recruited taxa. Thus we are able to study patterns of functional redundancy and complementation, finding that redundancy is more prevalent. We also show the correlation between particular metabolic pathways and niche specialization.

MULTI-OMICS OF PSEUDOALTEROMONAS HALOPLANKTIS TAC125: A QUEST FOR ANTIMICROBIAL METABOLIC PATHWAYS

M. Fondi[1], E. Perrin[1], A. Fiore[2], G. Diretto[2], I. Maida[1], A. Sutera[3], G. Renzone[4], G. Gallo[3], A. Scaloni[4], A.M. Puglia[3], C. Barbara[5], L. Carraro[5], R. Fani[1]
[1]University of Florence, Dep. of Biology, Florence, Italy
[2]Ente Nazionale per le Nuove Tecnologie- l'Energia e l'Ambiente, Dip. Innovazione-Divisione Biotecnologie e Agricoltura, Rome, Italy
[3]University of Palermo, Dip. STEBICEF, Palermo, Italy
[4]National Research Council, ISPAAM, Naples, Italy
[5]University of Padova, Dep. of Comparative Biomedicine and Food Science, Padova, Italy

Backgrounds

The Antarctic strain *Pseudoalteromonas haloplanktis* TAC125 is one of the model organisms of cold-adapted bacteria and is currently exploited as a new alternative expression host for numerous biotechnological applications. Interestingly, this bacterium has been reported to be able to inhibit the growth of *Burkholderia cepacia* complex (Bcc) strains, opportunistic pathogens responsible for the infection of immune-compromised patients. Most likely, this occurs through the synthesis of several different compounds, including Volatile Organic Compounds (VOCs), whose nature and characteristics are currently mostly unknown.

Objectives

To obtain a complete picture of cellular processes differentially regulated and associated with the capability of inhibiting Bcc growth.

Methods

Transcriptomic, proteomic and metabolomic experiments were carried out on *P. haloplanktis* TAC125 grown using two different cultivation media in which the strain is able to inhibit or not Bcc growth.

Conclusions

Bcc growth inhibition capability is deeply linked to the medium used to cultivate *P. haloplanktis* TAC125. Therefore, multi-omic data integration was used in order to explain the emergence of *P. haloplanktis* TAC125 phenotypes and, specifically, of cellular functional states associated to capability of inhibiting Bcc growth. In perspectives, the design of more focused strategies for a rational biotechnological exploitation of this strain will be boosted by the approach used and the results obtained in this work.

PRODUCTION OPTIMIZATION OF AN ANTICANCER COMPOUND, PRODIGIOSIN, FROM SERRATIA SP. S2B AND DESIGN OF ITS DRUG DELIVERY SYSTEM TO TARGET CELLS, USING NANOCARRIER

B. Rastegari[1], H.R. Karbalaei-Heidari[1], S. Zeinali[2], S. Heather[3]
[1]Shiraz University, Biology, Shiraz, Iran
[2]Shiraz University, Nanochemical engineering, Shiraz, Iran
[3]McMaster University, Chemical engineering, Hamilton, Canada

Backgrounds

Among several thousands of microbial secondary metabolites, the prodiginine family is considered as an antimicrobial, antimalarial, immunosuppressive, and remarkable anticancer agent - The selective cytotoxicity effect on malignant cell lines has motivated researchers to introduce them as a potent anticancer drug The main drawback of prodigiosin like other poor water soluble drugs is its limited bioavailability therefore, must be bound to biocompatible polymers to remain in its effective concentration in blood.

Objectives

Production optimization of the prodigiosin from a newly isolated bacterium, *Serratia* sp. S2B and its introduction as a selective anticancer drug to breast and hepatic cancerous cells by the design of protein based nanocarriers and polysaccharide coated magnetic nanoparticles.

Methods

A new bacterial strain S2B which produces prodigiosin was isolated and characterized as *Serratia* genus via 16S rDNA sequencing. Pigment production was optimized by assessment of different carbon, nitrogen sources and physicochemical factors effects using statistical approaches. Furthermore, the interaction of prodigiosin with human serum albumin and β- lactoglobulin as intravenous and oral scaffolds was studied by fluorescence, circular dichroism spectroscopy and molecular docking methods. Finally, fabrication of magnetite nanoparticles using chitosan and β-cyclodextrin was conducted to design an active targeting system.

Conclusions

Pigment production was optimized using low-cost medium containing sugar beet molasses and ammonium sulfate. The sulfate was introduced as an important factor in regulation of pigment biosynthesis pathway. Both tested protein nanocarriers as well as chitosan coated magnetic nanoparticles can be introduced as smart drug delivery system for breast and hepatic cancer chemotherapy

SMALL RNAS ACTIVATED BY THE PHOSPHATE STARVATION RESPONSE REGULATOR PHOP IN STREPTOMYCES

S. Martín-Martín[1], M. Ordóñez-Robles[1,2], F. Santos-Beneit[1,3], A. Sola-Landa[1], R. Pérez-Redondo[1], J.F. Martín[2], A. Rodríguez-García[1,2]
[1]Asociación de Investigación INBIOTEC Instituto de Biotecnología de León, Área de Genómica, León, Spain
[2]Universidad de León, Área de Microbiología- Departamento de Biología Molecular, León, Spain
[3]Center for Bacterial Cell Biology, Newcastle University, Newcastle, United Kingdom

Backgrounds

Streptomycetes are bacteria of high biotechnological relevance due to their diverse secondary metabolite production. Secondary metabolites are produced only under some nutritional conditions, e.g., phosphate starvation. As occurs in other bacteria, in *Streptomyces* the two-component system PhoR-PhoP triggers the response to phosphate limitation. PhoR, the sensor kinase, phosphorylates and, hence, activates the response regulator PhoP. The number of two-component systems that contain sRNAs (small RNAs) in their regulons is growing. sRNAs can inhibit or activate the expression of several target genes.

Objectives

Our general objective was to explore the role of sRNAs on the response to phosphate starvation mediated by the PhoR-PhoP two component system in *Streptomyces*.

Methods

Parental strain M145 and Δ*pho*P mutant strain INB201 of *Streptomyces coelicolor* were cultured in flasks containing defined MG medium. Samples were taken from 36 h to 42 h of culture, when phosphate becomes depleted from the medium and the *pho* regulon is activated. The transcriptomes of both strains were analyzed using dRNA-seq and bioinformatically predicted transcripts served to design Agilent 4x44k microarrays. Then, RNA samples were chemically label to avoid retrotranscription artefacts. Microarray profiles were analyzed as previously (PMID: 17623301).

Bioinformatics searches predicted putative PhoP binding sites in sRNA promoters. Gel-retardation and DNase I footprinting analyses were used to validate PhoP binding.**Conclusions**

A total of 74 sRNAs were identified as putative members of the *pho* regulon. Binding assays confirmed that the response regulator PhoP directly activates at least four of them.

Biotechnology / Synthetic Biology / Systems Biology - Part III

OMICS ANALYSES OF PHYTOSTEROLS-INDUCING DIFFERENTIAL EXPRESSION IN 'MYCOBACTERIUM NEOARUM' NRRL B-3805, A PRODUCER OF THE STEROIDS PRECURSOR ANDROSTENEDIONE

I. Vázquez-Iglesias[1], A. Morales[1], P. González-Álvarez[2], M. Castro-Mariñas[2], A. Sola-Landa[2], A. Rodríguez García[2], C. Barreiro[1]
[1]Asociación de Investigación INBIOTEC Instituto de Biotecnología de León, Área de Proteómica, León, Spain
[2]Asociación de Investigación INBIOTEC Instituto de Biotecnología de León, Área de Genómica, León, Spain

Backgrounds

The microbial bioconversion of phytosterols into steroid precursors is an industrial process that allows the economical production of steroid drugs. Phytosterols are a cheap source of the steroid carbon skeleton. '*Mycobacterium neoaurum'* NRRL B-3805 is a UV-mutant of a soil isolate that efficiently degrades the phytosterols side chain and produces the steroid precursor 4-androstene-3,17-dione (AD). The availability of the complete genome sequence of this strain, recently published by the group (PMID: 26988397), allows the development of transcriptomics and proteomics analyses.

Objectives

To identify key bioconversion genes for further improvement of the strain by means of a differential expression comparison between cells cultured in media with or without added phytosterols.

Methods

Cells were cultured in defined medium containing glycerol or glycerol plus sterols as the carbon sources. 2D-DIGE proteome analyses (intra- and extra-cellular) were performed and proteins were subsequently identified by means of a MALDI-TOF/TOF mass spectrophotometer. RNAseq data served to identify transcribed regions and then to design probes for differential transcriptomics with Agilent 8x15k microarrays. Metabolic pathway analysis were carried out using the BioCyc web server, which allowed the identification of pathways involved in sterols bioconversion.

Conclusions

The analysis of the results showed expression profiles clearly conditioned to the sterols addition, as well as, sterols dependent proteins/genes, which suggest a sterol specific response.

Biotechnology / Synthetic Biology / Systems Biology - Part III

A DNA METHYLATION-DEPENDENT SWITCH FOR THE CONSTRUCTION OF BIOLOGICAL SENSORS

D. R. Olivenza[1], *I. Cota*[1], *J. Casadesús*[1]
[1]*Universidad de Sevilla, Departamento de Genética, SEVILLA, Spain*

Backgrounds

The *Salmonella enterica ovpAB* operon encodes inner membrane proteins that control O-antigen chain length. Expression of *opvAB* undergoes phase variation under transcriptional control by Dam methylation and OxyR.

Objectives

We intend to use the OpvAB phase variation system for the construction of artificial toggle switches with potential uses as biological sensors.

Methods

A ~700 bp DNA fragment containing the *opvAB* promoter and the upstream control region is used to drive phase-variable transcription of reporter genes (e. g., the *E. coli lac* operon and the green fluorescent protein gene, *gfp*). The constructions are active in both *S. enterica* and *E. coli*.

Conclusions

1. A strain carrying a *gfp* fusion downstream of *opvAB* provides a highly sensitive sensor of Dam methylase inhibition. The size of the ON subpopulation permits quantitative assessment of the inhibition (measured by either fluorescence intensity or β-galactosidase activity). A sensor of this kind can be useful to search for drugs that inhibit DNA methylation.

2. OpvAB^{OFF} cells are sensitive to bacteriophages that target the O-antigen while OpvAB^{ON} cells are resistant. In the presence of a bacteriophage, OpvAB^{ON} cells take over the culture. The presence of a bacteriophage can thus be detected by an increase in fluorescence (if a *gfp* fusion is used) or in β-galactosidase activity (if a *lac::gfp* fusion is used). A sensor of this kind can be useful to monitor the presence of bacteriophages (and, in an indirect manner, to detect the presence of bacteriophage-sensitive bacterial cells).

BACTERIAL COMPUTATION USING PLASMIDS AS WIRES: POWERING THE MACHINE

R. Fernandez Lopez[1]
[1]*IBBTEC, Molecular Biology, Santander, Spain*

Backgrounds

Biological computation is a fundamental topic on synthetic biology. Usually the approach is to design gene regulation networks able to modulate reporter genes in response to chemical or physical inputs.

This approach poses some problems, specially related to scaling the computing system:

- Diffusible chemical signals are non-directional.

- There are few Input-regulator pairs available .

- Gene regulation is a stochastic process with big fluctuations associated.

Objectives

To address these issues we propose bacterial conjugation. It is a directional, modular, and binary system of communication, computing modules can be used as much as they are needed in a network and there are plenty of different orthogonal channels described (~50 relaxase-oriT pairs).

Bacterial conjugation consists on the cut and transport of a bacterial plasmid from a bacterium to another in contact using a Type IV Secretion System. Conjugative plasmids carry all the necessary genes. When these plasmids do not carry the secretion system genes, they are called *mobilizable*. As every gene involved in the process is essential, they can be complemented in *trans* (allowing conditional operations and building of AND gates).

Methods

In this work we first characterized conjugation of model plasmid R388 (40kb, IncW) and found an intrinsic limitation to the conjugation efficiency (number of plasmid transmissions per donor cell and per generation); as long as we need a highly efficient communication system, the original system was modified in order to increase this conjugation rate. For this purpose we used a systems biology approach, tuning gene expression of T4SS components.

Conclusions

. .

THE ROLE OF 3-HYDROXY-3-METHYLGLUTARYL COA REDUCTASE OF USTILAGO MAYDIS (HMGRUM) AND A PROPOSED RECOMBINANT ENZYME (REC-HMGRUM) TO TEST ANTIFUNGAL COMPOUNDS AND LIPID-LOWERING

B. Rosales Acosta[1], M.D.L. Villa Tanaca[1], J.A. Ibarra Garcia[1], C.H. Hernandez Rodriguez[1]
[1]Escuela Nacional de Ciencias Biológicas - Instituto Politécnico Nacional, MICROBIOLOGY, México, Mexico

Backgrounds

The enzyme 3-hydroxy-3-methylglutaryl Coenzyme A reductase (HMGR), catalyzes the synthesis of mevalonate from 3-hydroxy-3-methylglutaryl CoA, the key compound in the synthesis of cholesterol in humans and ergosterol in fungi. HMGRs have been widely studied in fungi because they share structural similarity with those from mammals. Amongst the most studied HMGRs are those from a *Saccharomyces cerevisiae*, *Saccharomyces pombe*, *Candida glabrata* and *Candida albicans*.

A phylogenetic analysis multiple HMGR from different organisms showed that the HMGR from human chas a higher similarity with that from *Ustilago maydis* than with other fungal HMGRs. Currently, several drugs have been designed derivatived from statins for using as hypolipemc that inhibit HMGR activity and hence cholesterol synthesis. System models used to test these drugs range from rat liver extracts to the use of a recombinant human HMGR, buts this latter is a hazle as it is hard to acquire the latter as it is the product of a human gene.

Objectives

To evaluate the effect of specific inhibitors of the enzyme 3-hydroxy-3-methylglutaryl CoA reductase from *Ustilago maydis* to know the role that this enzyme plays in the fungus life cycle

Methods

Using in silico analysis, the ORF codifying for HmgrUm wasidentified and the protein characteristics were deduced. The effect ofthe competitive inhibitors of HmgrUm on the viability of thisbasidiomycota, the synthesis of its sterols, and its mating wereevaluated.

Conclusions

In conclusion, the HmgrUm is proposed as a study model to test lipid-lowering and antifungal compounds

DIRIGENT PROTEINS AS VERSATILE TOOLS IN BIOTECHNOLOGY

J.F. Rosengarten[1], K.R. Hayes[2], J. Pietruszka[3], M. Holz[2], T. Classen[1]
[1]Institut für Bio- und Geowissenschaften IBG-1- Forschungszentrum Jülich GmbH, Chemie, Jülich, Germany
[2]Institut für Bioorganische Chemie der Heinrich-Heine-Universität Düsseldorf im Forschungszentrum Jülich, Chemie, Jülich, Germany
[3]Institut für Bio- und Geowissenschaften IBG-1- Forschungszentrum Jülich GmbH / Institut für Bioorganische Chemie der Heinrich-Heine-Universität Düsseldorf im Forschungszentrum Jülich, Chemie, Jülich, Germany

Backgrounds

The introduction of regio- and stereoselectivity to reactions does often go along with many efforts in the course of chemical synthesis. Dirigent Proteins (DPs) are promising tools used by nature to mediate selectivity towards usually unselective laccase-catalyzed reactions. The reaction for which DPs have been initially described is the coupling of two coniferyl alcohol radicals to yield optically pure (+)- or (-)-pinoresinol during lignan biosynthesis (1, 2, 3, 4).

Objectives

Although research in the field of DPs is ongoing since the first member of the DP family has been presented in 1992 (5), there is still much space left for their deeper investigation. Hereby, one of the main challenges is their soluble expression in the common lab workhorse *Escherichia coli*, as formation of inclusion bodies has been observed (4).

Methods

In our work we have generated an expression system allowing the recombinant production of the prominent Dirigent Protein AtDIR6 from *Arabidopsis thaliana* in a soluble form in bacteria. We are aiming at the detailed study of the molecular mechanisms of these bacterially produced DPs as well as at their application for synthetic purposes.

Conclusions

Our results give first evidence for the bacterial production of recombinant DPs in a soluble form and in scale allowing for in-depth studies of the purified protein.

ROLE OF TRANSCRIPTION ACTIVATOR CAT8 IN REGULATION OF XYLOSE METABOLISM AND ALCOHOLIC FERMENTATION IN THE THERMOTOLERANT YEAST OGATAEA POLYMORPHA

J. Ruchala[1], O. Kurylenko[2], K. Dmytruk[2], A. Sibirny[1,2]
[1]University of Rzeszow,
Faculty of Agriculture and Biology- Department od Biotechnology and Microbiology, Rzeszów, Poland
[2]Institute of Cell Biology- NAS of Ukraine, Department of Molecular Genetics and Biotechnology, Lviv, Ukraine

Backgrounds

Ogataea polymorpha is thermotolerant yeast capable of glucose, cellobiose and xylose fermentation, however, ethanol yield from xylose is very low. Several approaches have been developed for construction of the advanced ethanol producers from xylose; still ethanol yield and productivity from xylose have to be further improved. Till now, nobody studied the role of transcription activators in regulation of xylose metabolism and fermentation. We paid attention on Cat8 transcription activator involved in regulation of gluconeogenesis and catabolism of alternative carbon sources in *Saccharomyces cerevisiae*.

Objectives

We aimed to construct strains with deletion and overexpression of *CAT8* gene on background of the wild type and the best available ethanol producer of *O. polymorpha* and study the effects of such genetic modifications on xylose and glucose alcoholic fermentation.

Methods

Standard methods of yeast molecular genetics and biochemistry have been used.

Conclusions

Deletion of *CAT8* gene in *O. polymorpha* did not have effect on glucose alcoholic fermentation. At the same time, constructed knock out strains showed an improved xylose alcoholic fermentation relative to the parental strains. The ***cat8Δ*** strains isolated from the best available ethanol producer of *O. polymorpha* accumulated up to 12.5 g of ethanol/L at 45°C after 3 day fermentation without correction for evaporation or 25 times more relative to the wild-type strain. At the same time, overexpression of *CAT*8 inhibited xylose alcoholic fermentation. Accumulated data suggest that Cat8 protein acts as the specific regulator of xylose alcoholic fermentation. Expression of the genes involved in xylose fermentation was assayed.

UNCONVENTIONAL CATANIONIC MIXTURES OF GREEN SURFACTANTS: SYNERGIC ANTIMICROBIAL ACTIVITY

A. Ruiz[1,2], A. Pinazo[1], L. Pérez[1], A. Manresa[2], A. Marqués[2]
[1]IQAC-CSIC, Department of Chemical and Surfactant Technology, Barcelona, Spain
[2]Fac. of Pharmacy and Food Science - University of Barcelona, Lab. of Microbiology, Barcelona, Spain

Backgrounds

The huge consumption of surfactants in the biotechnological industry has created a strong demand for compounds that are more effective and environmentally friendly, as well as having new properties, such as antimicrobial activity. Catanionic mixtures present a wide variety of organized assemblies and aggregates with improved physicochemical and biological properties.

Objectives

In this work an anionic biosurfactant (lichenysin) was mixed with a battery of cationic amino acid-based surfactants ($C_3(CA)_2$, CAM, LAM, LLM, 1010R and $HisC_{12}$) in order to explore the surfactant molecular requirements for synergic antimicrobial activity.

Methods

The MICs of the surfactants and the catanionic mixtures were determined and the effect against the pathogens was observed using electron microscopy.

Conclusions

The gemini surfactant $C_3(CA)_2$ was found to be the most effective and its mixture was the only one that presented synergic antimicrobial activity against *Escherichia coli* O157:H7 (15.7 μM), *Yersinia enterocolitica* (7.8 μM), *Bacillus subtilis* (3.9 μM) and *Candida albicans* (7.8 μM). Electron microscopy images showed that $C_3(CA)_2$ changed its mode of action when mixed with lichenysin. Our hypothesis is that the catanionic aggregate is able to approach the anionic cell envelope by electrostatic interactions with its free cationic charge, which enables the lipopeptide to become attached to the cell membranes, thus enhancing the antimicrobial effect. On the other hand, when the cationic surfactant is completely neutralised, as occurred in the catanionic mixtures of lichenysin and monomeric amino acid-based surfactants, no synergic antimicrobial activity is detected.

EXTRACELLULAR ENZYMES PRODUCTION BY THE IMMOBILIZATION OF FILAMENTOUS FUNGI

Z. Suleimenova[1]
[1]*LLP Antigen, Biochemistry, Almaty, Kazakhstan*

Backgrounds

Almost all chemical reactions in a biological cell need enzymes which do differ from most other catalysts since they are highly specific for their substrates. As specific catalysts enzymes generally catalyze the conversion of only one type of substrate molecule into product molecules. That is why they are now finding widespread application in food and feed, beverage, detergent, biofuel, paper, brewing industries, molecular biology etc.

Objectives

Filamentous fungi are major producers of enzymes that have important applications in the food and beverage industries. The overall objective of this research is a strain improvement technology.

Methods

The new way of filamentous fungi cultivation method has been developed. It prolong producers' cultivation period up to 60 days and create the opportunity to obtain enzymes repeatedly in every 3 days of cultivation. This method is based on immobilizing enzymes producers with solid support in submerged conditions of growth. Design of proposed equipment gives the opportunity to increase the activity of immobilized cells culture filtrate comparing to free cells, growing in periodic culture conditions.

Conclusions

Such equipment construction allows to give a 10-times raise in fungal productivity; to prolong the process of fungi cultivation and periods of active culture liquid generation. Also, new devices and equipment give the way to improve quality of filtrates (to make them more clear) and exclude time-consuming processes.

ANTIBIOTICS PRODUCED BY PAENIBACILLI AND THEIR GENETICALLY MODIFIED DERIVATIVES AS A SOLUTION TO MULTIRESISTANT INFECTIONS

C. Salsano[1], S. Didelot[1], C. Barthélémy[1], V. Thiéry[1], R. Chevrot[1]
[1]Littoral Environnement et Sociétés LIENSs UMR CNRS 7266,
Institut du Littoral et de l'Environnement ILE Approches moléculaires environnement santé AMES, LA ROCHELLE, France

Backgrounds

With the rise in bacterial resistance and overuse of antibiotics, it is more and more difficult to find efficient treatments against human infections.

Objectives

One solution would be to discover new treatments or enhance existing molecules by genetic engineering.

Methods

In our team we have isolated two novel antibiotic producing strains of *Paenibacillus,* B-LR and P-32, from the environment and a sputum of a cystic fibrosis patient respectively. *Paenibacilli* are ubiquitous bacteria that produce antibiotics such as polymyxins and fusaricidins. These molecules are synthesized using specific enzymes called Nonribosomal Peptide Synthetases (NRPS). The strains B-LR and P-32 inhibit the growth of *Pseudomonas aeruginosa* and *Staphylococcus aureus* clinical strains (including methicillin resistant strains). These peptides were purified and characterized by LC-MS. B-LR produces polymyxin E (colistin) and ten different molecules while P-32 synthesizes a new depsipeptide. Two genomic libraries were constructed and screened in order to find the gene clusters responsible for the biosynthesis of these molecules. Thanks to this screening, the colistin gene cluster was discovered in B-LR. This new gene cluster covers 41 kb and includes 5 ORF. Three of them encode for NRPS involved in the colistin synthesis, whereas two others are ABC transporter-like genes that may release the antibiotic.

Conclusions

This study constitutes the first description of the biosynthesis pathway of this commercial antibiotic. Given that most of the antibiotics are nonribosomal peptides, our work could contribute to a better understanding of their biosynthesis. Moreover, it could lead to the biotechnological development of the pharmaceutical production of optimized antibacterial treatments.

CHARACTERIZATION OF A NOVEL ACETYLESTERASE AE-6L, USEFUL TO OBTAIN NEW FAMILIES OF LIPOPHILIC POLYPHENOLS WITH BROAD PHARMACOLOGICAL AND BIOTECHNOLOGICAL INTEREST

L. Sánchez Barrionuevo[1], A. González Benjumea[2], D. Cánovas López[3], J. Fernández Bolaños[2], I. Maya[2], Ó. López[4], M.T. García[1], E. Mellado[1]
[1]University of Seville, Department of Microbiology and Parasitology, Seville, Spain
[2]University of Seville, Department of Organic Chemistry, Seville, Spain
[3]University of Seville, Department of Genetics, Seville, Spain
[4]University of Seville, Department of Organic Chemistry-, Seville, Spain

Backgrounds

Natural phenolic compounds derived from olives display a potent and diverse profile of bioactivities, which make them excellent candidates for their use in pharmacology. However, the modification of this type of compounds to improve their properties is hindered by the limits of organic chemistry, as most of such procedures involve the use of hazardous reagents or non-green conditions, and they can only offer limited options.

Objectives

The aims of this work are to obtain a novel derivatives of the olive-derived phenolic compounds hydroxytyrosol, protocatechuic alcohol and 3,4-dihydroxyphenylglycol with improved lipophilic properties, but retaining their antioxidant capabilities

Methods

We have identified, cloned and purified an acetylesterase (AE-6L) from the lipolytic microorganism *Bacillus sp*. HR21-6, which can be used for tailoring a new set of compounds with broad biotechnological interest. The enzyme has been characterized including thermostability assays with the aim to optimize its industrial use. Site directed mutagenesis studies were performed to map the active sites and other conserved amino acids of AE-6L in order to identify the critical residues of the aminoacid sequence involved in the regioselectivity.
Finally, to substantiate the different bioactivities of these novel compounds, we have performed antioxidant, cytotoxicity and genotoxicity assays to evaluate their potential as anti-inflammatory compounds or in the prevention/treatment of cancer.

Conclusions

The performance of this work has allowed the development of novel catalytic procesess and the availability of a battery of semisynthetic regioisomers displaying different physicochemical properties.

ABRA1/A2, A KEY REGULATOR OF DEVELOPMENT AND ANTIBIOTIC PRODUCTION IN STREPTOMYCES COELICOLOR

R. Sánchez de la Nieta Moreno[1], *S. Antoraz Martín*[1], *R.I. Santamaría Sánchez*[1], *M. Díaz Martínez*[1]
[1]*University of Salamanca- CSIC, Department of Microbiology and Genetics, Salamanca, Spain*

Backgrounds

Two-component systems (TCSs) are included between the most important transduction signal mechanisms in bacteria, and are involved in many processes such as energetic metabolism or production of secondary metabolites. The AbrA1/A2 TCS has been described as a negative regulator of morphological differentiation and antibiotic production in *Streptomyces coelicolor*.

Objectives

The aim of this study is deciphering the regulon of AbrA1/A2 TCS.

Methods

Microarrays analysis comparing the wild-type strain and the corresponding mutant Δ*abrA1*/*A2* identified different expression of some key genes in metabolism (e.g. *SCO4562-4575*, *SCO4988-4990*), morphological differentiation (e.g. *chpA*, *rdlB*) and antibiotic production (e.g. *actII-4*, *redD*, *cdaR*). In this work, we use a promoter-probe system based in the production of the red antibioticic undecilprodigiosin to evaluate the regulation of promoters of interest *in vivo*. *S. coelicolor* M512 (a strain that does not produce any coloured antibiotic) and the isogenic mutant strain Δ*abrA1*/*A2* were used as hosts in the experiments.

Conclusions

The knowledge obtained may help us in the design of interesting strains to be applied in the biotechnology industry.

GENOME MINING OF THE LICHEN-ISOLATED STRAIN AMYCOLATOPSIS PRETORIENSIS CA-128772

M. Sánchez-Hidalgo[1], C. Díaz-Muñoz[1], I. González[1], J.R. Tormo[2], C. Moreno[2], J. Martín[2], O. Genilloud[1]
[1]Fundación MEDINA, Microbiology, Granada, Spain
[2]Fundación MEDINA, Chemistry, Granada, Spain

Backgrounds

Mining the genomes of microbial strains has become a main approach in the discovery of new secondary metabolites. While the genomes of *Streptomyces* spp. have been widely explored, *Amycolatopsis* spp. genomes have begun to be sequenced recently[1]. Strains from this genus are known to produce commercially important antibiotics such as balhimycin, vancomycin or rifamycin, which biosynthetic gene clusters (BGCs) have been characterized[2]. Many other cryptic BGCs have also been identified in the genomes of these strains, which pave the way for the discovery of novel compounds.

Objectives

Our main objective is to mine the genome of *Amycolatopsis pretoriensis* CA-128772*,* isolated from lichen samples collected in tropical areas from Hawaii[3]*,* in order to identify and characterize cryptic BGCs.

Methods

The *A. pretoriensis* CA-128772 genome was analyzed with antiSMASH[4] and PRISM[5] to detect potential BGCs. The strain was fermented in different media and incubation times. Fermentation broths were extracted and the metabolite profile of the extracts was analyzed.

Conclusions

The draft genome size was around 10.2 Mb with a GC content of 71.8%. A total of 140 putative BGCs were predicted, including lanthipeptides, lassopeptides, PKS-I, NRPS, terpenes, siderophores and bacteriocins. The connection between the predicted pathways and the detected compounds was established.

[3]Universitat Autonoma de Barcelona, Servei de Microscopia, Barcelona, Spain
[4]Universitat Autonoma de Barcelona, Servei de Cultius Cel·lulars- Producció d'Anticossos i Citometria SCAC, Barcelona, Spain
[5]Hospital de la Santa Creu i Sant Pau, Institut d'Investigacions Biomèdiques Sant Pau, Barcelona, Spain

Backgrounds

We have recently described an architectonic principle at the nanoscale that allows generating self-assembling nanoparticles formed by engineered proteins produced in bacteria. T22 is a cationic ligand of the cell surface cytokine receptor CXCR4, that specifically binding CXCR4+ cells also acts as an architectonic tag in GFP-based particles (T22-GFP-H6). Since CXCR4 is overexpressed in diverse malignant cancers, including colorectal cancer, pancreatic cancer and lymphoma, these protein constructs are promising vehicles for targeted drug delivery.

Objectives

The aim of this project was to insert the fusogenic peptide hemagglutinin-2 (HA2) from influenza virus to the protein T22-GFP-H6 in order to evaluate potential enhancement of cell internalization of the modified nanoparticles. HA2 is found on the surface of virus particles and is known to destabilize the lipid cell membrane to promote escape from the endosomes at acidic pH.

Methods

The engineered proteins were produced in *Escherichia coli* and purified through a His tag affinity chromatography. Physicochemical characterization was performed using Coomassie blue staining, Western blot, mass spectrometry, Dynamic Light Scattering and confocal and scanning electron microscopy. Cultured CXCR4+ Hela cells were also used for *in vitro* experiments to elucidate the internalization kinetics.

Conclusions

The addition of HA2 in two different positions (T22-HA2-GFP-H6 and T22-GFP-HA2-H6) provides an enhanced cell penetration although it is accompanied by a loss of specificity, especially when the HA2 is placed close to T22. Probably it is due to intra or intermolecular interactions that affect the exposure of the ligand, which is critical for the nanoparticle’s internalization.

EXTERNALLY ADDED CHOLINE-BINDING MODULES (CBMS) TARGET THE PNEUMOCOCCAL CELL WALL AND AFFECT BACTERIAL GROWTH

M. Sánchez[1], B. Maestro[2], E. Roig[2], F. Garcia-Asencio[3], J. Sanz[2]
[1]Universidad Miguel Hernandez, Dpt. Vegetal Production and Microbiology, Elche - Alicante, Spain
[2]Universidad Miguel Hernandez, Instituto de Biología Molecular y Celular, Elche - Alicante, Spain
[3]Universidad Miguel Hernandez, Instituto de Neurociencias, San Juan de Alicante - Alicante, Spain

Backgrounds

Streptococcus pneumoniae (pneumococcus) is one of the major bacterial pathogens. Due to the raise of antibiotic resistance, the search and development of new antimicrobial molecules is one of the main needs in modern Public Health services.

Objectives

One of the most attractive targets are the choline-binding proteins (CBPs). These are essential for cell processes such as viability, host colonization and virulence. Pneumococcal CBPs make use of the so-called choline-binding modules (CBMs) to specifically adsorb onto the bacterial cell wall through binding to the phosphorylcholine residues in the teichoic acids. In vitro experiments had shown that addition of CBMs from the LytA amidase, CbpD protein and the phagic CPL1 lysozyme (C–LytA, C-CbpD and C–CPL1 respectively) competes with their parental cell-wall hydrolases and inhibit their function. Thus CBMs might constitute a novel kind of anti-pneumococcal molecules.

Methods

To evaluate that, we first estimated the binding affinities of C–LytA, C-CbpD and C–CPL1 to DEAE-functionalised magnetic nanoparticles as bio-inspired mimics of the cell wall. The results indicate that all modules greatly differ in their binding mode and affinity to both free choline and DEAE nanoparticles.

Next, all CBMs were externally added to exponential cultures of *Streptococcus pneumoniae* R6. The chimeric proteins bind to the bacterial surface immediately and caused the inhibition of cell separation, leading to long bacterial chains and sedimenting aggregates.**Conclusions**

This results suggests that the use of CBMs might represent promising candidates for a streamlined action against pneumococcus based on bacterial aggregation and subsequent phagocytosis.

Biotechnology / Synthetic Biology / Systems Biology - Part III

GROWTH OF THERMUS THERMOPHILUS IN WATER-IN-OIL MICRODROPLETS

M. Sanchez[1], *E. Sanchez*[1], *J. Berenguer*[1], *A. Hidalgo*[1]
[1]*Centro de Biología Molecular Severo Ochoa UAM-CSIC, MOLECULAR BIOLOGY, MADRID, Spain*

Backgrounds

Microfluidic devices allow the generation of monodisperse water in oil microdroplets of picoliter volume that can be subsequently used for the incubation and manipulation steps required for super-high throughput screening at very low cost in personnel and equipment. The inclusion of single cells into these microdroplets and their growth could be used for in vivo screening of enzymes and products as also for cell biology studies

Objectives

To develop protocols for the growth of extreme thermophiles in water in oil microdroplets

Methods

Thermus thermophilus derivatives expressing thermostable derivatives of the Yellow Fluorescent Protein were included in microdroplets to analyse their growth capability by fluorescent microscopy

Conclusions

T. thermophilus can growth for several hours and form microcolonies inside microdroplets. Such microdroplets are stable for days and can be subjected to enzyme-presence assays

This work has been funded by the European project “MetaFluidics” (GA nº 685474)

SELECTION AND IDENTIFICATION OF CHITINASE PRODUCING BACTERIA RECOVERED FROM THE ANTARCTIC ENVIRONMENT

Y. Santa Cruz Vasquez[1], *A. Duarte Fernandes*[2], *T. Rodrigues e Silva*[1], *V. Maia de Oliveira*[1]
[1]*University of Campinas UNICAMP, Institute of Biology, Campinas, Brazil*
[2]*Federal University of Alagoas, Campus Arapiraca, Arapiraca, Brazil*

Backgrounds

The Antarctic environment has extreme climatic conditions, especially low temperatures, high incidence of UV radiation and water deficit. In this sense, microorganisms that survive in this environment are known as psychrophiles and psychrotolerant or "cold tolerant". So, the isolation of microorganisms may allow access to a genetic resource with biotechnological potential and little explored.

Objectives

The aim of this study was to investigate the ability of bacterial isolates recovered from Antarctica to produce cold-active chitinase at low temperature.

Methods

A total of 560 bacteria were isolated from marine sediments, macroalgae, sea star and sea sponge samples collected in Antarctica during the summer of 2013 following cultivation in R2A medium and incubation at 15 ºC. The functional screening was performed using c*olloidal chitin prepared* from shell of crab (Sigma) as carbon source. These assays were evaluated in 96-deep well plates incubated at 15 ºC and all positives strains were cultured individually at 5 and 15 °C during 326 h. Identification of the chitinase producers was done based on sequencing and phylogenetic analysis of 16S rRNA gene using *10f and 1100r* primers.

Conclusions

Nineteen chitinase producing bacteria producers of chitinase were identified as belonging to the genus Arthrobacter (A. psychrochitiniphilus and A. alpinus) and one to the genus Curtobacterium (C. luteum). The largest halos indicatingchitinase production were observed infor A. psychrochitiniphilus 492, followed by A.psychrochitiniphilus 363 of under incubation at 15 °C for 326 h. These bacteria are promising candidates for biotechnological processes at low temperature.

TAXONOMIC ASSESSMENT AND ANTIMICROBIAL SCREENING OF BACTERIA ISOLATED FROM MARINE AND TERRESTRIAL ANTARCTIC SAMPLES

Y. Santa Cruz[1], T. Rodrigues e Silva[1], A. Fernandes Duarte[2], V. Maia de Oliveira[1], F. Fantinatti-Garboginni1[1], M. Zambrano Passarini[3]
[1]University of Campinas, Institute of Biology, Campinas, Brazil
[2]Federal University of Alagoas, Campus Arapiraca, Arapiraca, Brazil
[3]Latin-American University UNILA, Biotechnology, Foz do Iguaçu, Brazil

Backgrounds

Microorganisms dominate most of the Antarctic environment and play a crucial role in its functioning and primary productivity. Several numbers of studies have shown that there is a great biodiversity in the polar regions and different types of biological activities.

Objectives

The aim of the present study was to survey microorganisms from Antarctic samples in the search for antimicrobial and antagonistic effects of clinical interest.

Methods

The screening of antimicrobial substances was performed by the agar diffusion method. Six hundred strains previously isolated from Antarctic samples were tested against the indicator strains *E. coli, Micrococcus luteus, Staphylococcus aureus, Bacillus subtilis* and *Candida albicans* for antimicrobial production. Bacterial identification was achieved by comparing the 16S rRNA sequences obtained with sequence data from reference type strains, as well as public databases GenBank and RDP.

Conclusions

Phylogenetic analysis revealed that most isolates shared high sequence similarity to recognized species, including those recovered previously from the Antarctica environment, which belong to four major phyla: Firmicutes, Bacteroidetes, Actinobacteria and Proteobacteria (Alpha and Gammaproteobacteria classes). A total of 361 bacterial strains, distributed in 38 different genera, were identified based on the 16S RNAr gene. The major representatives were *Arthrobacter*, *Psychrobacter*, *Pseudoalteomonas* and *Rhodococcus*. Antimicrobial screening revealed sixteen strains capable of inhibiting growth of, at least, one of the indicator strains. The psychrotolerant bacterial isolate *Pseudomonas mandelii* 99 showed a broad antimicrobial spectrum and low values in MIC assay and was then selected for further antiproliferative and antiparasitic tests. Our findings demonstrated that the extremophilic bacteria from Antarctica represent an untapped source of microorganisms capable of antimicrobial metabolite production.

UNDERSTANDING THE RATE LIMITING STEP IN XYLOSE UPTAKE IN CRYPTOCCOCUS HUMICOLA FOR BIOETHANOL PRODUCTION

A.C. Ramos Validvia[1], T. Ponce Noyola[1], L.M. Salgado Rodriguez[2], A. Santiago Benítez[1]
[1]CINVESTAV, Biotechnology and Bioengineering, Mexico City, Mexico
[2]CICATA, Scientific and Technologic Research, Queretaro, Mexico

Backgrounds

The fermentation of hexoses and pentoses of lignocellulosic origin is sought in the process of bioethanol production. Xylose is the second most abundant sugar in agroindustrial residues; for this reason scientists have searched microorganisms capable of xylose assimilation and fermentation. *Cryptococcus humicola* with the ability to grow in xylose, was isolated from *mezcal* mash in Oaxaca, Mexico. Due to its ability to also grow and ferment glucose and cellobiose, it is proposed as a good object of study for possible industrial application. Xylose reductase (XR) and xylitol dehydrogenase (XDH) are key enzymes in yeast for the production of ethanol from xylose.

Objectives

To understand the rate limiting step in xylose fermentation in *C. humicola* through the study of the enzymatic activity of XR and XDH, in addition to their level of expression.

Methods

C. humicola was cultivated in minimum medium in order to observe the inductive effect of the carbon source and aeration on enzyme activity. XR and XDH specific activities were measured under these conditions.

Conclusions

It was observed that even when the highest values of specific activity were found when the yeast was grown in xylose and in anaerobic conditions, xylose consumption and xylitol production were lower compared to aerobic conditions. It is, therefore, proposed that xylose intake seems not entirely dependent of enzymatic activity of XR and XDH or enzyme quantity but it is rather limited by other factors like redox state imbalance or low enzyme activity further in the route.

Biotechnology / Synthetic Biology / Systems Biology - Part III

DESIGNING RECOMBINANT BIOCATALYSTS FOR THE EFFICIENT REMOVAL OF AROMATIC ENDOCRINE DISRUPTING COMPOUNDS

D. Sanz[1], *J.L. García*[1], *E. Díaz*[1]
[1]*CIB-CSIC, ENVIRONMENTAL BIOLOGY, Madrid, Spain*

Backgrounds

Endocrine disruptors chemicals (EDCs) are persistent contaminants that distrub the endocrine system of humans and animals. The alkyl or di-alkyl esters of *o*-phthalic acid (1,2-benzenedicarboxylic acid) are synthesized in large quantities for the plastic industry and constitute one of the main sources of EDCs with carcinogenic activities [1].

Despite microbial degradation is an ecosystem friendly strategy to remove phthalates only few microorganisms have been identified as phthalates degraders in aerobic conditions and none of them degrade anaerobically phthalate esters. Hence, improving our knowledge on the biodegradation of toxic phthalates is crucial to develop new detoxification strategies.

Objectives

Engineering recombinant biocatalyst for the efficient removal of phthalates both under aerobic and anaerobic conditions.

Methods

Construction of mobilizable synthetic catabolic cassettes containing the genes for the uptake and conversion of *o*-phthalate to the central intermediate benzoyl-CoA [2], Efficient expression of the cassetes in model bacteria of the *Azoarcus* and *Cupriavidus* genus able to degrade benzoyl-CoA under anaerobic and/or aerobic conditions. Improving *o*-phthalate cassettes by engineering phthalate esterases able to remove the alkyl side chain(s) of the EDC phthalates.

Conclusions

Recombinant bacterial strains have been engineered for the first time for the efficient uptake and removal of *o*-phthalate and its mono- and di-alkyl esters under anaerobic (*Azoarcus* strains) or aerobic (*Azoarcus* and *Cupriavidus* strains) conditions. This work paves the way for a promising alternative to current phthalates detoxification strategies.

BIOENERGETICS OF PHOTOFERMENTATTION: EFFECT OF PROTONOPHORES OF MEMBRANE-ASSOCIATED ATPASE ACTIVITY IN RHODOBACTER SPHAEROIDES

H. Sargsyan[1], L. Gabrielyan[1], A. Trchounian[1]
[1]Yerevan State University, Biochemistry- Microbiology and Biotechnology, Yerevan, Armenia

Backgrounds

Nowadays, the current interest of bioenergetics in purple bacteria is their hydrogen (H_2) production ability. This process is mediated by nitrogenase, which requires energy of ATP; proton motive force is also required.

Objectives

In this work the effects of two protonophores (carbonyl cyanide m-chlorophenylhydrazone (CCCP) and 2,4-dinitrophenol (DNP)), and *N,N'*-dicyclohexylcarbodiimide (DCCD) on the F_oF_1-ATPase activity in *Rhodobacter sphaeroides* MDC6521 (from Armenian mineral springs) were studied in various illumination conditions.

Methods

The bacterium was cultivated in Ormerod medium anaerobically with carbon source – succinate. ATPase activity was measured by amount of inorganic phosphate, liberated after adding ATP to membrane vesicles of *R. sphaeroides,* which were prepared by Kaback's method. The H_2 yield was evaluated by the redox potential drop to low negative values during bacterial growth.

Conclusions

CCCP and DNP dissipate the proton motive force, which is responsible for ATP synthesis, whereas DCCD inhibits the ATP synthesis by blocking the proton flux through the F_oF_1-ATPase. The F_oF_1-ATPase activity of membrane vesicles was inhibited by DCCD on ~2 fold. Both protonophores stimulate ATPase activity on ~1.5-fold, which might be connected with compensation of proton gradient, dissipated by protonophores. H_2 yield is decreased ~5.0-7.5-fold in the presence of 0.5 mM CCCP and 10 mM DNP, respectively; and is not observed by addition of 2 mM CCCP and 50 mM DNP. This effect is coupled with suppression of ATP synthesis by photophosphorylation, which is important for nitrogenase-dependent photofermentative H_2 production by purple bacteria.

The results obtained would be important for understanding of bioenergetics of photofermentative H_2 production.

MODULATING THE REDOX HOUSEHOLD OF LACTOBACILLUS DIOLIVORANS BY THE CARBON FEED

A.K. Lindlbauer[1], H. Marx[1], M. Sauer[2]
[1]BOKU - University of Natural Resources and Life Sciences, Department of Biotechnology, Vienna, Austria
[2]BOKU - University of Natural Resources and Life Sciences, Department of Biotechnolog, Vienna, Austria

Backgrounds

Biorefineries can only be economically viable, when no waste stream is created, but the harvested biomass is entirely used and valorized. Biodiesel biorefineries produce large amounts of lignocellulosic biomass remaining from oil milling and the transesterification process leads to crude glycerol as a major side stream. Microbial processes for the valorization of these side streams to fuels or chemicals are highly desirable. It appears crucial for those tasks to exploit nature's biodiversity. Here, we report about an economic process for 1,3-propanediol production with the lactic acid bacterium *Lactobacillus diolivorans*. While the organism cannot grow on glycerol as sole carbon source it readily uses glycerol as electron acceptor, when a sugar is present.

Objectives

The objective of this work was to characterize the metabolism of *L. diolivorans* in respect to the carbon feeding strategy. Glucose and glycerol are co-metabolized. Part of the glycerol is reduced to 1,3-propanediol, while another part is oxidized to 3-hydroxypropanoic acid.

Methods

The microorganisms are grown in bioreactors under tightly controlled conditions. Different carbon feeding strategies have been tested and the cultures have been analyzed in respect to carbon uptake and metabolite accumulation.

Conclusions

Concluding, we can show that a pulsed addition of glucose shifts the glycerol metabolism nearly exclusively to its reductive branch, yielding 1,3-propanediol. This is in contrast to a constant glucose feed, which leads to the oxidation of a significant fraction of the glycerol. We speculate that not the uptake rate but the concentration of glucose in the medium is the decisive factor for the redox metabolism.

SCALING UP BIOREMEDIATION IN SOILS HIGHLY POLLUTED WITH HYDROCARBONS

M. Seeger[1], R. Orellana[2], M. Gonzalez[3], F. Cárdenas[3], A. Cumsille[3], C. Rojas[2], C. Stuardo[3], R. Wittwer[3], E. Becerra[3]
[1]Universidad Tecnica Federico Santa Maria, Chemistry, Valparaiso, Chile
[2]Universidad Técnica Federico Santa María, Chemistry, Valparaíso, Chile
[3]Universidad Técnica Federico Santa María, Chemistry, Valparaiso, Chile

Backgrounds

Petroleum hydrocarbon pollution is a global problem faced within the vicinity of urban and industrial areas and represent a significant health risk. Microbial degradation of hydrocarbons have been applied for bioremediation of polluted soils. Bioremediation approaches are often based on bioaugmentation using exotic hydrocarbon-degrading microorganisms or on biostimulation of the native communities using nutrients. The main knowledge on microbial degradation is based on lab scale studies, whereas its variation under *in situ* conditions remains unknown.

Objectives

The aim of this study is to compare bioremediation rates in hydrocarbon polluted soils at lab scale and field scale experiments.

Methods

On one side, bioaugmentation and biostimulation incubation experiments based on 1 L mesocosms were carried out. On the other side, degradation kinetic to similar treatments of 400 L biopiles were carried out outdoor during two months. For bioaugmentation a consortia of selected bacterial strains were applied. Biostimulation was done by the addition of organic amendments. Hydrocarbons were quantified by GC-FID. Culturable heterotrophic bacteria were monitored by CFU counting.

Conclusions

Both bioremediation approaches were able to remove hydrocarbons from soils at lab and field scale. At similar initial concentration of petroleum hydrocarbons, higher degradation rates in lab scale experiments were observed. In conclusion, laboratory scale studies, where conditions are acutely controlled and microbial communities can be managed, yielded higher degradation rates. Key factors determining the difference in degradation rates are discussed. This study emphasizes the need for more detailed analysis in field studies, which are crucial to move on industrial bioremediation of soils polluted with hydrocarbons.

METABOLIC ENGINEERING OF THE YEAST SACCHAROMYCES CEREVISIAE FOR CONSTRUCTION OF ANAEROBIC OVERPRODUCER OF GLYCEROL

M. Semkiv[1], K. Dmytruk[1], C. Abbas[2], A. Sibirny[1]
[1]Institute of Cell Biology NAS of Ukraine, Department of Molecular Genetics and Biotechnology, Lviv, Ukraine
[2]Archer Daniels Midland Co, Research Center, Decatur IL, USA

Backgrounds

Glycerol is widely used in the cosmetic, food and pharmaceutical industries. The promising way for glycerol production is microbial fermentation. Yeast *Saccharomyces cerevisiae* could be used for cost-effective glycerol production under anaerobic conditions, however, such producers have not been described yet. In *S. cerevisiae* glycerol synthesis starts from dihydroxyacetone phosphate by subsequent action of glycerol-3-phosphate dehydrogenase (Gpd1) and glycerol-3-phosphate phosphatase (Gpp2). Synthesized glycerol is exported via channel formed by aquaglyceroporin Fps1. In the wild-type strains, dihydroxyacetone phosphate is predominantly isomerized to glyceraldehyde-3-phosphate by triose phosphate isomerase (Tpi1) and subsequently converted to pyruvate and eventually to ethanol. Enzyme acetolactate synthase (Ilv2) can convert pyruvate to acetolactate and CO_2 thus decreasing amount of pyruvate available for alcohol dehydrogenase reaction which competes for NADH with Gpd-reaction.

Objectives

We aimed to construct recombinant strain with reduced Tpi1 activity, increased Gpd1 and Gpp2 activities, constantly active form of Fps1 channel and expression of cytosolic form of Ilv2.

Methods

Homologous recombination was used for partial substitution of *TPI1* gene promoter region with selective marker. Multicopy integration module was used for expression of hybrid fused *GPD1-GPP2* ORF under the control of strong promoter. Modified gene *FPS1* (with eliminated part encoding amino acid residues 76-230) and truncated gene *ILV2* were expressed under the control of *ADH1* promoter.

Conclusions

The constructed strain BY/tpi25/gpd1gpp2f/fps1m/ilv2 accumulated up to 9 times more glycerol under micro-aerobic conditions and up to 4.7 times more glycerol under anaerobic conditions relative to the parental strain. The increase in glycerol production led to a drop in ethanol and biomass accumulation.

ANTIBIOTIC-FREE SELECTION PLASMIDS IN STREPTOMYCES

L. Sevillano[1], M. Diaz[1], R.I. Santamaria[1]
[1]Salamanca University, IBFG, SALAMANCA, Spain

Backgrounds

Streptomyces is a promising bacterial expression system that has been used to produce high levels of several proteins. In previous work, we described a new strategy for the stabilization of expression plasmids in *Streptomyces* based on the use of a toxin-antitoxin system (*yefM/yoeBsl*) as selection marker. We demonstrated the effectiveness of this system for the production of high levels of proteins without the use of antibiotics during the production step. However, the host used and the expression vectors still have the antibiotics resistance genes needed for its construction.

Objectives

The objective of our work is the improvement of this system by the elimination of the antibiotic resistance genes still present in the host and in the expression plasmid.

Methods

We have integrated the toxin gene (*yoeBsl*) in the genome with a new plasmid, pTES-tox, that has the target sites for the Cre recombinase (*loxP*) flanking the toxin gene and the phage attachment site (*attP*). Thus, after the expression of Cre recombinase we have deleted the plasmid backbone leaving only the toxin gene in the genome. In the same way, we have introduced the target sites for the Dre recombinase (*rox*) flanking the neomycin gene in the expression plasmid, the subsequent expression of the recombinase allowed us to delete it.

Conclusions

We describe a system completely free of antibiotic resistance genes that is useful for the production of high yields of proteins in *Streptomyces*. This system could be a powerful tool for using *Streptomyces* as host to produce proteins at industrial and pharmaceutical level.

HIGH CAROTENOID PRODUCTION BY A HALOTOLERANT BACTERIUM, KOCURIA SP. STRAIN QWT-12 AND ANTICANCER ACTIVITY OF ITS CAROTENOID

S.A. Shahzadeh fazeli[1], A. Safarpour[2], M.A. Amoozegar[3]
[1]Iranian Biological Resource Centre, Microorganisms bank, Tehran, Iran
[2]University of Science and Culture, 4. Department of Developmental Biology, tehran, Iran
[3]University of Tehran, Department of Microbiology, Tehran, Iran

Backgrounds

Carotenoids are yellow to orange-red pigments widely distributed among nature of many organisms. Their existence happens from bacteria, yeast and algae to animal and plant cells

Objectives

Halophilic prokaryotes are extremophile microorganisms that grow optimally in media containing salts and almost appeared pigmented and many of them contain high concentrations of carotenoids. Several halophiles isolated from industrial wastewaters with upper mediate salinity.

Methods

Water samples were obtained from tannery wastewater of a company in Qom, Iran. After cultivation of samples, yellow colonies were selected and purified. Carotenoids of the selected strain were extracted by methanol. MTT assay for extracted Carotenoid was carried out to assess the viability of seven cancer cell lines belonging to Breast, Lung and Prostate cancer with negative control of fibroblast cell line through six concentration levels to find out IC50. .

Conclusions

Strain QWT-12 is a Gram-stain-positive coccoid, aerobic, non-endospore-forming, halotolerant bacterium and showed high capacities in the production of yellow carotenoids in a wide range of culture medium factors. Based on statistical analysis of data from MTT assay, IC50 of 1, 4, 4 and 8 mg/ml for MCF-7, A549, MDA-MB-468 and MDA-MB-231 was found respectively. According to the obtained results from TLC and Mass Spectrophotometry, absorption spectrum of carotenoid from strain QWT-12 is similar to the absorption spectrum of the carotenoid neurosporene. In this study we exhibited that strain QWT-12 has pigment likewise nourosporene pigments as major carotenoid pigment and its pigment were found to be cytotoxic against several cancer cell lines after 48 h with cell line specific activities. Carotenoids have been shown to suppress the cancer cell *in vitro* and *in vivo* and among different carotenoids,

CAROTENOIDS PRODUCTION WITH BIOLOGICAL ACTIVITY BY RHODOTORULA MUCILAGINOSA FROM SOLID WASTE COFFEE PROCESSING

C. Silva[1], M. Dias[1], M. Melo[1], J. Coimbra[1], R. Schwan[1], L. Batista[2]
[1]Federal University of Lavras, Biology/ Microbiology, Lavras, Brazil
[2]Federal University of Lavras, Food Science, Lavras, Brazil

Backgrounds

The three coffee process generates liquid and solid waste known as husks, pulp and waterwaste. Specially husks and pulp can be used as substrate to fermentation process producing add-value compounds.

Objectives

This work was aimed to evaluate the antioxidant and antimicrobial activities of carotenoids produced by *Rhodotorula mucilaginosa* CCMA 0156 in submerged fermentation using coffee processing solid waste

Methods

The production medium contained coffee pulp extract (6.68 %) added by yeast extract (3 g/L), peptone (10.04 g/L), glucose (2 g/L) and Tween 80 (0.5 %) or husk extract (8.36 %) added by peptone (3.68 g/L), glucose (6.36 g/L) and Tween 80 (0.5 %). The production of total carotenoids by yeast in the pulp extract was 16.36 mg/L (being 4.1% compound of β-carotene) and husk extract was 21.35 mg/L (being 4.5% compound of β-carotene).

Conclusions

Carotenoids produced, exhibited antioxidant and antimicrobial activities against pathogenic bacteria as *Salmonella colorless*, *Escherichia coli*, *Staphylococcus aureus* and *Listeria monocytogenes* and toxigenic fungi as *Aspergillus flavus*, *A. parasiticus*, *A. carbonarius* and *A. ochraceus.* These characteristics of these pigments are important for many industries. Mainly the food industry has become increasingly interested in the use of microbial technology to produce colors for use in foods. It can also help to overcome the growing public concern over the adverse health effects of addition of synthetic colors in food products.

BIOEMULSIFIER ACTIVITY ANALYSIS OF NOVEL PROTEIN FROM BACILLUS SUBTILIS

A. Simancas[1], T. Weiyi[2], F. Molina[1], S. Li[2]
[1]Universidad de Extremadura, Bioquímica- Biología Molecular y Genética, Badajoz, Spain
[2]Nanjing Tech University, School of Biotechnology and Pharmaceutical Engineering, Nanjing, China

Backgrounds

Biofilms in dairy industry are produced in instruments by contaminant bacteria from genus such as *Bacillus* and *Staphylococcus*, among others. These structures confer increased bacterial resistance to antibiotics and both chemical and mechanical removal, leading to a higher risk of microbiological contamination during the manufacturing processes. Despite being extensively used; these methods are often not efficient. Thus, we have started to develop a biocontrol strategy based on the use of bioemulsifier proteins, with the final aim of creating a bacterial strain suitable for reducing or eliminating these biofilms.

Objectives

We wanted to test *in vitro* bioemulsifier activity as well as emulsion stability of our novel isolated protein from *Bacillus subtilis* (strain CICC 20034), still under characterization, using different kinds of substrates, media and conditions. Additionally, we have compared the protein activity with other detergents such as SDS, Tween 20 or household detergent.

Methods

Novel protein was isolated and purified through HPLC techniques. Bioemulsifier activity was assayed, along with other detergents, measuring emulsion layer on glass vials with a 1:1 proportion of sterile water and substrate after 2 days of incubation.

Conclusions

The protein we have studied has proved in our *in vitro* tests to be a reliable alternative to the use of other detergents, leading to a possible application in the removal of biofilms in the dairy industry.

EFFECT OF TRIMETHYLATED POLY-(D)GLUCOSAMINE NANOPARTICLES CARRYING BACTERIOFERRITIN PROTEIN OF HELICOBACTER PYLORI FOR CANCER TREATMENT

N. Soleimani[1]
[1]*Shahid Beheshti University- Faculty of Life Sciences and Biotechnology, Department of Microbiology and Microbial Biotechnology, tehran, Iran*

Backgrounds

Breast cancer is one of the leading causes of death in women around the world. Conventional treatments use cytotoxic drugs which have high levels of side effects. Today's pharmacology is looking novel drugs for treatments with low side effects and maximum efficiency. The Helicobacter pylori neutrophil-activating protein (bacterioferritin) is a virulence factor that attracts and activates neutrophils, and promotes their endothelial adhesion and the production of oxygen radicals and chemokines. bacterioferritin is an immune modulator able to induce the expression of IL-12 and IL-23. In this study, we were evaluate, Preparation of trimethylated Poly-(D)glucosamine Nanoparticles carrying recombinant bacterioferritin Helicobacter pylori pylori for Breast cancer treatment.

Objectives

In this study, we were evaluate, Preparation of trimethylated Poly-(D)glucosamine Nanoparticles carrying recombinant bacterioferritin Helicobacter pylori pylori for Breast cancer treatment.

Methods

In this study, purification of recombinant H. pylori bacterioferritin was performed by Ni–NTA affinity chromatography. trimethylated Poly-(D)glucosamine Nanoparticles were produce. The size and morphology of the nanoparticles were investigated. recombinant bacterioferritin Helicobacter pylori were produce. SDS-PAGE analysis showed the expression of an approximately 20000 Dalton protein. Statistical analysis showed that bacterioferritin had not toxic effects on 4T1 cells in a concentration of 500 ng/ml after 24 and 48 h, and this toxic dose was not after 72 h.

Conclusions

bacterioferritin had not direct toxic effects on Breast cancer cell and the toxicity was observed when in vivo study. Perhaps This protein can active T lymphocyte and this cell secretory effective cytokine and damage cancer cell. The complex has the potential to shift antigen-specific T-cell responses from a predominant Th2 to a polarized Th1 cytotoxic phenotype, characterized by high levels of interferon-γ and tumor necrosis factor-a production. bacterioferritin may be a new tool for future therapeutic strategies aimed in cancer immunotherapy.

PRODUCTION OF BERRY ANTHOCYANINS IN LACTOCOCCUS LACTIS

A. Solopova[1], P. Gaspar[2], J. Förster[2], O.P. Kuipers[1]
[1]GBB, Molecular Genetics, Groningen, The Netherlands
[2]Danmarks Tekniske Universitet, Biosustain, Hørsholm, Denmark

Backgrounds

Anthocyanins have been used in folk medicine for generations, but only recently the specific pharmacological properties of these compounds became the target of extensive studies. In addition to their antioxidant properties, anthocyanins are valuable for their colors. The food industry actively searches for natural alternatives, such as anthocyanins, to replace synthetic dyes. Exploitation of microbial hosts as cell factories is an attractive alternative to extraction of anthocyanins and other flavonoids from plant sources or chemical synthesis. Lactic acid bacterium *Lactococcus lactis* is a promising host for production of plant high value chemicals. It has a long history of safe usage in food fermentations and has been granted a GRAS (Generally Regarded As Safe) status.

Objectives

Our aim was to reconstruct the pathway for plant anthocyanin cyanidin 3-*O*-glucoside production from flavan-3-ol catechin in a Gram-positive bacterium *L. lactis*.

Methods

Native genes coding for anthocyanidin synthase and anthocyanidin 3-*O*-glucosyltransferase from plants and synthetic codon-optimized genes were assembled to form a functional metabolic pathway in *L. lactis*.

Conclusions

Plant enzymes anthocyanidin synthase and anthocyanidin 3-*O*-glucosyltransferase were codon optimized and expressed in *L. lactis.* Anthocyanidin cyanidin and anthocyanin chrysanthemin (cyanidin 3-*O*-glucoside) were produced from flavan-3-ol catechin by engineered *L. lactis* strains and accumulated intracellularly. In summary, lactic acid bacterium *L. lactis* appears to be a valuable production host for plant-derived bioactive compounds for food applications.

Biotechnology / Synthetic Biology / Systems Biology - Part III

SOXR AS A SINGLE-CELL BIOSENSOR FOR OPTIMIZING NADPH-CONSUMING ENZYMES IN ESCHERICHIA COLI

A. Spielmann[1], *S. Siedler*[2], *M. Baumgart*[1], *M. Bott*[1]
[1]*Forschungszentrum Jülich, IBG-1, Jülich, Germany*
[2]*Technical University of Denmark, DTU BIOSUSTAIN, 2800 Kgs. Lyngby, Denmark*

Backgrounds

NADPH-dependent alcohol dehydrogenases (Adhs) play an important role in industrial biotechnology, especially for the production of chiral alcohols. A high-throughput *in-vivo* screening for these enzymes was established using suitable *Escherichia coli* reporter strains. The screening system is based on the genetically encoded NADPH biosensor pSenSox, which exploits the transcriptional regulator SoxR, its target promoter P_{soxS} and the reporter gene *eyfp*. It was shown that *E. coli* cells carrying pSenSox and expressing an NADPH-dependent *adh* of *Lactobacillus brevis* become fluorescent when the substrate methyl acetoacetate is reduced to (*R*)-methyl 3-hydroxybutyrate. Under suitable conditions, the specific fluorescence of the cells correlates with enzyme activity. Hence, the system enables high-throughput screening of large Adh libraries using fluorescence-activated cell sorting (FACS).

Objectives

As a prerequisite for potential improvements of the screening system, the NADPH biosensor was further characterized. Specifically, the influence of different growth media, hydrogen peroxide (H_2O_2), redox-cycling drugs (paraquat and menadione), the proposed SoxR reducing system (RseC and RsxABCDGE) and two transhydrogenases (SthA and PntAB) on the biosensor response was analyzed.

Methods

For the analysis of the biosensor response to altered conditions a BioLector® system was used. This system allows online recording of eYFP fluorescence and growth. HPLC analysis was used to confirm substrate biotransformation.

Conclusions

Except for H_2O_2, all other treatments influenced the sensor signal to different extent. These findings can be used for example to expand the dynamic range of the sensor, making it even more attractive and effective for the screening of NADPH-dependent Adh libraries.

Biotechnology / Synthetic Biology / Systems Biology - Part III

CLONING XYLOSE REDUCTASE AND XYLITOL DEHYDROGENASE GENES FROM SPATHASPORA YEASTS ISOLATED FROM BRAZIL

A. Mouro[1], G.F. Gubert[1], A.A. dos Santos[1], B. Stambuk[1]
[1]Universidade Federal de Santa Catarina- Centro de Ciências Biologicas, Bioquímica, Florianopolis, Brazil

Backgrounds

We analyzed the fermentation of xylose and glucose by 32 yeast strains isolated in Brazil. Under comparative conditions, yeasts from the *Spathaspora* clade produced more ethanol from xylose than from glucose. The determination in the *Spathaspora* yeast strains of xylose reductase, xylitol dehydrogenase and xylulokinase activities showed that all strains presented NAD^+-dependent xylitol dehydrogenase activity, and *Sp. passalidarum* had the highest activity of this enzyme. Interestingly, *Sp. passalidarum* and *Sp. arborariae* showed xylose reductase activities with both NADH and NADPH cofactors.

Objectives

From the draft genome sequence of *Sp. arborariae* and *Sp. passalidarum* we cloned xylose reductases and a xylitol dehydrogenase, and expressed them in a *Saccharomyces cerevisiae* strain overexpressing the endogenous xylulokinase gene (*XKS1*).

Methods

While the cloned xylose reductase gene from *Sp. arborariae* accepted both cofactors, the enzyme cloned from *Sp. passalidarum* used only NADPH, indicating the existence of different enzymes in this yeast. The genes expressed in *S. cerevisiae* allowed xylose consumption by the cells, and improved consumption rates were observed if the *PHO13* gene was deleted from the strain.

Conclusions

Thus, *Spathaspora* yeasts may be considered a valuable platform for new genes encoding enzymes involved in xylose fermentation to engineer industrial *S. cerevisiae* yeasts.

WASTE PRODUCTS FROM POULTRY INDUSTRY – THE SOURCE OF BIOACTIVE COMPOUNDS

H. Stiborova[1], B. Branska[2], P. Patakova[2], M. Jiru[3], J. Poustka[3], K. Demnerova[1]
[1]University of Chemistry and Technology, Biochemistry and Microbiology, Prague, Czech Republic
[2]University of Chemistry and Technology, Biotechnology, Prague, Czech Republic
[3]University of Chemistry and Technology, Food Analysis and Nutrition, Prague, Czech Republic

Backgrounds

Millions of tons of raw feather and biomass after chicken mechanical deboning are produced each year by the poultry industry. Despite the fact that feather contains more than 90% of protein keratin is simply disposed of in incineration plants.

Objectives

The aim of this study was to i) transform the raw feather waste using three different approaches (whole cell microbial digestion, enzymatic and chemical cleavage) and to test the usage of the hydrolysates as peptone substitutes in culture medium.

Methods

Among all isolated keratin-degrading bacteria, *Pseudomonas* sp. P5 achieved the highest feather hydrolysis. Over 300 mg/L of free amino acids and 6.2 g/L of peptides were released from 90 g/L of wet raw feather by microbial hydrolysis. Hydrolysates obtained by semi-purified keratinase contained 1191 mg/L of amino acids and 3.3 g/L of peptides. The highest amount of peptides (17.2 g/L) was achieved by mild alkali condition and this hydrolysate also proved the best properties as cultivation medium (1).

Conclusions

All approaches tested could convert raw feather waste into products of commercial value with proven use in a cultivation medium. The level of peptides, their molecular size and amino acid composition was dependent on the method used.

THE LANDSCAPE OF MICROBIAL PHENOTYPIC TRAITS AND THEIR GENETIC BASIS

M. Brbic[1], M. Piskorec[1], V. Vidulin[1], A. Krisko[2], F. Supek[1,3]
[1]Institut Ruđer Bošković, Division of Electronics, Zagreb, Croatia
[2]Mediterranean Institute of Life Sciences, Macromolecular homeostasis in aging, Split, Croatia
[3]Centre for Genomic Regulation, EMBL/CRG Systems Biology Research Unit, Barcelona, Spain

Backgrounds

Bacteria and Archaea display a variety of phenotypic traits and can adapt to diverse ecological niches. While the amount of sequenced genomes is increasing rapidly, systematic phenotypic annotation is not keeping pace, meaning that the potential for comprehensive genome-phenome association studies is yet to be realized.

Objectives

We have developed ProTraits, a computational pipeline that annotates microbes with phenotypes by text-mining the scientific literature and the broader World Wide Web, while also being able to define novel concepts from unstructured text.

Methods

ProTraits draws extensively on comparative genomics, capturing evolutionary patterns in gene repertoires, codon usage biases, proteome composition and co-occurrence in metagenomes. Notably, we find that gene synteny is highly predictive of many phenotypes, and highlight examples of gene neighborhoods associated to spore-forming ability. The ~545,000 inferred phenotypes are provided with false discovery rate estimates validated by literature curation and are available at http://protraits.irb.hr/. A global analysis of trait interrelatedness reveals a lower-dimensional structure that underlies the microbial phenotype space, suggesting common genetic underpinnings.

Conclusions

The extended set of phenotypic annotations allows detection of 57,088 high confidence gene-phenotype links - a 6.6-fold gain over previous databases. We highlight examples of recovered associations involving known sporulation, flagellar and catalase genes, as well as pathways linked to phenotypes such as aerobicity and photosynthesis. Over 99% of commonly occurring gene families are involved in genetic interactions conditional on a phenotype, suggesting that epistasis has a major role in shaping microbial gene repertoires.

BIOTECHNOLOGICAL POTENTIAL OF CAVES STRAINS

O. Suslova[1], *O. Tashyrev*[1]
[1]*Zabolotny Institute of Microbiology and Virology of the NAS of Ukraine, Biology of Extremophilic microorganisms, Kiev, Ukraine*

Backgrounds

Microbial biotechnologies became one of the most efficient ways to utilize wastewaters from mining or metal processing plants. The basic point of such technologies is bacterial strains that survive and interact with metals in high concentrations.

Objectives

During studies of microbial communities from Western Ukraine cave clays it was isolated two strains with high indexes of environmental plasticity – *Pseudomonas azothoformans* KC1 and *Rhodococcus erythropolis* P3. The aim was to analyze their survival rate during cultivation in the simultaneously presence of toxic metal (Cu^{2+} in the form of $CuCl_2$) and toxic organic compound (1-chloro-4-nitrobenzene - CNB).

Methods

Strains were cultivated in the NB medium (HiMedia Laboratories, India) with water solution of Cu^{2+} and alcohol solution of CNB in concentrations of 300 ppm (w/v). Optical density was controlled by spectrophotometer KFK-2MP (ZOMZ, Russia), the content of gas phase (CO_2, O_2, H_2) – by gas chromatography (LCM-8MD), the ability to transform CNB by mass-spectrum system Agilent 6890N/5973inert (capillary column HP-5MS (J&W Scientific, USA)), and the concentration of Cu^{2+} - by PAR analytical technique with titration by EDTA.

Conclusions

Both strains have shown the ability to survive in super high concentrations of organic and nonorganic xenobiotics – 300 ppm (compare 10 ppm is a well-known bactericidal concentration). Moreover, it was shown that even in such concentrations of toxic compound these strains could degrade CNB to nonaromatic compounds and extract up to 20% of Cu^{2+} from the media. Both bacterial strains were characterized by high adaptive potential and could be used in wastewaters treatment biotechnologies development.

ANALYSIS OF CHITINASE ACTIVITIES IN SMITTIUM FUNGI: PRODUCTION, ISOLATION, BIOCHEMICAL AND FUNCTIONAL CHARACTERIZATION

M. Takó[1], V. Bense[1], A. Kotogán[1], G. Nagy[2], Á. Csernetics[1,3], C. Vágvölgyi[1], T. Papp[1,2]
[1]University of Szeged, Department of Microbiology, Szeged, Hungary
[2]University of Szeged, HAS-USZ "Momentum" Fungal Pathogenicity Mechanisms Research Group, Szeged, Hungary
[3]Hungarian Academy of Sciences, -, Budapest, Hungary

Backgrounds

Smittium fungi (Kickxellomycotina) are living in the digestive tract of freshwater insect larvae. Although some strains were isolated, their physiology and enzyme production have not been investigated so far. And their relationship with the hosts is unknown. Chitinases are important in the biotechnology due to their ability to degrade chitin in the fungal cell wall and insect exoskeleton. This offers various applications as antimicrobial agents and chitinous waste degraders.

Objectives

The objective of our study was to analyze the chitinase production of five *Smittium* strains from Szeged Microbiological Collection. Then, biochemical and functional characterization of the promising chitinase activities. Until now, mostly bacterial chitinases were examined; therefore, our investigations would provide new chitinase producer fungal strains/enzymes.

Methods

Colloid chitin was used to induce the chitinase production. The enzyme was purified by ammonium sulfate precipitation, ion exchange and size exclusion chromatographies.

Conclusions

The *Smittium simulii* exhibited the highest chitinase yield. The molecular mass of its chitinase was about 60 kDa, and the optimum pH and temperature of the activity were pH 5.8 and 40 °C, respectively. The enzyme was stable between pH 5.4-6.6 and 10-50 °C, and in the presence of various cations, EDTA and SDS. The fungal cell wall-degrading activity of the chitinase was analyzed with the plant pathogenic fungus *Sclerotinia sclerotiorum*. The enzyme caused intensive vacuole formation in the mycelia after 24-h. This is the first chitinase from Kickxellomycotina, and results show that the enzyme is promising for biotechnological purposes. This research was supported by the NKFIH PD 112234 and GINOP-2.2.1-15-2016-00006.

THE SOLAR PANEL MICROBIOME: COMPOSITION, COLONISATION AND BIOTECHNOLOGICAL APPLICATIONS

K. Tanner[1], C. Vilanova[2], J. Peretó[1], M. Porcar[1]
[1]Institute for Integrative Systems Biology I2SysBio, Biotechnology, Paterna, Spain
[2]Darwin Bioprospecting Excellence SL, Bioprospecting, Paterna, Spain

Backgrounds

Bacterial communities are present in practically every natural and artificial environment. Up to date, many studies have addressed the microbial communities associated to natural habitats, but many artificial environments remain unexplored.

Objectives

This work aims at describing the bacterial communities associated to a high-temperature, highly irradiated and nutrient-poor artificial environment: solar panels. Furthermore, we aim to provide an insight on the biotechnological applications of the isolated bacterial strains and on the colonisation process of the glass panels.

Methods

By combining high-throughput 16S rRNA sequencing, metagenomic sequencing, metaproteomics, HPLC, *in vivo* assays and culture-based techniques, this research provides a holistic approach to the description of a previously unexplored environment.

Conclusions

Despite the harsh conditions, the sampled solar panels harboured a highly diverse microbial community rich in drought-, heat- and radiation-adapted bacterial genera. This bacterial community, similar to other highly-irradiated environments such as deserts or polar microbial mats, was also rich in carotenoid- and sphingolipid-producing bacteria, metabolites with potential biotechnological applications mainly as antioxidants or in UV-protecting creams. A further two-year colonisation experiment in which small solar panels will be sampled and analysed through 16S rRNA sequencing every seven weeks aims at elucidating the colonisation process of this artificial environment and the relationship of bacterial communities with photovoltaic efficiency.

USE OF WATER SOLUBLE EXTRACTS FROM ULVA SP. BY PROBIOTICS AND FISH BACTERIAL PATHOGENS

S.T. Tapia-paniagua[1], M. Fumanal[2], C. Fernández-Díaz[3], E. Clavijo[4], M.Á. Moriñigo[5], M.D.C. Balebona[5]
[1]Universidad De Malaga, Microbiologia, Malaga, Spain
[2]University Of Malaga, Microbiology, Malaga, Spain
[3]Instituto De Investigacion Y Formacion Agraria Y Pesquera, Acuicultura Y Recursos Marinos, Malaga, Spain
[4]University Of Malaga. Faculty Of Medicine, Microbiology, Malaga, Spain
[5]University Of Malaga, Microbiology, Malaga, Spain

BACKGROUNDS

The potential of seaweeds as dietary components is considered for a wide range of cultured fish species. In this context, *Ulva* is investigated as a good source of protein, minerals and vitamins. In addition, of probiotics are used to improve fish growth and modulate immune system and intestinal microbiota. To promote probiotics colonization and maintenance in the intestine, prebiotics are included in fish diets. Prebiotics are indigestible substrates used as energy sources for gastrointestinal microbiota, with a positive effect on the nutrition and health status of the host.

In the present work, ability of selected probiotic and fish pathogen strains to use water soluble extracts from *Ulva* as nutrient source has been evaluated.

MATERIALS AND METHODS

Water-soluble extracts from *Ulva* sp. prepared by sonication of dehydrated samples were used to supplement minimum medium (M9). Probiotics and pathogens growth was evaluated based on the optical densities measured with a microplate reader.

RESULTS AND CONCLUSIONS

Probiotics were able to grow in minimum medium using water soluble extracts as nutrient source. On the other hand, *P. damselae* subsp. *piscicida* and *V. harveyi* strains were also able to grow with *Ulva* extracts as nutrient source. However, incubation time to reach maximum growth was longer.

Although *Ulva* extract may support growth of both probiotics and pathogen bacteria, faster growth of probiotics may help for the establishment of probiotic populations in the intestinal environment. In addition, beneficial effects on growth performance, gut microbiota, immunity and disease resistance of *Ulva* for *Solea senegalensis* are being studied.

This work was funded by INIA, Ministerio de Economía y Competitividad and FEDER (RTA201400023 C0202).

USING BCG AS EXPERIMENTAL TREATMENT FOR ASTHMA IN MICE MODELS

R. Tarancon[1], S. Uranga[1], C. Martín[1], N. Aguiló[1]
[1]Universidad de Zaragoza, Microbiología- Medicina Preventiva y Salud Pública, Zaragoza, Spain

Backgrounds

Allergic diseases have reached epidemic proportions worldwide and its incidence continues increasing mainly due to the occidental lifestyle, generating huge economic burden. Therefore, it is essential to develop therapies targeting the cause of the disease and not just the symptoms, as is the case today (Stephen T. Holgate Nature Reviews.2015).

Objectives

The aim of this project is evaluating the impact of the potential treatment of asthma with BCG and other attenuated mycobacteria. This idea arose from the fact that mycobacteria triggers strong Th1 response that opposes the predominant Th2 response elicited in allergy.

This hypothesis has been tested in animal models (Carvalho Gouvela,J.Clin.Immunol.2013, Klaus Josef.Rockefeller University.1998) and in humans (Inseon Choi,Asthma Immunology.2002) using the BCG vaccine, with positive results.

Methods

We have developed a model for asthma induction in mice, using ovalbumin sensitization and challenge. We have also created a protocol to quantify eosinophils in the bronchoalveolar fluid (BAL) by flux cytometry. We have analyzed cytokines in BAL and in lung explants with the ELISA technique.

Conclusions

The analysis of BAL from mice treated with the allergen ovalbumin reflects a clear eosinophilic and interleukin-5 infiltration with respect to negative controls. The intranasal treatment with BCG after ovalbumin sensitization decreases eosinophilic and interleukin-5 concentration in BAL, decreases the interleukin-4 and increases the interferon-γ in lung explants compared to untreated animals.

We also demonstrate that the vaccine has a long-term protection against asthma.

These results are encouraging and suggest that BCG and other attenuated mycobacteria could be potential candidates for treatment of allergic asthma.

MARINE BACTERIA AS A PROLIFIC SOURCE FOR NOVEL BIOCATALYSTS

A. Bollinger[1], S. Thies[1], C. Coscolín[2], N. Katzke[1], S. Söltl[3], J. Navarro-Fernández[2], P. Golyshin[4], M. Ferrer[2], K.E. Jaeger[1]
[1]Heinrich-Heine-University Düsseldorf, Institute for Molecular Enzyme Technology, Juelich, Germany
[2]Consejo Superior de Investigaciones Científicas, Institute of Catalysis, Madrid, Spain
[3]Fachhochschule Aachen, Campus Jülich, Juelich, Germany
[4]Bangor University, School of Biological Sciences, Bangor, United Kingdom

Backgrounds

The demand for novel biocatalysts fitting industrial requirements is rapidly increasing. As it is accepted that the natural habitat of a given host organism shapes the properties of its enzymes, and that marine habitats are subject to dramatic variability, marine metagenomics can be expected to deliver novel biocatalysts with interesting properties.

Objectives

As part of the EU Horizon 2020 project “Industrial Applications of Marine Enzymes” (INMARE), we have mined the virtually untapped richness of marine microorganisms with different strategies to efficiently recover industrially relevant biocatalysts with a particular focus on transaminases and hydrolases that are among the two most important groups of biocatalysts for chemical synthesis.

Methods

Promising candidate biocatalysts were identified by a combination of *in silico* genome mining and activity-based functional screening. Screened libraries were constructed from metagenomic DNA[1] and genomic DNA obtained from hydrocarbonoclastic bacteria isolated from marine environments. Established and newly developed activity-based high-throughput screening strategies were applied allowing for the rapid determination of enzyme function and substrate specificity. Among other enzymes, 18 novel transaminases and a highly substrate promiscuous esterase-lipase, stable at 45°C and up to 40% of organic solvents, from *Alcanivorax borkumensis*, were identified. From a practical standpoint, data are provided that suggest that some of the versatile and robust marine-derived biocatalysts may compete with the best industrial prototypes.

Conclusions

Marine metagenomic libraries as well as genomes of hydrocarbonoclastic bacteria represent a prolific source for novel biocatalysts with industrially relevant properties.

ACTINOALLOMURUS, A GENUS WITH THE POTENTIAL FOR NOVEL ANTIMICROBIALS AND BIOACTIVE MOLECULES

A. Tocchetti[1], M. Iorio[1], J.C.S. Cruz[2], C. Brunati[2], S.I. Maffioli[1,2], M. Sosio[1,2], S. Donadio[1,2]
[1]Naicons Srl, Milano, Italy
[2]Ktedogen Srl, Milano, Italy

Backgrounds

The emergence of a dramatic landscape of infectious diseases in these past few years clearly calls for a constant and significant investment on drug discovery, as the spread of antibiotic resistance keep occurring by giving origin to more multi-drug resistant strains.

One possibility to enhance the antibacterial arsenal is to look into what Nature has been using to solve the inevitable phenomenon of antibiotic resistance. The idea is to screen the myriad of microbial species collected from different natural environments, giving priority to those less exploited but phylogenetically related to known producers.

Objectives

The metabolic potential of the promising genus *Actinoallomurus* was accessed by a screening program based on the dereplication process of a small selected portion of Naicons' library (ca. 200 *Actinoallomurus* microbial strains).

Methods

Small-scale fermentations were followed by cell-based bioactivity assays of the broths extracts. Positive samples were then subjected to a combination of chemical analyses and queries within a proprietary natural product database to determine the novelty of active compounds. The data obtained show that *Actinoallomurus* can produce a broad range of chemical classes, from lantipeptides to new hyperhalogenated angucyclines or new aromatic polyethers. Few examples of these will be presented.

Furthermore, genomic analysis of some interesting *Actinoallomurus* strains revealed the presence of a diverse set of clusters for secondary metabolites, corroborating the biosynthetic potentiality of this genus.

Conclusions

In conclusion, both cultivation screening and genomic analysis of *Actinoallomurus* supported this approach for the discovery of new interesting bioactive metabolites.

INTEGRATIVE ANALYSIS OF THE FITNESS EFFECTS OF PLASMIDS IN PSEUDOMONAS AERUGINOSA PAO1

M. Toll Riera[1], *A. San Millan*[2], *Q. Qi*[3], *C. MacLean*[4]
[1]*University of Zürich, Deparment of Evolutionary Biology and Environmental Studies, Zürich, Switzerland*
[2]*Hospital Universitario Ramon y Cajal IRYCIS, Department of Microbiology, Madrid, Spain*
[3]*University of Cologne, Institute for Theoretical Physics, Cologne, Germany*
[4]*University of Oxford, Department of Zoology, Oxford, United Kingdom*

Backgrounds

Plasmids mediate the horizontal transmission of genetic information between bacteria, facilitating their adaptation to multiple environmental conditions. Plasmids confer new adaptive tools to bacteria, but they also entail a metabolic burden that reduces the competitive ability of the plasmid-carrying clone in the absence of selection for plasmid-encoded traits. This reduction in fitness is the main constraint to the vertical and horizontal replication of these genetic elements. However, the molecular bases underlying the fitness costs produced by plasmids remain poorly understood.

Objectives

Our objective is to gain a better understanding of the bacterial response to the fitness cost caused by plasmids in the bacterium *P. aerugionsa PAO1*.

Methods

We introduced five different natural plasmids (three clinical, one isolated from soil and one isolated from waste water) into *P. aeruginosa* PAO1 and we combined an array of techniques (fitness assays, transcriptomics and metabolomics) to better understand how *P. aeruginosa* responds to the fitness costs

Conclusions

Preliminary results suggest that PAO1 differentially expresses a different set of genes when exposed to each plasmid. However, there is a common subset of genes, with an over-representation of genes involved in bacterial metabolism, which is differentially expressed in response to most plasmids. Finally, some hints suggest that the fitness cost caused by the plasmids might be explained by the difference in the codon usage with respect to *P. aeruginosa*, being the cost higher when the difference in codon usage is bigger.

HIGHER ANTIOXIDANT DEFENCES RESULT IN A BETTER INDUSTRIAL PERFORMANCE IN NON-SACCHAROMYCES WINE YEASTS

M. Torrellas[1], *E. Matallana*[1], *A. Aranda*[2]
[1]*Universitat de Valencia, Bioquímica y Biología Molecular, Valencia- Burjassot, Spain*
[2]*Instituto de Agroquímica y Tecnología de Alimentos CSIC, Biotecnología de Alimentos, Paterna, Spain*

Backgrounds

In recent years there has been a growing interest in the usage of non-*Saccharomyces* yeasts as co-inoculums in the wine industry. There have been many reports in which different species have been used in mixed fermentations alongside *Saccharomyces cerevisiae*. Their ability to produce secondary metabolites, reduce alcohol content or their specific enzymatic activities affect the wine profile, resulting in wines with enhanced and more complex flavours and aromas, which makes them important biotechnological tools. Most of these non-*Saccharomyces* yeasts occur naturally in grapes and wine environments, and although there are already commercially available strains, most inoculums have not been produced at an industrial scale.

Objectives

We aim to characterize the behaviour and redox state of a set of non-*Saccharomyces* yeasts during yeast biomass propagation and dehydration, the two main industrial processes in active dry yeast production. We also intent on understanding the effects of the oxidative stress associated with these processes in their industrial performance.

Methods

In this study we used a set of biochemical and physiological parameters that allowed us to determine the redox state of the studied yeasts, amongst them we analysed trehalose and gluthatione levels, gluthatione reductase and catalase activity, and lipid peroxidation. In order to analyse the industrial performance of our set of yeasts we measured the fermentative capacity and their viability after dehydration.

Conclusions

Our results show high variability between the studied yeasts, those with increased antioxidant defences present a better tolerance and a reduction in fermentative capacity loss after dehydration, due to reduced oxidative damage.

COMPARISON OF EFFECTIVENESS OF ROSEOFUNGIN-AS, 2% OINTMENT, AND CLOTRIMAZOLE, 1% CREAM, IN THE TREATMENT OF FUNGAL SKIN DISEASES: A RANDOMIZED, MULTICENTRE, DOUBLE-BLIND CLINICAL TRIAL

L. Trenozhnikova[1], A. Balgimbaeva[1], G. Ultanbekova[1], V. Berezin[1], A. Sadanov[1]
[1]Institute of Microbiology and Virology, Department of Microbiology, Almaty, Kazakhstan

Backgrounds

Despite the variety of forms, the therapeutic arsenal of antifungal drugs for local application is limited, and there is a clear need for new, more effective and less toxic antifungal agents.

Objectives

The antifungal drugs Roseofungin-AS, 2% ointment, and Clotrimazole, 1% cream.

Methods

The safety and effectiveness of antifungal drugs were compared in a multicenter, randomized, double-blind, parallel-group trial involving 466 patients. The drugs were used topically applying to the skin surface twice a day for 28 days.

Conclusions

A new representative of the polyene group of antibiotics - carbonyl-conjugated pentaen roseofungin – is an active ingredient of Roseofungin-AS, 2% ointment. The single- and multiple-dose application of Roseofungin-AS, 2% ointment did not produce any toxic effects. High effectiveness of Roseofungin-AS was established in dermatomycoses of different locations - athlete's foot and smooth skin mycoses caused by *Trichophyton rubrum*, *Trichophyton mentagrophytes*, *Trichophyton verrucosum*, *Microsporum gypseum*. Clinical recovery of patients was observed 2 weeks after using Roseofungin-AS, 2% ointment, in the treatment of smooth skin mycoses and 3 weeks after using it in the treatment of athlete's foot. Clotrimazole supported a regression of clinical signs following more prolonged application: during 3 weeks in the treatment of skin smooth mycoses and 4 weeks in the treatment of athlete's foot. In the open, prospective, randomized Phase II/III trial high clinical and mycological effectiveness of the antifungal agent Roseofungin-AS was established in patients with fungal skin infections as compared with the drug Clotrimazole for external use - 97.4% and 93.6%, respectively.

OPTIMIZATION OF A FAST AFFINITY ADSORPTION PURIFICATION METHOD OF FUNCTIONAL LPMOS

S. Valenzuela[1], *G. Ferreres*[1], *G. Margalef*[1], *M. Rodríguez-Astigarraga*[1], *F.I.J. Pastor*[1]
[1]*University of Barcelona, Department of Genetics- Microbiology and Statistics, Barcelona, Spain*

Backgrounds

The recently discovered LPMOs are crucial enzymes for the deconstruction of recalcitrant macromolecules, including lignocellulosic and chitin polymers, thus represent a promising component of industrial cocktail enzymes for degrading biomass. The LPMOs are metalloenzymes that oxidize glycosidic bonds and the catalysis requires the binding of an active oxygen molecule to the copper atom of the enzyme for the oxidative depolymerization of the substrate. Depending on the type of LPMO, the products released are gluco-oligosaccharides that are oxidized either at the reducing (C1) or in both, the reducing (C1) and the non-reducing (C4) end (3).

Objectives

To develop a simple and low-cost method for recombinant LPMOs purification.

Methods

We have cloned two orfs encoding for putatives LPMOs from *Streptomyces ambofaciens*, which is a soil bacterium industrially exploited for the production of antibacterial chemicals. We established a purification method for these enzymes based on the ability of the recombinant LPMOs to bind polysaccharides. In addition, one of the produced LPMOs, named SamAA10C was tested against a variety of cellulosic substrates, including for the first time for an LPMO, bleached pulps used in the paper industry.

Conclusions

We developed a simple and fast method to purify LPMOs in a single step without using any chromatographic column or periplasmic preparation, considerably reducing time used in others studies for the purification step. The purification method introduced for the LPMOs could be a cheap solution, to use these enzymes in industrial applications, and the activity of SamAA10C show the potential of LPMOs in biomass upgrading.

Biotechnology / Synthetic Biology / Systems Biology - Part III

BIOINFORMATIC SCREENING OF NOVEL ENZYMES FOR BIOMASS REVALORITZATION

P. Soteras[1], F.I.J. Pastor[1], S. Valenzuela[1]
[1]Universitat de Barcelona, Microbiology, BARCELONA, Spain

Backgrounds

The strain BP-23 isolated from soil presents a high depolymerizing activity of vegetal biomass due to its capability to degrade polysaccharides. One of the most relevant activity of the strain is xylanase. This activity allows the strain to grow in minimum medium with xylan, the second most abundant polysaccharide in the earth, as a unique source of carbon.

Objectives

The main objectives are to characterize all the xylanases involved in the xylanolytic system of the strain and to identify all the proteins involved in the degradation of this substrate.

Methods

As a first stage, the sequencing of the genome of the strain has been performed. Then a multiple alignment of sequences encoding known enzymes with the genome of the studied strain allowed the identification of several DNA segments showing homology to known genes. DNA segments with the best score were chosen and analysed their upstream and downstream sequences to identify putative *orfs*. As a fourth stage, a BLASTx focusing on microorganisms taxonomically related to BP23 was performed, in order to select those *orfs* with homology to genes encoding relevant enzymes. Specific primers were designed to amplify these *orfs* by PCR, which were cloned in expression vectors and transformed in *E. coli.* The recombinant strains obtained were cultured to produce the new enzymes, which were purified and characterized.

Conclusions

Multiple new *orfs* have been identified and most of them codify for active proteins. Among them, several new xylanases, expansins, celulases, esterases and pectatolyases from the strain have been characterized by the research group.

Biotechnology / Synthetic Biology / Systems Biology - Part III

HETEROLOGOUS EXPRESSION AND MODIFICATION OF ANTIMICROBIAL PEPTIDES FROM EUKARYOTES WITH LANTIBIOTIC BIOSYNTHETIC ENZYMES IN LACTOCOCCUS LACTIS

S.B. van der Meulen[1], *A. de Jong*[1], *O.P. Kuipers*[1]
[1]*University of Groningen, Molecular Genetics, Groningen, The Netherlands*

Backgrounds

Due to an ever increasing resistance of bacteria to available antibiotics, new types of antimicrobial molecules need to be developed and discovered. We focus on the mining of antimicrobial peptides from eukaryotic organisms, which are subsequently re-designed, heterogeneously produced and post-translationally modified in our expression host *Lactococcus lactis*.

Objectives

We aim to create highly stable lantibiotic peptides that are currently not produced in nature.

Methods

Mining for suitable candidate peptides was performed from more than 20.000 peptide sequences for the presence of a disulfide bridge and applicability for post-translational modification by the nisin biosynthesis machinery. Six peptides of 10-17 AA in length were selected and re-designed to enable lanthionine ring formation. The peptides were expressed in combination with the proteins that dehydrate serine and threonine residues (NisB), enable cyclization (NisC) and peptide transport (NisT). Activity tests have shown that two peptides are in particular active against *Lactococcus lactis*, *Micrococcus flavus* and *Streptococcus pneumoniae*. The production was scaled up to 1L batch production, followed by His-tag purification on NGC, HPLC and analysis on a mass spectrometer. This work is ongoing to proof dehydration and lanthionine ring formation.

Conclusions

We have successfully produced bioactive peptides that are derived from different eukaryotic organisms. Although the production of some of the peptides remains challenging, two promising peptides show a potent activity against various Gram-positive bacteria. We are currently working on purification of the peptides to enable quantitative tests, toxicity assays and to gain insight into the mode of action of the peptide.

CRSIPRI FOR OPTIMIZED ECTOINE PRODUCTION IN HALOMONAS ELONGATA

J. Vandrich[1], G. Alfaro Espinoza[1], H.J. Kunte[1]
[1]Federal Institute for Materials Research and Testing BAM, Materials and the Environment, Berlin, Germany

Backgrounds

Halophilic bacteria synthesize and accumulate organic osmolytes to cope with osmotic stress in saline environments. Ectoine is an important osmolyte synthesized by many halophilic bacteria. It is produced by industry because it possesses protecting properties and stabilizes proteins, membranes and whole cells against stresses such as UV radiation and cytotoxins.

Objectives

Today, industrial production processes rely on the halophilic bacterium *Halomonas elongata* and output ectoine on an annual scale of tons, which is then processed into cosmetics and pharmaceuticals. Still, the factors for optimum ectoine production remain to be fully explored. Therefore, we are establishing the CRISPR-Cas9 system in *H. elongata* DSM 2581^T to investigate basic metabolic pathways and subsequently optimize ectoine production.

Methods

The CRISPR-Cas9 system is a versatile molecular tool that allows simultaneous introduction of multiple genetic modifications. We are using the repurposed CRISPRi (CRISPR interference) variant for sequence-specific gene repression in *H. elongata*. The catalytically inactive dCas9 was integrated into the genome under the constitutive expression of the *teaABC* operon. Accurately designed guideRNA constructs were added to trigger site-directed repression of target genes.

Conclusions

The first target gene was one of the ectoine synthesis genes, *ectA*. The repression of *ectA* resulted in an easy-to-observe decrease of ectoine production. Additionally, changes in gene expressions levels were determined precisely via qRT-PCR measurements.This successfully established CRISPRi system will not only allow us to further investigate ectoine metabolism but it will also be a valuable tool for genomic research in *H. elongata* e.g. on the preferred glycolytic strategies under varying salt concentrations.

AN EXPEDITION INTO THE NEGLECTED HUMAN "MICROBIAL" ORGAN

L. Vasudevan[1], J. V[2], S. M.[2], C. T. S.[1]
[1]Indian Institute of Technology Madras, Department of Biotechnology, Chennai, India
[2]Global Hospital and Health City, Gastroenterology, Chennai, India

Backgrounds

'Gut microbiota' refers to the ecosystem of microorganisms that have adapted to live on intestinal mucosal surface or within gut lumen (WGO Handbook of gut microbes, 2014). Gut flora has received renewed research interest for potential associations with human health. Distortions in any of the microbiota functions result in a wide range of diseases. Hence it has earned the status of human "microbial" organ.

Microbial composition varies along the length of gastrointestinal tract. Use of tissue samples provides better expression of autochthonous bacterial population well-adapted to gut and they constitute better probiotic strains than allochthonous (foreign) strains.

Objectives

To exploit gut microbes for health benefits by isolating and characterizing the bacterial species inhabiting our gut.

Methods

Biopsy samples were collected from three different regions of colon (terminal ileum, caecum and recto-sigmoid) from healthy volunteers. They were homogenized, enriched and plated. The isolates were subjected to molecular fingerprinting (BOX PCR-RAPD) which helped to categorize them. Representative isolates were identified and subjected to probiotic characterization (acid and bile tolerance, antimicrobial activity, aggregation ability and vitamin biosynthesis).

Conclusions

Key observations include
i. Enrichment helps in increasing the number of surviving bacteria.
ii. Anaerobic enrichment gives higher colony number.
iii. Striking difference observed in colony numbers obtained under aerobic and anaerobic enrichment.
iv. Colony diversity, however, does not vary significantly
   a. Among the three regions – ileum, caecum, and recto-sigmoid.
   b. Between aerobic and anaerobic enrichments.
v. They were able to withstand acid and bile conditions similar to that found in human system.
vi. The strains differed in their antimicrobial activity and ability to produce vitamin.

The isolated strains represent autochthonous gut population with higher probiotic functionality (in terms of ecological competence, ability to thrive and produce beneficial metabolic products) as compared to those reported from faeces and/or dairy products, and hence can be exploited for overall health management.

FEMS7-2423
Biotechnology / Synthetic Biology / Systems Biology - Part III

WASTE OILS AS AN ALTERNATIVE INDUCTOR TO PRODUCE LIPASES BY SUBMERGED CULTURE OF FILAMENTOUS FUNGI

M.V. Tacin[1], A.V. de Paula[2], V.D.C.S. Ebinuma[2]
[1]School of Pharmaceutical Sciences of São Paulo State University-UNESP, Food and Nutrition, Araraquara, Brazil
[2]School of Pharmaceutical Sciences of São Paulo State University-UNESP, Bioprocess and Biotechnology, Araraquara, Brazil

Backgrounds

The production of enzymes by fungi has been highlighted in biotechnology due to the process simplicity. Fermentation parameters such as nitrogen and carbon sources are factors that influence both the characteristic of enzyme produced and the biomolecule final cost. Regarding to lipases production, oil is used as an inductor during the biosynthesis. Industries of food and textile generate oils rich in linoleic acid such as grape and cottonseed oil as waste that can be used to this purpose.

Objectives

The main goal on this work was to evaluate grape and cottonseed oil as an alternative inductor to produce lipase by *Aspergillus tubingensis* and improve its production employing statistic tools.

Methods

Grape oil promoted the highest production of lipases according the enzymatic activity and it was used in the following experiments. So, the variables bacteriological peptone, glucose and grape oil concentration were studied through a 2^3 full factorial design followed by two 2^2 central composite factorial design. The regression analysis pointed out that bacteriological peptone and glucose were the variables that influenced more in the lipase production. Under the best conditions of the second 2^2 central composite factorial design, bacteriological peptone was the variable that presented more significance at a confidence interval of 95%.

Conclusions

In the best experimental condition it was achieved an increase in the enzymatic activity around 30%. In this way, grape oil can be used to promote the production of lipases by filamentous fungi and the factorial experimental design demonstrated an important role in the improvement of enzymes production.

FEMS7-2434
Biotechnology / Synthetic Biology / Systems Biology - Part III

PRODUCTION OF LIPASES BY ASPERGILLUS TUBINGENSIS EMPLOYING SUBMERGED CULTURE

M.V. Tacin[1], A.V. de Paula[1], V.D.C.S. Ebinuma[1]
[1]School of Pharmaceutical Sciences of São Paulo State University-UNESP, Bioprocess and Biotechnology, Araraquara, Brazil

Backgrounds

Filamentous fungi are recognized as good lipases producer and to improve the production conditions such as nutrients sources, fermentation time, among others are important to make microbial lipases competitive in the market.

Objectives

The objective of this work was to evaluate the production of lipases by submerged culture of *Aspergillus tubingensis*.

Methods

The fermentation was proceed in orbital shaker at 150 rpm at 30°C in Erlenmeyers flaks (500 mL) containing 10 mycelial agar disc and 100 mL of culture medium composed of: 20.0 g/L bacteriological peptone, 8.0 mL/L grape oil, 0.6 g/mL $MgSO_4.7H_2O$, 1.0 g/L KH_2PO_4, 1.0 g/L NH_4NO_3. The experiments were conducted in duplicate, being samples taken daily during 5 days of culture. At the end of the culture, the fermented was filtered and the biomass was quantified by dry weight while the liquid fermented was used to determine the lipase enzymatic activity using p-nitrophenyl palmitate as substrate, protein by Lowry and pH.

Conclusions

The initial pH and biomass was 6.34 and 0.56 g/L, respectively. After 3 days of bioprocess, the pH of the medium remained between 3.46 and 3.77 due to the action of metabolites produced by the microorganism. The highest production of lipase was obtained after 4 days of culture being biomass of 9.70 g/L and enzymatic activity was of 20.74 U/mL (specific activity of 6.80 U/mg protein), with an average increase of 25% in activity per daily production. With these results, it can be concluded that 4 days of submerged culture generate lipase with the highest activity.

FEMS7-2729
Biotechnology / Synthetic Biology / Systems Biology - Part III

RANDOM STREAMLINING OF THE E. COLI GENOME

V. Vernyik[1], *Z. Gyorfy*[1], *G. Posfai*[1]
[1]*Biological Research Center, Institute of Biochemistry, Szeged, Hungary*

Backgrounds

Creation of bacteria with randomly reduced genomes would allow better understanding of causes and consequences of reductive genome evolution. Moreover, cells with streamlined genomes would provide dependable chassis for synthetic biology. Current approaches mostly use targeted genome reduction, relying on *a priori* knowledge of gene function. An efficient tool for random genome streamlining, however, coupled to selection of the fittest population, is still missing.

Objectives

We aimed to develop a novel scheme to generate random deletions in a large population of *E. coli* in a cyclic and efficient manner.

Methods

Steps of the iterated deletion cycles are: (1) Random genomic integration of a transposon cassette, which carries an antibiotic resistance gene, a negative selection marker and unique I-SceI recognition sites. (2) Generation of double-strand DNA breaks by induction of I-SceI expression. In the survivor cells the DNA break is repaired by the alternative end-joining mechanism, which is associated with the formation of random deletions. (3) Elimination of background by negative selection.

Conclusions

The proposed random deletion generating method is feasible: deletions of various size (up to tens of kbp) can be efficiently created at random genomic sites. The process can be applied to a large population of bacteria, allowing, in principle, selection of the fittest variants.

SURVIVAL STRATEGIES FOR PROKARYOTES LACKING ESSENTIAL DNA REPAIR FACTORS

B.G. Vertessy[1], V. Grolmusz[2], C. Kerepesi[2], J. Szabó[3]
[1]Budapest University of Technology and Economics, Dept of Applied Biotechnology, Budapest, Hungary
[2]Eötvös University, Dept Computer Science, Budapest, Hungary
[3]Research Center for Natural Sciences, Inst Enzymology, Budapest, Hungary

Backgrounds

Enzymes involved in maintaining genome integrity are expected to be ubiquitous and essential for viability. Such an enzyme is dUTPase, that is required for maintaining the correct low level of dUTP, hence preventing dUMP (uracil) incorporation into DNA. Lack of dUTPase leads to drastic increase in uracil-DNA levels and prompt cell death via overloading the uracil-DNA glycosylase - base-excision repair pathway and inducing DNA fragmentation. We, however, found that Staphylococcus aureus does not encode its own dUTPase and seems to rely only on phage infection to acquire phage-encoded dUTPases.

Objectives

The intriguing situation in Staphylococcus led us to examine all genomes published for bacteria and Archea.

Methods

We have performed a bioinformatic screen on all available prokaryte genomes to decide if these encode dUTPase and uracil-DNA glycosylase genes, or genes for inhibitory proteins of dUTPases or uracil-DNA glycosylases. We also determined the uracil-DNA level in selected Staphylococcal samples.

Conclusions

We have shown that the genes for the common dUTPase enzyme families are far from being ubiquitous in prokaryotes. This unexpected genotype is observed in evolutionary well-separated branches suggesting that loss of the *dut* gene(s) might have occurred on multiple independent occasions during evolution. We also observe that elements involved in uracil-DNA metabolism are interestingly found within mobile genetic elements. The biomedical significance of these findings are especially relevant for microbes of current high therapeutic challenge.

THE USE OF GLYCEROL AS A CARBON SOURCE FOR THE PRODUCTION OF COLD-ACTIVE B-GALACTOSIDASES BY RECOMBINANT PICHIA PASTORIS YEAST STRAINS

M. Wanarska[1], J. Barański[1], E. Krajewska[1], M. Wicka-Grochocka[1], H. Cieśliński[1]
[1]Gdańsk University of Technology, Department of Molecular Biotechnology and Microbiology, Gdańsk, Poland

Backgrounds

A methylotrophic yeast *Pichia pastoris* is frequently used as a host for the production and secretion of a wide variety of recombinant proteins. It can utilize glucose, glycerol and methanol as a carbon and energy source. Efficient utilization of crude glycerol, a by-product from biodiesel production, could bring significant economic and environmental benefits. β-Galactosidase catalyzes decomposition of β-galactosides such as lactose by hydrolyzing O-glycosidic bonds. Due to this activity it is used in the food industry for the production of dairy products with reduced lactose content.

Objectives

The purpose of this study was to evaluate the possibility of using pure glycerol as well as crude glycerol derived from biodiesel production as a carbon source in growth medium for recombinant *P. pastoris* yeast strains producing cold-active β-galactosidases.

Methods

Recombinant *P. pastoris* strains capable of producing and secreting β-galactosidases derived from psychrotolerant bacteria *Arthrobacter* sp. S3*, *Arthrobacter* sp. 32cB and *Paracoccus* sp. 32d were cultivated in media containing three different carbon sources: glucose, pure glycerol and crude glycerol. The activity of enzymes in post culture media was measured using *o*-nitrophenyl β-D-galactopyranoside as a substrate.

Conclusions

The cell growth and protein expression profiles were similar for glucose and analytical grade glycerol. The yield of biomass was slightly higher for crude glycerol. The activity of β-galactosidases in post culture media was lower for crude glycerol than for glucose and pure glycerol. However, these results demonstrate the potential of using crude glycerol as the sole carbon source in the production of recombinant proteins in *P. pastoris* expression system.

IMPACT OF RRN OPERON DELETIONS ON GROWTH PARAMETERS OF THE AMINO ACID PRODUCER CORYNEBACTERIUM GLUTAMICUM

S. Weinmann[1], T. Hahn[1], M. Ruwe[2], J. Kalinowski[2], B. Eikmanns[1]
[1]Institute of Microbiology and Biotechnology, AG Eikmanns, Ulm, Germany
[2]Center for Biotechnology CeBiTec- Bielefeld University, CeBiTec, Bielefeld, Germany

Backgrounds

Bacterial 5S, 16S, and 23S ribosomal RNAs are encoded by the so-called *rrn* operons. There is a distinct number of *rrn* copies in each bacterium; *Escherichia coli* and *Corynebacterium glutamicum* possess seven and six *rrn* copies, respectively, whereas slow-growing *Mycobacterium* species contain only one or two *rrn* operons. Previous studies with *E. coli* indicated a correlation between the number of ribosomes and growth rate, the number of ribosomes being probably dependent on the availability of ribosomal proteins and rRNAs.

Objectives

Our project aims to analyze expression of individual *rrn* operons in *C. glutamicum* and to investigate the impact of the total chromosomal *rrn* copy number on various growth parameters of this organism.

Methods

Using a reporter gene system, the activities of all six *rrn* promoters were determined. Single and multiple *rrn* deletion mutants of *C. glutamicum* CR099 (up to five *rrn* operons deleted) were constructed and tested for growth rate, biomass, protein content, glucose consumption rate, cell size, and glutamate production.

Conclusions

The results indicate that the six *rrn* operons in *C. glutamicum* are differentially expressed and that there is negligible impact of *rrn* deletions on biomass, protein content, cell size, or glutamate production. However, when five of the six *rrn* operons were deleted, the growth and glucose consumption rates were impaired up to 40 %. These results show that *C. glutamicum* can compensate the loss of up to four *rrn* operons by so far unidentified mechanisms.

ETHYL ACETATE PRODUCTION BY THE ELUSIVE ALCOHOL ACETYL TRANSFERASE FROM YEAST

A. Kruis[1], M. Levisson[2], A. Mars[2], M. van der Ploeg[2], F. Garces Daza[1], V. Ellena[1], S. Kengen[1], J. van der Oost[1], R. Weusthuis[3]
[1]Wageningen University, Laboratory of Microbiology, Wageningen, The Netherlands
[2]Wageningen Research, Biobased Products, Wageningen, The Netherlands
[3]Wageningen University, Bioprocess Engineering, Wageningen, The Netherlands

Backgrounds

Ethyl acetate is an industrially relevant ester that is currently produced exclusively through unsustainable processes. Many yeasts are able to produce ethyl acetate, but the main responsible enzyme has remained elusive, hampering the engineering of novel production strains.

Objectives

Here we describe the discovery of a new enzyme (Eat1) from the yeast *Wickerhamomyces anomalus.*

Methods

When expressed in *Saccharomyces cerevisiae* and *Escherichia coli* it resulted in high ethyl acetate production. Purified Eat1 showed alcohol acetyltransferase activity with ethanol and acetyl-CoA. Homologs of *eat1* are responsible for most ethyl acetate synthesis in known ethyl acetate-producing yeasts, including *S. cerevisiae*, and are only distantly related to known alcohol acetyltransferases.

Conclusions

Eat1 is therefore proposed to compose a novel alcohol acetyltransferase family within the α/β hydrolase superfamily. The discovery of this novel enzyme family is a crucial step towards the development of biobased ethyl acetate production and will also help in selecting improved *S. cerevisiae* brewing strains.

MONASCUS RUBER AS CELL FACTORY FOR LACTIC ACID PRODUCTION AT LOW PH

R. Weusthuis[1]
[1]*Wageningen University, Bioprocess Engineering, Wageningen, The Netherlands*

Backgrounds

Lactic acid is a microbial product traditionally used to conserve food and feed products. Lactic acid is also used in technical applications, e.g. as building block of poly lactic acid (PLA). Lactic acid is inhibitory for microorganisms, especially at low pH values. The general strategy followed is to use well-known yeast cell factories and to convert them into lactic acid producers. Lactic acid tolerance is a complex trait and therefore difficult to engineer.

Objectives

We followed an alternative approach in which we searched for lactic acid tolerant microbial species in natural habitats and converted the most tolerant strain into a lactic acid producer.

Methods

A *Monascus ruber* strain was isolated that was able to grow on mineral medium at high sugar concentrations and 175 g/l lactic acid at pH 2.8. Its genome and transcriptomes were sequenced and annotated. Genes encoding lactate dehydrogenase were introduced to accomplish lactic acid production and two genes encoding pyruvate decarboxylase were knocked out to subdue ethanol formation. The strain preferred lactic acid to glucose as carbon source, which hampered glucose consumption and therefore also lactic acid production. Lactic acid consumption was stopped by knocking out 4 cytochrome-dependent genes, and evolutionary engineering was used to increase the glucose consumption rate.

Conclusions

Application of this strain in a fed-batch fermentation resulted in a maximum lactic acid titer of 190 g/l at pH 3.8 and 129 g/l at pH 2.8, respectively 1.7 and 2.2 times higher than reported in literature before. Yield and productivity were on par with the best strains described in literature for lactic acid production at low pH so far.

EXPRESSION OF GDSL ESTERASE FROM PSYCHROTOLERANT PSEUDOMONAS SP. S9 ISOLATED FROM SPITSBERGEN ISLAND SOIL IN PICHIA PASTORIS

M. Wicka-Grochocka[1], *E. Krajewska*[1], *H. Cieśliński*[1], *M. Wanarska*[1]
[1]*Gdansk University of Technology, Molecular of Biotechnology and Microbiology, Gdansk, Poland*

Backgrounds

Lipolytic enzymes isolated from cold adapted microorganisms are promising to replace the lipolytic enzymes recently used in biotechnological processes. One of the most important feature of the cold-active lipases and esterases is that they offer economic benefits through energy saving. Novel esterolytic enzyme was isolated from psychrotolerant *Pseudomonas* sp. S9. The enzyme is tolerant to alkaline pH and effective at medium to low temperatures (40-25°C). Amino acid sequence analysis revealed that the enzyme contained a G-D-S-L motif centered at a catalytic serine, an N-terminal catalytic domain and a C-terminal autotransporter domain.

Objectives

In our previous study, the genes estS9 and estS9auto was expressed in *E. coli* cells as His-tagged fusion proteins. Like many other recombinant proteins, EstS9Auto (variant which consist of two domains) and EstS9 (variant containing only the catalytic domain) were produced in *E. coli* in inclusion bodies. For these reason, we decided to check usefulness of other expression host for obtaining the extracellular active esterases. During this study we constructed recombinant *P. pastoris* strains for production of EstS9Auto and EstS9 proteins. The genes estS9 and estS9auto were expressed in the yeast *Pichia pastoris* under the control of alcohol oxidase (*AOX1*) promoter.

Methods

Methods included PCR, cloning of DNA fragments, transformation and gene expression in *P. pichia* system.

Conclusions

The EstS9Auto enzyme was effectively produced, but it was bound to yeast cell wall. However, EstS9 enzyme was produced to the culture medium. The biotechnological potential of new production system of EstS9 enzyme is tested at now.

NOVEL ACTIVITIES OF THE IRON–SULFUR PROTEIN ISPH AND ITS POTENTIAL IN PRODUCTION OF ISOPRENE AND ISOAMYLENE

Y. Xue[1], D. Ge[2], Y. Ma[1]
[1]Institute of Microbiology- CAS, Microbial Resources, Beijing, China
[2]Anhui University of Science and Technology, College of Medicine, Huainan, China

Backgrounds

Isoprene is an important chemicals and can be produced naturally by a wide variety of organisms, including animals, plants, and bacteria. *Bacillus* species, possessing the methylerythritol phosphate (MEP) pathway for the synthesis of isoprenoid feedstock, are the highest producers of isoprene among bacteria; however, the enzyme responsible for isoprene synthesis has not been identified.

Objectives

The iron–sulfur protein IspH is the final enzyme of the MEP pathway and catalyses the reductive dehydration of (E)-4-hydroxy-3-methyl-2-butenyl diphosphate (HMBPP) to form isopentenyl diphosphate and dimethylallyl diphosphate (DMAPP). In this study, we demonstrated two unexpected activities of IspH from alkaliphilic *Bacillus* sp. N16-5.

Methods

GC-MS analysis showed that IspH could catalyse the formation of isoprene from HMBPP and the conversion of DMAPP into isoamylene *in vitro* in the reaction system including IspH, NADPH, ferredoxin and ferredoxin-$NADP^+$-reductase. By site-directed mutagenesis, two variants (H131N and E133Q) were found to have lost the HMBPP reductase activity but could still catalyse the formation of isoprene. Overexpression of IspH H131N in *Bacillus* sp. N16-5 resulted in a twofold enhancement of isoprene production, and the yield of isoprene from the strain expressing E133Q was increased 300% compared with the wild-type strain.

Conclusions

IspH from *Bacillus* sp. N16-5 is a multifunctional enzyme that is responsible for isoprene and isoamylene synthesis in *Bacillus* sp. N16-5. The H131N and E133Q variants could be used for isoprene production from HMBPP, which may avoid the accumulation of prenyl diphosphate in the host cell.

PURIFICATION AND SOME PROPERTIES OF A THERMOSTABLE B-1,3-GLUCANASE FROM THERMOPHILIC ACTINOMYCETES

C.H. Yang[1], H. Jo-Chieh[1], C. Cheng-Yu[1], C. Wei-Lin[1], H. Yu-Chun[1]
[1]Providence University, Department of Cosmetic Science, Taichung, Taiwan R.O.C.

Backgrounds

Beta-1,3-gluans are complex biopolymers mainly found in mushroom yeast cell wall. Beta-1,3-gluanases can break down β-1,3-glucans such as callose or curdlan. To produce enzymes for the development of enzymatic degradation of the natural biopolymers, we isolated a potent extracellular hydrolases-producing thermophilic actinomycete, *Thermobifida fusca* BCRC 19214, from compost soils collected in Taiwan.

Objectives

The present study is concerned with the purification and properties of extracellular beta-1,3-glucanase from *T. fusca* BCRC 19214.

Methods

A beta-1,3-glucanase from *Thermobifida fusca* BCRC 19214 was purified from crude culture filtrate by DEAE-Sepharose CL-6B and Sepharose CL-6B column chromatography. The beta-1,3-glucanase activity was assayed with laminarin as a substrate. One unit of enzyme activity was defined as the amount of enzyme releasing 1 mmole glucose per minute under the assay condition. The amount of reducing sugar released in the mixture was determined by the dinitrosalicylic acid method.

Conclusions

The overall yield of the purified enzyme was 6.0%. The purified enzyme gave an apparent single protein band on an SDS-PAGE. The molecular mass of purified enzyme as estimated by SDS-PAGE was found to be 60 kDa. The optimum pH and temperature for the purified enzyme were 8.0 and 60^{o}C, respectively. The Zn^{2+}, Hg^{2+} inhibited the enzyme activity.

SIMULTANEOUS EXPRESSION OF THE POLYPHENOL OXIDASE AND XYLANASE GENE FROM THERMOPHILIC ACTINOMYCETES IN YEAST EXPRESSION SYSTEM

C.H. Yang[1], Y.C. Huang[1], Y.S. Lin[1], C.Y. Chen[1], W.L. Chen[1]
[1]Providence University, Department of Cosmetic Science, Taichung, Taiwan R.O.C.

Backgrounds

Thermobifida fusca is a thermophilic actinomycetes. It has the abilities to degrade plant biomass and to catalyze the oxidation of phenolic compounds. The polyphenol oxidase gene (*Tfu*-0957) and xylanase gen (*Tfu-xyl*) were cloned from *T. fusca* and expressed in *Escherichia coli* BL21 (DE3).

Objectives

The present study is concerned with the simultaneous expression of the polyphenol oxidase and xylanase gene from *T. fusc*a in *Pichia pastoris* expression system.

Methods

The *Tfu*-0957 and *Tfu-xyl* gene were cloned into pPICZαA and pPGAPZαA expression vectors, respectively, and then transformed into *P. pastori*s X-33 by electrophoresis.

Conclusions

The *P. pastoris* transformant selected by culture plates containing Zeocin and Geneticin could express two recombinant proteins. Xylanase was expressed constitutively and polyphenol oxidase was expressed inducibly. After cultivation in YPD medium for 5 days, there were 0.65 U/ml of polyphenol oxidase and 20.9 U/ml xylanase activities accumulated in the culture broth.

ENANTIOSELECTIVE SYNTHESIS OF (R)-PHENYLEPHRINE BY SERRATIA MARCESCENS BCRC10948 CELLS THAT HOMOLOGOUSLY EXPRESS SM_SDR

M.T. Yang[1], Y.C. Kuan[1], Y.B. Xu[1], W.C. Wang[2]
[1]National Chung Hsing University, Molecular Biology, Taichung, Taiwan R.O.C.
[2]National Tsing Hua University, Institute of Molecular and Cellular Biology, Hsinchu, Taiwan R.O.C.

Backgrounds

Optically active phenylephrine (PE) plays a rapidly growing role as a building blocks for the synthesis of pharmaceuticals and fine chemicals. Compared to chemical synthesis, the enzymatic synthesis of the chiral compounds is highly enantioselective and eco-friendly. To convert 1-(3-hydroxyphenyl)-2-(methylamino) ethanone (HPMAE) to optically pure (*R*)-PE, an NADPH-preferred short-chain alcohol dehydrogenase/reductase from *Serratia marcescens* BCRC10948, SM_SDR, had been cloned and expressed in *Escherichia coli*. However, a low conversion yield and productivity limited the application of this method in industrial processes.

Objectives

To produce optically pure (*R*)-PE from HPMAE with improved bioconversion efficiency, yield and productivity.

Methods

The homologous expression of SM_SDR in its native host *S. marcescens* BCRC10948 was carried out to produce optically pure (*R*)-PE from HPMAE with improved bio-catalytic efficiency. The cloned *SM_SDR* was driven by the T5 promoter and whole-cell bioconversion was applied to efficiently replenish the cofactor NADPH in the biocatalytic process. Glycerol was found to be the most effective carbon source for conversion of HPMAE to (*R*)-PE, and 6.50 mM of (*R*)-PE with more than 99% enantiomeric excess was produced from 10 mM HPMAE after a 10 h conversion at 30°C by the recombinant *S. marcescens* cells. The recombinant *S. marcescens* cells could be recycled 6 times for the production of (*R*)-PE, and the bioconversion efficiency remained at 85% when compared to that at the first cycle.

Conclusions

Our data indicated that a high conversion efficiency of HPMAE to optically pure (*R*)-PE could be achieved by using *S. marcescens* BCRC10948 cells that homologously express the *SM_SDR*.

GLYCEROL TRANSPORTER 1 INVOLVED IN THE REPRESSION OF GLYCEROL ON AOX1 EXPRESSION IN PICHIA PASTORIS

Y. Yang[1], *C. Zhan*[1], *Z. Bai*[1]
[1]*Jiangnan University, National Engineering Laboratory for Cereal Fermentation Technology, Wuxi, China*

Backgrounds

The P_{AOX1} (promoter of *alcohol oxidase 1* (*aox1*)) is the most efficient promoter used for promoting recombinant protein expression in *P. pastoris.* It is repressed by the presence of glycerol in the culture medium, thus glycerol must be exhausted before methanol can be taken up by *P. pastoris,* and subsequently the expression of heterologous protein is induced.

Objectives

Whether glycerol transporter exists and involves in the regulation of Aox1 expression or not?

Methods

A candidate GT1 (glycerol transporter 1) was identified by bioinformatics. It has been shown that GT1 is a transmembrane protein, and *Schizosaccharomyces pombe* (*S. pombe*) carrying *gt1* could grow on a medium containing glycerol as the sole carbon source while the wild type could not. The relationship between *aox1*, methanol expression regulator 1 (*mxr1*) and *gt1* was studied. It was found that the overexpression of *gt1* could increase the glycerol content in cells and repress the expression of *mxr1* and *aox1*, and the deletion of *gt1* reduced the glycerol content in cells and promoted the expression of *aox1*. The overexpression of *mxr1* could repress the expression of *gt1*, and the deletion of *mxr1* could promote the expression of *gt1* to some extent. By EMSA, Mxr1 could regulate the expression of *gt1* by binding to P_{Gt1}.

Conclusions

The Gt1 is the glycerol transporter and represses Mxr1 and Aox1 through increasing the glycerol content in cells. Mxr1 represses Gt1 through binding to $P_{Gt1,}$ which provides a reference for the understanding of the mechanism of glycerol repression on P_{AOX1}.

SCREENING AND IDENTIFICATION OF CHITINOLYTIC ENZYME FROM NATIVE HALOPHILIC ARCHAEA

M. yavari bafghi[1], *M.A. amoozegar*[1]
[1]*Faculty of Biology - College of Science - University of Tehran -, microbiology, Tehran, Iran*

Backgrounds

Chitin is the second most abundant natural polysaccharide. Chitinases are glycoside hydrolases catalyzing the hydrolytic degradation of chitin and have a wide range of applications including preparation of bioactive oligosaccharides, production of single cell proteins, pathogen inhibition and increasing the immune system of plants. Halophilic microorganisms are expected to produce extremozymes which are tolerable in high salt concentration and low water activity. These features are crucial in harsh conditions of industrial enzyme production.

Objectives

The aim of this study was to screen the chitinolytic enzyme produced by haloarchaea isolated from different saline and hypersaline lakes and wetlands in Iran, applying colloidal chitin as a sole source of carbon in culture media.

Methods

A total of 100 halophilic strains were selected for this project. Modified Growth Medium (MGM) supplemented with 1% colloidal chitin was used for qualitative assay of chitinase. After incubation at 40˚C and spending appropriate time, chitinolytic activity was visualized by a clear zone around colonies.

Conclusions

Among 100 strains, 3 strains were chitinase positive. Phylogenetic studies showed that these strains belonged to genera: *Haloarchaeobius*, *Halorubrum* and *Haloarcula*. This research showed that halophilic archaea from different saline environments in Iran have a potential of producing hydrolytic enzymes which may possess commercial value. Our further investigations will measure the enzyme activity and optimize the enzyme production by potent archea.

GENOME-WIDE IDENTIFICATION OF GENES INVOLVED IN NADPH SUPPLY

L. Ye[1], S. Cardinale[1], S. Siedler[1], M.M.H. Ellabaan[1], S.H. Kim[1], M.O.A. Sommer[1]
[1]Technical University of Denmark, DTU Biosustain, Kgs. Lyngby, Denmark

Backgrounds

NADPH is a crucial cofactor in reductive enzymatic reactions to synthesize valuable compounds. Previous designs to increase intracellular NADPH availability mainly focused on the modification of central metabolism. However, this may cause unexpected growth defect, such as the deletion of phosphoglucose isomerase (*pgi*) gene would dramatically slow down the growth rate compares to wildtype, letting alone the redirection of glycolysis flux significantly reduces the substrates level for the biosynthesis of most valuable chemicals.

Objectives

To identify mutants with both high NADPH supply and growth fitness.

Methods

We combined the fast fitness quantification by random barcoded transposon library (RB-TnSeq) and fluorescence-activated cell sorting (FACS) based on a NADPH biosensor. The mutant library (approximately 9×10^5 mutants each with unique useful barcode distributed in 3,882 genes) was constructed and characterized, and then transformed with plasmids containing the soxR NADPH biosensor. Libraries were selected in NADPH consuming condition, fitness/fluorescence change between NADPH depletion and control condition allows us to profile the intracellular NADPH level of each mutant. Thirty mutants were selected for better performance in NADPH consuming condition. These mutants were confirmed to have increased tolerance in NADPH depletion condition due to higher NADPH/$NADP^+$ ratio. They were further proved to have different levels of improvement for isobutyric acid and mevalonate production, both titer and yield compared to wildtype.

Conclusions

We established a high-throughput phenotype screening platform for *E. coli* K-12 strain. We proved the sufficiency to improve redox cofactor pool by eliminating unnecessary function genes, and extended the strain engineering space to genome-wide.

LACTOBACILLUS CASEI METABOLIZES THE GLYCOAMINOACID FUCOSYL-ALPHA-1,6-N-ACETYLGLUCOSAMINE-ASPARAGINE THAT FORMS PART OF HUMAN MILK AND MUCOSAL GLYCOPROTEINS

J.E. Becerra[1], J. Rodriguez-Diaz[2], M. Palomino-Schätzlein[3], M. Zuñiga[1], V. Monedero[1], M.J. Yebra[1]
[1]Instituto de Agroquímica y Tecnología de Alimentos, Biotecnología de Alimentos, Paterna, Spain
[2]Universidad de Valencia, Departamento de Microbiologia, Valencia, Spain
[3]Centro de Investigación Príncipe Felipe, RMN facility, Valencia, Spain

Backgrounds

Glycoproteins from human milk could play a significant role in the establishment of the infant gut microbiota. *N*-glycans contain an *N*-acetylglucosamine (GlcNAc) linked to asparagine and they can be modified with core alpha1-6-fucosylation. We have previously characterized the alpha-L-fucosidase AlfC encoded by *Lactobacillus casei* and analyzed the DNA region around *alfC*. This region (*alf2*) spans a hypothetical operon *alfHC*, encoding a permease and AlfC, respectively, and divergently oriented, a cluster of genes annotated as *asdA*, *alfR2*, *pepV*, *asnA2* and *sugK*, encoding hypothetical aspartate decarboxylase/aminotransferase, transcriptional regulator, peptidase, glicosylasparaginase and sugar kinase, respectively.

Objectives

1) To study the role and transcriptional regulation of the *alf2* operon from *L. casei*.

2) To synthesize 6'fucosyl oligosaccharides and fucosyl-alpha-1,6-*N*-GlcNAc-Asn (6'FN-Asn) using AlfC in transglycosylation reactions.

Methods

Construction of mutant strains by plasmid insertional inactivation of genes in *L. casei*; RNA isolation and RT-qPCR; transglycosylation reactions with purified 6X(His)AlfC and *p*-nitrophenyl-alpha-L-fucopyranoside as donor; HPLC analysis; RMN.

Conclusions

1) 6'FN-Asn, fucosyl-alpha1,6-glucose, fucosyl-galactose and fucosyl-*N*,*N*'-diacetylchitobiose were synthesized by AlfC in transglycosylation reactions with maximum yields of 3.6, 3.3, 1.3 and 1.8 g/l, respectively.

2) *L. casei* is able to grow in the presence of the glycoaminoacid 6'FN-Asn, and the permease AlfH and the alpha-L-fucosidase AlfC, encoded in the *alf2* operon, are involved in its metabolism.

3) The expression of *alf2* operon is induced by 6'FN-Asn through the AlfR2 transcriptional repressor. Unlike the wild-type, an *alfR2* mutant strain can metabolize the disaccharides fucosyl-alpha-1,6-GlcNAc, fucosyl-alpha1,6-glucose and fucosyl-galactose, and the trisaccharide fucosyl-*N*,*N*'-diacetylchitobiose.

PRODUCTION OF LACCASE AND CELLULASES BY PYCNOPORUS SANGUINEUS (DMSZ 3024) USING HAZELNUT HUSK

Z. Yılmaz Serçinoğlu[1], N.A. Sayar[1], D. Kazan[1]
[1]Marmara University, Bioengineering, İstanbul, Turkey

Backgrounds

The cost of enzyme cocktails used for the pretreatment and hydrolysis of lignocellulosic raw material is one of the main obstacles to the successful commercialization of second-generation bioethanol. Integrated production of these enzymes and the subsequent bioethanol production may be an approach to lower overall production costs. Using the lignocellulosic raw material as substrate for the production of the lignocellulolytic enzymes may help simplify the integration of enzyme and bioethanol production processes. Hazelnut husk is an abundant agricultural waste in Turkey which can be used as lignocellulosic raw material. It is comparably lignin rich and its biological pretreatment with laccase to enhance delignification is important for later efficient hydrolysis. So, the production of an enzyme cocktail containing laccase and cellulase enzymes using hazelnut husk as substrate may be advantageous for later integration with bioethanol production.

Pycnoporus sanguineus DMSZ 3024 (*P.sanguineus*) is a white rot fungus which is a potential producer of an enzyme cocktail containing laccase and cellulase enzymes.

Objectives

Our aim is to identify and assess the potentiality of *P. sanguineus* as a producer of the lignocellulolytic enzyme cocktail using hazelnut husk as substrate.

Methods

Laccase, CMCase, β-glucosidase are produced by *P. sanguineus*. Activity of lignocellulolytic enzymes are measured daily by using CMC, pNPG and ABTS as substrate, respectively.

Conclusions

It is found that *P. sanguineus* produces the lignocellulolytic enzyme cocktail containing laccase, CMCase, β-glucosidase and is open to further optimization and integration with bioethanol production processes.

Biotechnology / Synthetic Biology / Systems Biology - Part III

MICROALGAE AS CELL FACTORIES: SYNTHETIC TRANSFER RNA GENES AS GENETIC ENGINEERING TOOLS FOR THE CHLAMYDOMONAS REINHARDTII CHLOROPLAST

R. Young[1], *S. Purton*[1]
[1]*University College London, Structural and Molecular Biology- Darwin Building, London, United Kingdom*

Backgrounds

Single-celled eukaryotic microalgae such as *Chlamydomonas reinhardtii* have potential as an alternative platform for the production of vaccines, antibiotics and a variety of chemicals. Benefits include their ability to fix carbon using sunlight, ease of scaleup, lack of endotoxins and the availability of genetic engineering tools.

Objectives

We previously developed a chloroplast transfer RNA (tRNA) that allows the constitutive translation of UGA codons as tryptophan; UGA is not naturally used as either a sense or stop codon in the *C. reinhardtii* chloroplast. This tool has applications for cloning antibacterial genes and biocontainment. We now aim to address the pressing need for a simple inducible system for the expression of foreign proteins and metabolic pathways in the microalgal chloroplast.

Methods

We are working to identify temperature-sensitive variants of our original trnW-UCA tRNA in order to develop a cold-inducible expression system for transgenes with internal TGG-to-TGA alterations. One variant in particular is displaying promising thermolabile behaviour and we are characterising this further.

Conclusions

A temperature-inducible protein expression system would avoid the need for an expensive chemical inducer and could be used in any *C. reinhardtii* strain background. We hope to adapt the stable and thermolabile versions of trnW-UCA for other industrially relevant microalgae such as *Phaeodactylum* and *Chlorella*.

Backgrounds

The Education and Communication Division (Docencia y Difusión, D+D SEM; www.semicrobiologia.org/ddm) of the Spanish Society for Microbiology (Sociedad Española de Microbiología, SEM; www.semicrobiologia.org) was created as a transversal group in which researchers, teachers, journalists and others can collaborate to promote quality and veracity in Microbiology transmission.

Objectives

To improve the microbiological knowledge of the society and to promote the elaboration and open exchange of materials and resources for Microbiology Education.

Methods

University and Research Centers' staff who teach or investigate in diverse Microbiology areas all along Spain are members of the Division, ensuring a diversity of knowledge and interests.

D+D SEM searches to establish links with professionals at primary and secondary schools, offering assessment and support about microbiological subjects, aiming to the content of official teaching modules and text books and editing a book of educative short stories aimed to children. Moreover, members publish microbiological concepts by participating in scientific fairs, advising journalists and by the use of the internet and social networks (official and personal blogs and networks).

D+D SEM organizes yearly workshops on "Initiation to Research in Microbiology" for brilliant students and hosts the Group of Young Researchers (sites.google.com/site/jovenesinvestigadoressem).

Periodically, D+D SEM organizes congresses and meetings so that its members and any teacher or researcher interested can share experiences and knowledge and also promotes the participation in any event of interest.

Conclusions

We seek to share our experience and to coordinate our effort with similar initiatives in other countries.

Education / Professional Development / Policies

ACTIVITIES OF THE YOUNG RESEARCHERS GROUP OF THE SPANISH SOCIETY FOR MICROBIOLOGY

I. Belda[1], S. Bárcena[2], J.D. Flores-Felix[3], D. Thomas-Lopez[4], B. Vera-Gargallo[5]
[1]Biology Faculty- Complutense University of Madrid, Department of Microbiology, Madrid, Spain
[2]University of Navarra, Department of Microbiology and Parasitology, Pamplona, Spain
[3]University of Salamanca, Department of Microbiology and Genetics, Salamanca, Spain
[4]Faculty of Veterinary Medicine and VISAVET- Complutense University of Madrid, Animal Healh Department, Madrid, Spain
[5]Faculty of Pharmacy- University of Sevilla, Department of Microbiology and Parasitology, Sevilla, Spain

Backgrounds

The current socio-economic situation has led to young scientists facing a harsher, more competitive, more dispiriting workplace than previously. In this context, Scientific Societies must promote and facilitate scientific careers by boosting motivated and vocational researchers from undergraduate levels and improving later scientific networks.

Objectives

Since 2012, a group of PhD students have developed the Young Researchers Group (JISEM) within the Spanish Society for Microbiology (SEM). Our goal is to increase the bonds of young Spanish microbiologists with our Society-SEM, by improving their “scientific experience” during their PhD and first postdoc stages.

Methods

We have established different work fronts:

- Communicating and sharing research opportunities

- Introducing young researchers in the Boards of Trustees of different SEM Committees

- Contributing to the SEM annual course “Research in Microbiology”

- Promoting the participation of SEM-granted students in National Meetings

- Writing outreach articles in SEM-Newsletter about “Success stories” of Spanish and International young microbiologists

- Developing census and statistics about Spanish microbiologists

Conclusions

66 students received a SEM Fellowship for the “Research in Microbiology” course and to attend SEM National Congresses. 48 of those are now young members of SEM starting their PhDs projects.

We have a *junior* representative in 3 SEM-Scientific Committees now, and we expect this number to increase during the next years.

We have organized 2 successful “Young researchers” discussion forums at SEM Conferences and written 27 articles regarding worldwide initiatives and microbiologists. Our active Facebook group shares scientific information, with more than 1500 interactions per week.

Education / Professional Development / Policies

A LABORATORY ACTIVITY USING BACTERIOPHAGES, THE FORGOTTEN WEAPON AGAINST BACTERIA

S. Campoy[1], C. Pilar[1], J. Aranda[1], M. Sánchez-Osuna[1], J. Barbe[1], M. Llagostera[1]
[1]Universitat Autònoma de Barcelona, Departament de Genètica i de Microbiologia, Cerdanyola del Vallès, Spain

Backgrounds

Soon after their discovery, 100 years ago, phages were used to treat patients suffering from dysentery or cholera and to promote wound recovery. Although the results were promising, interest in phage therapy waned until it was mostly forgotten, as penicillin and other antibiotics became widely available. Today, the emergence of multidrug-resistant bacteria has rekindled the interest in bacteriophages as antibacterial tools. Despite phages are the most divers and abundant entities in our planet and their multiple applications, biology students remain largely unaware of these entities and are offered few opportunities to explore them in the laboratory.

Objectives

In this activity, students are introduced to the discovery of bacteriophages and encouraged to design an experiment demonstrating the possible use of lytic phages as biocontrol agents and comparing their efficacy with that of other antimicrobial agents. Further, they also formed hypotheses about the expected results and then, using quantitative data, tested their validity.

Methods

Experimental data were obtained by measuring absorbance and cell viability of *Salmonella enterica* sv Typhimurium LT2 cultures treated with either the P22 lytic derivative bacteriophage or different antibiotics (streptomycin, ampicillin or spectinomycin).

Conclusions

The obtained data, combined with class data or student autonomous learning, contributed to providing insights into the lytic and lysogenic cycles of bacteriophages, the molecular processes that finally kill the bacteria, and the appearance resistant bacteria. Further, using the scientific method, students were able to explore the nature of antimicrobial agents and the possible use of phages, phage cocktails, and phage derivative compounds as antibacterial tools.

Education / Professional Development / Policies

CONTINUOUS ASSESSMENT IN MICROBIOLOGY SUBJECTS IMPROVES ACADEMIC PERFORMANCE IN UNDERGRADUATE MEDICAL STUDENTS

M.F. Colom[1]
[1]*Universidad Miguel Hernández, Producción Vegetal y Microbiología, Sant Joan d'Alacant, Spain*

Backgrounds

The influence of the method of assessment, regardless the teaching system, is always critical in training the students and in the whole teaching process.

During the Bologna process we had the chance to review our teaching and training methods in higher education. This analysis together with the results obtained in local, specific surveys carried out in our faculty of medicine, were the basis for a major modification in the teaching methodology in Microbiology subjects for medical students.

Objectives

Assessment of the learning process based on continuous assessment methodology for teaching microbiology to medical students

Methods

After 10 academic years using continuous assessment methodology in teaching microbiology to medical students, we assess the assessment method through the analysis of three parameters: final grades, students' direct answers in quality surveys and the teacher’s grades in the university official assessment of the teaching system.

Conclusions

Analysis of the grades obtained in the ordinary call (February or June), show a significative increase in the mean (from 6.1 to 6.7) and the mode values (from 5.4 to 6.4) of final grades and in the percentage of students who passed the subject (from 61.8 to 96.2%). Similar results were obtained globally in teachers' assessments and the teaching quality surveys, with a positive increase of the qualitative and quantitative parameters evaluated.
The evaluation of three parameters related with the quality of the teaching process evidenced that continuous assessment method improve the performance of undergraduate medical students

FEMS7-0601
Education / Professional Development / Policies

SIMPLE PROTOCOL FOR MOLECULAR FINGERPRINTING OF HUMAN ORAL MICROBIOTA SAMPLES IN LAB CLASSES

A.C. Henriques[1], P. De Marco[1]
[1]IUCS, IINFACTS, Paredes, Portugal

Backgrounds

The increasing significance of molecular biology in different circumstances of our daily life implies that it is very important that biomedical students deal with the principles and techniques underpinning its application. Human DNA fingerprinting is a major tool in identifying individuals and in evidence matching. However, this technique can be difficult to reproduce in practical classes.

Objectives

Create a practical class activity suitable for undergraduate students that elucidates how human oral microbiota is diverse and individually unique.

Methods

Here we report on distinct PCR profiles obtained when amplifying saliva DNA of a score of distinct individuals with RAPD primer BOXA1R. RAPD is a simple method efficiently used for discrimination between bacterial strains and is used in this instance to obtain personalized fingerprints of each individual's oral microbiota.

Conclusions

We present real results with undergraduate students confirming that this procedure is easily feasible in practical classes. Based on the results presented, we suggest a laboratory activity for undergraduate Molecular Biology / Microbiology students.

Education / Professional Development / Policies

GETTING INTO THE SWING OF THINGS - COMMITTING TO LIFELONG LEARNING AND DEVELOPMENT (FROM UNDERGRADUATES TO ACADEMICS)

B. Fahnert[1]
[1]*Cardiff University, Cardiff School of Biosciences, Cardiff, United Kingdom*

Backgrounds

In a rapidly changing world, where jobs are no longer for life or change beyond recognition, lifelong learning is required of everyone. Educators need to support learners early on in understanding this need and developing necessary skills and reflection. So initial Personal Development Planning prepares and becomes Continuous Professional Development. Equally, these educators need sufficient opportunity for pedagogic training, also perceived as valuable by undergraduates and benefitting academic career establishment/advancement. Teaching professionalism is not developed through traditional academic apprenticeship (i.e. doctoral studies), and -along with high graduate employability rates- has become a focus for Higher Education Institutions to boost institutional reputation.

Objectives

Better understand behaviour and drivers around committing to lifelong learning at two stages:

a) graduate attributes and career skills development
to inform practice when equipping/empowering undergraduates for successful transition into employment;
b) teaching training for early career academics
to achieve long-term benefit for all stakeholders.

Methods

Stakeholder and discourse analyses and ethically cleared mixed method studies (interviews, questionnaires) were conducted, qualitatively analysing experiences and perceptions of:

a) under/postgraduates, academics, employers, alumni;

b) teaching training participants and non-participating academics.

Conclusions

In both contexts behaviour is affected by conflicting demands on time at present and obtaining intangible benefits for an unknown future.

Undergraduates prioritise subject rather than career skills unless incentivised, which still does not guarantee meaningful engagement.

Challenges to teaching training were e.g. non-peer trainers, unfamiliarity with terminology and using qualitative methodology/findings.

Using identified drivers to tailor developmental provision and communication with stakeholders towards cultural change is outlined.

FEMS7-2205
Education / Professional Development / Policies

UNDERGRADUATE EDUCATION IN MICROBIOLOGY - A MULTIPLE APPROACH IN UNIVERSITY OF PORTO

R. Mota[1], J. Palmeira[2], D. Gonçalves[3], H. Ferreira[2]
[1]University of Porto, Microbiology - Pharmacy Faculty, Porto, Portugal
[2]University of Porto, Microbiology - Pharmacy Faculty - UCIBIO, Porto, Portugal
[3]University of Porto, Microbiology - Pharamacy Faculty - UCIBIO, Porto, Portugal

Backgrounds

University of Porto has implemented a program of stimulation of Science Education of secondary school students emphasizing Microbiology. Community joined this approach particularly Municipality of Porto in cooperation with University and Research Institutes.

Objectives

Enhance scientific literacy in Microbiology and interest of the youngsters for science and health related experimental areas.

Methods

Junior University is a Summer School program including Microbiology related programs as "Microbiology an experimental approach" that develops skills in laboratory research in Microbiology. Another program intended for older excellent secondary school students, School of Sciences of Life and Health as for example "Colonization and infection two faces of the coin" and "Antimicrobial Resistance an ecological perspective".

Junior Research at University of Porto is another approach in which undergraduate students participate in research in different faculties with a great impact in Microbiology studies.

The interest of these approaches is shown by the dynamism of participation in National Science divulgation events as Young Scientists Annual Competition, private foundation awards and University of Porto Young Researchers Congress.

Conclusions

Junior University turned into an ex-libris of University of Porto and every year Junior University program has a very competitive choice by thousands of students of all over the Country. Microbiology is one of the most wanted areas. This approach is relevant in terms of areas and courses that young students will choose for University. This engages community in public presentations of works at the end of the program in a true scientific congress. There are enthusiastic results for the long term impact of these programs.

Education / Professional Development / Policies

SOCIAL NETWORKS AS KEY TOOLS IN MICROBIOLOGY DIVULGATION

J.D. Flores Felix[1], P. García-Fraile[2], P. Martínez-Hidalgo[1], M. Marcos-García[1], L. Celador-Lera[1], A. Díez-Méndez[1], X.A. Cruz-González[1], A. Jimenez-Gomez[1], R. Rivas[1]
[1]University of Salamanca, Microbiología y Genética, Salamanca, Spain
[2]Academy of Science of the Czech Republic, Department of Microbiology, Prague, Czech Republic

Backgrounds

YouTube is the major online video platform, with a high diversity of contents and over a billion of users from all around the world. Therefore, this platform has a high potential as education and divulgation tool. The combination of this platform with the social networks, such as Facebook or Twitter, has a great potential to introduce academic contents to a non-academic audience

Objectives

Our aim was to use of social networks as a tool to improve the diffusion of the Microbiology using multimedia contents guested in YouTube, increasing the number of potential spectators reached by our videos about microbiology techniques hosted in of YouTube channel.

Methods

We created different profiles in YouTube, Facebook and Twitter. The Youtube profile was linked to own channel, which has with 215 subscriptions and counts more than 30.000 video visualizations. On Facebook, we opened a Facebok Page named “Microbiología y Genética. Interacciones Planta-Microorganismo. USAL” (translated into English: Microbiology and Genetics. Plant-Microbes Interactions. USAL”) and on Twitter we created the profile @MicrobioUSAL. Then, we shared our Microbiology YouTube videos on our social networks.

Conclusions

We have seen than YouTube is a useful tool to disseminate microbiology contents into academic and non-academic fields and moreover, the use of social networks such as Facebook and Twitter to share the videos hosted on YouTube allowed us to increase the number of spectators, proved by peaks in the numbers of visualizations and minutes with clear activity during few hours following their shares on the social networks.

IMPACT OF SWI@SPAIN PROJECT IN DIFFERENT EDUCATIONAL AND SOCIAL CONTEXT HIGH SCHOOLS FROM THREE AREAS OF COMUNIDAD DE MADRID

C. Vázquez[1], J. Gil-Serna[1], M. García-Díaz[1], C. Briceño[2], T. Patiño[3], A. Zorrilla[4], A. García-López[1], C. Martín[1], A. Martinez[1], R. Pedrero[1], G. Saiz[1], B. Salazar[1], P. San Segundo[1], J. Sempere[5], I. Veliz[1], B. Patiño[1]
[1]Universidad Complutense de Madrid, Facultad de Biologia- Microbiología III, Madrid, Spain
[2]IES El Escorial, Ciencias, El Escorial, Spain
[3]IES Calderón de la Barca, Ciencias, Madrid, Spain
[4]IES Margarita Salas, Ciencias, Majadahonda, Spain
[5]Universidad Complutense de Madrid, Facultad de Químicas, Madrid, Spain

Backgrounds

Antimicrobial resistance (AMR) is a global concern that affects all society. An effective prevention involves a coordinated action at all levels including the educational one. The university has always served as a motor in which knowledge is transmitted and transformed to benefit society. In this context, SWI@Spain (Small World Initiative at the Complutense University of Madrid, Spain) is an Educational Project that implements the American SWI program in Spain.

Objectives

To encourage high school students to pursue careers in science while addressing AMR by establishing the first steps of scientific investigation in this matter, under the supervision of SWITAs, SWIPIs and high school students tutors.

Methods

The Spanish SWI project units undergraduate and Education master students from the Biological Science Faculty, all supervised by a Microbiology professor. SWI protocols were used for establishing the experiments with International Baccalaureate students, Bilingual Baccalaureate students and Baccalaureate students who were 18+ years old. The tasks included: preparing teaching and lab materials as well as supervising the development of the experiment. In addition, we evaluated the pedagogical effects of implement this innovative initiative by conducting satisfaction surveys.

Conclusions

The results of the various surveys among high school students have reflected a positive impact on motivation and basic AMR knowledge. In addition there is a growing interest in general science interest and curiosity, highlighting how high school students aim their classmates to participate in the SWI project.

Education / Professional Development / Policies

IMPACT OF SWI@SPAIN PROJECT IN SMALL WORLD INITIATIVE TEACHER ASSISTANTS (SWITAS)

J. Gil Serna[1], C. Vazquez[1], A. García-Lopez[1], C. Martin[1], A. Martinez[1], R. Pedrero[1], G. Saiz[1], B. Salazar[1], P. San Segundo[1], J. Sempere[2], I. Velez[1], B. Patiño[1]
[1]Complutense University, Microbiology III, Madrid, Spain
[2]Complutense University, Facultad de Quimicas, Madrid, Spain

Backgrounds

Antimicrobial resistance (AMR) is a global concern that affects all society. An effective prevention involves a coordinated action at all levels including the field of education. The university has always served as a motor in which knowledge is transmitted and transformed to benefit society. Undergraduate students are not accustomed to be in contact with teaching and real-life research experiences. SWI@Spain (Small World Initiative at the Complutense University of Madrid, Spain), which is supported by INNOVA- Docencia program, helps our students at this level.

Objectives

To offer STEM undergraduate students the possibility to expand their knowledge and open a wide variety of new job opportunities, while addressing AMR by doing all the main steps in scientific research under the supervision of SWIPIs.

Methods

SWITAs are undergraduate students from the Biology and Biochemistry degree who were selected by a Microbiology professor. These students were informed about the international Small World Initiative, as they received an intensive training to prepare them to being able to teach high school students the AMR issue and scientific method: highlighting biosecurity, tenacity and scientific accuracy. The pedagogical and scientific effects of this innovative initiative was evaluated among the students. They completed a-15 question survey, which include questions related to science, teaching and AMR aspects.

Conclusions

The result of the different surveys reflected a positive impact on motivation and general AMR knowledge, as well as an increment in investigation and teaching interest. Some of these students have joined various university investigation teams, improving their scientific knowledge.

Education / Professional Development / Policies

"HOW ARE MICROBES USEFUL TO US?": MICROBIOLOGY LEARNING IN EUROPEAN RESEARCHER'S NIGHT.

A. Jiménez-Gómez[1], X. Cruz-González[1], J.D. Flores-Félix[1], L. Celador-Lera[1], A. Diéz-Mendez[1], E. Menéndez[2], M. Marcos-García[1], P. García-Fraile[3], R. Rivas[1]
[1]University of Salamanca, Department of Microbiology and Genetics, Salamanca, Spain
[2]Instituto de Ciências Agrárias e Ambientais Mediterrânicas, ICAAM, Evora, Portugal
[3]Academy of Science of Czech Republic., Institute of Microbiology, Prague, Czech Republic

Backgrounds

European Researcher's Night is one of the most important scientific events in Europe. It takes place every year on the last Friday in September. More than 30 countries and over 300 cities participate organizing scientific dissemination activities, showing to citizens what researchers really do for society and increasing the possibility to promote research careers to young people. In addition, Microbiology is one of the subjects which does not have an important relevance in the current high schools' curricula, and however has a big relevance in our lives. Moreover, microbiology requires from society the comprehension of many complicated concepts, which are easy to learn if taught in a practical way.

Objectives

In this context, our main objective was to offer society the possibility of seeing colonies of microorganisms cultured in Petri dishes, observing different samples under the microscope and showing the essential importance of microorganism in many key points of our daily life.

Methods

The activity was carried out in one of the microbiology laboratories of the University of Salamanca (Spain). The 40 participants were divided into small groups and were rotating to perform the different activities in one-hour sessions. The language used was suited to the different age of the participants (between 14 and 70 years old) and the topics presented were selected according to general society interests.

Conclusions

The experience was gratifying and positive not only for the participants but also for the researchers who organized the activity. It was an exchange of questions and answers which showed the general doubts of the society about Microbiology. The success of the activities shows us that the topics presented were interesting to both children and adults.

Education / Professional Development / Policies

HOW DO BACTERIAL PATHOGENS SPREAD IN A COMMUNITY?

M. Llagostera[1], S. Campoy[1], J. Barbe[1], M. Marco[2], N. López[3], S. Lope[4]
[1]Universitat Autònoma de Barcelona, Departament de Genètica i de Microbiologia, Cerdanyola del Vallès, Spain
[2]Institut Sant Quirze del Vallès, Secció Biologia, Sant Quirze del Vallès, Spain
[3]Generalitat de Catalunya, CESIRE - àmbit de ciències CDEC- Servei d'Innovació i Formació de l'Educació Primària. Departament d'Ensenyament, Barcelona, Spain
[4]Generalitat de Catalunya, CESIRE - àmbit de ciències CDEC- Servei d'Innovació i Formació de l'Educació Secundària. Departament d'Ensenyament, Barcelona, Spain

Backgrounds

Numerous bacterial infections may be transmitted through direct or indirect contact with a reservoir of infectious bacteria. Direct person-to-person contagion occurs when an individual comes into contact with the reservoir via touching infected bodily fluid; sharing beverages containing bacteria or inhaling the pathogens contained in little water droplets, often emitted by sneezing or coughing or even by a person when speaks. This can happen before an infected person is aware of the illness. Here we present a laboratory activity designed by the µBIO Cat Group to introduce primary and secondary education students to the contagion of bacterial diseases.

Objectives

In this activity the students simulate the pathogen bacteria spread from an infected person to the rest of the community. The challenge is to identify the infection focus and to propose methods for the contagion prevention.

Methods

Rhodobacter sphaeroides, a non-pathogenic bacteria that give rise red colonies, was chosen as the bacterial agent to be spread and students shook their hands to promote the person-to-person contact. In order to identify the first infected person, samples from each student's hand were taken, plated onto suitable media and bacterial colonies were quantified.

Conclusions

This activity was performed in different educational centers. The experimental obtained results and the conclusions achieved in each case have been exposed and discussed. Further, the opinions and satisfaction levels of both, teachers and students, about the activity have been also collected and analyzed.

FEMS7-3117
Education / Professional Development / Policies

ESSENTIAL MICROBIOLOGY: THE FIRST GENERAL MICROBIOLOGY TEXT-BOOK WRITTEN BY SPANISH MICROBIOLOGISTS

A. Martin-Gonzalez[1], V. Bejar[2], J.C. Gutierrez[1], M. Llagostera[3], E. Quesada[2]
[1]Universidad Complutense UCM, Microbiologia-III Fac. Biologia, Madrid, Spain
[2]Universidad de Granada, Microbiologia. Fac. Farmacia, Granada, Spain
[3]Universidad Autonoma de Barcelona., Genetica y Microbiologia, Barcelona, Spain

Backgrounds

Four years ago, we embarked on an exciting adventure to elaborate the first Spanish textbook on General Microbiology. The aim was that this book could be used as a basic tool for teaching the microbial word to undergraduate students of very diverse University Degrees, such as Biology, Biochemistry, Biotechnology, Environmental Sciences, Microbiology, Pharmacy, etc. Fortunately, this adventure has become a reality and finally, the textbook, entitled *Essential Microbiology*, is already in press. It will be published by Panamericana Press (Editorial Panamericana) in 2018.

Objectives

The elaboration of the different book chapters has been carried out by 33 different authors, which are Spanish microbiologists, all members of diverse specialized groups of the *Spanish Society of Microbiology* (SEM). *Essential Microbiology* is organized in 38 chapters, distributed in seven thematic blocks (Introduction, Microbial Structure and Cell Differentiation, Metabolism and Growth, Microbial Genetics and Genomics, Microbial Diversity, Ecology and Microbial Interactions, and Microbial Biotechnology).

Methods

Some of these chapters are usually included in Microbiology textbooks. Nevertheless, in this book, new views have been incorporated, such as Immunology as an aspect of human-microbe interaction; it also contains a number of new chapters habitually not included in a traditional Microbiology book; for instance; microbial gene expression regulation, microbial genomics, sexual processes in eukaryotic microorganisms, eukaryotic microbial structure, viruses of eukaryotic microorganisms and plants, and interactions among microorganisms.

Conclusions

Likewise, all chapters include: illustrative schematic diagrams, sample and self-evaluation questions, short hot topics in Microbiology, a summary of the main concepts, basic references, a glossary, and other tools to facilitate the learning and curiosity of potential students. We hope that this book becomes an useful tool for both university students and professors, in a next future.

FEMS7-2399
Education / Professional Development / Policies

THE SMALL WORLD INITIATIVE AS A TOOL TO LEARN ABOUT ANTIFUNGAL DRUG DISCOVERY, TARGET-BASED SCREENING AND SYNTHETIC BIOLOGY

H. Martín[1], A. Alvarez[1], I. Bascones[1], P. Calomarde[1], T. Sardón[1], B. Ureña[1], A. García[2], T. Martin[2]
[1]Universidad Complutense de Madrid, Microbiología II, Madrid, Spain
[2]Colegio Mirabal, Bachillerato, Boadilla del Monte, Spain

Backgrounds

Introduced at Yale University in 2012, the Small World Initiative (SWI) is an educational program that encourages young students to pursue careers in science and to raise awareness about what is considered for WHO one of the main health threats: the scarcity of effective antibiotics. This is particularly for antifungal drugs since resistance to them has emerged as a therapeutic challenge.

Objectives

We wanted to extend the main objectives of the general SWI program to (i) the awareness of the antifungal drugs insufficiency, (ii) the knowledge about the use of target-directed screenings to search for antibiotics with a specific mode of action and (iii) the possibilities and concerns about the use of synthetic biology for reprogramming cell behavior.

Methods

A group of 5 Pharmacy students coursing Microbiology at the third year, supervised by a Faculty Microbiology professor and two high-school professors, implemented SWI on a group of 32 high-school students taking biology at the Mirabal School. A total of 16 soil samples were screened for the existence of bacteria able to produce antibacterial or antifungal molecules. Whereas classical bacterial strains were used for detecting antibacterial producing microorganisms, a novel yeast strain constructed by a synthetic biology approach was used to sense cell wall altering antifungal molecules.

Conclusions

As a service-learning project, this SWI project has been useful not only to search for novel antibiotics but also to help students to learn and think about the necessity of antifungal drug discovery programs and the utility of synthetic biology to this end.

Education / Professional Development / Policies

HIGH SCHOOL STUDENTS FOR MICROBIOLOGICAL SCIENCE RESEARCH

F. Martinez-Abarca[1], *A. Quesada-Ramos*[2], *F.J.P. Caceres*[3]
[1]*Estación Experimental del Zaidín-Consejo Superior de Investigaciones Científicas, Microbiología del Suelo y Sistemas Simbióticos, Granada, Spain*
[2]*IES Zaidin Vergeles, Departamento de Biologia y Geologia., Granada, Spain*
[3]*Universidad de Granada, Departamento de Didáctica de las Ciencias Experimentales, Granada, Spain*

Backgrounds

Innovative ideas are always welcomed to improve learning in educational environments. Innovation at High School in Andalucía (current acronym *Science-IES*; http://piiisaandalucia.blogspot.com.es/p/que-es-piiisa.html) was run last years as the collaboration among centers of the Consejo Superior de Investigaciones Científicas (CSIC) , Universities and Secondary Schools of Junta de Andalucía (Spain). *Science-IES* brought High School Students to laboratories of the Research Institutes to develop small research projects during 7-9 sessions throughout the academic course. Those projects allow the interrelationship among students, teachers and scientists to work “hand in hand” for the same objective. The microbiology discipline has been already present in 6 editions of this event (2012-).

Objectives

To design simple or not so simple experiments to introduce Microbiology concepts (gene, genome, mutation, mutagenic effects, …) to teenager students finishing in a written and oral comunications.

Methods

Students (15-16 years old) will become familiar with Molecular Biology concepts and basic techniques in Microbiology (dilutions, colony counts, DNA isolation, PCR, DNA sequencing, …) in order to acquire how research in Microbiology is conducted (Example in http://mutandogenes.blogspot.com.es/).

Conclusions

This model has created a new manner to built science, with very profitable results in laboratories, but, as the most prominent consequence, it has proposed a new way to understand how to delight/teach/learn microbiology (as well as other disciplines) at high schools. *Science-IES* shows to high school students how research is performed today.

Acknowledgements: FECYT-FCT-12-3552 and research-projects CSD2009-00006; BIO-2011-24401 and BIO2014-51953-P *from the Spanish Government all including European Regional Development Funds.* Also we appreciate the coordination of Secondary Schools teachers involved

STUDENT-GENERATED MULTIPLE-CHOICE PRE-EXAM QUESTIONS: AN EFFECTIVE TOOL FOR PARTICIPATORY LEARNING IN MICROBIOLOGY

M. Marvasi[1], M. Teplitski[2], M. Di Cesare[1], C.J. Krediet[3]
[1]Middlesex University, Natural Sciences, London, United Kingdom
[2]University of Florida, Water and Soil Science, Gainesville, USA
[3]Eckerd College, Marine Biology Department, St. Petersburg, USA

Backgrounds

It is commonly recognized that the act of creating questions enhances learners' understanding of course materials and promotes deep learning. Student-generated questions that involved higher cognitive skills (compared to a simple recall) have been linked to self-directed learning and improved conceptual understanding.

Objectives

In this multi-year study, students designed multiple-choice pre-exam questions during a Microbiology course aimed at higher levels of learning, followed by their discussion. Students were instructed to construct questions on the higher domains of Bloom's taxonomy. We tested the hypothesis that this intervention improves student learning.

Methods

Learning gains were measured as student achievement on the exam following the intervention, and compared to student achievement on the traditional exam (prior to which a review session was focused on instructor-led recitation of the key concepts). Over the duration of the experiment 162 students chose to participate in this study from 2009 to 2015.

Conclusions

Following the intervention in all years, average grade on the post-intervention exam increased by 7.4% points. It is important to point out that not all students benefited equally from this activity. The lowest quintiles improved their scores on the second exam in a range of 6.8% to 9.9% percentage points, respectively. Students who were in the 3rd quintile based on the results of the first exam demonstrated the highest achievement improving their performance on an average by 12.3% percentage points. The students within the forth quintile improved their performance by 10.8% percentage points. Such gains were not observed in the semesters when the intervention was not implemented.

Education / Professional Development / Policies

PROJECT-BASED LEARNING METHODOLOGY IN MEDICAL MICROBIOLOGY

E. Mateo[1], *E. Sevillano*[1]
[1]*Universidad del País Vasco UPV/EHU, Immunology- Microbiology and Parasitology, Leioa, Spain*

Backgrounds

«Research Project» is an annual subject of 6 ECTS included in the third year of the Degree of Medicine (School of Medicine and Nursery. UPV/EHU) in which our Department is involved. There is evidence that students with a research experience during their training acquire knowledge and skills that increase the probability of getting involved in research more successfully.

Objectives

The aim of this work was to implement a project-based learning methodology in this subject, with the students working on microbiology, and to analyse its impact along time.

Methods

The students were monitored in groups of 20 students, working in groups of 4-5 people. Given an initial scenario, they had to come up with a research idea related to medical microbiology and to carry out a research project, including writing a funding proposal, developing the experimental assays, and analyzing and presenting their results to a congress organized by the University. Continual assessment was performed by both students and teachers. A satisfaction survey was carried out to gather the students' opinion.

Conclusions

The overall results regarding to the classroom dynamics, learning results and motivation after a three year period of implementation were favourable. Marks were higher after the implementation. The students referred more implication in the subject and self- demanding, and a greater capacity to interpret the results following the scientific method. They stated a greater interest about research than they had before coursing this subject. In addition, all of them would choose the project based methodology versus the traditional one.

Education / Professional Development / Policies

SWI@SPAIN: A VERSATILE PLATFORM FOR STUDENTS OF DIFFERENT AGES AT HIGH SCHOOL LEVEL TO AWARE ABOUT THE WORLDWIDE ANTIMICROBIAL RESISTANCE PROBLEM

F. Navarro-García[1], C.C. Casares-Salve[1], R. Clemente-Caballero[1], C. González-Pérez[1], M. Ortega[1], L. Papineschi[1], A. Pérez-Domingo[1], J.H. Quispe-Abregú[1], L. Torroba-Vicario[1], J.L. Veiga-González[1], I. Navarro-Muñoz[1], R.M. Jiménez de la Vega[2], J. Medina[3], J. Pla[1]
[1]Departamento de Microbiologia II, School of Pharmacy, Universidad Complutense de Madrid
[2]Colegio Arturo Soria, C/Duque de Tamames-4., Madrid, Spain
[3]IES Alpajés, C/ de las Moreras- 1, Aranjuez, Spain

Backgrounds

SWI@Spain is the Spanish implementation of the Small World Initiative program (SWI) firstly developed in the USA. This educational program aims to expand into the society the importance of preserving antibiotics in view of the increase of the antimicrobial resistance among bacterial isolates throughout the world. Choosing High School students will help broaden the target audience in an attempt to spread the message into the society through their families.

Objectives

To evaluate the influence of the SWI program on the perception of microorganisms, the responsible use of antibiotics and the burden of antimicrobial resistance at different levels of High School students.

Methods

Two different high school groups (12 years-old, 1º ESO, and 17 years-old, 2º Bachillerato) were selected to implement the SWI program. Sessions were developed in the laboratories of selected schools in Madrid with the help of Degree students. Soils from different parts of Spain were obtained and analyzed for the presence of antibiotic-producing microorganisms, as well as ampicillin-resistant strains. This was financed by a project in educative innovation awarded by University Complutense de Madrid (INNOVA-Docencia 2016-2017, Project 40).

Conclusions

We will present the influence of this program in the perception of two groups of High School students of different ages about the use and importance of antibiotics through the analysis of questionnaires run before and after the sessions. The importance of soil microbiology will be highlighted as a method to find new antibiotics, as well as a possible origin of antimicrobial resistance.

PARTICIPATORY WORKSHOPS: THERE IS NOT AGE TO DISCOVER MICROBIOLOGY

M. Orruño[1], *I. Arana*[2]
[1]*Faculty of Pharmacy - University of the Basque Country UPV/EHU, Immunology- Microbiology and Parasitology, Vitoria-Gasteiz, Spain*
[2]*Faculty of Science and Technology - University of the Basque Country UPV/EHU, Immunology- Microbiology and Parasitology, Leioa, Spain*

Backgrounds

Every year the University of the Basque Country (UPV/EHU) organizes the Science Week (ZientziaAstea). This annual event, aimed at audiences of all ages, tries to bring science to a non-specialist public by means of workshops, scientific shows, conferences and other activities. The microbiology has been present in this event from the first edition.

Objectives

To try to transmit microbiology in a more efficient and participatory way.

Methods

In recent years we have launched 2 workshops aimed at children and adults. The first workshop we implemented, *Microorganisms working*, tries to refute the bad image of microorganisms and to highlight their benefits and their ecological and industrial relevance. Among others, attendees can taste several foods and beverages obtained with microbial participation and discover that microorganisms are involved in the production processes of numerous common household product.

As the format was not the most suitable to keep the attention of the younger participants, we decided to launch a new workshop specifically aimed at children between 6 and 12 years, *Small microbiology for small scientists,* which tries to introduce children the microbial world through games and activities. They can use a microscope to discover the microbial diversity in natural samples, simulate the bacterial growth or become aware of their own *microbiological fingerprint*.

Conclusions

The workshops have been quite successful, with all the available places filled and a high level of satisfaction among attendees. In addition, the children's workshop has been exported to other fairs and adapted to schools.

ISSUES OF INTEREST AMONG AUTHORS PUBLISHING IN MEDICAL MICROBIOLOGY AND INFECTIOUS DISEASES JOURNALS: IS MULTIRRESISTANCE A TREND TOPIC IN SPAIN?

M.E. Pablo-hernando[1], *S. Pablo-hernando*[2]
[1]*Hospital Severo Ochoa, Microbiologia, LEGANES, Spain*
[2]*Fundación BIOEF, Unidad de Investigación en Atención Primaria- Bizkaia, Bilbao, Spain*

Backgrounds

WHO states that “antimicrobial multirresistance is an increasingly serious threat to global public health that requires action across all sectors involved”. In Spain, 50% of antibiotic prescriptions are unnecessary and the time practitioners invest in antimicrobials and continuous training influences their performance.

Nowadays, scientific journals become the main mechanism to diffuse knowledge. They structure the functioning of academic communities, prioritize the research agenda and provide the training contains.**Objectives**

Thus, this descriptive longitudinal study aims to identify “interests” among authors contributing to Medical Microbiology journals, as an indirect approach to know whether “Multirresistance” attracts attention. Two questions are formulated:

- What topics EIMC authors have chosen to publish?

EIMC (*Enfermedades Infecciosas y Microbiología Clínica*) is the Clinical Microbiology and Infectious Diseases Spanish Society main publication.

- Are these issues considered in analogous European Journals?

Methods

Thoughts, experiences or comments are reflected on editor’s or scientific letters and their titles synthesize author’s perspectives.
“Iramuteq” (content-analysis software) has been used to analyze two groups of titles: EIMC with 1.792 headings and “European group” with 1.353 titles extracted from analogous journals: *European Journal of Clinical Microbiology and Infectious Diseases, Journal of Medical Microbiology*, *Infection* and *Scandinavian Journal of Infectious Diseases*.
This methodology helped to identify topics, to classify them creating thematic clusters and to study their progress over time.

Conclusions

Results show how HIV disease, methodology and severe infections have fed opinion articles over time, and how multirresistance has been unnoticed in Spain. This fact could be linked to the poor prescription outcome.

Education / Professional Development / Policies

TAKING CHARGE OF MICROBIOLOGY PRACTICAL LESSONS IN HIGH SCHOOL AS A TRAINING FOR MASTER STUDENTS

D. Prieto[1], E. Roman[1], T. Fernandez-Acero Bascones[1], J. Pla[1]
[1]Dept. Microbiología II- School of Pharmacy- Universidad Complutense de Madrid, Microbiología II, Madrid, Spain

Backgrounds

The Small World Initiative (SWI) is an educational program based in Microbiology experiments that has been recently implemented in Spain (SWI@Spain). In the SWI@Spain version the experiments are carried out by High School students. These practical lessons are usually organized by undergraduate students and a Professor or a Researcher.

Objectives

To analyze the didactic suitability of applying the Small World Iniciative program (SWI@Spain) to Master students (MS) in accordance to the Master Program.

Methods

Volunteer students from the Master of Microbiology and Parasitology (UCM) were included in the SWI program, adopting the service-learning strategy (SWI@Spain). During the experience, different aspects about the teaching-learning process were collected from the supervisor and the MS and analyzed. The information obtained was compared with the aims and skills proposed from the Master program. This was financed by a project in educative innovation awarded by University Complutense de Madrid (INNOVA-Docencia 2016-2017, Project 40).

Conclusions

The participation in the SWI program was considered as positive or very positive, in general and in the context of the Master degree, by all the MS. The learning achievements derived from the SWI experience gained by the MS correlate with most of the aims and skills defined in the Microbiology and Parasitology Master Program. Besides, the practical essence and the active learning result in an interesting complement for the MS formation.

LOOKING FOR NEW ANTIBIOTICS: THE SMALL WORLD INICIATIVE IN SPAIN.

C. Rodríguez[1], B. Conde[1], V. Fernández[1], P. Higueras[1], M. Rodrigo[2], D. Ruiz[1], J.A. Valdés[1]
[1]Universidad Complutense Madrid, Microbiology II, Madrid, Spain
[2]Universidad Complutense Madrid, Microbiology III, Madrid, Spain

Backgrounds

One of the main problems in the 21th Century is the lack of new therapeutic agents for fighting against multi-resistant bacteria. Looking for antibiotics and doing science in high school education will have a significant impact in society, especially among young people. The *Small World Iniciative* (SWI-USA), now introduced in Spain (SWI@Spain) for the first time, aims the students to become increasingly aware of problems with the over prescription and misuse of antibiotics, and the failure of treatments. Moreover, this experience can approach them to science and stimulate young scientific vocations. This is also a system of self-learning and an excellent way to open their minds to the future.

Objectives

The main goal is to concern the students about the clinical, social and economic impact of the treatment of bacterial infections. They are also introduced to the scientific method, microbiological techniques and the research of new soil bacterial strains.

Methods

We have applied the SWI strategy in the *IES Madrid Sur*. One microbiology faculty member (SWI Partner Instructor, SWIPI) and six undergraduate and graduate students (SWI Teaching Asistants, SWITAs) have been working with 36 high school students, during five sessions, two hours each. We have a special interest in divulgation of science, particularly through social networks (Facebook, Twitter, and a public blog) and official websites. Financed by INNOVA-Docencia 2016-2017, Project 40.

Conclusions

We have found new interesting bacterial strains producing antibiosis against the ESKAPE microorganisms used as testers. These strains have been identified by microbiological and molecular methods.

FEMS7-1832
Education / Professional Development / Policies

PROMOTING SOFT-SKILLS DEVELOPMENT IN MICROBIOLOGY PRACTICAL CLASSES

B. Sampaio-Maia[1], P. Vieira-Marques[2], J.S. Maia[3], V. Teixeira[4]
[1]University of Porto, Faculdade de Medicina Dentária- I3S-
Instituto de Investigação e Inovação em Saúde- INEB-Instituto de Engenharia Biomédica, Porto, Portugal
[2]University of Porto, CINTESIS- Faculdade de Medicina, Porto, Portugal
[3]Universidade Lusófona de Humanidades e Tecnologias, CeiED-
Centro de Estudos Interdisciplinares em Educação & Desenvolvimento, Lisboa, Portugal
[4]Universidade de São José, Faculdade de Psicologia e Educação, Macau, Macau

Backgrounds

It is currently recognized that universities have limited impact on students' 'soft' skills development. Taking in consideration the present employment competitiveness, the soft-skills seem to assume great importance at the time of employer's recruitment. It is important, therefore, that the University promotes among its students the development of a wide range of complementary skills to their specialization area.

Objectives

To compare the impact of two teaching / learning strategies aiming at developing Microbiology students' soft-skills: A) Laboratory protocols - traditional laboratory practice, where students follow pre-defined protocols and B) Elementary Research Project, where students are challenged to formulate a research question and subsequently design and perform a study to answer that question (including laboratory work).

Methods

Microbiology students from Dentistry Bachelor plus Master from University of Porto performed both Laboratory protocols and Research Project methodologies. Data was collected trough a self-perception questionnaire (n = 39) evaluating 40 soft-skills scored on a Likert scale of 5 levels. Statistical analysis was performed by Wilcoxon assuming $p<0.05$.

Conclusions

In students' perception, the Research Project contributed more than the Laboratory protocols to the development of soft-skills related to personal development (Initiative, Innovation and Creativity, Planning, Ability to question and Written Communication), collaborative work (Group Work and Influence / Persuasion skills), Information technologies (including Collection and Processing of Information) and Numeracy. These results suggest that challenging students with a Research Project in addition or in alternative to traditional Laboratory protocols foster a wider soft-skills development and encourage students' engagement.

#MICROMOOCSEM: A MICROBIOLOGY MASSIVE ONLINE OPEN COURSE VIA TWITTER (1ST EDITION)

I. López-Goñi[1], M. Sánchez[2]
[1]Universidad de Navarra, Microbiología y Parasitología, Pamplona, Spain
[2]Universidad Miguel Hernandez, Dpt. Vegetal Production and Microbiology, Elche - Alicante, Spain

Backgrounds

Social networks are increasingly used by the population on a daily basis. They are considered a powerful tool for Science communication. However, there are yet scarce examples on the use of Twitter in Science teaching and communication.

Objectives

Here we present and analyze the results of our pioneering experience imparting a full Basic Microbiology course via Twitter using the hashtag #microMOOCSEM (1st edition).

Methods

The course has consisted of 29 sessions, involving 1,225 tweets, 702 images, 265 hyperlinks to web pages and 136 videos related to Microbiology. Each lecture consisting of a series of 30-50 sentences (tweets) was programed to be of 40-45 minutes, at a one tweet per minute rate, along 10 weeks. Students were encouraged to follow the course through their mobile devices or computers, either live at 22:00 h (GMT+1) or later, following the hashtag.

Conclusions

Data analyses on the impact and acceptance of the course are encouraging, promoting a 330% enhancement in the followers of the Twitter account of the host institution, and reaching almost one third of overseas visits among the total amount of roughly 175,000. Certain classes became a Twitter *trending topic* in Spain.
Massive online open course via twitter in the format we adopted are highly dynamic, interactive and accessible to great audiences, providing a valuable tool for social learning and communicating Science, promoting the interest of students towards particular topics in the field, and complementing academic activities, especially in multidisciplinary areas like Microbiology.
A new proposal for a European edition will be presented.

FEMS7-1600
Education / Professional Development / Policies

"MICRO-MOVIE CLIPS", A STRATEGY TO IMPROVE CLASS ATTENTION

M. Sánchez[1]
[1]*Universidad Miguel Hernandez, Dpt. Vegetal Production and Microbiology, Elche - Alicante, Spain*

Backgrounds

One of the main challenges that any teacher faces when he starts giving his class time is to get the attention of the students. Some situations (e.g., first time in the morning or last class of the day) have in common that the student has difficulty paying attention at the beginning of the class, a period of time that the teacher uses to introduce the subject to be exposed that day setting the tone of the explanation later.

Objectives

Several strategies have been used to attract the attention of the students in those first moments (KA Feldman, 2013). Based on previous results (M Sánchez, 2011) I have used several movie clips from famous films to introduce the different lectures on the Industrial Microbiology course in order to increase the interest on the subject.

Methods

30 different "micro-movie clips" were used. Most of them were directly related to the topic to be dealt with on that day - e.g., a clip from "Extraordinary Measures" (T. Vaughan 2010) was used for introducing the lecture on Biotechnology Entrepreneurship. This teaching strategy has been used from the 2013 course to this day. The results were evaluated through a voluntary and anonymous survey conducted among the students.

Conclusions

Around three quarters of the students that completed the survey answered "It was very interesting and helped me understand the subject that was presented that day ". After the implementation of this strategy the percentage of exam failure never exceeded the 15%.

SMALL WORLD INITIATIVE AT THE DEUTSCHE SCHULE MADRID: CITIZEN EDUCATION TO FIGHT THE ANTIMICROBIAL RESISTANCE

C. Serna Bernaldo[1], I. Sánchez Méndez[1], C. Valenzuela Agüi[1], R. Martín[2], F. Müller[2], B. González-Zorn[1]
[1]Universidad Complutense de Madrid, Departamento de Sanidad Animal- Facultad de Veterinaria, Madrid, Spain
[2]Deutsche Schule Madrid, Biología, Madrid, Spain

Backgrounds

Antimicrobial resistance is an issue of international concern that will impact all of us. Discovering novel antibiotics and improving awareness and understanding of this problems are some of the strategies to avoid the spread of antibiotic resistance. The Small World Initiative ™ (SWI) started at Yale University in 2012 with the purpose of increasing public awareness among students (not only healthcare professionals), in addition to the possible discovery of new molecules acting as antibiotics from soil bacteria.

Objectives

We are students of the Veterinary School at University Complutense of Madrid (Spain). For this project, we have woked with the Deutsche Schule Madrid, focusing on pre-university students, 17-18 years old. Our main aim is to teach our knowledge about antimicrobial resistance to highschool students, encouraging them to start taking an active part in combating resistance and getting them involved in the scientific world. Besides, due to our Veterinary studies, we encourage a One Health approach which explains and fights antibiotic resistance in humans, animals and environment.

Methods

Soil samples were collected from various locations throughout the Madrid region. Bacteria from soil were isolated, and then cultivated with ESKAPE-like bacteria to evaluate if any of the isolated bacteria would produce an antibiotic substance. After that, potential candidates of antibiotic producer were identified with molecular techniques.

Conclusions

This poster will be used to describe the antibiotics producers found in this study.

Education / Professional Development / Policies

TESTS ON LINE DURING THE CLASSROOM TEACHING TO INCREASE THE ATTENTION AND UNDERSTANDING OF THE SUBJECT

E. Sevillano[1], R. San Millán[1], E. Eraso[1]
[1]Universidad del País Vasco UPV/EHU, Immunology- Microbiology and Parasitology, Bilbao, Spain

Backgrounds

During the last years, new tools to increase the active participation of the students and the teacher/student interaction have been introduced. These methodologies have evolved allowing real time participation of the students answering questions by electronic devices that enables to get an immediate insight into students understanding.

Objectives

The aim of this work was to formulate multiple choice questions via Socrative Application after each lecture of the subject «Microbiology and Immunology» programmed in the first year of the Dentistry Degree in the University of the Basque Country (UPV/EHU).

Methods

After each lecture, the students were asked to log in the application with their mobile phones, tablets or computers, and to answer 4-5 multiple choice questions. The results were obtained in real time by the teacher and the wrong answers or possible doubts were cleared up straightaway. Students were presented with a satisfaction survey for feedback on the usefulness of the methodology.

Conclusions

The results obtained showed a global positive evaluation with 93.4% of students that would repeat the experience, and from 74 to 80% thinking that the methodology helped them to a better understanding of the subject, to pay more attention during the lectures and as a practice for the exam. Socrative was a very intuitive application and easy to use for the 95% of students. Most of them (80%) think that this learning experience had contributed more to the comprehension of the subject than traditional methodologies. Tests on line are useful in the university teaching activity for improving the learning process.

FEMS7-0922
Education / Professional Development / Policies

STANDARDISED METHODS IN PRACTICAL LAB WORK GENERATES IMPORTANT KNOWLEDGE FOR STUDENTS, SCIENTISTS AND THE FOOD SAFETY AGENCIES

C.S. Svanevik[1], *B.T. Lunestad*[1]
[1]*National Institute of Nutrition and Seafood Research, Contaminants and Biohazards, Bergen, Norway*

Backgrounds

The background for this work was to use standardised laboratory methods for both practical and theoretical teaching in seafood microbiology, where the achieved data also generates new knowledge for scientist and the government. As contaminated water is globally the main vehicle for microbial pathogens in most regions, we find that teaching future microbiologist and employees in the food industry on the importance of hygienically satisfactory water, microbiological analyses and how to ensure good water quality and safety, is highly relevant.

Objectives

This work present a complete experimental design for water analyses as a tool to teach students the methods and other key elements in microbiology, including food safety, environmental dissemination and survival of microorganisms, laboratory practices, water legislation and critical evaluation of results.

Methods

Analyses for the detection culturable bacteria (ISO 6222) and of fecal contamination in water (ISO 4788:1990, 4792:1990, 7899-2:2000) were used as an educational tool during a University course in seafood microbiology over a ten-year period (2006-2015). In addition to the lab results, the achieved knowledge among the students was examined by two retrospective questionnaires (about water analysis and lab course) conducted during June 2015. The questionnaires were circulated and made available for students back to 2006.

Conclusions

The questionnaires revealed that the laboratory course is highly appreciated, and that many students remembered important aspects of the water analysis, even after several years. The questionnaire results were consistent with our perception that some students find calculation of dilutions difficult to comprehend.

FEMS7-0976
Education / Professional Development / Policies

HANDS-ON STAINING TECHNIQUES TO LEARN ABOUT BACTERIA

A. Martins[1,2], C. Dias[1,2], M.J. Fonseca[2,3], F. Tavares[1,2]
[1]Faculdade de Ciências da Universidade do Porto, Departamento de Biologia, Porto, Portugal
[2]CIBIO - Centro de Investigação em Biodiversidade e Recursos Genéticos/InBIO Laboratório Associado, Microbial Diversity and Evolution, Porto, Portugal
[3]Universidade do Porto, Museu de História Natural e da Ciência da Universidade do Porto MHNC-UP, Porto, Portugal

Backgrounds

Practical work-based approaches have long been regarded as privileged educational tools in biology education. These practices lead to opportunities for students to develop conceptual, procedural and attitudinal skills.

Objectives

1. Assess the impact of a practical approach based on staining procedures on the learning process concerning bacteria;
2. Clarify misconceptions about bacteria;
3. Acquaint students with microscopy and staining techniques;
4. Foster the development of critical observational skills.

Methods

The activity, trialed and tested with 15/16 year-old students, included the observation and identification of prokaryotic cell structures using the optical microscope, and microscope slides prepared by the students and from collections. Data was gathered through a pre-/post-test design mixed-method approach with the use of an out-group. Statistical analyses were carried out using IBMS' SPSS v.21.

Conclusions

The findings revealed the overcoming of frequent bacteria-related misconceptions. Experimental group students listed notions such as "show non defined nucleus" [16 (post-test)vs.11(pre-test);$\chi 2(1)=12.07;p<0.001$] or "with capsule which confers resistance" [6 vs. 0;$\chi 2(1)=5.14$; $p=0.02$]. Both groups agreed that microscopy is important to diagnose bacteria (Expgroup:M=4.27;Dp=1.20;Z=340.5;p<0.001,d=0.14; Cntgroup:M=4.48;Dp=0.70;Z=300; p<0.001, d=0.01) and perceived laboratory work as an important learning tool (Expgroup:M=4.90; Dp=0.31;Z=465;p<0.001;d=0.42; Cntgroup:M=4.93; Dp=0.27;Z=378;p<0.001;d=0.50), allowing them to understand issues addressed in their classes (Expgroup:M=4.79;SD=0.48;Z=-1.42;p=0,15;d=0.16; Cntgroup:M=4.67;SD=0.48;Z=378;p<0.001;d=0.16). Regarding microscopy techniques, students emphasized their impact, namely at a motivational level, stating that these allow to "study bacteria in more detail".
The laboratory activity implemented had a positive effect in the participants' conceptual learning (morphology and physiology of the bacterial cell) and allowed the development of their procedural capabilities, as well as of their critical thinking skills.

FEMS7-0494
Education / Professional Development / Policies

DEVELOPING COMMON CURRICULUM AND IMPROVING TEACHING APPROACHES OF MICROBIOLOGY EDUCATION

A. Netrusov[1], A. Trchounian[2]
[1]M.V. Lomonosov Moscow State University, Microbiology, Moscow, Russia
[2]Yerevan State University, Biochemistry- Microbiology & Biotechnology, Yerevan, Armenia

Backgrounds

Microbiology is one of the major subjects in Biology Education. New achievements of biology and formed basic and applied microbiology problems, on the one hand, the mobility of students and the labor market demands in microbiology specialists, on the other hand, require the development of a common (European or international) curriculum of academic microbiology [1].

Objectives

Microbiology in undergraduate education appears in two directions (areas) - General Microbiology and Applied (Medical) Microbiology.

Methods

By study and comparison of the microbiology programs for different universities, the following is proposed.

Conclusions

The new curriculum of General Microbiology may include three modules: (1) structure of the microbial cell (morphology), physiology, biochemistry and genetics of microorganisms; (2) biodiversity, ecology and systematics of microorganisms; (3) types, methods and directions of microbial biotechnology. A certain part of the program (to a quarter of volume) can include regional microbiology problems associated with microbial diversity, prevention of microbial diseases and environmental problems. It is important to highlight the objectives and output to ensure practical relevance. Special courses in undergraduate and graduate microbiology education in-depth subjects are in two areas and three modules.

To improve teaching approaches the problematic (interactive) lectures, practical classes and laboratory work, tests, and various forms of individual work should be implemented. The ratio of lectures and laboratory work should be offered approximately equal. Laboratory work must be carried out accordingly by general (international) protocols. Also important are consistent actions for the implementation to include assessment of the knowledge and learning feedback.

[1] Recommended curriculum guidelines for undergraduate microbiology education. ASM, 2012.

COST EFFECTIVENESS ANALYSIS REFLECTS THE IMPORTANCE OF INFECTION CONTROL IN BURN CARE

T. Shin-Yi[1], L. Chon-Fu[2], H. Cheng-Wei[1], L. I-Hong[1], H. Yan-Jiun[1], Y. Chia-Meng[3], K. Chien-Feng[4], S. Shou-Chuan[5]
[1]Mackay Memorial Hospital, Department of Laboratory Medicine, Taipei, Taiwan R.O.C.
[2]Macao Centro Hospitalar Conde de Sao Januario- Macao,
Centro Hospitalar Conde de Sao Januario, Macau, Macau
[3]Mackay Memorial Hospital, Department of Plastic Surgery, Taipei, Taiwan R.O.C.
[4]Mackay Memorial Hospital, Department of Infectious Disease, Taipei, Taiwan R.O.C.
[5]Mackay Memorial Hospital, Department of Medical Research, Taipei, Taiwan R.O.C.

Backgrounds

There are profound differences in the cost of burn care all over the world.

Objectives

We aim to investigate the affected factors and to delineate the strategy to improve the cost-effectiveness of burn management.

Methods

A retrospective analysis of 66 patients suffering from acute burns was conducted from 2013 to 2015. The average age was 26.7 years old and TBSA was 42.1% (±25.9%). T-test and Chi-squared tests were used to compare clinical characteristics between patients with and without bacteremia. A univariate regression and a multiple regression sequentially were used to examine the relationship between a variety of dependent factors, and individual and total costs.

Conclusions

The group of patients with bacteremia, incidence rate as 18.2%, had larger total burn surface area (TBSA), inhalation injury and full thickness significantly and the cost in that group significantly increased, especially medication expenditure. Through a multivariate regression analyses (Adjusted R^2=77.2%) to develop a normogram which can estimate the total cost of acute burn management, as follows. Estimated cost of acute burn care (10000 TWD)= -19.80 + (2.67 x percentage of TBSA) + (124.29 x status of inhalation injury) + (147.63 x status of bacteremia) + (130.32 x status of respiratory tract infection)
Our findings are compatible the previous studies indicating drug expenditures, the vast majority related to the use of antibiotics, on burns care were found to be high. Consequently, it is crucial to prevent nosocomial infection in order to promote our healthcare quality and reduce the in-hospital cost.

Education / Professional Development / Policies

SERVICE-LEARNING IN THE SMALL WORLD INITIATIVE PROGRAM: AN OPORTUNITY FOR UNDERGRADUATES TO LEARN MICROBIOLOGY BY TEACHING YOUNGER STUDENTS

M.J. Valderrama[1], M.I. de-Silóniz[1], G. Barcia[1], L. Caballero-Nadal[1], P. Calvin[1], S. Fernández[1], N. García[1], M. Gómez[1], R. Gómez[1], N. Martínez[1], E. Palomino[1], M. Pérez[1], C. Rodrigo[1], R. Rojas[1], G. Velayos[1]
[1]UNIVERSIDAD COMPLUTENSE DE MADRID, Dpt. Microbiology, MADRID, Spain

Backgrounds

The University plays an important role in transmitting knowledge in benefit of the society. In the novel educational strategy Service-learning the university students learn while participating in real community needs. This methodology has been used in the implementation in Spain of the Small World Initiative (SWI), an educational program focused on crowdsourcing antibiotic discovery which also aims to aware about the antimicrobial resistance problem.

Objectives

Our objective was to carry out a service-learning experience by getting university students fully involved in the SWI project, in order to promote a more significant learning of Microbiology.

Methods

University students from Biology, and Biochemistry Degrees and the Master in Education participated in the Project. Following SWI protocols they were made responsible for organizing and carrying out visits to Secondary Schools, where they would teach young pupils: preparing laboratory materials, explaining the antimicrobial resistance problem, demonstrating and supervising microbiological methods, conducting the discussion of results with the school students and their teachers, Surveys were made to evaluate the effects on the teaching/learning process.

Conclusions

The Project had a high positive impact on motivation and awareness of antibiotic resistance, and the University students acquired a deeper and longer-lasting knowledge of practical microbiology. The Master students, soon secondary school teachers, considered this challenge a very valuable educational experience. The main keys to this success were: becoming involved in the learning process rather than being passive receptors, being responsible for specific tasks and teaching other students.

FEMS7-1352
Education / Professional Development / Policies

DYNAMIZATION OF BACTERIAL METABOLISM AND TAXONOMY STUDY FOR BIOTECHNOLOGY STUDENTS AT FRANCISCO DE VITORIA UNIVERSITY

O. Zafra[1], *E. Pérez Lago*[1], *C. Santos*[1]
[1]*Universidad Francisco de Vitoria, Experimental Sciences, Pozuelo de Alarcón Madrid, Spain*

Backgrounds

Microbiology is a key subject for Biotechnology students. In Francisco de Vitoria University (UFV), is taught during the second year of the degree and for lecturers is a great challenge to transmit the metabolic diversity and versatility of microorganisms as a source of tools for industry, medicine and the development of welfare in society.

Objectives

During this academic year we are trying to evaluate the perception of the students about the subject, applying some didactic tools to raise it and quantify the improvement. As bacterial metabolism and taxonomy are the items usually thought as more difficult and boring, we developed a dynamic method to improve the teaching.

Methods

First of all, we designed an inquiry to quantify the perception of the student about the importance of the bacterial metabolism and taxonomy items. This inquiry was done before and after the application of the new didactic tools. In this case, we used an advanced organizer for the student to deduce the types of metabolic reactions based on Barbosa *et al*, 2005 and asked them to classify some taxonomic groups on it. This would help the student to relate the knowledge and fix it in a dynamic way.

Conclusions

As a general conclusion is worth to highlight that taxonomy clearly improved its rate in dynamism. In the poster presentation we will explain the method and the whole statistics.

Education / Professional Development / Policies

ACCESS AND USE OF MICROBIAL RESOURCES: THE CONVENTION ON BIOLOGICAL DIVERSITY AND THE NAGOYA PROTOCOL

A. Zuzuarregui[1], R. Aznar[1]
[1]Colección Española de Cultivos Tipo - Universidad de Valéncia, Microbiology and Ecology, Burjasot Valencia, Spain

Backgrounds

The Convention on Biological Diversity (CBD) entered into force on December 1993 and has three main objectives:

- the conservation of biological diversity,

- the sustainable use of its components,

- and the fair and equitable sharing of benefits arising from the use of genetic resources.

The Nagoya Protocol (NP) is a supplementary agreement of the CBD and entered into force on October 2014. It provides instructions to implement the third objective of the CBD, e.g. the access to the genetic resources and the fair and equitable sharing of benefits arising from their utilization (ABS).

According to the CBD, the States have the sovereign right to exploit their own resources and may regulate access to such resources (procedure to apply for the Prior Informed Consent, PIC) and the conditions on which this access and the subsequent use are granted (Mutually Agreed Terms, MAT).**Objectives**

To raise awareness about the international regulations related with ABS and show a simplified flow diagram covering the main aspects to reach compliance.

Methods

Analysis of the regulations and internet resources:

- CBD https://www.cbd.int/
- PN https://www.cbd.int/abs/
- ABS Clearing House https://absch.cbd.int/
- European Commission's ABS information http://ec.europa.eu/environment/nature/biodiversity/international/abs/index_en.htm

Conclusions

Researchers collecting strains from countries Party to the CBD must observe their national regulations regarding access to genetic resources. If the country has put in place ABS measures, the researcher(s) must apply for the PIC and the MAT. The information about national legislative measures and national focal points for ABS issues is available at the ABS Clearing-House (ABSCH).

ANALYSIS OF RESISTANCE TO ERTAPENEM OF BACTERIA ISOLATED FROM THE TINTO RIVER ESTUARY (HUELVA, SPAIN) AND THE WATER FALL CHORRERA DE DESPENALAGUA (GUADALAJARA, SPAIN)

J.P. Abad[1], B. Eduardo-Correia[2], H. Morales-Filloy[3]
[1]Universidad Autónoma de Madrid, Departamento de Biología Molecular, Cantoblanco, Spain
[2]UKM Münster, Clinic of anaesthesiology- Intensive care and pain treatment, Münster, Germany
[3]University of Heidelberg, Institute of Pharmacy and Molecular Biotechnology IPMB, Heidelberg, Germany

Backgrounds

Resistance to antibiotics is an ever-growing threat that may be related to the abuse in the use of these substances and their arrival to the environment. Among the resistances to antibiotics are included those to antibiotics used as last resource as i.e. the carbapenems.

Objectives

The objective of our study was determining the prevalence of bacteria resistant to ertapenem among isolates resistant to ampicillin obtained from two aquatic biological systems, a contaminated and cuasi marine at SW Spain, and another cuasi-pristine and of fresh water at central Spain.

Methods

The growth of a collection of about 1000 isolates from both systems was tested at several concentrations of ertapenem (0.063-8.0 µg/mL) using solid nutritive or marine media. MIC values for each of the environmental isolates were determined based on the results obtained. Phylogenetic adscription was performed by partial sequencing of 16S rDNA.

Conclusions

Considerable percentages of the isolates were resistant to 2 µg/mL of ertapenem, 79.7% of the isolates from the Tinto river estuary and 43.5% of those from the Chorrera de Despeñalagua. These values increased when considering only bacteria isolated on marine medium from each system. The antibiotic MIC values were also higher for the isolates from the salty system than for those from the fresh water one. An effect of the medium composition was observed on the resistance to this antibiotic, which seems to be also related to the specific phylogenetic adscription of the isolates. The results will be reported and discussed.

METAGENOMIC AND FUNCTIONAL ANALYSES OF AIRBORNE MICROORGANISMS IN FINE PARTICULATE MATTER (PM2.5) DURING PM EVENT AND NON-EVENT DAYS

A. Abd Aziz[1], B. Park[2], H. Park[2], K. Lee[1], K. Park[1], I.G. Choi[2], I.S. Chang[1]
[1]Gwangju Institute of Science and Technology GIST,
School of Earth Sciences and Environmental Engineering SESE, Gwangju, Republic of Korea
[2]Korea University, College of Life sciences and Biotechnology, Seoul, Republic of Korea

Backgrounds

With a great concern on the risk of airborne particulate matter (PM) towards human health, especially the $PM_{2.5}$ (particulate matter of aerodynamic diameter < 2.5 µm), this study focuses on the biological components and changes in the air which may also impose threat towards human health.

Objectives

Whole metagenomics shotgun sequencing (WGS) was conducted to see whether the microbial community and metabolic functions of PM event day (designated daily $PM_{2.5}$ concentration > 50 µg m^{-3}) are changed in the sample compared to PM non-event day.

Methods

MG-RAST server was used to analyze the annotated sequences, and the results showed that *Bacteria* was dominant domain with 95% and 45%, respectively in both non-event and event day samples. Followed by *Eukaryota*, with 3.7% and 52%, respectively. Additionally, there was an increase to 1.9% of *Firmicutes* group in the PM event day sample. Under this phylum, there are opportunistic pathogenic species such as *Staphylococcus aureus* and *S. haemolyticus* were significantly detected. Furthermore, by comparing the annotated proteins within KEGG Orthologs functional category, functional genes related to metabolism was predominant for both samples at 55%. Also, the functional genes related to human diseases such as Prion diseases had newly detected in the PM event day sample.

Conclusions

The results of this study suggest the public should be more cautious attending outdoor activities during PM event days, because on such days more pathogens and allergens were detected as well as an increase in functional genes related to human diseases.

ANTIMICROBIAL EFFECT AND BIOCOMPATIBILITY STUDY OF POLY(EPSILON-CAPROLACTONE) SUPERFICIALLY MODIFIED BY OXYGEN PLASMA AND BIOCIDE STRUCTURES

C. Abrusci[1], A. Morro[1], T. Corrales[2], J.L. Pablos[2], I. Marin[1], F. Catalina[2]
[1]Universidad Autónoma de Madrid, Biología Molecular, Madrid, Spain
[2]Consejo Superior de Investigación Científica, Instituto de Ciencia y Tecnología de Polímeros, Madrid, Spain

Backgrounds

The development of anti-infective biomaterials is regarded as the main strategy to prevent the bacterial colonisation and biofilm formation. In this study, poly(ε-caprolactone) (PCL) is superficially modified with antimicrobial active structures (tetrabutylammonium, ampicillin, silver cations and cetylpyridinium) which were prepared via a two-step process. Firstly, PCL was exposed to an oxygen plasma for surface activation, and then immersed into aqueous solutions of biocides for their adsorption.The antibacterial effect of oxygen plasma treatment and the biocides loaded onto the surface were evaluated by measuring the adhesion and growth of two clinically significant bacteria *Bacillus cereus* and *Pseudomonas aeruginosa*. In order to assess the degree of biocompatibility, the adhesion and proliferation of murine L929 fibroblasts were studied by performing *in vitro* and *in vivo* assays. Also, cell viability and cell death assay were carried out.

Objectives

To design anti-infective and biocompatible PCL-based materials.

Methods

The modified PCL materials were characterized by different techniques (ATR-FTIR, Chemiluminescence, SEM, AFM). In this study, the biophysical responses of bacteria and murine cell fibroblasts towards the prepared material films as model device surfaces were elucidated.

Conclusions

The obtained results demonstrated that, except for the materials loaded with silver cations and cetylpyridinium, the PCL materials prepared in this work are adequate as anti-infective biomaterials.

STUDY OF INHERENT ANTIMICROBIAL ACTIVITY AND IN VITRO BIOCOMPATIBILITY OF COPOLYMERS FILMS CONTAINING SULFADIAZINE ACRYLIC MOIETIES

C. Abrusci[1], A. Morro[1], J.L. Pablos[2], I. Marin[1], F.C. García[3], J.M. García[3]
[1]Universidad Autónoma de Madrid, Biología Molecular, Madrid, Spain
[2]Consejo Superior de Investigaciones Científicas, Insitituto de Ciencia y Técnología de Polímeros, Madrid, Spain
[3]Universidad de Burgos, Departamento de Química, Brugos, Spain

Backgrounds

Microbial colonisation of synthetic material, is a great concern in many fields, e.g., in implant surgery and medical devices; therefore biocompatible hydrophilic organic materials with inherent antimicrobial and anti-biofilm properties are of current research interest.In this work, we describe the preparation of antimicrobial and biocompatible polymeric film based on *N*-vinyl-2-pyrrolidinone (VP) and 2-hydroxyethyl acrylate (HEA), using ethyleneglycol dimethacrylate (EGDMA), and synthetic acrylic monomer containing sulfadiazine chemically anchored.

Objectives

To design a PVP-based polymer with antibacterial properties.

Methods

The synthetized PVP-based films were characterized by different techniques (^{1}H and ^{13}C NMR, ATR-FTIR, SEM, TGA). In this study, the biophysical responses of bacteria and L929 cells towards the prepared materials as model device surfaces were evaluated.

Conclusions

The polymers obtained showed excellent antibacterial activity against *E.coli*, with inhibition values higher than those of silver and allowed to control the biofilm formation that can cause medical device contamination by *E.coli*. Cell adhesion and cytotoxicity studies assessed the biocompatibility of the polymer, being a good candidate for medical applications as a biomaterial.

MOLECULAR MICROBIOLOGY APPROACH TO ASSESS THE BIODEGRADATION POTENTIAL OF AN ENVIRONMENTAL INOCULA FOR ORGANIC POLLUTANT

K. Acharya[1], J. Dolfing[1], P. Meynet[1], W. Mrozik[1], D. Werner[1], R. Davenport[1]
[1]Newcastle University, School of Civil Engineering and Geosciences, Newcastle Upon Tyne, United Kingdom

Backgrounds

Activity of potential degraders is one of the major factor that determines the biodegradation potential on an environmental inocula for any organic pollutant. Little attention has been given to the investigation of the activity of potential degraders in mixed microbial communities in the degradation of organic pollutants.

Objectives

Our work focuses on the development of a robust tool to estimate and understand the biodegradation potential of activated sludge for phenol and 2,4-dichlorophenol, as model organic pollutants.

Methods

Batch laboratory assays were conducted in 500 mL glass bottles containing activated sludge from different Waste Water Treatment Plants (WWTP) and spiked with known concentration of model chemicals. Chemical concentration, CO_2 development in the headspace, DOC and total bacteria count were monitored and quantified over time. The key catabolic genes involved in the model chemical biodegradation pathway were identified from literature, specific primers were developed and used for the quantification in the batch reactors, using molecular techniques (e.g., qPCR and RT-qPCR).

Conclusions

Phenol was completely mineralized in the activated sludge from all WWTPs and followed 1st degradation kinetic, whereas 2,4-dichlorophenol was only degraded in one WWTP activated sludge. There was significant increase in the catabolic genes copies number over the duration of experiment ($p < 0.05$) and expressed significantly. Dichlorocatechol-1,2-dioxygenase (catabolic gene for 2,4-dichlorophenol biodegradation) gene were not detected in activated sludge not supporting 2,4-dichlorophenol degradation. Our results suggest that key catabolic genes involved in the pollutant biodegradation can be a biological marker to access the biodegradation potential of an environmental inocula against that pollutant.

EMERGING INSIGHTS INTO THE TYPE IV CRISPR/CAS SYSTEMS FROM GENOMIC ANALYSES THE ACIDITHIOBACILLUS SPECIES COMPLEX

L.G. Acuña[1], P.C. Covarrubias[1], A. Moya-Beltrán[1], O. Salgado[1], H. Nuñez[1], R. Quatrini[1]
[1]Fundacion Ciencia & Vida, Microbial Ecophysiology Laboratory, SAntiago, Chile

Backgrounds

Many bacteria and most archaea have genetically encoded Clustered Regularly Interspaced Short Palindromic Repeat (CRISPR) regions and CRISPR-associated proteins (Cas) that confer immunity to viruses and other mobile genetic elements. According to recent classifications the extreme acidophiles, *Acidithiobacillus caldus*^{T} and *A. ferrooxidans*^{T}, harbor Type U CRISPR/Cas loci on integrative conjugative elements present in their genomes. Both systems are only partially conserved between each other and other sequences deposited in public databases.

Objectives

Very little insight has been gained to date on the general occurrence, evolution and function of these systems. To advance in this direction we profiled the CRISPR/Cas systems in an extensive set of strains spaning the *Acidithiobacillus* species complex.

Methods

For that purpose we collected available genomic sequences, and screened experimentally additional strains of the genus. The CRISPR/Cas systems were characterized bioinformatically using comparative genomics stategies.

Conclusions

Nearly 50% of the strains analyzed (63 strains) harbored CRISPR/Cas systems in their genomes. Class IV (type U) system was widespread within the group (22% of strains spanning 5 linages), followed by Class 1 subtypes I-C (10%), I-E (10%) and I-F (6%), which were restricted to fewer taxa. Variant forms of the type U system were identified in the acidithiobacilli, providing hints on the inherent diversity and nature of this unusual class. Herein, we explore relevant aspects of the genes, repeats and spacers that conform these enigmatic CRISPR/Cas systems in the context of the emerging phylogenetic structure of the taxon.

A GREENHOUSE ASSESSMENT OF COAL MINE SOIL STOCKPILES: ARBUSCULAR MYCORRHIZAL FUNGAL SPORE DENSITY AND COLONIZATION IN MAIZE (ZEA MAYS) TRAP CULTURES

O. Ezeokoli[1], R. Adeleke[2], C. Nwangburuka[3], A. Roopnarain[2], M. Maboeta[1], C. Bezuidenhout[1], D. Paterson[2]
[1]North-West University, Environmental Sciences and Management, Potchefstroom, South Africa
[2]Agricultural Research Council-Institute for Soil- Climate and Water, Soil Health, Pretoria, South Africa
[3]Babcock University, Department of Agriculture- School of Science and Technology, Ogun State, Nigeria

Backgrounds

Arbuscular mycorrhizal fungal (AMF) symbiotic colonization of roots is essential for nutrient uptake and growth of most vascular plants. Successful establishment of AMF mycorrhization in plant roots is dependent on the soil condition and soil management practice.

Objectives

This study investigated AMF spore density and colonisation in maize (*Zea mays*) trap cultures grown in stockpile soils obtained from three South African opencast coal mines

Methods

Stockpiles were randomly sampled at depths of ≤20 cm (topsoil) and >20 cm (subsoil), and used for mycorrhizal trap culture experiments in the greenhouse. Following a 12-week post germination period, AMF spore density in pot soils was enumerated, while plant roots were assessed for AMF colonisation and diversity by using classical staining and targeted amplification and sequencing of the nuclear rRNA gene of the *Glomeromycota* phylum.

Conclusions

AMF spore density was significantly different ($P<0.05$) between soil samples and highest in topsoil from unmined soils (control soil). The AMF spores were morphologically identified as belonging to the genera *Acaulospora*, *Gigaspora* and *Scutellospora*. DNA-based detection revealed that AMF colonisation was more associated with topsoils than with subsoils. Furthermore, species of the genus *Paraglomus* were the only colonisers of the maize roots in all soils, suggesting a very low diversity of viable AMF spores, poor support for the establishment of root-AMF symbioses or the presence of a single maize (host)-specific AMF symbiont in these soils. Overall, the results suggest that stockpiling and stockpile depths may have an effect on spore density and mycorrhization

AN ASSESSMENT OF BACTERIOPHAGES SPECIFIC TO E. FAECALIS AND E. FAECIUM AS POTENTIAL MARKERS TO DETECT FAECAL CONTAMINATION IN WATER

M.R. Adem[1], A. Kumar[1], C.N. Ateba[1]
[1]North-West University Mafikeng Campus, Biological Sciences, Mahikeng, South Africa

Backgrounds

Enterococcus species reside in the gastrointestinal tract of humans and animals have been used as indicators of faecal contamination in water. Due to the fact that bacteria counts are usually not reliable and reproducible bacteriophages are now used as potential tools for assessing bacterial contamination.

Objectives

This study was designed to evaluate the potential of *E. faecalis and E. faecium* and their specific phages as indicators water contamination.

Methods

Methods: A total of 162 water samples were collected and analysed and 119 presumptive enterococci were subjected to Gram staining, growth in 6.5% NaCl, oxidase and catalase as well as *E. faecalis* and *E. faecium* species specific PCR analysis (*ddl* gene PCR). *E. faecalis* and *E. faecium* specific bacteriophages were also isolated using standard methods. Phage morphologies were determined using electron microscopy. The antimicrobial resistance profiles of enterococci were determin**ed.** Results: A large proportion 50 (42%) of the isolates were confirmed as *E. faecium* while 16 (13%) were *E. faecalis*. Large proportions (62.1% to 100%) of these isolates were resistant to Erythromycin, Ampicillin, Gentamycin, Tetracycline and Chloramphenicol. However, only 27 (41%) and 12 (18.2%) of the isolates were resistant to Vancomycin and Amocyxillin respectively. Cluster analysis of 66 isolates produced two major clusters (Cluster 1 and Cluster 2). Resistance data indicated that isolates shared similar profiles. *E. faecalis* and *E. faecium* specific bacteriophages were detected and TEM data indicated that morphologies were similar to those of the family *Siphoviridae*.

Conclusions

These bacteriophages can be reliable indicators of faecal pollution in water.

[8]Université Félix Houphouët-
Boigny- UFR STRM- Département des Sciences du Sol- 22 BP 582 Abidjan 22- Côte d'Ivoire., Géologie marine, Cocody- Abidjan, Ivory Coast

Backgrounds

In Côte Ivoire, most of the landfills are open air and contain different categories of wastes (municipal wastes, hazardous wastes, non-hazardous wastes). This practice can result in air, soil and groundwater pollution, with a potential risk to human and environment. Because of this problem, there is a great interest to rehabilitate of these polluted sites.

Objectives

The goal of this work is to test two catalyzers: earthworm (P. corethrurus) and symbiotic microorganism (*Bradyrhizobium)* on the processes of phytoremediation.

Methods

To obtain this objective, an experimental system are realized coupling P. corethrurus/ *Bradyrhizobium* with the plant *Acacia mangium* to study if this this combination can decontaminate the soils contaminated with ETM (Cr and Ni).

Conclusions

The results obtained after (03) months of culture in jars controlled condition, show that the pollution affects the vegetative development of *A.mangium*, but in presence of earthworm and *Bradyrhizobium* a better vegetative development had been noticed. Furthermore, a high content of metals (Cr and Ni) are been determined in plant (roots, sterm and leaves) in presence of the two catalyzer. However, our results reveal a translocation of Cr in leaves and stems and an accumulation of Ni in the roots. These results show the capacity of phytoextraction and phytostabilisation of *Acacia mangium*.

GENOMIC FEATURES OF BACTERIAL STRAINS UNIQUELY COMPATIBLE WITH PEA (PISUM SATIVUM L.) LINES WITH RESTRICTIVE SYMBIOTIC PHENOTYPE

A. Afonin[1], *A. Sulima*[1], *V. Zhukov*[1], *I. Tikhonovich*[2]
[1]*All-Russia research institute for agricultural microbiology, Laboratory for genetics of plant-microbe interactions, St-Petersburg, Russia*
[2]*All-Russia research institute for agricultural microbiology, Department of biotechnology, St-Petersburg, Russia*

Backgrounds

Garden pea (*Pisum sativum L.*) is a plant capable of forming nitrogen fixing nodules through beneficial symbiosis with *Rhizobium leguminosarum*. Various pea cultivars differ in the range of compatible micro symbionts - evidence of the everlasting arms-race between the plant and bacteria. Some pea lines of middle-eastern origin are highly selective in the choice of symbiotic partner, in some instances due to a naturally occurring allele of the *Sym6* gene. Strangely enough, similar heightened specificity can also be exhibited by mutants in *Sym37* and *Sym26* symbiotic genes. The genetic traits, making bacteria capable of nodulating these restrictive lines previously described as non-nodulating, are as of yet unknown.

Objectives

The aim of this work was to characterize and compare genomes of strains A1, RCAM1026, 3841, R.A.17 and R.A.11 to identify the genetic bases of strain-to-line specificity.

Methods

Strains were tested for their ability to form nodules with pea lines carrying restrictive alleles of genes *Sym37* (RisNod4 and K24), S*ym26* (P61) and *Sym6* (line 2150). Genomes of the strains were sequenced, assembled and analysed. Genome comparison showed a number of unique traits, possibly responsible for unique symbiotic properties of the strains.

Conclusions

Bacterial genome determines the compatibility between pea lines and bacterial strains. High number of secretion systems in the strain 3841 may be the cause of its' incompatibility with the P61 line. Strains A1 and RCAM1026, although similar in genetic composition possess a number of unique genetic characteristics, defining their host range.
This work was supported by Russian Science Foundation [grant 14-24-00135].

RESPONSE OF BACTERIAL COMMUNITIES FROM OCEANIC ENVIRONMENTS TO ELEVATED PCO2 AND LOW PH: A MICROCOSM APPROACH

P. Aguayo[1,2], D.L.I. Rodrigo[3], H. Carlos[4], U. Osvaldo[4], V. Cristian[4]
[1]Millennium Institute of Oceanography, Oceanography, concepcion, Chile
[2]Centro EULA Chile, Sistemas Acuáticos, Concepcion, Chile
[3]Millennium Institute of Oceanography,
Molecular Genetic and Microbiology - Pontificia Universidad Católica de Chile, Santiago, Chile
[4]Millennium Institute of Oceanography, Oceanography, Concepción, Chile

Backgrounds

Ocean acidification (OA) is one of the global issues caused by rising atmospheric CO2. The rising pCO2 and resulting pH decrease has altered ocean carbonate chemistry. Microbes are key components of marine environments involved in nutrient cycles, carbon flow in marine ecosystems. However, these marine microbes and the microbial processes are sensitive to ocean pH shift. Considering that there is little information on how communities of marine bacteria and archaea respond to chemical changes in the ocean and how these changes interfere with biogeochemical cycles

Objectives

It was postulated that CO_2 changes and the consequent decrease in ocean pH values modify the diversity of marine microorganisms .The response of the communities to the was evaluated by the use of microcosms the pH levels investigated were in situ seawater pH (7,99–8.05), pH 7.82 and pH 7.67, representing the present-day situation and two acidification scenarios projected for the year 2100.

Methods

The results obtained from the molecular analyses will be contrasted with abundance and composition of photosynthetic eukaryotes, heterotrophic bacteria from water samples and low and high pCO_2 treatment

Conclusions

The results indicate that there is a marked difference between controls and treatments, as well as it is possible to observe that bacterial communities respond rapidly to changes in ocean chemistry than eukaryotic photosynthetic communities. results generated will assess vulnerability and resilience of microorganisms against changes resulting from acidification, and the consequences that could have for the rest of the biological community that depends on this link key ocean food webs and ecosystem.

BACTERIAL COMMUNITY STRUCTURE AND FUNCTION IN THE WATER OF THE SODA SALINE CRATER LAKE FROM ISABEL ISLAND, MEXICO

J.F. Aguirre Garrido[1], H.C. Ramírez Saad[2], F. Martinez-Abarca Pastor[3], N. Toro García[3]
[1]Universidad Autonoma Metropolitana, Ciencias Ambientales, Lerma de Villada, Mexico
[2]Universidad Autonoma Metropolitana, Sistemas biológicos, Ciudad de México, Mexico
[3]Estación Experimental del Zaidín, Consejo Superior de investigaciones científicas, Granada, Spain

Backgrounds

Isabel Lake is a moderate saline soda crater lake located in Isabel Island in the eastern tropical Pacific coast of Mexico. Lake is mainly formed by rainfall and is strongly affected by evaporation and high input of nutrients derived from excretions of a large bird community inhabiting the island. The knowledge of the prokaryotic biota inhabiting the upper layers of this meromictic lake can give clues for the maintenance of this ecosystem.

Objectives

The aim of this work was to assess the diversity, composition and function of bacterial community in water of the Isabel Island crater lake in Mexico.

Methods

The study area is located in Isabel Island, a small volcanic island (2 km2) located 30 km off the Pacific coast of Mexico (21° 52′ N and 105° 54′ W). We sequenced three samples of water obtained around a dry season using a random whole-genome shotgun (WGS) approach and 16S rRNA amplicon masive sequencing using Illumina platform. Bioinformatic analyses were performed using MOTHUR version 1.33, STAMP, MG-RAST and MEGAN version 5.

Conclusions

The bacterial community is dominated by halophilic and halotolerant microorganisms. The lake water is dominated by γ- Proteobacteria belonging to four main families where Halomonadaceae presents the highest abundance. Aerobic, phototrophic, and halotolerant prokaryotes such as *Synechococcus, Rhodopirellula, Halomonas, Alcanivorax* and *Marinobacter* genera are commonly found. We identified several functions related with molybdate and zinc system permease proteins, antibiotic transport systems proteins.

WET WIPES WHICH IS SOLD IN MARKETS EVALUATION FOR THE MICROBIOLOGICAL RESPECT

B. Sapmaz[1], Ö. Akgül[2], P. Yüksel Mayda[3], R. Çalışkan[3], M. Samastı[3]
[1]Nişantaşı University, Vocational School, Istanbul, Turkey
[2]Üsküdar University, Vocational School of Health Services, Istanbul, Turkey
[3]Istanbul University Cerrahpaşa Medical Faculty, Medical Microbiology, Istanbul, Turkey

Backgrounds

Hands in continuous and close contact with the environment, they carry to a rich microbial flora. Neglected hand hygiene is caused the remaining of contamination of hands so inadequate implementation. The general purpose of hand hygiene is; temporary flora to be completely removed, reduction the number of permanent flora and thus to prevent transfer of bacteria via the hands.

Objectives

The aims of the present study was evaluate and compared the efficacy of wet wipes, soap with water, 70% alcohol and gel with alcohol against resident and transient flora.

Methods

We have investigated as compared different brands which do not contain the antiseptic wet wipes and including antiseptic wet wipes effects of resident and transient flora against of the washing with soap and water, 70% alcohol and gel with alcohol.

Conclusions

In our study, all forms of alcohol (liquid, gel and alcohol-impregnated wipes) by washing with soap and water was found to be much more effective. However, on the resident flora when compared to alcohol (62.5% and 65%) gel preparations, liquid alcohol (70%) and alcohol (70%) wipes form was less effective. Also, washing with soap and water eliminates the transient flora can be exactly that after the cleaning with a wet wipes in hand in excess of contaminant bacteria was found to remain. In the lights of our study, even the ensuring the hand hygiene have in many ways, alone wet wipes are not enough, water-washing facilities with soap and non-cases, preparations with antiseptic effect could be an alternative, but non antiseptic alone impurities can not be eliminated should not be forgotten either.

THE COMPLEX AND ALARMING RESISTANCE STATUS ON CLOSTRIDIUM DIFFICILE IN TURKEY

Ö. Akgül[1], B. Sapmaz[2], F. Çatal[3], P. Yüksel[3], R. Çalışkan[3], H. Kırkoyun Uysal[4], Ö.F. Karasakal[1], G. Aygün[3]
[1]Üsküdar University, Vocational School of Health Services, İstanbul, Turkey
[2]Nisantasi University, Vocational School, Istanbul, Turkey
[3]Istanbul University Cerrahpasa Medical Faculty, Medical Microbiology, İstanbul, Turkey
[4]Istanbul University Istanbul Medical Faculty, Medical Microbiology, İstanbul, Turkey

Backgrounds

Clostridium difficile infection is commonly recognized as one of the most frequent nosocomial infections and has led to high mortality, heavy health burden and increased healthcare costs. The incidince of nosocomial diarrhoea, *C. difficile*-associated nosocomial diarrhoea rates and the resistance status of this nosocomial pathogen are not clear in our country.

Objectives

To determine the *C. difficile*-associated nosocomial diarrhoea incidence and to review the current resistance status of *C. difficile* were the major aims of the present study.

Methods

This prospective clinical study included 100 diarrhoea samples from hospitalized patients in İstanbul, Turkey. The diarrhoea samples were investigated by culture methods via *Clostridium difficile* selective agar and bacterial resistance profiles were calculated with the E-test method.

Conclusions

The *C. difficile* resistance rates were determined for metronidazole as 29.4%, for vancomycin and teikopilanin as 2.9%. Our findings corroborate the alarming reports about the increasing metronidazole resistance rates of *C. difficile*. Our results support that the *C. difficile* is still an important factor in nosocomial diarrhoea. Furthermore, highness of antibiotic resistance for metronidazole may be caused by difficulties in treatment. The results indicate the necessity of further studies to develop control measures and effective treatment options for patients.

Faculdade de Ciências- Universidade Lisboa, Lisboa, Portugal

Backgrounds

Xanthomonas arboricola pv. *juglandis* (*Xaj*) is the most important phytopathogenic bacteria affecting walnut-growing areas worldwide. Serious concerns about its economic impact made *Xaj* the focus of several epidemiological studies. Regardless the genetic diversity of *Xaj* reported to date, further studies are needed to fully characterize the diversity of *Xaj* and determine its significance.

Objectives

This study aimed to unveil the genetic diversity of Portuguese *Xaj* populations, and determine possible correlations between distinct *Xaj* clonal lineages and: walnut cultivars; bioclimatic factors; virulence fitness in leaves and fruits; and co-infection potential.

Methods

One hundred and seven *Xaj* isolates were obtained from leaves, fruits, branches, catkins and buds of symptomatic walnut trees distributed throughout distinct climatic regions of Portugal. Isolates' diversity was assessed using a dot blot hybridization platform with nine *Xaj*-specific DNA markers and by MLSA, using four housekeeping genes (*acnB*, *fyuA*, *gyrB* and *rpoD*).

Conclusions

MLSA allowed to verify that Portuguese *Xaj* lineages are genetically heterogeneous, comprised of at least eight different clusters. Such diversity was further sustained by the sixteen different hybridization patterns obtained. A cluster of six isolates was shown to diverge from the main lineages of the other *Xaj* characterized in this work or other *X. arboricola* strains previously described. Furthermore, the present study suggested that *Xaj* variability is not dependent on geographical areas, walnut cultivars, plant organ or isolation date, which is evocative of a cosmopolitan dispersion. Interestingly, the results highlighted the presence of different lineages within the same walnut host tree.

OPTIMISATION OF 16S RRNA GUT MICROBIOTA PROFILING OF EXTREMELY LOW BIRTH WEIGHT INFANTS

C. Alcon[1], S. Mitra[2], J. Ketskemety[1], U. Wegmann[1], J. Wain[3], G. Belteki[4], P. Clarke[5], L. Hall[1]
[1]Institute of Food Research, Gut and Health, Norwich, United Kingdom
[2]Leeds Institute for Biomedical and Clinical Sciences,
Leeds Institute for Biomedical and Clinical Sciences, Leeds, United Kingdom
[3]University of East Anglia, Norwich Medical School, Norwich, United Kingdom
[4]The Rosie Hospital, Neonatal Instensive Care Unit, Cambridge, United Kingdom
[5]Norfolk and Norwich University Hospital, Neonatal Intensive Care Unit, Norwich, United Kingdom

Backgrounds

Preterm birth infants, particularly those born with an extremely low weight (<1kg), may have an altered gut microbiota due to disturbances induced by factors including; gut immaturity, delivery mode and antibiotic treatments. These microbiota disturbances may increase the risk of certain preterm-associated diseases such as necrotising enterocolitis. Therefore there is a requirement to optimally characterise gut microbial profiles in this at-risk cohort, particularly for studying the influence of microbiota therapies (e.g. probiotic supplementation) on microbial profiles and health outcomes.

Objectives

NA

Methods

Next generation sequencing targeting the bacterial 16S rRNA region allows in-depth and high-throughput characterisation of complex microbial communities. However, previous studies using adult samples indicate DNA extraction and the hypervariable region targeted can significantly impact the representative microbiota profile. We have optimised a protocol for studying the composition of the very early life gut microbiota, with a particular focus on the beneficial bacterial genus Bifidobacterium. Our study comprises Extremely Low Birth Weight (ELBW) infants (<27 week's gestation with/without probiotic supplementation), and control term infants. We compared three different DNA extraction methods, and subsequently PCR amplified and sequenced three hypervariable regions of the 16S rRNA gene (V1+V2+V3), (V4+V5) and (V6+V7+V8), which we compared to paired shotgun metagenomic data.

Conclusions

Our data indicate that all steps of the 16s microbiota profiling pipeline significant effect the microbiota profiles obtained from ELBW. Thus, it is important to carefully optimise 16s protocols for specific patient cohorts as different methodologies may lead to misrepresentation of profiles and overall conclusions about the impact of different interventions.

Environmental Microbiology/Microbial Ecology /Microbial Communities

RESPONSES OF SOIL BACTERIA COMMUNITIES TO VARIOUS HYDROCARBON CONTAMINANTS

H. Aldosari[1], *A. Grant*[1]
[1]*University of East Anglia, School of Environmental Sciences, Norwich, United Kingdom*

Backgrounds

Hydrocarbons contamination of soil is a widespread and urgent environmental problem. Many studies have examined impacts of a single crude or fuel oil on microbial community composition. Other studies have examined effects of one or more polycyclic aromatic hydrocarbons (PAHs), but rarely at the same time as crude or fuel oil.

Objectives

In consequence we do not know which components of oil have the biggest effects on microbial communities in the soil.

Methods

We compare responses of bacteria communities to a linear alkane (hexadecane), a PAH (fluoranthene) and diesel oil in different soil types, using Illumina sequencing of PCR amplified bacterial 16S sequences supplemented with metagenomics data.

Conclusions

There were significant impacts of all hydrocarbons on the communities in both soil types, with fluoranthene having the greatest effect. The extent to which the responses of communities in the two soils are similar depends upon the taxonomic level at which the comparison is made, helping to explain reports in the literature that different soils show idiosyncratic responses to hydrocarbon contamination.

GROWTH IN BIOFILM ENHANCES THE POTENTIAL TO FORM NEW BIOFILM IN CLINICAL ISOLATES OF KLEBSIELLA PNEUMONIAE

A. Hossain[1], M. Alharbi[2], A. Alateeq[2], A. Alatig[2], I. Alolayt[2], A. Alsayegh[2]
[1]University Of Hail, Microbiology, Hail, Saudi Arabia
[2]University Of Hail, Medicine, HAIL, Saudi Arabia

Backgrounds

Production of biofilm correlates with virulence as bacteria in biofilm often exhibit enhanced resistance to antibiotics and reduced clearance by immune system. Biofilm production potential of fresh clinical isolates of *Klebsiella pneumoniae* was investigated in this study emphasizing on whether growth in biofilm modulates the potential of the strains to form new biofilm and whether presence of normal human serum (NHS) in growth medium affects biofilm production potential.

Objectives

To determine whether growth in biofilm enhances the potential of new biofilm formation by *K. pneumoniae*.

To determine the influnece of normal human serum on biofilm forming potential of *K. pneumoniae* strains.

Methods

K. pneumoniae strains were obtained from the King Khaled Hospital, Hail. Saudi Arabia. Trypticase soy broth (TSB) was used for bacterial growth. Bacterial samples taken from biofilm or planktonic culture were used to initiate the formation of new biofilm for comparison. Crystal violet dye binding spectrophotometric assay was used for quantitation of biofilm. TSB was supplemented with 20% normal human serum (NHS) was used to determine whether NHS influences biofilm production.

Conclusions

The results of this study show that growth in biofilm enhances the potential to form new biofilm and production of biofilm was increased in presence of NHS.

BACTERIOPHAGES TO INCREASE THE SUSCEPTIBILITY OF A PATHOGENIC ANTIBIOTIC RESISTANT ESCHERICHIA COLI IN PRESENCE OF SOLAR DISINFECTION

N. Al-Jassim[1], D. Mantilla-Calderon[1], P. Hong[1]
[1]King Abdullah University of Science & Technology KAUST,
Environmental Science and Engineering- Division of Biological and Environmental Science and Engin eering, Thuwal Jeddah, Saudi Arabia

Backgrounds

Antibiotic-resistant bacteria (ARB) are emerging contaminants of growing concern. Our previous work characterized a pathogenic carbapenem-resistant *E. coli*, named PI-7, from the influent of a local wastewater treatment plant (Mantilla *et al*, 2016). To assess its fate/persistence upon release into the environment, its inactivation under simulated solar irradiance was examined. *E. coli* PI-7 underwent a 6-h lag-phase without decay, and took >12 h to achieve 5-log inactivation (decay half-life 2.85±0.46 min) (Al-Jassim *et al*, submitted). A persisting fraction remained detectable at 11-17 h, decaying almost three times slower (half-life 7.76±1.27 min).

Objectives

The prolonged persistence of this pathogenic ARB means that it is important to explore biocontrol strategies to attenuate its propagation. The current work explores using bacteriophages to increase the susceptibility of *E. coli* PI-7 upon solar inactivation, as gene-expression analysis on PI-7 revealed downregulation of phage-shock functions under simulated solar irradiance.

Methods

Seven bacteriophage isolates targeting PI-7 were isolated from wastewater influent, and checked for their lytic-specificity. Then, three bacteriophage isolates that showed the best stability under simulated solar irradiance conditions were selected for further trials with *E. coli* PI-7.

Conclusions

Bacteriophages showed lytic activity only against *E. coli* PI-7 and no other tested strains of *E. coli* and non-*E.coli* isolates. Under simulated solar irradiance, the selected bacteriophages significantly reduced *E. coli* PI-7 lag-phase length from 6.64±0.63 h to <1-4 h ($p \leq 0.0012$) compared to controls. These preliminary results show potential of bacteriophages as biocontrol agents that can be complementarily used with solar disinfection to prevent dissemination of *E. coli* PI-7.

BACTERIAL DIVERSITY ANALYSIS IN VINEYARD SOILS FROM RIBERA DEL DUERO

A. Alonso[1], J. García-Ruiz[1], P. García-Gonzalo[2], M.C. Lobo[2], E. Navascués[3], A. Santos[1], D. Marquina[1]
[1]Complutense University of Madrid, Microbiology III, Madrid, Spain
[2]IMIDRA, Agri-environmental research, Alcalá de Henares, Spain
[3]Pago de Carraovejas S.L., Research & Development, Peñafiel, Spain

Backgrounds

Vineyard soils are poorer in nutrients (potassium, iron, boron, manganese, copper and zinc) than other agricultural soils. Other environments showing high biodiversity indexes, such as reefs or jungle, are also poor in nutrients. Vineyards, usually distinguished for their antiquity and their poor nutrient status, tend to have ecological resilience and thus biodiversity stability.

Objectives

This project aims to determine the biodiversity (both culturable and non-culturable bacteria), associated to different vineyard soils from Ribera del Duero D.O., estimating the metabolic state of that soils.

Methods

Soil samples were collected along the entire physiological cycle of vines (including dormancy, budbreak and harvest status). Soil samples were collected from 5–30 cm depth from twelve different vineyard blocks, air-dried and then passed through a 2 mm sieve.

Culturable heterotrophic bacteria were estimated by count on TSA plates. In addition, *Actinomyces* species and nitrogen-fixing bacteria populations were estimated by culturing on appropriate selective media. Substrate Inducted Respiration (SIR) was used to determinate the oxidative metabolism of heterotrophic microorganisms present in soils. Edaphic bacterial biodiversity was determined by Denaturing Gradient Gel Electrophoresis (DGGE) using 70%-30% urea/formamide.

Conclusions

In dormancy and budbreak states, Shannon-Wiener index keeps on the highest values. SIR assay is a reliable method to estimate the non-culturable fraction of soil population, by comparing with total cell counts on TSA plates.

A population bloom in nitrogen-fixing bacteria occurs during budbreak, however it does not modify biodiversity index. Contrary, during harvest, bacterial biodiversity indexes decrease since a significant growth of *Actinomyces* spp. population (over 52%) is observed.

ISOLATION OF INDIGENOUS HYDROCARBON TRANSFORMING BACTERIA FROM OIL CONTAMINATED SOILS IN LIBYA: SELECTION FOR USE AS POTENTIAL INOCULA FOR SOIL BIOREMEDIATION

H. Althalb[1], *I. Elmisurati*[1]
[1]*Libyan Petroleum Institute, Industrial & Production Chemistry, Tripoli, Libya*

Backgrounds

Abstract The Libyan oil industry has left a significant legacy of contamination and methods are required to remediate oil- contaminated soils in the area.

Objectives

In this work hydrocarbon utilizing microorganisms were isolated and identified from contaminated soil samples obtained from an oil Refinery (Zawia, Libya).

Methods

After initial screening of eleven isolates capable of growth on hexadecane, the five most promising hydrocarbon–utilizing bacteria were isolated and tested for biosurfactant production and emulsification activity. They were identified (using 16S rRNA sequence analysis) as *Pseudomonas putida*, *Pseudomonas species, Betaproteobacterium, Actinomyces species*, and *Bacillus species*.

Conclusions

Among the five species tested, *Pseudomonas putida* showed superior performance in terms of growth on hydrocarbons (1.0×10^{10} CFU (ml)), E24 emulsifying activity (86%) and ability to transform hydrocarbons in pure culture. Interestingly, gas chromatographic analysis of crude oil treated with *P. putida* showed a decrease in heavy hydrocarbon fractions demonstrating a clear potential for this microbe to be used as a soil inoculant in bioremediation.

FROM PAULOVIAN TO MICROBIAL CONDITIONING: MODULATION OF S. AUREUS QUORUM SENSING BY P. AERUGINOSA

C. Amador[1], *L. Jelsbak*[1]
[1]*Technical University of Denmark, Department of Biotechnology and Biomedicine, Kgs. Lyngby, Denmark*

Backgrounds

Pseudomonas aeruginosa and *Staphylococcus aureus* are pathogens frequently co-isolated in cystic fibrosis (CF) airway infections. We have previously determined the genetic basis of adaptation in the transmissible, CF-adapted *P. aeruginosa* DK2 lineage (PADK2).

Objectives

We aimed at elucidating whether and how the genetic changes in PADK2 may have re-modelled its ability to interact with other pathogenic bacteria, such as *S. aureus* (SA).

Methods

Infecting bacteria can grow as aggregates on the airway surfaces, hence we examined the *in vitro* transcriptional pattern of mono-culture or co-culture spots grown on LB agar. RNA-sequencing was performed for all samples, a pairwise analysis conducted for each strain and data validated by RT-qPCR and transcriptional fusions.

Conclusions

In co-culture, SA showed a general tendency of gene expression down-regulation, including many genes encoding virulence factors and regulated by the Agr Quorum Sensing (QS) system such as proteases, leukocidins, leukotoxins and haemolysins. Remarkably, the *agrD* gene encoding the precursor of the auto-inducing peptide – AIP – regulating QS, was also down-regulated in co-culture, pointing to inhibition of the Agr QS system. Conversely, PADK2 showed up-regulation of the *pqsD* gene – involved in biosynthesis of the QS molecule HHQ and a general pattern of enhanced gene expression.

Our *in vitro* approach evidences that interspecies interactions can alter pathogen behaviour and – in the case of *S. aureus* – results in a phenotype compatible with a persistent infection and enhanced survival in the host. The mechanism exerted by *P. aeruginosa* DK2 for down-regulation of *S. aureus* QS is however yet to be identified.

PROTECTOR AND BENEFACTOR FOR PLANTS: ACC DEAMINASE POSITIVE BACTERIA IN STRESSED ENVIRONMENTS

G. Anand[1], V.S. Bisaria[1], S. Sharma[1]
[1]Indian Institute of Technology, Department of Biochemical Engineering & Biotechnology, NEW DELHI, India

Backgrounds

Agriculture is under tremendous pressure worldwide to feed an ever increasing population. The misuse of chemicals as fertilizers and pesticides for increasing productivity has led to ecological and human health hazards. Bioinoculants as plant growth promoting rhizobacteria (PGPR) present an eco-friendly, long term and sustainable alternative to these chemicals. ACC deaminase protects the plant from all biotic and abiotic stresses by degrading the phytotoxic levels of ethylene produced when a plant encounters any stress. Also the diversity of ACC deaminase producers in the rhizosphere plays an important factor in amelioration of stress. Salinity and drought are the major factors impacting Indian agriculture and worldwide.

Objectives

The objectives were (i) diversity analysis of ACC deaminase producers in stressed agricultural environments to derive a correlation between the two, and (ii) enumeration and isolation of potent ACC deaminase producers along with other desirable PGP properties for amelioration of stress in fields.

Methods

Plant growth experiment was setup in natural conditions using *Cajanus cajan* UPAS 120 as the model crop with simulated salinity and drought conditions.

Conclusions

High salt and natural drought conditions increased the abundance of probable ACC deaminase positive bacteria. Isolates obtained were screened for other PGP properties; subsequently plant growth experiment was set up in controlled condition for validation. Extensive analysis of plant parameters responsive to stress were measured. The plants with bioinoculants performed better in stressed conditions than the untreated control. ACC deaminase producers was found to serve dual function: protecting the plant from stress conditions and also promoting plant growth and productivity.

ANALYSIS OF THE BIOFILM FORMATION IN A HYDROTHERMAL SPRING CAVE USING IN SITU EXPERIMENTAL MODEL SYSTEM

D. Anda[1], J. Makk[1], A. Szabó[1], P. Bodor[2], J. Mádl-Szőnyi[2], K. Márialigeti[1], A. Borsodi[1]
[1]Eotvos Lorand University, Department of Microbiology, Budapest, Hungary
[2]Eotvos Lorand University, Department of Physical and Applied Geology, Budapest, Hungary

Backgrounds

The Buda Thermal Karst System (Budapest, Hungary) is one of the few hydrogeological systems, where springs, caves and the effects of hydrothermal fluids on carbonates can be evaluated. The number of microbiological studies related to the karst waters and biofilms developed on the surface of spring caves has been increased in the last decade in Hungary.

Objectives

However, the phases of biofilm formation and the influencing factors remained unknown. The Rudas-Török spring cave located in the southern part of Buda Thermal Karst System has optimal conditions as a study model.

Methods

For the evaluation of factors influencing biofilm formation, glass sides were immersed into the water-filled cave, and samples were taken at three weekly intervals during the 30 weeks of the monitoring phase. Besides field measurements and microscopic (light microscopy and FIB-SEM) techniques applied for the determination of physical and chemical parameters; a pyrosequencing approach based on the variability of the bacterial 16S rRNA gene was used to reveal the characteristic taxa and major shifts in the structures of the developing bacterial community.

Conclusions

The experiment resulted in an increase in the taxonomic diversity of bacterial communities which reached the maximum at phylum level in the third week. The members of phyla Chloroflexi, Parcubacteria, Plantomycetes, Proteobacteria, WCHB1-60 and Nitrospirae proved to be most abundant but their relative abundance changed at different rates during the studied period. Furthermore, there were remarkable changes in the OTU composition during the development of the biofilm.

This research was supported by the Hungarian Scientific Research Fund (OTKA) Grant NK101356.

SHIFT OF MICROBIAL COMMUNITY COMPOSITIONS IN DENTAL BIOFILMS AND CONSEQUENTIAL MINERAL CHANGES OF DENTAL ENAMEL FOLLOWING DIETARY CHANGES

A.C. Anderson[1], M. Rothballer[2], M.J. Altenburger[1], L. Karygianni[1], J.P. Wölber[1], E. Hellwig[1], M. Schmid[2], A. Al-Ahmad[1]
[1]Albert-Ludwigs University Freiburg, Department of Operative Dentistry and Periodontology, Freiburg, Germany
[2]Helmholtz Center- German Research Center for Environmental Health, Research Unit Microbe-Plant Interactions, Munich, Germany

Backgrounds

Caries development is associated with a shift in microbial communities of dental biofilms. Increasing numbers of acidogenic bacterial species, due to frequent simple carbohydrate consumption, result in cariogenic plaque.

Objectives

Few studies have analyzed environmentally induced shifts in oral biofilms *in situ*. Here the influence of a defined dietary change on the microbial community has been studied.

Methods

Eleven individuals wore splint systems containing bovine enamel slabs for 3x7 days with 7-day intervals to obtain dental biofilm samples, while keeping their regular diet. Subsequently, individuals sucked rock candy 5x per day for 3 months. Biofilm samples were collected at the end of this phase. The regular diet of the individuals was monitored. The microbial community of the dental biofilm was analyzed using Illumina MiSeq sequencing, amplifying variable regions v1-v2. Streptococci sequences were manually analyzed to the species level using ARB. Changes in mineral loss and lesion depth of the bovine enamel were investigated using transverse microradiography (TMR).

Conclusions

Permanova analysis revealed a significant difference in beta-diversity in the two phases. The individual dental biofilm communities were dominated in both phases by oral streptococci with a highly significant increase of *Streptococcus gordonii* ($p \leq 0.001$) and significant increases of *Streptococcus parasanguinis* ($p=0.04$) and *Streptococcus sanguinis* ($p=0.01$) in phase II. Simultaneously TMR showed significant demineralization of dental enamel ($p=0.0095$).
Our results showed that the prevalence of streptococci other than mutans streptococci correlates with enhanced enamel demineralization due to high acid production, following elevated simple carbohydrate consumption, supporting the extended ecological plaque hypothesis.

INFLUENCE OF SOLAR RADIATION AFTER MECHANICAL REVOLVING ON THE MICROBIOLOGICAL QUALITY OF THE DRY SANDS OF COASTAL BEACHES STATE OF PARANA-BRAZIL

S. Andraus[2], J. Alves Dionisio[1]
[1]Universidade Federal Do Parana, Solos E Engenharia Agricola, Curitiba, Brazil
[2]Instituto Ambiental do Paraná, Curitiba, Brazil

Backgrounds

Microbiological contamination of beach sand is a global reality which represents a potential for transmitting diseases.

Objectives

The purpose of the study, which is being carried out over the last four years, is to improve the sanitary aspects of the sands of the beaches of Paraná, by cleaning and revolving the organic debris and thus contribute to the reduction of diseases transmitted by direct contact.

Methods

During the study period, from January 2016 to February 2017, 15 samples were taken on three beaches along the coast of Paraná (Caiobá, Matinhos and Guaratuba), which have a high concentration of bathers, mainly in the summer. Two points were selected by beach, demarcated with an area of 50 m^2 (5 m x 10 m) and the dry sand samples were collected manually, of the superficial layer of approximately 10 cm. For the accomplishment of the microbiological analyzes, the enzymatic system fluorogenic and chromogenic substrate was used to isolate the Escherichia coli and the chromogenic substrate for Enterococcus.

Conclusions

The results of the sand analyzes, regarding the monitoring carried out from January 2016 to February 2017, using the indicators Escherichia coli and Enterococos, show a significant decrease in the summer seasons of 2015-2016 and 2016-2017. The results can be attributed to the action of solar rays, such as ultraviolet, on the surface of dry sands, reducing the action and eliminating pathogens, responsible for numerous diseases, acquired by direct contact.

Environmental Microbiology/Microbial Ecology /Microbial Communities

TOP-DOWN REGULATION OF PROKARYOTIC GROWTH EFFICIENCY IN TEMPERATE FRESHWATER PELAGIC ENVIRONMENTS

A.S. Pradeep Ram[1], J. Colombet[1], A. Thouvenot[2], T. Sime Ngando[1]
[1]Université Clermont Auvergne, LMGE- UMR CNRS 6023, AUBIERE, France
[2]Université Clermont Auvergne, Athos Environnement, AUBIERE, France

Backgrounds

In aquatic systems, limited data exists on the impact of mortality forces such as viral lysis and flagellate grazing when seeking to explain factors regulating prokaryotic metabolism.

Objectives

We explored the relative influence of top-down factors (viral lysis and heterotrophic nanoflagellate grazing) on prokaryotic mortality and their subsequent impact on their community metabolism in the euphotic zone of 21 temperate freshwater lakes located in the French Massif Central.

Methods

Viral lysis was determined from frequency of visibly infected prokaryotic cells by transmission electron microscopy whereas heterotrophic nanoflagellate grazing potential was calculated from flagellate clearance rate estimates.

Conclusions

Prokaryotic growth efficiency (PGE, index of prokaryotic community metabolism) determined from prokaryotic production and respiration measurements varied from 5 to 74% across the lakes. Viral and potential grazer induced mortality of prokaryotes had contrasting impact on PGE. Potential flagellate grazing was found to enhance PGE whereas viral lysis had antagonistic impacts on PGE. The average PGE value in the grazing and viral lysis dominated lake water samples was 35.4% (± 15.2%) and 17.2% (± 8.1%) respectively. Selective viral lysis or flagellate grazing on prokaryotes together with the nature of contrasted substrates released through mortality processes can perhaps explain for the observed variation and differences in PGE among the studied lakes. The influences of such specific top-down processes on PGE can have strong implications on the carbon and nutrient fluxes in freshwater pelagic environments.

Environmental Microbiology/Microbial Ecology /Microbial Communities

CHARACTERISING THE MICROBIAL COMMUNITIES ASSOCIATED WITH THE WATER DISTRIBUTION SYSTEM OF A BROILER FARM AND THEIR ROLE IN CAMPYLOBACTER INFECTION

P. Aranega Bou[1], *I. Goodhead*[1], *R. Birtles*[1], *C. James*[1]
[1]*University of Salford, School of Environment and Life Sciences, Salford, United Kingdom*

Backgrounds

Campylobacter is the most frequent food-borne illness in the EU with 190,000 cases reported annually. Poultry is an important reservoir for this zoonosis and the handling and consumption of chicken meat may directly account for 20-30% of cases. Despite the large body of research, sources of on-farm contamination remain unidentified. It has been suggested that natural microbial communities may influence *Campylobacter* survival in environmental niches.

Objectives

This study characterises the microbial communities that inhabit the broiler farm water system of a commercial farm in UK and how it changes over the 7-week production cycle and correlates with the presence of *Campylobacter*.

Methods

DNA was extracted from weekly biofilm and bulk water samples for 16S and 18S amplicon profiling. In parallel, selective media and molecular techniques were used to detect *Campylobacter* ssp.

Conclusions

Microbial communities were shown to vary significantly across different sample types (biofilm vs. bulk water and broiler farm vs. source water) and also temporally. Broiler house bacterial communities were dominated by Proteobacteria with a shift towards Firmicutes mainly due to an increase in *Lactobacillus* and *Staphylococcus* towards the end of the cycle. *Campylobacter*-specific 16S rRNA reads were detected in weeks 5 and 7 suggesting a possible role of the water distribution system in *Campylobacter* transmission. However, no viable *Campylobacter* colonies were isolated, suggesting a viable but non-culturable state. The emerging pathogens *C. ureolyticus* and *Helicobacter pullorum* were also detected. Microbial profiling could provide clues about which farm conditions might promote or inhibit survival of *Campylobacter* and other pathogens.

Environmental Microbiology/Microbial Ecology /Microbial Communities

EFFECT OF ELECTRO FENTON TREATMENT ON MICROORGANISMS OF WASTEWATER TREATMENT PLANT EFFLUENTS

R.M. Araujo Boira[1], E. Anfruns-Estrada[1], H. Salvadó[2], C. Bruguera-Casamada[1], I. Sirés[3], E. Brillas[3]
[1]Universitat de Barcelona, Genetica- Microbiologia i Estadistica, Barcelona, Spain
[2]Universitat de Barcelona, Department de Biologia Evolutiva- Ecologia i Ciencies Ambientals, Barcelona, Spain
[3]Universitat de Barcelona,
Laboratori d'Electroquímica dels Materials i del Medi Ambient- Departament de Química Física, Barcelona, Spain

Backgrounds

Electrochemical advanced oxidation processes (EAOPs) have been gaining increasing interest for wastewater decontamination. Conversely, much less attention has been paid to their ability for water disinfection. One of these processes is electro-Fenton (EF), which involves the use of an anode like boron-doped diamond (BDD) and an air-diffusion cathode to produce H_2O_2 on site. Fe^{2+} is added as catalyst, yielding various reactive oxygen species that act as oxidants. Among them, hydroxyl radicals can potentially inactivate microorganisms, including pathogens and, furthermore, are able to gradually destroy the organic matter.

Objectives

The main goal of this work was to study the performance of EF for the inactivation of the microorganisms contained in treated urban wastewater.

Methods

Microorganisms decays represented as log (N_t/N_0) reductions were tested at different times for 30 min during EF treatment of a primary and a secondary effluent obtained from a wastewater treatment plant (WWTP) located near Barcelona. Four bacteria and one bacteriophage were assayed by culture and active eukaryote community was analyzed by microscopy.

Conclusions

Important microbial reductions were obtained using EF in both wastewater effluents after 30 min. Heterotrophic bacteria showed a decay of 4.1 log units in primary effluent and 3.2 log units in secondary effluent. *Escherichia coli*, *Enterococcus* sp. and Somatic Bacteriophages were rapidly inactivated, whereas protozoa were severely reduced in 10 min. In contrast, spores of *Clostridium perfringens* were the most resistant. In summary, EF is able to inactivate microorganisms with high efficacy and could be further explored as wastewater treatment.

[4]São Carlos Institute of Physics- University of São Paulo,
Department of Physics and Interdisciplinary Science, São Carlos, Brazil

Backgrounds

Biosurfactants (BS) have several industrial and environmental applications whose processes involve extremes of temperature, pressure, pH, and salinity, stimulating the research of microorganisms that produce BS under these conditions. In the petroleum industry, BS have potential to enhance the removal of oil from reservoirs, increasing oil production.

Objectives

To evaluate biosurfactant production by bacterial strains isolated from an oil reservoir, under conditions of high salinity and/or temperature, with a view to its application in tertiary oil recovery.

Methods

Strains were isolated from culture media inoculated with rock (strains Ar70C2, Ar35B3 and Ar70C7-2) and oil samples (strains O9-1 and O27-2) from an offshore Brazilian oil reservoir. Growth and BS production were measured from aerobic liquid cultures in LB broth, with salinity of 35g/L or 70g/L, without agitation, and incubation at 37^{o}C or 55^{o}C for 6-8 days. BS production was evaluated by E24 emulsification index and surface tension measurements. The identification of the isolates was done by sequencing the 16S rDNA gene.

Conclusions

The maximum E24 values recorded and the measured surface tension values were: 73% and 40.7mN/m for Ar70C2, 67% and 38.2 mN/m for Ar35B3, 70% and 46.1 mN/m for Ar70C7-2, 53% and 50.1 mN/m for O9-1, and 45% and 49.7mN/m for O27-2. Strain Ar70C2 was identified as *Pseudomonas libanensis* (96% similarity), Ar35B3 as *Melghirimyces thermohalophilus* (90%), Ar70C7-2 as *Bacillus alveayuensis* (99%), O9-1 as *Bacillus aquimaris* (99%), and O27-2 as *Bacillus subterraneus* (99%). All of these are described as species belonging to extreme environments in salinity and/or temperature, except *P.libanensis*.

RESISTOME OF CULTURABLE SOIL BACTERIA AND WHOLE SOIL OBTAINED FROM ECOLOGICAL AND INTENSE FARMING SITES

J. Armalyte[1], J. Skerniskyte[1], R. Juskaite[1], R. Krasauskas[1], M. Ruzauskas[2], E. Suziedeliene[1]
[1]Life Sciences Center- Vilnius University, Institute of Biosciences, Vilnius, Lithuania
[2]Lithuanian University of Health Sciences, Microbiology and Virology Institute, Kaunas, Lithuania

Backgrounds

The resistance of non-pathogenic soil microorganisms to modern day antibiotics has come into notice in the recent years. The ecology, evolution and development of natural resistome and its possible spread to humans and animals is an area of interest and concern.

Objectives

In this study we aimed to compare the resistomes of bacterial populations in various farming environments and distinguish the influence of human interference. This could help indicating the possible routes of antibiotic resistance gene dissemination.

Methods

MIC values of antibiotic resistant bacteria from ecological and intensive wheat farming fields (soil 1 and 2) were tested. Clinically important genes responsible for enzyme-mediated resistance to β-lactams (including 3th and 4th generation of cephalosporins, carbapenems), quinolones, and transferable genetic determinants integrons were investigated in culturable bacteria and total DNA extracted from the same soils.

Conclusions

Antibiotic-resistant culturable bacteria from both soils were mostly comprised of *Pseudomonas* genus. Most of the isolates were highly resistant to antibiotics, on the average to 8 and 11 antibiotics for soils 1 and 2, respectively. None of the isolates tested were positive for clinically important resistance genes. Similar results were observed when total soil DNA was screened. The only resistance genes detected in total soil DNA were bla_{TEM} and *tetM*. The mechanisms responsible for antibiotic resistance of soil bacteria differ from those observed in clinical settings and should be investigated as a potential source of new antibiotic resistance genes.

SEARCH FOR ANTIBIOTIC RESISTANCE MECHANISMS IN STENOTROPHOMONAS MALTOPHILIA RECOVERED FROM SOIL USING FUNCTIONAL DNA LIBRARIES

J. Armalyte[1], J. Skerniskyte[1], R. Krasauskas[1], M. Ruzauskas[2], E. Suziedeliene[1]
[1]Life Sciences Center- Vilnius University, Institute of Biosciences, Vilnius, Lithuania
[2]Lithuanian University of Health Sciences, Microbiology and Virology Institute, Kaunas, Lithuania

Backgrounds

Stenotrophomonas maltophilia is an ubiquitous environmental bacterium found in soil and water. It is also associated with an increasing number of nosocomial infections, affecting immuno-compromised patients. Treatment of this opportunistic pathogen is often difficult due to its intrinsic resistance to antibiotics.

Objectives

The resistance of *S. maltophilia* to antibiotics could be addressed to low membrane permeability, antibiotic modifying enzymes, multidrug efflux pumps, which functions often cannot be predicted from sequence information. In this work we aimed to distinguish genes responsible for antibiotic resistance of *S. maltophilia* using functional DNA fragment libraries.

Methods

Genomic DNA was isolated from 6 isolates of *S. maltophilia* recovered from wheat field, resistant to at least 2 classes of antibiotics. All the selected isolates showed resistance to imipenem. gDNA was fragmented and used to create functional DNA fragment library with fragment sizes of >3 kb. The library was transformed to *E. coli* and screened for antibiotic (β-lactams, aminoglycosides, quinolones) resistant clones.

Conclusions

Despite selected *S. maltophilia* soil isolates being resistant to β-lactams, aminoglycosides and quinolones, the search of resistant DNA fragment library clones only produced several clones of moderate imipenem resistance. None of the clones encoded β-lactamases, but one clone was found to contain major facilitator superfamily (MFS) transporter protein.

MOLECULAR CHARACTERISATION OF EXTENDED SPECTRUM BETA-LACTAMASES PRODUCING ESCHERICHIA COLI AND KLEBSIELLA PNEUMONIAE

P. Montso[1], N.C. Ateba[1]
[1]North West University, Biological Sciences, Mafikeng, South Africa

Backgrounds

Extended Spectrum beta-lactamase producing *Enterobacteriaceae* particularly *Escherichia coli* and *Klebsiella pneumoniae* that possess ESBL traits cause hospital and community acquired infections worldwide.

Objectives

isolate and identify ESBL producing *Escherichia coli and Klebsiella pneumoniae* from cattle faeces and raw beef samples

Methods

Methods: A total of 151 samples were analysed and 259 presumptive isolates screened for characteristics of *Enterobacteriaceae* using biochemical tests and 16S rRNA universal gene. All the 259 isolates were subjected to *uidA*, *uspA* and *ntrA* specific PCR confirmed them as *E. coli* and *K. pneumoniae*. ESBL traits were detected on Brilliance ESBL agar and amplification of ESBL (bla_{TEM}, bla_{SHV}, bla_{OXA}, bla_{CMY-1}, bla_{CMY-2} and bla_{CTX-M}) gene determinants. Antimicrobial susceptibility test was performed to determine antibiotic resistance profiles of the isolates. Cluster analysis was performed using antibiotic inhibition zone diameter data to determine the relatedness between isolates from cattle faeces and beef samples. The genetic relatedness of all confirmed *E. coli* and *K. pneumoniae* was determined using ERIC-PCR analysis.

Results: A total of 114 and 82 *E. coli* and *K. pneumoniae* respectively were obtained. Large proportions (66.7-100%) of isolates were resistant to Amoxicillin, Aztreonam, Ceftazidime, Cefotaxime and Piperacillin. A total of 53.1% ESBL isolates were detected on Brilliance ESBL agar. The bla_{TEM}, bla_{SHV} and bla_{CTX-M} genes were detected in 85.5%, 69.6% and 58% of the isolates respectively. The bla_{CTX-M} and bla_{OXA} genes were dominant in *E. coli* and *K. pneumoniae* isolates respectively. Genetic fingerprints of *E. coli* and *K. pneumoniae* isolates were very similar.

Conclusions

Need for continuous monitoring of ESBL in animals.

Environmental Microbiology/Microbial Ecology /Microbial Communities

MOLECULAR CHARACTERISATION OF VIRULENCE DETERMINANTS IN ESCHERICHIA COLI PATHOTYPES ISOLATED FROM ABATTOIRS

C. Tchatchouang[1], A. Kumar[1], C. Ateba[1]
[1]North West University, Biological Sciences, Mafikeng, South Africa

Backgrounds

Food products of animal origin particularly beef are known to cause *E. coli* related diseases in humans worldwide. *E. coli* strains are classified into different pathological groups (EPEC, EHEC, ETEC, EAEC, DAEC and EIEC) based on virulence characteristics and they can contaminate meat in abattoirs.

Objectives

isolate and characterize *E. coli* pathotypes from beef carcasses

Methods

Methods: A total of 2196 beef swab samples were collected, analysed on EMBA and 152 samples that were positive for *E. coli* based on macroscopic morphologies. 291 metallic sheen isolates were subjected to Gram-staining, oxidase, TSI, citrate utilization and *uidA* specific PCR analysis. *E. coli* isolates were screened for the presence of *stx1*, *stx2*, *eaeA* and *hlyA* virulence gene determinants. The combinations of the various virulence genes per isolate were used to determine their genotypes.

Results: A large proportion 152 (77.6%) of the samples were positive for *E. coli* macroscopically. A large proportion 256 (88 %) were positive for the *E. coli uidA* gene. Sixteen major genotypes designated G1 to G16 were identified and 199 (77.7%) isolates harboured the stx_1 gene while 70.7% to 77.7% harboured the stx_1, stx_2 and *eaeA* genes. Only 3 (1.2%) harboured both stx_1, and stx_2 genes (Genotype G6). Six (2.3%) isolates harboured all the four virulence gene determinants investigated while only 16 (6.3%) possessed the stx_1 and stx_2 genes respectively in combination with the two accessory virulence gene determinants (*eaeA* and *hlyA*) (G14, G15 and G16). ERIC fingerprints comprised 1 to 17 polymorphic bands per isolate.

Conclusions

Need for continuous monitoring

Environmental Microbiology/Microbial Ecology /Microbial Communities

EFFECTS OF NOVEL NANOCOMPOSITES ON MORPHOLOGICAL AND FUNCTIONAL PARAMETERS OF BACTERIA

A. Augustyniak[1], K. Cendrowski[2], P. Nawrotek[1], M. Barylak[2], E. Mijowska[2]
[1]West Pomeranian University of Technology- Szczecin- Faculty of Biotechnology and Animal Husban dry, Department of Immunology- Microbiology- and Physiological Chemistry, Szczecin, Poland
[2]West Pomeranian University of Technology- Szczecin- Institute of Chemical and Environment Engine ering, Department of Nanotechnology, Szczecin, Poland

Backgrounds

Novel nanostructures of various applications are being synthetized every year. Nevertheless, these substances may enter natural environment where their activity has not been fully understood. First organisms that will likely come into contact with nanostructures are environmental bacteria. Therefore, there is a necessity to evaluate the impact of nanostructures on these microorganisms.

Objectives

The goal of study was the evaluation of selected morphological and functional parameters of model and environmental bacteria in reaction to silica-based (nanospheres and nanotubes) and carbon-based (carbon nanotubes, and graphene oxide nanoflakes) nanomaterials functionalised with metals or titanium dioxide, and a comparison of the results between microorganisms.

Methods

Studies were conducted on selected bacteria from genera *Escherichia*, *Pseudomonas*, *Staphylococcus*, and *Streptomyces*. Nanocomposites selected for the experiments included silica nanospheres and nanotubes, carbon nanotubes, and graphene oxide flakes, modified with copper, cobalt, or titanium dioxide. Morphology and viability was evaluated by culture methods, phase-contrast microscopy, scanning and transmission electron microscopy. Metabolic activity was measured in the alamarBlue® assay. Secretion of pigments was measured by UV-Vis spectroscopy. Biofilm formation was evaluated in method based on staining with crystal violet. Absorbed nanostructures were detected by energy dispersive X-ray spectroscopy. Expression of selected genes was measured in Two-Step RT-qPCR reactions.

Conclusions

Environmental bacteria (streptomycetes and pseudomonads) show different reaction to nanocomposites than model strains (*Escherichia*, *Staphylococcus*). Nanocomposites may induce rapid clustering behaviour and secretion of secondary metabolites. Influence on biofilm formation is dependent on the type of nanomaterial and microorganism, and may be either induced or inhibited.

ISOLATION AND CHARACTERISATION OF FIFTY STREPTOMYCETES ISOLATED FROM VARIOUS ENVIRONMENTAL SAMPLES

A. Augustyniak[1], B. Grygorcewicz[2], M. Roszak[1], J. Jabłońska[1], P. Nawrotek[1]
[1]West Pomeranian University of Technology- Szczecin- Faculty of Biotechnology and Animal Husbandry, Department of Immunology- Microbiology- and Physiological Chemistry, Szczecin, Poland
[2]West Pomeranian University of Technology- Szczecin Faculty of Biotechnology and Animal Husbandry, Department of Immunology- Microbiology- and Physiological Chemistry, Szczecin, Poland

Backgrounds

Streptomycetes are microorganisms that inhabit many terrestrial and aqueous ecosystems. These bacteria are known for their ability to produce many useful secondary metabolites including antibiotics, enzymes, and pigments, that is probably affected by the environment of their origin. Although intensive studies on genre *Streptomyces* has been conducted, every year brings novel outcome on features of these microorganisms. This encourages to gather collections of microorganisms that will be tested in direction of future application in biotechnological purposes.

Objectives

The aim of the study was to isolate and evaluate biotechnological potential of fifty distinguishable streptomycetes isolated from various environmental samples.

Methods

Isolation was conducted from soil samples collected in agricultural, industrial and environmentally protected areas, as well as from a swine slurry. Bacteria were isolated with the use of serial dilution method. Gained monocultures were evaluated in terms of lytic activity, pigment secretion, growth in high salt concentrations, and antagonistic activity against opportunistic pathogens including Gram-positive (*Staphylococcus aureus*) and Gram-negative (*Escherichia coli*, *Pseudomonas aeruginosa*) bacteria, and yeast (*Candida albicans*).

Conclusions

Results confirm that the source of isolation may affect the characteristics of streptomycetes. Moreover, majority of isolated streptomycetes show antagonistic activity against yeast, while only one strain was able to inhibit growth of *Pseudomonas aeruginosa*. Swine slurry may be considered as a source of streptomycetes of high proteolytic activity.

COMMUNITY ECOLOGY OF AEROBIC ANOXYGENIC PHOTOTROPHIC (AAP) BACTERIA AT VARIOUS TEMPORAL AND SPATIAL SCALES

A. Auladell[1], P. Sánchez[1], J.M. Gasol[1], I. Ferrera[1]
[1]Marine Sciences Institute - ICM-CSIC, Dept. of Marine Biology, Barcelona, Spain

Backgrounds

Aerobic anoxygenic phototrophs (AAPs) are photoheterotrophic microorganisms that require organic substrates for growth, but can derive a portion of their energy harvesting light using bacteriochlorophyll *a*. Their ecology, metabolism and physiology have been intensively studied during the last two decades, but there is still a lack of large-scale analyses needed to unravel their spatio-temporal dynamics.

Objectives

Here, we focus in the community ecology of AAPs by analyzing the diversity of their marker gene *pufM* in large metagenetic (PCR-amplification and Illumina sequencing) and metagenomic datasets from 2 global circumnavigation expeditions, Tara Oceans and Malaspina, as well as from a decade-long time-series in the NW Mediterranean Sea (Blanes Bay Microbial Observatory).

Methods

At the spatial scale, we observed that variation in community structure was driven both by geographical location and by environmental conditions. In most stations phylogroups associated with the *Gammaproteobacteria*, *Roseobacter* and *Rhodobacter* were dominant but, interestingly, in some stations half of the sequences could not be associated to any defined phylogroup. At temporal scales, seasonality clearly differentiated AAP communities and half of the variation was explained by day length, temperature, water transparency, chlorophyll *a*, salinity and phototrophic nanoflagellates abundance. Comparing spatial and temporal scales, we observed that although higher richness was observed at temporal scales in a single site, dissimilarities between samples at spatial scales presented more variation, which increased with geographical distance.

Conclusions

Our work shows that a combination of large genetic studies with global and eulerian sampling have the most powerful potential to discern the spatio-temporal dynamics of marine microbial communities.

EFFICIENCY OF DRILLING FLUID ISOLATED BACTERIA ON CYANIDE TREATMENT

N.H. Avcioglu[1], *S. Bilen Ozyurek*[1], *I. Seyis Bilkay*[1]
[1]*Hacettepe University Faculty Of Science, Biology Biotechnology Section, Ankara, Turkey*

Backgrounds

Anthropogenic effects and industrial processes are the main sources of cyanide and cyanogen compounds which are known as important toxic chemicals for living organisms. Accordingly, by means of cyanide accumulation in environment, chemical composition of soil may change and it may also contaminate underground water and cause serious effects on aquatic organisms.

Objectives

It is very important to protect living organisms from the toxic effects of cyanide and cyanogen compounds. In that case, biological treatment methods are seen as advantageous for the removal of cyanide into nontoxic products. Accordingly, in biological treatment processes, lots of microorganisms and plants are being used in order to protect environment from the toxic, carcinogenic and mutagenic effects of cyanogen wastes.

Methods

In this study, cyanide removal efficiencies of *Proteus mirabilis*, *Klebsiella pneumoniae, Bacillus tequilensis, Bacillus axarguiensis* and *Enterobacter cloacae* which were isolated from drilling fluid, were investigated. Additionally, mix cultures were prepared and antagonistic and synergetic interactions between these bacterial species were also determined.

Conclusions

The results of this research demonstrated the usability of *Proteus mirabilis*, *Klebsiella pneumoniae, Bacillus tequilensis, Bacillus axarguiensis* and *Enterobacter cloacae* on cyanide treatment processes including different cyanogen wastes. Additionally, the importance of antagonistic and synergetic interactions between these microorganisms was also examined with this study. In this respect, the results are promising for the future researches on cyanide removal by using mix cultures of bacterial species.

INVESTIGATION OF CYANIDE TOLERANCE IN MICROCOCCUS LUTEUS

N.H. Avcioglu[1], S. Bilen ozyurek[1]
[1]Hacettepe University Faculty Of Science, Biology Biotechnology Section, Ankara, Turkey

Backgrounds

In parallel with the population increase all over the world, industrial production increases and high volumes of cyanide containing wastes originate from different industrial processes. Especially, untreated wastewaters discharged from these processes pollute the environment and cause toxic effects on cellular metabolism of living organisms.

Objectives

Removal of cyanide especially in industrial wastewaters by using effective methods is an important issue in order to protect the health of living organisms.Accordingly, wastewater management by means of using biological systems is environmentally friendly and new researches focus on the improvement of effective treatment methods by using microorganisms.

Methods

In this study, cyanide biodegradation capability of *Micrococcus luteus* against different cyanide compounds were investigated. Additionally, cyanogen waste forming industrial processes' wastewaters were selected and the usability of this strain in wastewater treatment was also investigated. Lastly, different concentrations of cyanide containing culture media were prepared and cyanide tolerance of *Micrococcus luteus* was also determined.

Conclusions

In the view of the results of this research, *Micrococcus luteus* is found as a usable agent in cyanide removal processes with its high cyanide tolerance ability.

AN IN VITRO STUDY OF HUMAN BACTERIAL COMMUNITY DYNAMICS AFTER FECAL TRANSPLANTATION

J. Arnold[1], I. Williamson[2], I. Carroll[1], J. Rawls[3], S. Magness[4], M.A. Azcarate-Peril[1]
[1]University of North Carolina at Chapel Hill,
Medicine – Division of Gastroenterology and Hepatology and Microbiome Core Facility- Center for Gastrointestinal Biology and Disease- University of North Carolina- Chapel Hill- NC, Chapell Hill, USA
[2]University of North Carolina at Chapel Hill, Biomedical Engineering, Chapell Hill, USA
[3]Duke University Medical Center, Department of Molecular Genetics & Microbiology, Durham, USA
[4]University of North Carolina at Chapel Hill, Cell Biology and Physiology and Biomedical Engineering, Chapell Hill, USA

Backgrounds

Fecal microbiota transplantation (FMT) treatments have been reported to successfully treat *Clostridium difficile* infections (CDI), and are currently considered for other dysfunctions like diabetes, IBD, IBS, metabolic syndrome, neurodevelopmental disorders, autoimmune diseases and allergic diseases. One drawback of FMT is the dependence on stool donors, and the potential unexpected consequences of using an undefined mixture of microbial species. Moreover, the impact of handling and processing of fecal samples on microbial viability and community dynamics has not been addressed.

Objectives

To monitor bacterial community dynamics of human stool samples post processing and FMT into stem cell-derived organoids.

Methods

We evaluated the impact of sample processing for FMT by 16S rRNA amplicon sequencing. Processed stool samples and pure bacterial cultures were inoculated into colonoids grown from conventionally raised mouse crypts. Plating, quantitative PCR, and 16S rRNA amplicon sequencing determined microbial survival, growth, and community dynamics inside the organoids. The impacts of antibiotics and oxygen exposure on live transplanted microbes were also evaluated.

Conclusions

Processing human fecal samples via homogenization and filtration did not significantly disrupt microbial diversity. Bacterial communities within the pseudo-lumen changed over 96 hours, showing an early bloom in Proteobacteria and subsequent recovery of Firmicutes. *Bifidobacterium adolescentis,* an obligate anaerobe, was able to survive and grow inside the organoid pseudo-lumen. Future studies will utilize this platform to determine impacts of microbiota colonization on cellular physiology, and how beneficial modulators of the microbiota effect microbial communities.

ENTERIC VIRUSES AMELIORATE GUT INFLAMMATION VIA TOLL-LIKE RECEPTOR 3 AND TOLL-LIKE RECEPTOR 7-MEDIATED INTERFERON-B PRODUCTION

J.W. Bae[1]
[1]*Kyung Hee University,*
Department of Life and Nanopharmaceutical Sciences and Department of Biology, SEOUL, Republic of Korea

Backgrounds

Metagenomic studies show that diverse resident viruses inhabit the healthy gut;

Objectives

however, little is known about the role of these viruses in the maintenance of gut homeostasis.

Methods

Mice deficient in both TLR3 and TLR7, which lack the ability to recognize viral single- and double-stranded RNAs, were more susceptible to DSS-induced experimental colitis. Furthermore, antiviral (AV) cocktail significantly decreased the abundance of enteric DNA and RNA viruses. To identify the genotypic changes of enteric DNA and RNA viruses, we conducted a metagenomic analysis of fecal VLP-derived metagenomic DNA and RNA using Illumina MiSeq sequencing.

Conclusions

In Jaccard and Hellinger distance-based principal coordinate analysis (PCoA), before and after paired samples of the VLP-derived metagenomes were distant from each other, and fecal VLP-derived DNA and RNA metagenomes were clustered by AV cocktail treatment ($P < 0.05$). Interestingly, we found an increase in the richness and abundance of *Caudovirales* bacteriophages in the enteric DNA virome of the mice treated with an AV cocktail, which corresponds with findings in a cohort of IBD patients. These results indicate that the genotypic changes in the community composition of enteric DNA and RNA viruses are implicated in deterioration against DSS-induced colitis by AV cocktail treatment. The recognition of resident viruses by TLR3 and TLR7 is required for protective immunity during gut inflammation.

Environmental Microbiology/Microbial Ecology /Microbial Communities

DIFFERENTIAL GENE EXPRESSION OF VIBRIO TORANZONIAE IN RESPONSE TO ADVERSE CONDITIONS.

S. Balboa[1], A. Lasa[1], R. Jesús L.[1]
[1]CIBUS- Facultad de Biología. Universidade de Santiago de Compostela, Microbiology and Parasitology, Santiago de Compostela, Spain

Backgrounds

Viable but not culturable state (VBNC) can be defined as a dormancy phase in which bacterial cells maintain its viability but suffer major morphological and metabolic modifications becoming resistant to harsh conditions but losing culturability.

Objectives

To determine the capacity to enter in VBNC of environmental and pathogenic strains of *V. toranzoniae*.

Methods

Artificial seawater (15 ‰) microcosms were inoculated with the different bacterial strains and maintained at 4ºC. Expression of different genes was comparatively analysed by qPCR, among exponential growth, VBCN state and after resuscitation.

Conclusions

Environmental strain CECT 7225^T, entered in VBNC after 49 days of incubation and was resuscitated after 24h at 24ºC. However, the pathogenic strain R17 remained viable after 60 days, although bacterial counts dropped 4 log-units.

CECT 7225^T cells became coccoid after 24h. Concomitantly, the expression of the gene encoding for the cell shape protein, *mre*B, was reduced (2.5-fold) and recovered during the resuscitation although never reached the original levels. While in VBNC, cells were not able to divide, and thus, the *fts*Z expression was found to be reduced. The pathogenic strain R17 also showed rounded morphology and reduction of the *mre*B and *fts*Z expression after 50 days (8-fold). This results suggest that the morphology change is a response to the starvation rather than a VBNC characteristic.

The expression of the osmosensor *env*Z gene was up-regulated in strain CECT 7225^T during VBNC, while a dramatic down-regulation (5-fold) was found in starved R17 isolate, suggesting the importance of this sensor to trigger the entry in VBNC state.

CHARACTERIZATION OF THE AQUATIC MOBILOME IN A RIVER INFLUENCED BY A WASTEWATER TREATMENT PLANT

I. Lekunberri[1], J.L. Balcazar[1], C.M. Borrego[1,2]
[1]Catalan Institute for Water Research, Scientific and Technological Park of the University of Girona, Girona, Spain
[2]Group of Molecular Microbial Ecology, University of Girona, Girona, Spain

Backgrounds

Transfer of antibiotic resistance genes (ARGs) among bacteria through mobile genetic elements (MGEs), such as plasmids and bacteriophages, has been widely studied and demonstrated, especially in clinically relevant isolates. However, few studies have been undertaken to examine the role of MGEs in environmental settings.

Objectives

We investigated the abundance of ARGs in plasmid and phage DNA fractions from water samples collected upstream and downstream of the WWTP discharge point into the Ter River, Spain. The abundance of ARGs in bacterial DNA fractions was also analyzed for comparative purposes.

Methods

Real-time PCR assays were used to determine the abundance of genes encoding resistance to β-lactams, fluoroquinolones, tetracyclines, sulfonamides, glycopeptide antibiotics and macrolides. In the three DNA fractions, higher copy numbers of ARGs were detected in impact (after the WWTP effluent discharge) than in control sites, showing significant differences ($p < 0.05$) for most genes. Interestingly, genes conferring resistance to β-lactams (*bla*$_{TEM}$, *bla*$_{NDM}$ and *bla*$_{KPC}$) and vancomycin (*van*A) showed significant differences ($p < 0.05$) in DNA from MGEs (phages and plasmids) between control and impact sites but no statistical significance was obtained for these genes in the bacterial DNA fraction.

Conclusions

These results demonstrated that plasmids and phages play an important role in the mobilization of ARGs.

Environmental Microbiology/Microbial Ecology /Microbial Communities

CONTRIBUTION OF FUNGI AND BACTERIA TO ECOSYSTEM PROCESSES IN FOREST SOILS: TRACING THE ACTIVITY OF COMMUNITIES AND INDIVIDUAL TAXA

P. Baldrian[1]
[1]*Institute of Microbiology of the CAS, Laboratory of Environmental Microbiology, Prague 4, Czech Republic*

Backgrounds

In forest soils, microbes are important drivers of soil processes, because they mediate decomposition as well as nutrient transfer from primary producers into soil.

Objectives

Here we have explored the involvement of microorganisms in ecosystem processes in coniferous forest topsoil.

Methods

Metatranscriptomics, metaproteomics and enzyme activity assays were combined with strain isolation and genome sequencing of major bacterial and fungal taxa to track microbial activity across seasons.

Conclusions

The results indicate that ecosystem processes exhibit seasonality with a fungal dominance in summer and bacterial dominance in winter affecting multiple processes ranging from ectomycorrhizal symbiosis to decomposition. Summer season is characterized as a period with rapid microbial growth accompanied by decomposition of recalcitrant plant biopolymers likely induced by the priming effect of photosynthates delivered by plant roots. Winter appears to be a period of slow growth when reserve compounds such as starch, glycogen and trehalose are utilized. Methods focusing environmental metacommunities are, however, not able to identify individual microbial species, participating in the soil processes. To do that, dominant bacterial strains were isolated and genome sequenced and genomes of ectomycorrhizal fungi were sequenced from fruitbodies. Mapping of metatranscriptomic reads on genomes of dominant bacteria showed, interestingly, that Acidobacteria are the likely major producers of decomposition-related enzymes that possess high counts of glycosyl hydrolases in their genomes, in contrast to Bacteroidetes and Proteobacteria. Transcript profiles of bacteria and fungi *in situ* differ among horizons as well as among seasons showing the effect of environmental conditions on transcription.

CLEARCUTTING INITIATES COMPLEX RESTRUCTURALIZATION OF FUNGAL COMMUNITIES IN SOIL AND TREE ROOTS AND ALTERS DECOMPOSITION

M. Charvátová[1], P. Kohout[1], M. Šťursová[1], M. Tomšovský[2], P. Baldrian[1]
[1]Institute of Microbiology of the CAS, Laboratory of Environmental Microbiology, Prague 4, Czech Republic
[2]Mendel University in Brno, Faculty of Forestry and Wood Technology, Brno, Czech Republic

Backgrounds

Forest trees act as major suppliers of carbon into forest soils through their production of litter and rhizodeposition. Ectomycorrhizal fungi (ECM) produce their mycelia on expense of the rhizodeposited C and are thus dependent on their host.

Objectives

Here we followed fungal community composition in fine roots, rhizosphere soil and bulk soil of spruce (*Picea abies*) forest over two years following tree harvest.

Methods

Biomass and community analysis, enzyme assays.

Conclusions

Under living trees, rhizosphere contained significantly more fungal biomass than bulk soil and slightly less than roots. After tree harvest, fungal biomass in bulk soil remained unchanged, in the rhizosphere it decreased 4-fold while in decomposing roots it increased up to fivefold. This was associated with the increase in activity of decomposition-related enzymes in roots and decrease in rhizosphere. Fungal community composition changed over time. In the soil and rhizosphere, share of ECM decreased from 50% under living trees to <10% after two years. In roots of living trees, ECM represented 56% of all sequences and persisted until two months, but their abundance dropped to <2% after one year to be replaced by wood-decomposing taxa. Recently, the saprotrophic abilities of ECM are under debate and indirect evidences increase about the possible ability of certain taxa to decompose biopolymers, but although the persistence of ECM on dead roots was species dependent, our results do not support this view. Clearcutting induces sharp decrease in photosynthate allocation belowground and this is reflected by both the activity of soil microbiota and the composition of fungal communities.

Environmental Microbiology/Microbial Ecology /Microbial Communities

EVALUATING THE USE OF MICROBIAL SOURCE TRACKING TECHNIQUES IN A MEDITERRANEAN CATCHMENT

E. Ballesté[1], C. García-Aljaro[1], M. Pascual-Benito[1], F. Lucena[1], A.R. Blanch[1]
[1]University of Barcelona, Genetics- Microbiology and Statistics, Barcelona, Spain

Backgrounds

Several host-specific markers to detect the source of faecal pollution in waterbodies have been designed and evaluated worldwide. These methods are mainly based in qPCR assays. They can be used for water management strategies and to model pollution events. However, geographical variability has been observed regarding the markers. Thus, the sensitivity and specificity has to be evaluated in the area of interest before their implementation and persistence studies have to be performed to model they fate in the environment.

Objectives

The aim of this study was to evaluate the sensitivity, specificity, and inactivation of 5 MST markers targeting human and animal pollution and finally model their fate in a river catchment.

Methods

The sensitivity and specificity of MST makers to detect human (HMBif and HF183), porcine (Pig2Bac), ruminant (BifCW) and poultry (BifPL) pollution was evaluated in 26 faecal samples collected in Spain. On the other hand, persistence analysis was performed onsite using dialysis bags. They were collected regularly during 2 weeks and inactivation of the MST markers was monitored. Finally the markers performance was evaluated in Riera de Cànoves after 8 sampling campaigns during one year. Samples were collected after the effluent of a WWTP, 500m and 1km downstream.

Conclusions

HMBif was the best option to determine human pollution with 100% sensitivity and 95% specificity. The sensitivity and specificity of animal markers was higher than 80% and 60%, respectively, being Pig2Bac the less specific. The inactivation of the markers was similar in summer (T_{90} between 1 – 2.2 days). On the other hand, in winter higher difference between them was observed (T_{90} between 2.1 - 6.9 days). Organic matter can play an important role working as a shelter for certain bacteria. In the river catchment, markers decreased 1 log after a rank of 200m to 2.6km depending the season and marker.

DYNAMICS OF MICROBIAL COMMUNITIES IN THE DECOMPOSITION OF LEAF LITTER IN FOREST ENVIRONMENTS

A. Bani[1], L. Borruso[1], S. Pioli[1], C. Wellstein[1], L. Brusetti[1]
[1]Free University of Bolzano, faculty of science and technology, Bolzano, Italy

Backgrounds

Litter decomposition is a key step in carbon flux cycle, in soil formation and stabilization. Fungi exert the major role in the decomposition and only recently has been given more attention to the bacterial community.

Objectives

This study aims to highlight the role of the microbial community involved in leaf decomposition in the mountain areas of South Tyrol (Italy). The goal is to study the decomposition of litter fall in their natural environment and in a transplantation experiment, simulating an environment with increased average temperature.

Methods

We selected litters characterized by tree different plant species and altitudes: oaks forest at 500, beech at 1000 and rhododendron at 1500 m.a.s.l. The decomposition was studied using *in situ* litterbags. In each sampling sites, litter bags containing leaves from own sites and from the others two sites were located and left for two years. The investigation foresaw the use of biomolecular fingerprinting techniques, Real Time PCR, Thermogravimetric analysis of the litter and enzymatic activity. In addition, environmental variables have been measured.

Conclusions

The results showed that the bacterial community is strongly affected by the sampling time, supporting the idea of a temporal succession of different taxa. Fungal community behaved differently with not clear assemblages. Within each single event, the plant species was the main driver of the bacterial community composition in all the time points, whereas fungal community showed a similar trend only in the first year of the experiment. Other environmental variables, such as average temperature, seemed to have little importance.

Environmental Microbiology/Microbial Ecology /Microbial Communities

EFFECT OF OZONE ADDITION TO CONTROL GORDONIA FOAMING ON THE NITRIFYING BACTERIAL COMMUNITIES IN A MUNICIPAL WASTEWATER TREATMENT PLANT

P. Barbarroja[1], *A. Zornoza*[1], *J.L. Alonso*[1], *S.V. Marin*[2]
[1]*Universitat Politècnica de València, Instituto de Ingenieria del Agua y Medio Ambiente, Valencia, Spain*
[2]*Universidad de Santander, Facultad de Ciencias Exactas- Físicas y Naturales, Bucaramanga, Colombia*

Backgrounds

The ozonation of activated sludge has been used as a technical measure for bulking control in a high number of full-scale wastewater treatment plants (WWTP), despite of the imprecise predictions on the level of reduction in filament grow or the lack of knowledge on impact on microbial community. Studies to elucidate the impact of this process on nitrifying bacterial community have not been carried out to date.

Objectives

The aim of this study was to evaluate the use of ozone for *Gordonia foaming* elimination on dynamic population of nitrifying bacterial community and nitrification performance of activated sludge system.

Methods

Full-scale studies were conducted over a period of 12 months at the two bioreactors of municipal WWTPs of Castellón (Spain). Both bioreactors were treated with different ozone dosages during this period. Samples from activated sludge, influent and treated effluent were collected every fifteen days and nitrifying community structures were analyzed using quantitative fluorescence in situ hybridization (qFISH). We investigated models of environmental interpretation of biological variables using of distance-based linear models (DISTLM).

Conclusions

Nitrosomonas oligotropha and members of the genus *Nitrotoga* were found by FISH as the dominant nitrifiers responsible for ammonia and nitrite oxidation, respectively. The DISTLM analysis showed that different ozone dosages determined the nitrifying activity, although ozone not appears to be an environmental factor influencing the dynamic of nitrifying bacterial community.

COMPARISON OF NITRIFYING MICROBIAL COMMUNITIES OF TWO FULL-SCALE MEMBRANE BIOREACTORS TREATING WASTEWATERS FROM MUNICIPAL SOLID WASTES USING 16S RDNA GENE AMPLICON SEQUENCING

P. Barbarroja[1], L. Moreno-Mesonero1[1], A. Zornoza[1], J. Fernández-Navarro1[1], J.L. Alonso[1], F. Muñagorri[2], C. García[2], C. Álvarez[2]
[1]Universitat Politècnica de València, Instituto Universitario de Ingeniería del Agua y Medio Ambiente, Valencia, Spain
[2]URBASER, Camino de las Hormigueras 171- 28031, Madrid, Spain

Backgrounds

Landfill leachate is a complex composition containing high levels of ammonia nitrogen. Membrane bioreactor systems (MBRs) are used for this type of complex wastewater treatment, because of their capacity of working at high concentrations levels of suspended solids and high cell retention times.

Objectives

In this study, 16S rRNA gene amplicon sequencing (NGS) combined with fluorescent *in situ* hybridization (FISH) were performed to identify detailed changes of nitrifying bacterial communities in activated sludge of two full-scale MBRs treating the waste effluents from landfill leachate treatment systems

Methods

Samples from activated sludge were collected monthly during fifteen months from two MBR systems. The nitrifying bacterial communities were analyzed using 16S rRNA gene amplicon sequencing (NGS) and fluorescence in situ hybridization (FISH). Distance-based linear models (DISTLM) were applied to investigate models of environmental interpretation of biological variables.

Conclusions

The two MBRs had different nitrifying microbial community compositions. In the MBR treating the waste effluents with high solids anaerobic digestion the ammonia oxidizing community was predominated by the family *Nitrosomonadaceae* y and the genus *Nitrosococcus*. In the MBR treating waste effluents with low solids the family Nitrosomonadaceae predominated but the genus *Nitrosococcus* was present a considerable lower abundances. We investigated models of environmental interpretation of nitrifying variables using of distance-based linear models (DISTLM).

EVIDENCES FOR A PHYSIOLOGICAL LINK BETWEEN HYDROCARBONS AND LIPIDS DEGRADATION IN THE MARINE ENVIRONMENT

C. Barnier[1], R. LAMI[2], P. LEBARON[2], L. INTERTAGLIA[3], F. HAKIL[1], P. SIVADON[1], L. URIOS[1], R. GRIMAUD[1]
[1]IPREM UMR CNRS 5254, EEM, Pau Cedex, France
[2]UPMC- Observatoire Océanologique de Banyuls-sur-Mer,
Laboratoire de Biodiversité et Biotechnologies Microbiennes, Banyuls-sur-Mer, France
[3]UPMC- Observatoire Océanologique de Banyuls-sur-Mer, CNRS- UMS 2348, Banyuls-sur-Mer, France

Backgrounds

Marine hydrocarbonoclastic bacteria belonging to the genera, among others, *Alcanivorax*, *Marinobacter*, *Cycloclasticus* and *Thalassolituus* have been recognized as main actors of the biodegradation of hydrocarbons in marine environment. Assimilation of these nearly water insoluble substrates involves the formation of a biofilm at the oil-water interface, which improves mass-transfer of hydrocarbons to the cells. Many of these strains have been described as having a very narrow substrate range mostly restricted to hydrocarbons. However, *Marinobacter hydrocarbonoclasticus* SP17 is able to assimilate a wide range of hydrophobic organic compounds (HOC) including alkanes and various lipids through the formation of an oleolytic biofilm at the HOC-water interface.

Objectives

Evaluate the diversity of oleolytic bacteria and their substrate range to determine if there is a link between hydrocarbon and lipid degradation.

Methods

A collection of more than 200 marine strains was screened for oleolytic biofilm formation on paraffin, triglycerides, fatty acids and wax esters.

Conclusions

About 25% of the tested strains were able to form a biofilm on at least one HOC, wax ester being the most utilized substrate. Most of the strains forming a biofilm on alkanes do so on triglycerides or/and wax esters suggesting that marine hydrocarbonoclastic bacteria are not restricted to the degradation of hydrocarbons. This also hints to the existence of a physiological link between the assimilation of hydrocarbons and lipids.

ONE YEAR SURVEY OF SOFT ROT ENTEROBACTERIA ALONG THE RIVER DURANCE ANTHROPOGENIC GRADIENT

M.A. barny[1], L. Blottiere[1], A. Lecomte[1], E. Rochelle Newall[1], F. Van Gijsegem[1], O. Berge[2]
[1]UPMC, IEES, PARIS, France
[2]INRA, Plant pathology, Monfavet, France

Backgrounds

Soft rot enterobacteria (SRE: Pectobacterium spp. and Dickeya spp.) infect a large number of plant species worldwide, including economically important plants. While the diversity of SRE observed on plant is fairly well described, the presence and diversity of SRE outside the plant context is not known in detail.

Objectives

To anticipate disease emergence from environmental reservoirs and to propose regulatory guidelines and good practices for crop health management it is important to gain knowledge of SRE ecology outside of agronomic context.

Methods

SRE sampling was performed all along the Durance river catchment in winter, spring, summer and autumn 2016. This river catchment is interesting because it linked alpine stream above the Serre-Ponçon lac to the Mediterranean agricultural basin of Avignon along an anthropogenic gradient. SRE sampling was coupled to detail analysis of water physicochemical characteristics. Diversity of isolated SRE was further characterized through sequencing of one house-keeping gene.

Conclusions

SRE repartition along the river stream was uneven, subjected to seasonal variation, land use and water physicochemical characteristics. This study further revealed a large previously unrecognized SRE diversity and pointed differential ecological behaviours of Pectobacterium spp. and Dickeya spp. The potential virulence of sampled SRE on various crops is currently under investigation.

ISOLATION AND CHARACTERIZATION OF B-TRIKETONE HERBICIDES DEGRADING BACTERIA ISOLATED FROM AN ARABLE SOIL

L. Barthelmebs[1], S. Romdhane[1], M. Devers-lamrani[2], C. Bertrand[3], F. Martin-laurent[2]
[1]University UPVD, BAE, Perpignan CEDEX, France
[2]INRA, Agroecology, Dijon, France
[3]University UPVD, CNRS, Perpignan CEDEX, France

Backgrounds

Microbial degradation is considered as the major process involved in the elimination of pesticides in the environment.

Objectives

In this context, our work aims to study the role of soil bacteria in the degradation of synthetic and natural β-triketone herbicides and to elucidate genetic mechanisms involved in their biotransformations.

Methods

Therefore, a microcosm approach was performed using an agricultural soil, in order to isolate bacterial strains capable of degrading β-triketone herbicides.

Conclusions

Two bacterial strains were isolated : *Bradyrhizobium* sp. SR1 able to degrade sulcotrione and mesotrione, two synthetic herbicides, and *Methylophilus* sp. LS1 degrading leptospermone, a natural one. The metabolism of these compounds was studied showing that their biodegradations resulted in the formation of several metabolites previously described in the literature, such as 2-chloro-4-mesylbenzoic acid, 4-methylsulfonyl-2-nitrobenzoic acid and 2-amino-4 methylsulfonylbenzoic acid from the two synthetic compounds, but also of two new metabolites identified as hydroxy-sulcotrione from sulcotrione and hydroxy-leptospermone from leptospermone.
In order to characterize degradation genes from *Bradyrhizobium* sp. SR1, a library of 14 000 mutants was constructed allowing the selection of two Sul^- mutants. The interrupted genes didn't code for sulcotrione degradation enzymes, but for transcriptional regulatory genes potentially involved in the regulation of stress. In the case of mesotrione, a nonspecific system involving a nitroreductase was identified. For leptospermone, the natural herbicide, degradation by *Methylophilus* sp. LS1 was most likely supported by a nonspecific system.
Our study reveals the existence of several degradation strategies used by soil bacteria for β-triketone herbicide degradation.

Environmental Microbiology/Microbial Ecology /Microbial Communities

MOLECULAR AND PHENOTYPIC CHARACTERIZATION OF PSEUDOMONAS SYRINGAE PV. ACTINIDIAE (PSA) FROM CHILEAN INFECTED KIWIFRUIT ORCHARDS

O. Flores[1], M. Nuñez[1], X. Besoain[2], C. Yañez[1], R. Bastías[1]
[1]Pontificia Universidad Católica de Valparaíso, Instituto de Biología, Valparaíso, Chile
[2]Pontificia Universidad Católica de Valparaíso, Escuela de Agronomía, Valparaíso, Chile

Backgrounds

In the last years the Chilean kiwifruit production has been affected by the phytopathogen *Pseudonomas syringae* pv. *actinidiae* (Psa). However few studies have been conducted about their phenotypic and genetic variability.

Objectives

The objetive of this work was to perform a molecular and phenotypic characterization of 18 Psa isolates obtained from infected Chilean kiwifruit orchards in 2012 and 2016.

Methods

The identity of Psa isolates was confirmed by conventional and duplex PCR with primers specific for Psa. Genetic variability of isolates was analyzed by Box/Eric-PCR fingerprinting and Multi Locus Sequence Typing (MLST) of four housekeeping genes sequences (*gyrB, rpoD, gltA* and *gapA*). For the phenotypic characterization, growth kinetic parameters, biofilm formation, phytohormone (AIA) production, and streptomycin/copper resistance were analyzed. The biochemical activity of isolates was determined by BIOLOG GEN III system.

Conclusions

MLST dendrogram analysis suggest that the Psa Chilean isolates are genetically homogenous and belong to biovar 3. Similar results were obtained by Box/Eric-PCR fingerprinting, which only one isolate presenting a slightly different pattern. However, we found differences in 21 of 94 biochemical assays. According to our results, all Chilean Psa isolates are able to produce the auxin IAA and present biofilm formation at 4°C. No isolate resistant to streptomycin or copper were detected. This work confirms the high genetic homogeneity between Chilean Psa isolates obtained from different geographic origin, which is in contrast with the phenotypic variation found in the biochemical activity. The biochemical characterization could be a good alternative to distinguish the different Psa isolates present in Chile.

INVESTIGATION OF VIABLE VIBRIO SPP. DYNAMIC IN NW MEDITERRANEAN COASTAL AREA USING A ONE STEP MULTIPLE OLIGONUCLEOTIDE FLUORESCENT PROBES AND SOLID PHASE CYTOMETER

J. Baudart[1], L. Girard[2], S. Peuchet[2], P. Servais[3], A. Henry[4], N. Charni-Ben-Tabassi[4]
[1]Sorbonne Universités- Université et Marie Curie Univ. Paris 06- CNRS, Observatoire Océanologique-Laboratoire de Biodiversité et Biotechnologies Microbiennes LBBM, Banyuls sur mer, France
[2]Sorbonne Universités- Université Pierre et Marie Curie- Univ. Paris 06- CNRS, Observatoire Océanologique-Laboratoire de Biodiversité et Biotechnologies Microbiennes LBBM, Banyuls sur mer, France
[3]Université Libre de Bruxelles, Ecologie des Systèmes Aquatiques, Bruxels, Belgium
[4]Veolia Environnement, Centre d'Analyses Environnementales, Saint Maurice, France

Backgrounds

Vibrios are physiological sensitive to changing environmental conditions and they are able to quickly adapt to these changes making them highly dynamic at short-term and seasonal scales.

Objectives

We investigated the weekly dynamic of viable vibrios cells in seawater over a 10-month period at two northwestern Mediterranean coastal sites through a high resolutive FISH-based method.

Methods

The Direct Viable Count assay was combined to a Fluorescent In Situ Hybridization approach using a one step-multiple oligonucleotide probes and the Solid Phase Cytometry (DVC-FISH-SPC) to monitor the total viable vibrios, in comparison to culturable counts. A multivariate analysis was used to identify environmental parameters explaining the abundances of culturable and total viable cells.

Conclusions

The specificity of the FISH approach was obtained by the combination of three different probes targeting specific sequences located at different positions on 16S rRNA of Vibrio and Aliivibrio members. Counts of total viable and culturable vibrios showed the same temporal pattern during the warmer season, but the ratios between both counts were inverted during the colder seasons (<16°C). We make the evidence that an important part of the viable vibrios are non-culturable during the colder seasons and that the seawater surface temperature identified as the main factor explaining the variations of culturable populations, was not an explanative variable for the total viable vibrios. The results highlighted the importance in the choice of the methodological approach to investigate the dynamic of viable vibrios in coastal water

Environmental Microbiology/Microbial Ecology /Microbial Communities

THE IMPACT OF INCREASED SANDSTORM ACTIVITIES ON THE RED SEA MICROBIOTA

H. Behzad[1], H. Ohyanagi[1], K. Mineta[1], Y. Saito[1], T. Gojobori[1]
[1]King Abdullah University of Science & Technology-KAUST,
Computational Bioscience Research Center CBRC / Biological and Environmental Sciences and Engineering BESE, Thuwal Jeddah, Saudi Arabia

Backgrounds

Large areas of lands around the world are faced with increased desertification and sandstorm activities, in part due to global warming effects. From the perspective of global environmental assessment, it is important to examine whether sandstorms can have significant impacts on microbial community structures in marine environments. We, thus, examined the effect of sandstorms on microbial communities in the Red Sea, since the Red Sea is a relatively isolated seawater region with no river inflow, minimal precipitation, and in close proximity to large deserts.

Objectives

To study the impact of increased dust activities on the Red Sea microbiota.

Methods

Metagenomics was used to investigate potential changes in microbial diversity in the Red Sea in response to two major sandstorms that severely impacted the Red Sea region in Sep 7-9 2015 and July 24-25 2016. DNA was extracted from the Red Sea water samples at different time points before and after sandstorms, 16S rRNA gene amplicon libraries were prepared and sequenced using Illumina MiSeq platform.

Conclusions

Bioinformatics analysis by QIIME revealed a consistent increase in the abundance of reads corresponding to Prochlorococcus, Archaea, and Bacteroidetes only in samples collected immediately following sandstorms. In addition, a number of Bacteroidetes phyla belonging to the order Flavobacteriales were present only in sandstorm-associated samples. Our results suggest that increased dust activities can change the relative abundance and composition of microbial communities in the Red Sea. We concluded that increased desertification and sandstorm activities due to global warming could lead to significant changes in marine environments.

BIOPESTICIDE ACTIVITY OF BACILLUS ATROPHAEUS STRAIN L193 AGAINST RHOPALOSIPHUM PADI

M. Rodríguez[1], A. Marín[1], M. Torres[1], I. Sampedro[1], L. Fernández[2], M. Campos[2], V. Béjar[1]
[1]Universidad de Granada, Microbiología, Granada, Spain
[2]Estación Experimental del Zaidín-CSIC, Protección Ambiental, Granada, Spain

Backgrounds

Rhopalosiphum padi is an aphid species that affects several cereal crops producing severe economic losses. Many depredator insects are used for its control in greenhouse crops; however the efficacy of these treatments in open fields is very low. Interestingly, within the genus *Bacillus* there are different species with insecticidal activity that could be used for the bio-control of *R. padi* due to the production of toxins, enzymes and surfactants.

Objectives

To determine the insecticidal activity of the *Bacillus atrophaeus* strain L193 against *R. padi*, and to characterize the compounds responsible for it.

Methods

The strain L193 was selected after a screening conducted with halotolerant strains in search of producers of surfactant and hydrolytic enzymes in order to find insecticidal activity. The biopesticide activity was tested using the purified surfactant, the culture supernatant and the whole culture by applying it on barley seedlings infested with *R. padi*. The type of surfactants was determined by mass spectrometry and by PCR using specific primers.

Conclusions

Strain L193 produces proteases, lipases, chitinases and glucanases. In addition, it produces 0.8 g/L of surfactants in TSB medium, which is a highly efficient compared to surfactants produced by other strains. The produced surfactants are surfactins and fengycins. The purified surfactants, the supernatant and also the whole culture produced a significantly higher mortality of *R. padi* than the control with a confidence level higher than 0.95. This strain could, therefore, be used for the biological control of aphids in open field crops.

PLANT-GROWTH PROMOTING PROPERTIES OF BACILLUS VELEZENSIS XT1, AN HALOTOLERANT BACTERIUM ISOLATED FROM A SALINE SOIL LOCATED IN SOUTH OF SPAIN

M. Torres[1], I. Llamas[1], E. Quesada[1], V. Béjar[1]
[1]University of Granada, Microbiology, GRANADA, Spain

Backgrounds

The plant-growth promoting rhizobacteria (PGPR) are microorganisms which live in soil near roots. Some of them control the pathogens of plants and moreover act as fertilizers. *Bacillus velezensis* XT1 is an halotolerant bacteria with PGPR properties.

Objectives

The aim of this work is to study the effect of *B. velezensis* strain XT1 in the growth of various horticultural species and the biochemical characteristics related to this activity.

Methods

The PGPR characteristics analyzed were nitrogen fixation, phosphate solubilization, and production of hydrolytic enzymes and siderophores. *In vivo* studies were performed in outdoor and in greenhouse crops. The statistical tests were done with *Statgraphics Centurion XVII* and *R* software.

Conclusions

The strain XT1 significantly increased the total weight (g/plant) and height (cm/plant) of tomato, pepper, squash and cucumber, when they were cultivated outdoors in pots during 50 days. The average values of the increase of these parameters were respectively (%): tomato, 52 and 31; pepper, 63 and 22; squash, 129 and 10; and cucumber, 101 and 8. Moreover, the number of fruits and flowers increased significantly in all the experiments. In addition, the crops of tomatoes in greenhouse, which were grown during 75 days, increased significantly the biomass area and the height (41 and 22% respectively). The metabolic activities of XT1 related to its PGPR properties were: the ability to fix nitrogen, solubilize organic and inorganic phosphate, produce siderophores, proteases, glucanases and ACC deaminase. The main conclusion is that the strain XT1 is a strong biostimulant of plant growth.

DOES SHEWANELLA LOHICA BIOREDUCE IRON OXIDES IN ANAEROBIC SEA SEDIMENTS?

R. Benaiges[1], J. Palau[2], E. Torres[2], J. Cama[2], J. Urmeneta[1,3], B. Dold[4,5]
[1]Universitat de Barcelona, Department of Genetics- Microbiology and Statistics, Barcelona, Spain
[2]IDAEA- CSIC, Institute of Environmental Assessment and Water Research, Barcelona, Spain
[3]Universitat de Barcelona, Biodiversity Research Institute IRBio, Barcelona, Spain
[4]Luleå University of Technology,
Department of Civil- Environmental and Natural Resources Engineering, Luleå, Sweden
[5]Sustainable Mining Research & Consultancy, EIRL, San Pedro de la Paz, Chile

Backgrounds

Shewanella is a well known genus of marine bacteria capable to perform the dissimilatory reduction of heavy metals. Previous studies have shown that *Shewanella loihica* is able to reduce not only soluble iron compounds but also magnetite in mineral form through polysaccharide attachment. However, reduction of natural iron oxides in marine conditions has not been studied yet.

Objectives

The main goal is the quantitative understanding of the capacity of *Shewanella loihica* to bioreduce natural iron oxides (e.g., magnetite) contained in marine sediments under anoxic conditions

Methods

In this study, natural iron oxides from different ore deposits were characterized and cultured along with *Shewanella loihica* strain PV-4 in microcosm batch experiments with a specific media that consists of synthetic sea water and lactate.

Conclusions

The results obtained showed an increase in dissolved iron concentration (up to 1000-50.000 µg/L) which suggests a significant *Shewanella*-mediated Fe reduction in all the studied iron oxides, in contrast to abiotic experiments, proving the existence of iron oxide bioreduction in anoxic marine sediments. The differences in dissolved iron concentrations from the microcosms prepared with different iron oxides are in part associated to their different specific surface area. Due to low iron bioavailability in the ocean, the bioreduction of mine oxide tailing disposed on the anoxic seafloor could have a major ecological impact. Moreover, this study may have implications for the assessment of the environmental impact of heavy metals contaminated sites as well as for potential biotechnology applications.

Environmental Microbiology/Microbial Ecology /Microbial Communities

HARNESSING LONG READ SMRT SEQUENCING TECHNOLOGY FOR NATURAL PRODUCT GENE DISCOVERY IN POLAR DESERT SOILS

N. Benaud[1], E. Zhang[1], J.A. Kalaitzis[1], B.C. Ferrari[1]
[1]University of New South Wales, School of Biotechnology and Biomolecular Sciences, Sydney, Australia

Backgrounds

The majority of clinically useful antibiotics are derived from microbial natural products, typically produced through non-ribosomal peptide synthetase (NRPS) and polyketide synthase (PKS) pathways. Prolific biosynthetic Phyla include environmentally ubiquitous Actinobacteria, Proteobacteria, Firmicutes and Cyanobacteria.

Objectives

To combat the growing global antibiotic resistance crisis, novel chemical structures are urgently required. Extreme environments are expected to harbour unique microorganisms whose metabolic adaptations may also include novel natural products; however, this remains under-investigated, particularly as the majority of microorganisms defy cultivation. Next-generation sequencing offers the ability to screen environmental samples for NRPS and PKS genes.

Methods

Here, we have performed the first extensive survey of natural product-encoding genes in a range of Antarctic and High Arctic polar soils, where environmental conditions are some of the most extreme on earth, and where microorganisms dominate. Third generation PacBio ® SMRT sequencing offers longer reads than next-generation methods, as well as improved performance for GC-rich sequences. We will discuss the use of this platform to identify NRPS and Type I PKS gene sequence diversity from > 200 soil samples, spanning 12 polar sites.

Conclusions

Our findings reveal NRPS are more widely distributed in polar soil than Type 1 PKS genes. Additionally, recovered NRPS and PKS reads exhibited low amino acid sequence identity (%) with known biosynthesis proteins, indicating a high potential for novel compound production. We believe this workflow is highly relevant and applicable to a range of environmental samples, with the long reads provided by the SMRT platform delivering enhanced taxonomic resolution over second generation approaches.

Environmental Microbiology/Microbial Ecology /Microbial Communities

VISUALIZATION OF MICROMONOSPORA IN NITROGEN FIXING NODULES

P. Benito[1], *M.E. Trujillo*[1]
[1]*University of Salamanca, Microbiology and Genetic, Salamanca, Spain*

Backgrounds

Nodular tissues can be considered an excellent habitat for bacteria, not only for nitrogen fixing rhizobia; the number of reports related to the presence of non-rhizobial microorganisms associated with nitrogen fixing nodules has increased in the past ten years. *Micromonospora*, a filamentous actinobacterium has also been reported as a normal inhabitant of actinochizal and legume nodules, but hitherto, the specific localization of the bacterium within the nodule structure or in relation to the nitrogen fixing bacteria is unknown. This information is key to understand their role in this plant-microbe interaction.

Objectives

The aim of this work was to locate *Micromonospora* in nodules of *Lupinus* plants coinoculated with *Bradyrhizobium* and to determine its occupancy within the different zones of a determinate nitrogen fixing nodule and the nitrogen fixing bacterium.

Methods

Lupinus albus plants were inoculated with *gfp*-tagged *Micromonospora lupini* (ML01) and the wild-type strain, *Bradyrhizobium* (CAR 08). After 40 days, mature nodules were examined using confocal laser scanning microscopy (CLSM), and transmission electron microscopy (TEM) coupled with immunogold labeling with antibodies raised against *gfp.*

Conclusions

Confocal microscopy showed that fresh effective lupine nodules contained *Micromonospora* expressing *gfp* and that it was located in the internal cortex and infected zones together with *Bradyrhizobium*. Moreover, immunogold labeling specifically localized *Micromonospora* within the infected plant cells. Taken together, our results demonstrate that the combined use of these two techniques provided a very strong evidence for infection of *Lupinus* by *Micromonospora* presenting clear evidence of the presence of this bacterium in nitrogen fixing nodules.

Environmental Microbiology/Microbial Ecology /Microbial Communities

EFFECT OF DIET AND ANTIBIOTIC TREATMENT ON THE HINDGUT MICROBIOTA OF RETICULITERMES GRASSEI, A LOWER TERMITE

M. Berlanga[1], *G. Ricardo*[2]
[1]*University of Barcelona, Biology- Health and Environment, Barcelona, Spain*
[2]*Academia europaea, Barcelona Knowledge Hub, Barcelona, Spain*

Backgrounds

Insects form a myriad of associations with microorganisms, ranging from pathogenic to intracellular symbiotic relationships. Lower termites are key models to understand insect-microbe symbiosis because of the diversity, complexity and functionality of their unique tripartite symbiosis (host, bacteria, and protists).

Objectives

Ecological interactions among members of the microbial communities may have differing net impacts on host fitness according to the actual environmental circumstances. We analyzed two aspects of the environment, nutrition and antibiotic, to show the shaping of the responses of the holobiont system.

Methods

We compared gut microbiota of *Reticulitermes grassei* lower termite using NGS to determine 16S rRNA microbial communities in control individuals (wood diet and no antibiotic treatment) versus individuals with a diet of cellulose and individuals with a diet of cellulose and antibiotic treatment (ciprofloxacin). All individuals were from the same termite colony.

Conclusions

Our results revealed that the hindgut prokaryotic communities in *Reticulitermes* (in all environmental conditions) are dominated by members of four Bacteria phyla: Bacteroidetes, Spirochaeta, Firmicutes, Proteobacteria, and Actinobacteria. Community similarity based on phylogenetic relatedness by unweighted UniFrac analyses indicated that the composition of the bacterial community in *Reticuliermes* with a wood or cellulose diet was no significantly different ($P \geq 0.05$), but it was significantly different in termites treated with ciprofloxacin versus termites without the treatment (wood or cellulose diet).

CRUDE OIL BIODEGRADATION BY MICROCOCCUS LUTEUS ATCC 4698

S. Bilen Ozyurek[1], *N.H. Avcıoglu*[1]
[1]*Hacettepe University Faculty Of Science, Biology/biotechnology, Ankara, Turkey*

Backgrounds

The leakage from oil and gas pipelines and oil wells, wrong methods for removing oil wastes, various human activities and accidental oil spills are among the main reasons for the pollution of environment by crude oil. Approximately 25% of oil contaminated areas are cleaned with natural remediation methods. In this context, various microorganisms play an important role in the environmental removal of oil pollutants.

Objectives

Determination of crude oil biodegradation with microbial growth intensities, gravimetric analysis and Gas Chromatography (GC) analysis by oil field isolated *Micrococcus luteus* ATCC 4698.

Methods

The microorganism was incubated under appropriate conditions in Bushnell Haas Broth medium containing oil as the sole carbon and energy source. After the incubation period, bacterial growth by utilizing crude oil was detected via measuring the turbidity of microbial suspension with UV-visible spectrophotometer at 600 nm against a blank. For the estimation of crude oil biodegradation by gravimetric analysis, residual crude oil was extracted with dichloromethane (DCM) (1:2). The crude oil biodegradation was calculated from the difference between initial and final concentrations of crude oil. Biodegradation ratios of hydrocarbons constituting the content of crude oil were determined by GC analysis.

Conclusions

As a result, the crude oil biodegradation efficiency of *Micrococcus luteus* ATCC 4698 was detected. In this regard, it was determined that this strain may be an alternative to advanced bioremediation studies.

INVESTIGATION OF THE DIFFERENT PHYSIOLOGICAL CONDITIONS ON PETROLEUM BIODEGRADATION BY RHODOTORULA MUCILAGINOSA

S. Bilen Ozyurek[1], N.H. Avcıoglu[1], I. Seyis Bilkay[1]
[1]Hacettepe University Faculty Of Science, Biology/biotechnology, Ankara, Turkey

Backgrounds

Petroleum production, drilling operations and improperly abandoned oil wells are the most important sources of oil contamination in soil, surface and ground waters. Petroleum leads to economic losses due to organic pollution in groundwater as well as decreasing of agricultural productivity on soil. In addition to the physical and chemical methods used to remove petroleum pollution, biological remediation is one of the most preferred methods.

Objectives

Determination of optimum physiological conditions for effective petroleum biodegradation by *Rhodotorula mucilaginosa.*

Methods

It was investigated that the effect of different pH, temperature, petroleum concentration (%) and incubation conditions on petroleum biodegradation by *Rhodotorula mucilaginosa.* To determine the petroleum biodegradation rates of bacteria, gravimetric analyses were carried out. The petroleum biodegradation rates were detected from the difference between initial and final concentrations of petroleum.

Conclusions

Petroleum biodegradation varies according to physiological conditions. In this manner, optimum physiological conditions for petroleum biodegradation are required to be determined for advanced bioremediation process.

Environmental Microbiology/Microbial Ecology /Microbial Communities

RESPONSE OF ACTIVE BACTERIA TO ORGANIC AMENDMENT PRACTICES AND CONSEQUENCES ON VOLATILE ORGANIC COMPOUND (VOC) EMISSIONS FROM AGRICULTURAL SOILS

C. Monard[1], K. Potard[1], N. Le Bris[1], J.P. Caudal[1], J.L. Le Garrec[2], F. Binet[1]
[1]CNRS - University of Rennes 1, ECOBIO, Rennes, France
[2]CNRS-Université de Rennes 1, Institut de Physique de Rennes, Rennes, France

Backgrounds

Microbial degradation of soil organic matter (SOM) generates volatile organic compounds (VOCs) which may constitute a significant loss of soil C and take part in greenhouse gases production in the atmosphere. Since agricultural land uses may control the SOM decomposition by changing microbial communities and SOM sources, there is a need to assess the consequences of perennial organic waste inputs onto the soil on VOC emissions.

Objectives

Based on an experimental site dedicated to study the agronomic and environmental effects of livestock effluent inputs (EFELE, France), our study aimed to determine the response of soil living bacteria to organic amendments and the following VOC emissions by soil.

Methods

Just before and up to two months after the amendments, we simultaneously sampled soil and gases on plots receiving Pig Slurry (PS) or Methanised Pig Slurry (MPS) and Control (C) plots. The living bacterial diversity was analysed by Illumina sequencing and linked to the VOC emissions measured with a PTR-MS.

Conclusions

In all soils, the living bacterial communities were dominated by *Proteobacteria* and *Acidobacteria* and varied temporally. A 2-ways ANOVA of the VOC dataset indicated that seasonal pattern and organic manure inputs significantly changed the VOC emissions, manure effects being timely dependent. These spectra were dominated by methanol and acetonitrile, methanol emissions being stimulated after PS inputs leading to an increase in C-VOC fluxes from soil to the atmosphere. We showed that i) VOCs emitted by organic amended soils were not negligible, ii) soil organic amendments induced bacterial changes and iii) MPS inputs reduced VOC emissions by soils compared to PS ones which is of great interest to mitigate GHG emissions in agriculture.

Environmental Microbiology/Microbial Ecology /Microbial Communities

NOVEL MICELLE PCR-BASED METHOD FOR ACCURATE, SENSITIVE AND QUANTITATIVE MICROBIOTA PROFILING

S. Boers[1], J. Hays[1], R. Jansen[2]
[1]Erasmus University Medical Centre, Department of Medical Microbiology and Infectious diseases, Rotterdam, The Netherlands
[2]Regional Laboratory of Public Health, Department of Molecular Biology, Haarlem, The Netherlands

Backgrounds

16S rRNA gene profiling has revolutionized the field of microbial ecology. Unfortunately however, microbiota profiling methods are semi-quantitative methods, where the microbiota results are presented as proportional abundances rather than absolute abundances. This restriction lowers the reproducibility of microbiota results and complicates cross-study comparability. Additionally, the validity of microbiota results is threatened by the presence of contaminating bacterial DNA derived from the laboratory environment and the reagents/consumables used.

Objectives

Development of a novel approach employing micelle PCR (micPCR) in combination with an internal calibrator (IC) that allows for standardization of microbiota profiles via their absolute abundances and subtraction of contaminating bacterial DNA.

Methods

MicPCR is a single-molecule clonal amplification method in which template DNA molecules are separated into a large number of physically distinct reaction compartments using a water in oil emulsion. This compartmentalization allows accurate quantification of target sequences due to a lower susceptibility to variations in PCR amplicon efficiencies and amplification biases. The addition of an IC allows to express the resulting operational taxonomic units (OTUs) as a measure of 16S rRNA gene copies. Further, the quantification of contaminating bacterial DNA via the use of negative extraction controls allows the subtraction of contaminant bacterial DNA from actual samples.

Conclusions

The micPCR/NGS approach generates accurate quantitative microbiota profiles that are free of contaminating bacterial DNA from environmental sources. The general adoption of this approach will greatly improve the standardization of microbiota profiling results between individual experiments, laboratories and scientific publications.

IN SILICO DETECTION OF HYDROLASES IN THE METAGENOME OF THE COLOMBIAN ANDEAN FOREST SOIL AND THEIR INDUSTRIAL IMPORTANCE

I. Bolaños[1], P. Velez[1], P. Moreno[2]
[1]Universidad del Cauca, Biologia, Popayan, Colombia
[2]Universidad del Valle, EISC, Cali, Colombia

Backgrounds

Colombia has an immeasurable environmental richness due to the variety of the environmental conditions given by a complex topography. For example, the Colombian Andean forest is home of incalculable species, such as the extremophile microorganisms from which the extremophilic enzymes (extremozymes) as esterases, Laccases, and hydrolases are obtained. Because their unique features, the hydrolases represent one of the most important enzymes of the pharmaceutical industry. The Colombian metagenome soil high Andean forest (BAA), located at the national natural park “Los Nevados” shows extreme environmental conditions in respect of the height, 3.590 masl, low temperatures, low oxygen levels and high radiation levels which makes it part of a very interesting reservoir of extremozymes. detection of hydrolases in the metagenome of the BAA was made by using the reads kept in the servers of the Colombian Center for Genomics and Bioinformatics of Extreme Environments (GeBiX).

Objectives

For that reason, the current investigation was focused on the detection of hydrolases deriving of the extremophile microorganisms from the BAA metagenome.

Methods

The detection of hydrolases in the metagenome of the BAA was made by using the reads kept in the servers of the Colombian Center for Genomics and Bioinformatics of Extreme Environments (GeBiX). The functional annotation was carried out through a BlastX analysis againts not redundant database of proteins of the NCBI and Pfam web sites.

Conclusions

This is one of the two main investigations of the high Andean forest metagenome allows to find that about 20% of the detected enzymes corresponds to the so-called hydrolase type. This finding, this is a base line of great interest for future biotechnology development from creation and evaluation of BAA metagenome libraries, with potential impact for studying the Colombian soils.

EXPLORING THE RHIZOSPHERIC MICROBIOME OF VITIS VINIFERA CV. PINOT NOIR USING METAGENOMIC AND METAPROTEOMIC APPROACHES: PHYLOGENETIC AND FUNCTIONAL CHARACTERIZATION

E. Bona[1], P. Cesaro[2], G. Novello[2], L. Boatti[3], V. Magnelli[2], N. Massa[2], M. Manfredi[4], G. Lingua[1], F. Mignone[2], E. Marengo[2], G. Berta[2], E. Gamalero[2]
[1]Università del Piemonte Orientale, Dipartimento di Scienze e Innovazione Tecnologica, Vercelli, Italy
[2]Università del Piemonte Orientale, Dipartimento di Scienze e Innovazione Tecnologica, Alessandria, Italy
[3]SmartSeq s.r.l., spin-off of the Università del Piemonte Orientale, Alessandria, Italy
[4]Isalit srl, spin-off of the Università del Piemonte Orientale, Novara, Italy

Backgrounds

Vitis vinifera is a Mediterranean crop with relevant impact on the Italian landscape, culture and economy. The rhizosphere is a hotspot where the release of root exudates stimulates bacterial density and diversity. Thanks to culture-independent methods (metagenomics) the complexity of the soil/rhizosphere microbial community has been explored. However, metagenomics doesn't provide information regarding the activity and the molecular interactions between the bacterial communities and roots. Proteins are the drivers of cellular activities encoded by the genome. Therefore, proteomic tools could be useful to gain information about microbial community activity and to better understand the real interactions pathways between roots and soil.

Objectives

Actinobacteria were the dominant class in all the soil samples, followed by Proteobacteria, Gemmatimonadetes and Bacteroidetes. While Actinobacteria and Proteobacteria are well known as dominant in soil, for the first time members belonging to Gemmatimonadetes have been observed in vineyard soils. Bacteria belonging to Streptomyces, Bacillus and Pseudomonas genera were the most active. The identified genera were mainly involved in phosphorus and nitrogen soil metabolism.

Methods

A comparison between the microbial community structure in rhizospheric and bulk soil using metagenomics (pyrosequencing of 16S rDNA) and proteomics (MS/MS analysis of the total protein occurring in soil samples) was performed.

Conclusions

Our results underlined the difference between the metagenomic and metaproteomic approaches and the potentiality of proteomics in describing the environmental bacterial communities and their activity.

TALES FROM THE UNDERGROUND: SPATIAL VARIATIONS IN THE ABUNDANCE OF ANTIBIOTIC RESISTANCE GENES AND PUTATIVE PATHOGENS IN SEWER BIOFILMS

C. Borrego[1], O. Auguet[2], M. Pijuan[2], X. Triadó-Margarit[3], S. Varela Della Giustina[4], S. Rodríguez-Mozaz[4], O. Gutiérrez[2]
[1]Catalan Institute for Water Research, Quality and Microbial Diversity, Girona, Spain
[2]Catalan Institute for Water Research, Technology and Evaluation, Girona, Spain
[3]Centre d'Estudis Avançats de Blanes CEAB-CSIC, Integrative Freshwater Ecology Group, Blanes, Spain
[4]Catalan Institute for Water Research, Quality, Girona, Spain

Backgrounds

A large part of antibiotics consumed by humans are not metabolised but excreted with urine and faeces and transported to wastewater treatment plants via sewer systems. Transport of wastewater along sewers promotes the development of biofilms, which are characterised by a high cell density and a heterogeneous composition. Sewer biofilms provide an optimal environment for the accumulation of antibiotic resistance genes (ARGs).

Objectives

Our main goal was to characterise the changes in both the abundance of ARGs and the composition of bacterial communities, including potential pathogens, in different sewer compartments (flowing wastewater and biofilms) along a sewer pipe (inlet/outlet).

Methods

The concentration of antibiotics and ARGs were analysed by UPLC-MS and qPCR, respectively, in biofilm and wastewater samples at the inlet and the outlet sections of a full-scale sewer. Composition of bacterial communities was assessed by high-throughput sequencing. Occurrence of potential pathogens was estimated by comparing representative OTU sequences against an in-house database of bacterial pathogens.

Conclusions

The abundance of antibiotic residues and ARGs was uncoupled in both sewer compartments (wastewater/biofilms). The relative concentration of *qnrS*, *sul1*, *sul2*, bla_{TEM} and *intI1* was significantly higher in biofilms at the inlet section of the pipe, whereas no spatial differences were observed neither for *ermB* in biofilms nor for any gene in wastewater. This spatial heterogeneity was congruent with differences in the composition of biofilm communities between inlet and outlet sections of the sewer, especially regarding the relative abundance of several well-known human pathogens that were significantly higher in inlet biofilms.

INCREASED NITROGEN DEPOSITION ON TREE LEAVES PHYLLOSPHERE AFFECTS FUNGAL COMMUNITY DIVERSITY BUT NOT BACTERIAL COMMUNITY

L. Borruso[1], A. Bani[1], M. Ventura[1], P. Panzacchi[1], L. Antonelli[2], G. Tonon[1], L. Brusetti[1]
[1]Free University of Bolzano, faculty of science and technology, Bolzano, Italy
[2]AIT Austrian Institute of Technology, Department of Health & Environment, Vienna, Austria

Backgrounds

In the last decades, atmospheric nitrogen deposition (N) onto forests has constantly increased and is expected to double by 2050. The increased N flux is likely to affect forest ecosystems, most of which are considered particularly sensible to increased N availability. Several studies have already investigated the effects of soil N fertilization on forests, evidencing negative effects on plant biodiversity and the associated biota. However, there is a lack of knowledge regarding the effects of N depositions applied directly on the tree canopies on the associated microbiota.

Objectives

This study aims to investigate the influence of increased N deposition on the microbial communities associated with leaves phyllosphere, in a temperate forest dominated by sessile oak (*Quercus petraea* Liebl.).

Methods

The study area is located in Monticolo natural reserve (South Tyrol, Italy) where a long-term ecosystem experiment has been established simulating increased N deposition. The experimental design consisted in three control plots and three plots treated with canopy N fertilization. A total of 20 kg N ha^{-1} y^{-1} were provided as NH_4NO_3, with five applications from May 2015 until September 2015. Fifteen days after the last fertilization, tree biological replicates were collected in each plot. Bacterial and fungal communities were investigated via Illumina Hiseq and quantitative PCR. N leaves concentration was measured via mass spectrometry.

Conclusions

Results highlight that increasing N deposition affect the fungal community diversity, even in the short term, whereas the bacterial community is not affected by the treatments.

Environmental Microbiology/Microbial Ecology /Microbial Communities

THE EFFECT OF GLOBAL WARMING ON COLD ADAPTED YEAST AND FILAMENTOUS FUNGI IN MIAGE GLACIER (ITALY)

C. Sannino[1], L. Borruso[2], S. Filippucci[1], G. Tasselli[1], P. Buzzini[1], L. Brusetti[2], B. Turchetti[1]
[1]University of Perugia,
Department of Agricultural Food and Environmental Science & Industrial Yeasts Collection DBVPG, Perugia, Italy
[2]University of Bolzano, Department of Science and Technology, Bolzano, Italy

Backgrounds

Cold environments have been considered for a long time habitat supporting only latent forms of microbial life. However, several studies have reported the presence of psychrophilic and psychrotolerant microorganisms, including fungi, in cold habitats. The first studies on cold adapted fungi were performed on Polar areas and only at the beginning of XXI century, where few authors reported the presence of eukaryotic microorganisms in Alpine glaciers.
Although Alpine glaciers represent an interesting habitat for microbial life, global warming is causing the dramatic retreat of ice-covered areas including glaciers, thus implying the potential loss of cold-adapted microbial biodiversity.

Objectives

The aim of the present study was to investigate the non-cultivable eukaryotic diversity (yeasts and filamentous fungi) of debris covering ice surface of Miage glacier (Italian side of Mont Blanc).

Methods

Replicates of debris samples from Miage glacier were collected in three consecutive years. A Next Generation Sequencing (NGS) approach (Illumina Miseq) has been used to amplify the ITS rRNA region. Sequences were used to study the non-cultivable yeast and fungal microbioma.

Conclusions

The biodiversity achieved by NGS may be an useful approach to investigate the diversity of yeast and filamentous fungi colonizing cold ecosystems of Alpine glaciers. The possible impact(s) of environmental changes on cold-adapted eukaryotic diversity is discussed

Environmental Microbiology/Microbial Ecology /Microbial Communities

ASSESSMENT OF BACTERIAL DIVERSITY IN THE MOLNAR JANOS HYPOGENIC CAVE (HUNGARY)

A. Borsodi[1], D. Anda[1], A. Szabó[1], L. Jurecska[1], G. Krett[1], J. Mádl-Szőnyi[2], K. Márialigeti[1], J. Makk[1]
[1]Eotvos Lorand University, Department of Microbiology, Budapest, Hungary
[2]Eotvos Lorand University, Department of Physical and Applied Geology, Budapest, Hungary

Backgrounds

The Molnár János cave belonging to the northern Rose Hill discharge area of Buda Thermal Karst System (Hungary) is the largest active thermal water cave in Europe. Discharges of two types of water are characteristic for this area with different temperatures, therefore, mixed corrosion proved to be the dominant cave forming process. This study looked at different ecological niches (hot, cold and mixed water, sediment and reddish-brown biofilm on the subaqueous cave wall) within the phreatic zone of the cave system.

Objectives

Our study aimed to obtain a detailed view about the taxonomic diversity of microbial communities using next generation sequencing (NGS).

Methods

The samples were collected in January 2014. For the identification of bacteria primers specific for the V3-V4 region of the 16S rRNA gene were used and amplicons were analyzed on a Roche GS Junior platform.

Conclusions

Proteobacteria, Acidobacteria, Chlorobi, Chloroflexi and Nitrospirae were abundant in all samples. Dominance of ammonia-oxidizing bacteria (*Nitrosococcus*) and nitrite-oxidizing bacteria (*Nitropspirae*) were revealed from the cold water sample. Members of the phylum Nitrospirae were also abundant in the cave sediment sample. The mixed and hot water samples were predominated by the genus *Sulfuricurvum* related sequences belonging to the class Epsilonproteobacteria, but this class was almost completely absent in other samples. It seems that sulfide, oxygen and water flow characteristics were critical for niche differentiation among major bacterial groups participating in the sulfur cycle of Molnár János cave.

This research was supported by the Hungarian Scientific Research Fund (OTKA) Grant NK101356.

CAMPANOPHYLLUM: BIO-PROFILING THE ENDANGERED MUSHROOM FROM INDIA

M. Borthakur[1], *S.R. Joshi*[1]
[1]*North Eastern Hill University, Biotechnology and Bioinformatics, Shillong, India*

Backgrounds

Meghalaya, India located in the domain of mega-biodiversity hotspots, is an abode to diverse wild mushrooms.The present study dealt with exploration of a rare gilled Agaricales listed as endangered under IUCN A4c criteria due to its habitat decline.

Objectives

The current investigation was undertaken to assess the various nutritional, toxicological, antioxidant and bio-profiling of an endangered mushroom *Campanophyllum proboscideum* from a high altitude geographical area of Northeastern India.

Methods

The species was identified based on phenotypic and molecular characterization. Nutritional profiling was performed according to AOAC 1995. Phytoconstituents were characterized and Meixner test was performed. Bioactive components were determined including DPPH radical scavenging and antimicrobial efficiency evaluated against clinical pathogens. Gas Chromatographic profiling was performed to infer the active components as a natural dietary supplement.

Conclusions

The rare species was characterized as *Campanophyllum proboscideum* based on Neighbour joining (NJ) and Bayesian phylogeny. Being negative in Meixner, it doesnot contain hallucinic alkaloid. Moisture content was high with 76.58%, 5.6% of fiber and ash respectively in dried mass with protein content of 11.50±0.18.The extract exhibited the potent radical-scavenging activity at a maximum concentration of 10 mg/ml and the scavenging effect was 50.62%with IC_{50} at 94.46.The extract showed significant ($p < 0.05$) reducing power (1.285) and flavonoid content (0.94±0.037). β-carotene and lycopenes were 0.143±0.26µg/g and 0.141±0.14 µg/g respectively. The methanolic extract showed two-fold increase in antimicrobial activity when combined with common antibiotic Chloramphenicol. Bioactivity profiling revealed the presence of aliphatic hydrocarbons, terpene, alcohol, volatile organic compound and a phenolic compound, Phenol, 2, 4-Bis (1, 1-Dimethylethyl) (2, 4-DTBP).

This study indicates the endangered *Campanophyllum proboscideum* as potent source of supplementary food rich in natural antioxidants which can also be explored as a pharmaceutical agent.

EVALUATION OF CARBON AND NITROGEN SOURCES IN THE PRODUCTION OF BIOSURFACTANT BY A BACILLUS AQUIMARIS HALOPHILIC STRAIN ISOLATED FROM OIL RESERVOIR

K.F. Carvalho[1], M.N. Argentin[2], L.F. Martins[3], N.R.S. Bossolan[4]
[1]Federal University of São Carlos - UFSCar,
Graduate Program in Evolutionary Genetics and Molecular Biology, São Carlos, Brazil
[2]São Carlos Institute of Physics- University of São Paulo,
Graduate Program in Physics - Applied/Biomolecular option, São Carlos, Brazil
[3]PETROBRAS, CENPES - Petrobras Research & Development Center, Rio de Janeiro, Brazil
[4]São Carlos Institute of Physics- University of São Paulo,
Department of Physics and Interdisciplinary Science, São Carlos, Brazil

Backgrounds

Biosurfactants (BS) have potential to be applied in petroleum industry, as the case of advanced oil recovery processes using microorganisms and/or their products (MEOR). Production of BS is influenced and regulated by several factors, including carbon (C) and nitrogen (N) sources available, as well as the C/N ratio, therefore, the control of these factors is important to improve BS production.

Objectives

To evaluate the production of BS by *Bacillus aquimaris* O9-01 isolated from an oil reservoir, using different N and C sources and varying the C/N ratio, aiming to improve its BS production.

Methods

Bacillus aquimaris O9-01 was isolated from aerobic culture in LB broth (70 g/L salinity), at 37°C, inoculated with oil (10% v/v) from an offshore Brazilian oil reservoir. Mineral medium was used to test the N and C sources, as well C/N ratios, by varying one factor and keeping the other two fixed. The N sources tested were $NaNO_3$, NH_4Cl and NH_4NO_3 at a fixed concentration of 1.0 g/L; C sources were glycerol, glucose, mannose, kerosene, petrolatum and crude oil; and the C/N ratios 2, 4, 8, 16 and 20 (w/w). Bacterial growth was measured by optical density and BS production by emulsification index E24.

Conclusions

Glycerol, NH_4Cl and C/N 2 stimulated the largest BS production, reaching 67% E24 with 102 hours of incubation. These results indicate the potential for BS production by *B.aquimaris* O9-1 in a low C/N ratio and with a low cost carbon source.

THE UNEXPLORED FUNGAL COMMUNITY OF THE SPONGE GRANTIA COMPRESSA: IDENTIFICATION AND METABOLIC FINGERPRINT

E. Bovio[1], L. Garzoli[1], D. Firsova[2], G.P. Mc Cormack[3], M. Mehiri[4], G.C. Varese[1]
[1]University of Turin, Department of Life Sciences and Systems Biology, Turin, Italy
[2]University of Ireland Galway, Marine Biodiscovery laboratory, Galway, Ireland
[3]University of Ireland Galway, Molecular Evolution & Systematics Laboratory, Galway, Ireland
[4]University Nice Sophia Antipolis, Institute of Chemistry of Nice, Nice, France

Backgrounds

Marine environment represents an untapped source of microbial diversity. Less than 0.1% of marine microorganisms are known, and only recently researchers have focused on marine fungi. These organisms are considered a valuable source of natural products, by the activation of different metabolic pathways. The One Strain-Many Compounds approach (OSMAC) is a powerful method to obtain these interesting secondary metabolites.

Objectives

The aims of this study were: i) to identify the fungal community associated with the sponge *Grantia compressa* to deepen the knowledge on sponge mycobiota; ii) to apply the OSMAC approach to highlight the metabolic potential of marine fungi in a biotechnological perspectives.

Methods

The mycobiota associated with *G. compressa* was isolated using different growth media and incubation temperatures, to increase the number of cultivable fungi. Fungal strains were identified combining morpho-physiological and molecular features. The OSMAC approach was applied to stimulate the production of metabolites of the isolated fungi, using 12 growth conditions, including a co-culture with marine bacteria. The crude extracts of fungi, grown in different conditions, were analyzed by HPLC-DAD to highlight each fungal metabolomic fingerprint.

Conclusions

The culturable mycobiota (18 taxa) of *G. compressa* is dominated by Ascomycota (72%), followed by Basidiomycota (28%). The preliminary chemical results showed that the OSMAC approach is a powerful technique to detect a high number of metabolites and to stimulate the expression of different metabolic pathways. The results of the chemical fingerprints lead to the selection of the best growth conditions for the isolation and identification of novel molecules for biotechnological applications.

THE MICROBIOME IN HEALTH AND DISEASE: USING A FLY MODEL TO UNDERSTAND HOST-MICROBE INTERACTIONS

N. Broderick[1]
[1]*University of Connecticut, Molecular and Cell Biology, Storrs, USA*

Backgrounds

Gut microbiota provide key contributions to host health and many studies have correlated perturbations of the microbiota with disease. There is increasing data that the microbiome is a critical factor in the susceptibility and progression of disease. The *D. melanogaster*-microbiome system provides a simple model ecosystem to interrogate mechanisms of host disease ecology that are largely inaccessible in other systems.

Objectives

Here, we use two well characterized bacterial pathogens of *D. melanogaster*, *Pectobacterium carotovora* (*Ecc15)* and *Pseudomonas entomophila*, to explore the contribution of gut microbiota to host susceptibility.

Methods

We reared flies in the presence (conventional) or absence (axenic) of their microbiome and compared adult survival following infection with either *P. carotovora* or *P. entomophila*. Host survival, immune and stress responses, as well as microbiome and pathogen colonization were measured over time.

Conclusions

Flies reared without gut microbiota are less susceptible to oral infection by *P. entomophila and* exhibit lower immune and stress responses. Ingestion of *P. carotovora* is not lethal to wild-type flies, but injection into the fly hemocoel increases mortality. Initially, *P. carotovora*-infected axenic male flies die faster than conventionally reared flies. However, both male and female axenic flies show greater long-term survival than flies reared with microbiota. These results suggest *Drosophila* microbiota influence susceptibility to infection through interactions with the host immune and stress response, but that this effect can be dependent on sex, the route of infection, and assay duration.

Environmental Microbiology/Microbial Ecology /Microbial Communities

DRINKING WATER MICROBIOME: A NEGLECTED BIODIVERSITY REVEALED

A. Bruno[1], A. Sandionigi[1], M. Bernasconi[2], E. Siani[1], M. Labra[1], M. Casiraghi[1]
[1]University of Milano-Bicocca, Biotechnologies and Biosciences, Milan, Italy
[2]Metropolitana Milanese spa, Metropolitana Milanese spa, Milan, Italy

Backgrounds

Drinking water shows a wide diversity of microorganisms interacting in a dynamic network. Recent studies revealed that drinking water treatment process can affect the microbiome community structure. Moreover, scientists recently reported the presence of neglected and poorly known biodiversity in groundwater.

Objectives

Drinking Water Treatment Plants (DWTPs) can be a source of unexpected biodiversity in terms of environmental microorganisms, still poorly known. Molecular techniques can give a deeper knowledge, going beyond the limit of culture-dependent methods.

We evaluated and standardized a new experimental workflow for microorganisms concentration, DNA extraction and amplification, suitable for molecular analysis and optimized for High-Throughput DNA Sequencing approaches.

Methods

A one-year sampling campaign was carried out in a DWTP in Milan (Italy) in collaboration with Metropolitana Milanese S.p.A. We collected samples at different steps of the potabilization processes, from groundwater, through carbon filters, to the last treatment (chlorination). Drinking water microbiome was investigated with Illumina MiSeq paired-end sequencing of 16S rRNA gene.

Conclusions

The results obtained showed the occurrence of unexplored bacteria in the entire DWTP, from groundwater, across carbon filters, to post-chlorination.

Secondly, our data suggested that carbon filters can be a substrate for microorganism growth and can contribute to seed water downstream, since chlorination does not greatly modify the composition of the incoming bacterial community.

Poorly known bacteria can be pivotal in the microbial dynamics of drinking water: DWTPs are complex ecosystems, where a neglected network of microbial interactions take place from the source to the tap in our house, raising new questions about drinking water management.

Environmental Microbiology/Microbial Ecology /Microbial Communities

DETECTION OF THE ARXA GENE ENCODING ARSENITE OXIDASE IN VARIOUS ECOSYSTEMS BY USING NEWLY DESIGNED PCR PRIMERS

M.C. Cabrera Ospino[1], *H. Kojima*[1], *T. Watanabe*[1], *T. Iwata*[2], *F. Manabu*[1]
[1]*Hokkaido University, The Institute of Low Temperature Science, Sapporo, Japan*
[2]*University of Yamanashi, Environmental Sciences, Kofu, Japan*

Backgrounds

Arsenic (As) is a toxic metalloid found as inorganic arsenate (AsV) and arsenite (AsIII) in the environment. Some bacteria can use AsIII as an electron donor, utilizing one of the two arsenite oxidase, coded by *aio*, and *arx* genes. The latter has been found only in relatively limited number of organisms, and its diversity and distribution in the environment are hardly known. In a previous study, a primer pair to detect the *arxA* gene was designed from the sequences of gammaproteobacterial strains. With the primer pair, some *arx* gene sequences were directly detected in alkaline/saline environments. However, this primer pair failed to get a PCR product from arsenic rich sites with different pH. This may be related to the coverage of the primers, because the primers have many mismatches with the *arx* gene found in a betaproteobacterial strain.

Objectives

The aim of this study was to design a new PCR primer set in order to detect more diverse *arx*A sequences in various ecosystems.

Methods

The primer pair was designed on the basis of 20 *arx* gene sequences. It was experimentally confirmed that it can amplify the *arxA* gene from more diverse organisms. By using the new primer pair, diversity of *arxA* gene in some circumneutral sites was analyzed.

Conclusions

The partial *arxA* sequences obtained in this study were phylogenetically distinct from those of higher pH sites and the genes of the alkaliphilic isolates previously reported. This study provides an important proof of a wider diversity and distribution of *arxA* sequences in the environment.

Environmental Microbiology/Microbial Ecology /Microbial Communities

MICROORGANISM ROLE ON CULTURAL HERITAGE LIFE

L. Scrano[1], S. Sasso[2], M.G. Bonomo[2], L. Calabrone[2], G. Salzano[2], R. Laviano[3], S.A. Bufo[2]
[1]Università degli Studi della Basilicata,
European and Mediterranean Cultures. Architecture- Environment and Cultural Heritage, Matera, Italy
[2]Università degli Studi della Basilicata, Sciences, Potenza, Italy
[3]Università di Bari, Earth and geo-environmental sciences, Bari, Italy

Backgrounds

Microorganisms play an important role in biodeterioration processes of cultural heritage, because they mostly represent the founder organisms of the ecological successions which develop on the artefact. The consideration of the artistic heritage as a sensing receptor, is an extremely complex issue: each material with morphological, chemical and physical properties totally dissimilar, makes it an "*unicum*", characterized by a specific vulnerability. Conservation of historic buildings and monuments is a major problem in modern societies from both an economical and cultural point of view. Solutions for the safeguard of cultural heritage are usually based on different procedures to remove microorganisms not taking into account that the 'Nature' creates an important balance between all living organisms. In fact, it is true that the bacteria create a substrate for successive specialized colonizers but it is also true that, on the stones, there are bacteria repairers of environmental damage*.*

Objectives

The aim of this research was to identifying and studying the role of microorganisms present on the stones of two historical bridges located in Basilicata region.

Methods

Identification of microorganisms collected from the bridges; evaluation of bacteria' role; assessment of the quality of the locally produced bio-calcite for the stone consolidation.

Conclusions

Microbial species identified on both the artifacts belong to Firmicutes, Actinobacteria and Proteobacteria phyla. Among the bio-consolidant bacteria, *Bacillus thuringiensis* has been demonstrated to produce the greatest amount of crystals, coherent with the limestone substrate.
"*We follow the nature, excellent guide as a deity and obey it*" (CICERO).

FOOD COMPONENTS AFFECT THE IN VITRO ADHESION OF ORAL BACTERIA TO THE INTESTINAL MUCOSAL NICHE

M. Calatayud[1], E. Hernandez-Sanabria[1], A. Rizky Ferdina[1], N. Boon[1], T. Van de Wiele[1]
[1]Ghent University, Center for Microbial Ecology and Technology CMET, Gent, Belgium

Backgrounds

The oral cavity is a dynamic environment with relevant impact on host physiology. Food and saliva are the main sources of bacteria incoming the small intestine, which potentially impact the structure and function of native intestinal microbial communities.

Objectives

Assessing the impact of food components (oil, meat, and sugar) on the survival and intestinal adhesion of a synthetic oral community exposed to an *in vitro* gastrointestinal digestión.

Methods

A synthetic biofilm of 14 species underwent to an *in vitro* digestion, in absence or presence of different food components (meat, oil, and sugar). Samples from oral, stomach and small intestine digestions were analyzed by flow cytometry to count live/dead cell. DNA was extracted from each digestion step and the community composition and structure was assessed by 16S rRNA amplicon sequencing. Bacterial adhesion was evaluated by adding 10^5-10^3 live bacteria/ml from the small intestinal digestion into a differentiated co-culture of Caco-2/HT29-MTX cells in a Transwell® system. Live/dead bacteria were quantified from the epithelial layer and the mucus niche by flow cytometry.

Conclusions

Meat had a protective effect towards bacterial survival, increasing the number of intact bacteria from 5 log units to 7 log units after gastrointestinal digestion. In addition, meat significantly supported the adhesion of bacteria to the small intestine mucosal surface (1.5 ± 0.1 log units) compared with control (1.3 ± 0.04 log units, $p < 0.001$). *Veillonella*, *Fusobacterium*, *Streptococcus* and *Aggregatibacter* were the genera with the highest relative abundances after the intestinal digestion. Structure and diversity were significantly different among communities co-digested with diverse food components.

The interaction between food and oral microbiota may affect the bacterial community survival, structure, and adhesion capacity to the small intestine. Further impact on host physiology remains to be elucidated.

Environmental Microbiology/Microbial Ecology /Microbial Communities

DISPERSAL OR SELECTION, THE CASE OF ATMOSPHERIC MICROBIAL COMMUNITIES

J. Caliz[1], X. Triadó-Margarit[1], V. Jiménez-Ontiveros[2], D. Alonso[2], A. Àvila[3], E. O. Casamayor[1]
[1]Center for Advanced Studies of Blanes CSIC, Integrative Freshwater Ecology Group, Blanes, Spain
[2]Center for Advanced Studies of Blanes CSIC, Theoretical and Computational Ecology Laboratory, Blanes, Spain
[3]CREAF, Global Ecology Unit, Cerdanyola del Vallès, Spain

Backgrounds

The transport of particle-bound microorganisms over long distances throughout the atmosphere implies the annual mobilization around the planet on the order of 10 trillion of cells. Our knowledge on the processes that drive the atmospheric microbial communities is however still in its infancy. Airborne microorganisms are in constant interaction with human life, both directly as a source of pathogenic and beneficial microbes, and indirectly through biological effects on atmospheric processes. Most studies have suggested that changes on the composition of airborne microorganisms are related to the source of aerosols (dispersal) and selective processes mediated by environmental factors (environmental filtering). However, a long-term and well-tracked dataset has never been used to address these issues.

Objectives

The aim of this study is to determine the influence of dispersal and selection on atmospheric microbial communities.

Methods

In this study we applied high-throughput sequencing techniques (16S rRNA and 18S rRNA genes amplicons) to characterize the airborne microbial communities weekly collected in wet precipitations at La Castanya station (Montseny mountains, NE Spain, 41°46′N, 2°21′E), along 25 years.

Conclusions

We characterize the origin of air masses by modelled back trajectories and chemical composition of depositions. Depositions with non-ambiguous origin were used for microbial analyses to test whether the source of aerosols and/or the annual time period (related to environmental conditions) determine the composition and dynamics of airborne microbial communities.

STAPHYLOCOCCUS AUREUS SUPERNATANTS INHIBIT BIOFILM FORMATION IN CANDIDA GLABRATA

O. Camarillo-Marquez[1], C.H. Hernández-Rodríguez[1], A.V. Rodríguez-Tovar[1]
[1]National School of Biological Sciences-National Polytechnic Institute, Department of Microbiology, Ciudad de Mexico, Mexico

Backgrounds

It has been shown that with the presence of *Candida albicans* and *Staphylococcus aureus* significantly improves biofilm formation and its resistance to vancomycin, there is little information on the interaction of *Candida glabrata* and interaction with *S. aureus*.

Objectives

To standardize the formation of monospecies biofilms of *C. glabrata* and *S. aureus* and mixture of *C. glabrata-S. aureus* ,To determine the type of interaction between *C. glabrata* and *S. aureus*, Describe the ultrastructure of biofilms in co-culture.

Methods

To investigate the type of interaction between these microorganisms, the cells were examined in co-culture by scanning electron microscopy SEM, transmission electron microscopy TEM and confocal laser scanning microscopy CLSM.

Conclusions

It was evidenced the binding of *S. aureus* to the conidia of *C. glabrata*, the ultrastructure of the cells of *C. glabrata* had characteristic of dead cells, the same was observed with the CLSM the fungal cells were dead, but the cell wall was maintained intact. To demonstrate if cell-cell interaction was required, the free supernatants of *S. aureus* cells were obtained and they were found to inhibit the growth of *C. glabrata*, the mechanism of death is still unknown, a possible response is that the supernatants cause apotosis in fungal cells.

DOUBLE ACTION AGAINST DENTAL CARIES BY THE PROBIOTIC STREPTOCOCCUS DENTISANI

A. Camelo Castillo[1], A. López López[1], M. Ferrer Garcia[1], R. Cebrián Castillo[2], M. Martinez Bueno[2], A. Mira[1]
[1]Fundación para el Fomento de la Investigación Sanitaria y Biomédica FISABIO, Center for Advanced Research in Public Health. Genomics and Health Unit, Valencia, Spain
[2]University of Granada, Department of Microbiology, Granada, Spain

Backgrounds

A new Streptococcal species, isolated in our laboratory from tooth surfaces of caries-free humans, known as *Streptococcus dentisani sp.nov*, has been proposed to have a potential probiotic activity.

Objectives

Identify the mechanisms that *S.dentisani* uses to inhibit the oral pathogens and to buffer extracellular pH.

Methods

Using supernatants from *S. dentisani* cultures, we performed inhibition experiments against oral pathogens under solid and liquid media and we observed their antimicrobial effect using SEM.

By HPLC, MALDI-TOF-MS and the use of ion-exchange and hydrophobicity resins, the antibacterial compounds were purified from the supernatants of the probiotic culture. The growth and pH of *S. dentisani* in BHI medium enriched with L-arginine was measured for a 24h period, and the expression of arginolytic genes was measured by qPCR, performed in triplicates.

Conclusions

S.dentisani inhibits the growth of *S. mutans*, *S. sobrinus*, *Prevotella intermedia* and *F. nucleatum.* We have identified at least four matching peptide sequences of bacteriocins, in a region of about 16 kb, which we have called " Anti-Caries Defense Cluster" (ACDC).

S. dentisani buffers acidic pH in the presence of arginine, over-expressing genes for the production of ammonia when the pH becomes acidic.

We propose *S.dentisani* as a promising probiotic against tooth decay, with a double probiotic action, inhibiting the growth of major oral pathogens through the production of bacteriocins, and also buffering acidic pH (the primary cause of dental caries) through an arginolytic pathway.

CHARACTERIZATION OF SULFATE-REDUCING BACTERIA CONSORTIA AT ACIDIC CONDITIONS

N.G. Campos-Quevedo[1], E. Razo-Flores[2], N.E. Lopez-Lozano[2], I. Sánchez-Andrea[3], M.D.L.B. Celis Garcia[2]
[1]Instituto Potosino de Investigacion Cientifica y Tecnologica, Environmental Sciences, San Luis Potosi, Mexico
[2]Instituto Potosino de Investigación Científica y Tecnológica, Environmental Sciences, San Luis Potosi, Mexico
[3]Wageningen University, Microbial Physiology, Wageningen, The Netherlands

Backgrounds

Acid mine drainage (AMD) is an effluent generated from the weathering of mining waste and it causes several environmental problems. Sulfate reducing bacteria (SRB) are responsible for the production of sulfide which reacts with dissolved metals, forming precipitates (metal sulfides). However, the major drawback is that acetate cannot be degraded completely, and it can be toxic at the acidic conditions prevailing in AMD (pH 2-4).

Objectives

From the sequences analysis we aim to establish the potential novelty of some members that compose the consortia due to the fact that they are cultivable at lab-working conditions, and are able to consume acetate completely at acidic pH (4.0).

Methods

We managed to obtain 7 different cultivable consortia by traditional microbiology techniques (successive transfers), from a natural acidic environment (pH around 2). These consortia completely consume the substrate at acidic pH, either lactate or glycerol. Using molecular techniques (cloning-sequencing) it was possible to obtain the composition of the 7 cultivable consortia, which showed to have a great heterogeneity, although they were obtained from the same sediment, reflecting the effect of the culture conditions on the community.

Conclusions

From the data analysis we also could figure out the interactions between the community, and possibly identify new strains that could be isolated.

HYDROLASE-PRODUCING CHAOTOLERANT MICROBES ISOLATED FROM DIVERSE ENVIRONMENTS

P.E. Canales[1,2], *T.J. McGenity*[1]
[1]*School of Biological Sciences, University of Essex, Colchester, United Kingdom*
[2]*Laboratorio de Biología Molecular - Facultad de Farmacia y Bioquímica, Universidad Nacional Mayor de San Marcos, Lima, Peru*

Backgrounds

Chaotropic agents have the capability to disrupt biological systems like membranes, proteins and DNA. Chaotropicity has been studied to get more insights into the limits of life and, also, for its implications in fields like biotechnology, microbial ecology and astrobiology. Highly active enzymes under such extreme conditions are of interest for understanding cellular response and adaptation under chaotropic conditions, and even for potential industrial applications.

Objectives

The aim of this study was to determine the production of hydrolases by chaotolerant strains, compared under both chaotropic and kosmotropic conditions, isolated from diverse environments.

Methods

Samples included hypersaline and non-hypersaline environments: salt marsh (Colne Estuary, UK), agricultural soil (Colchester, UK) and Discovery deep-sea brine interface (Mediterranean Sea). Microbes belonged to the genera *Bacillus* sp., *Microbacterium* sp. and *Penicillium* sp. We compared the ability of chaotolerant microbes to produce hydrolases under both chaotropic (1 M $MgCl_2$) and kosmotropic (1 M NaCl) conditions using agar plate/tube assays supplemented with 1% yeast extract and the corresponding polymer for each test, except for the DNase test agar. Screening for proteases, amylases, lipases, cellulases, and DNases was carried out. One *Bacillus* sp. strain was able to produce a variety of extracellular enzymes (protease, lipase and DNase) under both chaotropic and kosmotropic conditions. Proteases able to degrade casein were produced in the highest number of strains (4 out of 5) under both conditions.

Conclusions

Diverse hydrolytic enzymes were produced under chaotropic conditions, but most chaotolerant microbes were able to grow faster and show higher production under kosmotropic than in chaotropic conditions.

Environmental Microbiology/Microbial Ecology /Microbial Communities

THE EXTREMES OF ROGOZNICA LAKE (EASTERN ADRIATIC COAST): IN-DEPTH CHARACTERISATION OF THE PROKARYOTIC COMMUNITY BENEATH THE OXIC ZONE

M. Čanković[1], G. Collins[2], E. Porca[2], I. Petrić[1], I. Ciglenečki[1]
[1]Institut Ruđer Bošković, Division for Marine and Environmental Research, Zagreb, Croatia
[2]School of Natural Sciences- NUI Galway, Microbiology, Galway, Ireland

Backgrounds

A large fraction of all prokaryotes is thought to inhabit anaerobic environments, which represent a pool of genetically diverse microorganisms. Earth's oxygen-depleted zones are expanding areas that are the site of, and are implicating in, changing biogechemical cycles. Under these conditions, microbial populations are essential mediators of elemental cycling and energy transfer. Rogoznica Lake, situated on the eastern Adriatic coast, and known as Dragon's Eye, is a highly eutrophic marine lake. With no fresh water inflow or drifts, it is considered a self-sustaining environment. This uniquely extreme ecosystem is euxinic (i.e. sulfidic) and meromictic. Due to its steep physico-chemical gradient (particularly oxygen and sulfide) it provides a suitable environment for the development of microaerophilic and anaerobic prokaryotic communities.

Objectives

Although extensively studied, nothing is yet known about the microbial community living beneath the oxic zone in Rogoznica Lake.

Methods

We investigated the spatio-temporal dynamics of the active bacterial and archeal communities by sequencing of 16S rRNA amplicons generated from cDNA.

Conclusions

Clear differences in the structure of the active community were observed across the vertical profile as well as during different seasons, all of which corresponded closely to environmental parameters. A complex and diverse distribution of microbial populations was revealed, supporting the idea that anaerobic degradation of organic matter in the Lake is driven by a range of taxa adjusted to environmental constraints.

WILD GRAPE-ASSOCIATED YEASTS AS A PROMISING STRATEGY OF BIOCONTROL AGAINST VITIS VINIFERA FUNGAL PATHOGENS

C.B. Gustavo[1], V. Ileana[2], F. Roberto[2], M. David[3], M. Nicola[2], J.M. Cantoral Fernandez[1]
[1]Universidad De Cadiz, Biomedicina- Biotecnologia Y Salud Publica. Lab. Microbiologia, Puerto Real, Spain
[2]Universita Degli Studi Di Milano, Department Of Food- Environmental And Nutritional Sciences, Milano, Italy
[3]Agricultural University Of Georgia, Institute Of Horticulture- Viticulture And Oenology, Tbilisi, Georgia

Backgrounds

The increasing level of hazardous residues in the nature and food has led to the European Union to restrict the use of chemical fungicides, addressing the researchers to face this challenge. Exploiting new natural antagonistic microorganisms against fungal diseases could serve agricultural production reducing pre- and postharvest losses.

Objectives

The main aim of this work was to isolate epiphytic and endophytic yeasts from grape berries collected from *Vitis vinifera* ssp *sylvestris* populations in the Mediterranean Basin and from *Vitis vinifera* ssp *vinifera* cultivars in three different farming systems: organic, biodynamic and conventional.

Methods

Strains able to prevent fungal pathogenic attacks of grape-berries were selected for in *vitro* and in *vivo* antagonism experiments against *Botrytis cinerea*, *Aspergillus carbonarius* and *Penicillium expansum* species. The more effective antagonist yeast strains were subsequently assayed for their capability to colonize and grow in grape wounds. Finally, the possible modes of action: nutrients and space competition, iron depletion, cell-wall degrading enzymes, diffusible and volatile antimicrobial compounds, and biofilm formation, were investigated as well.

Conclusions

245 yeasts strains belonging to 8 species were isolated, 20 of them showed antagonistic action against all molds. Yeast strains isolated from grape-berries from *V. vinifera* ssp *sylvestris* were more effective (up to 60%) against *B. cinerea* rather than other strains isolated from *V. vinifera* ssp *vinifera*. Six antagonistic yeasts, all isolated from wild vines, belonging to 4 species (*Meyerozyma guilliermondii*, *Hanseniaspora uvarum*, *Hanseniaspora clermontiae* and *Pichia kluyveri*) revealed phenotypical characteristics associated to the analysed modes of action.

GUT MICROBIOME AND SOCIAL COOPERATION IN DROSOPHILA MELANOGASTER

P. Carazo[1], R. García-Roa[1], A. Bartolomé[1], L. Bartolomé[2], A. Latorre[3]
[1]Cavanilles Institute of Biodiversity and Evolutionary Biology, Ecology- Ethology and Evoltion Group, Valencia, Spain
[2]Science and Technology Faculty- the Basque Country University/EHU, Central Analytical Service SGIker, Bilbao, Spain
[3]Institute for Integrative Systems Biology, Evolutionary Systems Biology of Symbionts, Valencia, Spain

Backgrounds

Understanding the evolution and maintenance of cooperation is an enduring question in biology. Kin selection favours the appearance of adaptations that foster cooperation between related individuals, and has proven to be a fundamental process in the evolution and maintenance of cooperation, and of social evolution at large. Kin selection frequently relies on the ability to recognize kin from non-kin and recent evidence suggests that, by modifying body odours, gut microbiota might be crucially involved in kin recognition in species that largely rely on olfaction.

Objectives

In this study, we assess the role of the gut microbiota in kin recognition in *Drosophila melanogaster*. Recent studies have shown that kin recognition mediates a variety of social cooperative behaviours in this species, but the mechanisms underlying kin recognition remain poorly understood.

Methods

Here, we studied the relative effects of genotype (i.e. family) and rearing environment (i.e. diet) in determining the gut microbiome of flies, how variation at this level translates into variation in body odours (i.e. cuticular hydrocarbons; CHCs), and how this in turns affects kin recognition and social cooperation.

Conclusions

Our results have important bearing to understand the evolution of social cooperation in *D. melanogaster*, and more generally the role of gut microbes in kin recognition in insects.

EEL MICROBIOME REVEALS THAT SKIN MUCUS OF FISH IS A NATURAL NICHE FOR AQUATIC INTESTINAL PATHOGEN EVOLUTION

M. Carda-Diéguez[1], R. Ghai[2], F. Rodríguez-Valera[3], C. Amaro[1]
[1]Universitat de Valencia, Microbiología y Ecología. ERI Biotecmed, Burjassot, Spain
[2]Institute of Hydrobiology- Biology Center of the Academy of Sciences of the Czech Republic, Department of Aquatic Microbial Ecology, České Budějovice, Czech Republic
[3]University of Miguel Hernández, Evolutionary Genomics Group- Producción Vegetal y Microbiología, San Juan de Alicante, Spain

Backgrounds

Accidental pathogens of aquatic origin such as vibrios evolve in their natural environment usually by horizontal gene transfer events. We hypothesized that fish's skin-mucosal-surface (SMS) can act as a niche that accelerates and favors the emergence of new accidental intestinal pathogens in the environment.

Objectives

i) To determine the SMS's microbiome, virulome, resistome and mobilome from eels and the differences from that of the surrounding water (W); ii) to describe the specific functionalities associated to SMS-microbiome (mucus-signature); iii) to sequence isolated opportunistic pathogens present in the SMS and compare them with the genomes of true pathogenic isolates.

Methods

We have determined the SMS- and water-microbiome by using metagenomic and bioinformatic tools. Intestinal pathogens were cultured, identified by phenotypic and genotypic tests, sequenced and compared with that deposited in the databases.

Conclusions

Vibrio species monopolized wild-eel's SMS-microbiome from natural ecosystems. *V. anguillarum/V. vulnificus* and *V. cholerae/V. metoecu*s being the most abundant ones in SMS from estuary and lake, respectively. Functionalities of the SMS-microbiome differed significantly from those of W-microbiome and suggested that colonizers should contain specific genes for attachment, bacterial competition and communication, and resistance to mucosal innate immunity, predators and heavy metals/drugs. Furthermore, some of these genes were associated to mobile genetic elements, mainly Integrative and Conjugative Elements. Finally, the genomic comparisons of a *V. metoecus* isolate from SMS presented characteristics intermediate between *V. metoecus* from water/extra-intestinal infections and *V. cholerae* O1 from cholera patients suggesting that HGT events between close *Vibrio* species could take place in this mucosal environment.

ANALYSIS OF THE MOLECULAR MACHINERY IMPLICATED IN MULTICELLULARITY IN BACILLUS CEREUS

J. Caro Astorga[1], D.F. Romero Hinojosa[1], A. De Vicente Moreno[1], E. Frenzel[2], O. Kuipers[2]
[1]Facultad de Ciencias., Microbiologia, Málaga, Spain
[2]Groningen Biomolecular Sciences and Biotechnology Institute GBB.,
2Department of Molecular Genetics. University of Groningen, Groningen, The Netherlands

Backgrounds

Bacillus cereus is a Gram-positive bacterium usually implicated in food poisoning outbreaks and human infections that sometimes result fatal. These events are closely related to the assembly of a biofilm that serves as a reservoir of cells, a nest for sporulation and protection from environmental stresses, host defenses or chemotherapy.

Objectives

To perform a comprehensive comparative study of biofilm and planktonic cells to: i) delineate the molecular machinery implicated in the different steps of the biofilm life cycle, and ii) define new genes dedicated to biofilm formation.

Methods

Bacteria were grown under biofilm inducing conditions. Biofilm cells were separated from planktonic cells at different times and their whole mRNA was isolated, sequenced and analyzed.

Conclusions

Our results reveal a high number of genes associated to biofilm, many of them with unknown function, but highly conserved in others bacterial species. Besides, we found global changes in cell wall synthesis, metabolism and interspecies interaction molecules. The interaction of *B. cereus* with other bacteria is conditioned by secondary metabolites, which are apparently overexpressed in biofilm. On the other hand, toxins are mainly expressed in planktonic cells, which are more oriented to interact with its hosts. These results reveal the defense and attacking positions of *B. cereus* in biofilm vs planktonic states.

This work was supported by grants AGL-2012-31968 and ERC-Starting Grant BacBio ERC637971. Joaquin Caro-Astorga is supported by a PhD fellowship from the FPI program of the Spanish Government.

GENETIC DIVERSITY AND ANTIMICROBIAL SUSCEPTIBILITIES OF NOCARDIA CYRIACIGEORGICA STRAINS ISOLATED FROM SOIL

G. Carrasco[1], M. Sansegundo[1], M.A. Fernández[1], A.C. Ramírez[2], E. García-Amor[2], N. Garrido[1], P. Villalón[1], J.A. Saez-Nieto[1], S. Valdezate[1]
[1]National Centre of Microbiology / Institute of Health Carlos III,
Taxonomic Reference and Research Laboratory, Majadahonda Madrid, Spain
[2]Faculty of Pharmacy and Bioanalysis- Los Andes University,
Laboratory of Soil Microbiology. Department of Microbiology and Parasitology, Mérida, Venezuela

Backgrounds

Nocardia genus is a gram-positive rod present in soil, which shares ecological habitat with other *Actinomycetes* as *Streptomyces* spp. From soil, *Nocardia* spp. infection is mostly acquired by humans via inhalation or after skin injury.

Objectives

Comparison of the diversity of *N. cyriacigeorgica* soil population and their susceptibilities respect to human strains.

Methods

Twenty-eight *N. cyriacigeorgica* strains isolated from the soil (100m^2/10cm-depth) of nine areas of Lara state (Venezuela) were compared to 30 human strains from Spain. 16S rRNA, *gyrB* full genes and 16S-*gyrB-hsp65-secA1* concatenated MLSA (McTaggart *et al*., 2010) sequences were analyzed. Antimicrobial susceptibilities were undergone by microdilution method with RAPMYCO panels (Thermo-Scientific). MIC values were categorized following Clinical Laboratory Standard Institute interpretative criteria (CLSI, 2011).

Conclusions

N. cyriacigeorgica was the major *Nocardia* species obtained in the studied Venezuelan soil (71.8%). Respect to the human strains, higher variability was found in the 16S rRNA gene sequence in soil strains ($HGDI_{soil}$ 0.57 vs. $HGDI_{human}$ 0.0), but lower in *gyr*B (0.79 vs. 0.94). The phylogenetic MLSA tree of soil strains clustered the main *gyr*B haplotype (n=13) in 12 clades. The soil strains exhibited resistance rates up to 25% for amoxicillin-clavulanic acid, cefoxitin, fluoroquinolones, clarithromycin and doxycycline. Differences in MIC distribution and resistance rates were found among soil and human strains, being the soil strains more susceptible. Statistical differences *($p \leq 0.05$)* were found with amoxicillin-clavulanic acid, third generation cephalosporins, imipenem, fluoroquinolones and minocycline**.** Our study gives insight into unreported diversity and susceptibility of soil *N. cyriacigeorgica* strains, one of the main agent of human nocardiosis.

BRIDGING THE GAP BETWEEN EMPIRICAL MICROBIAL ECOLOGY AND THEORIES OF BIODIVERSITY ORGANIZATION IN SPACE AND TIME

E.O. Casamayor[1], D. Alonso[1], J.A. Capitan[2], X. Triadó-Margarit[1], J. Caliz[1], R. Ortiz-Alvarez[1], V. Jimenez-Ontiveros[1]
[1]Center for Advanced Studies of Blanes CSIC, Continental Ecology, Blanes, Spain
[2]UNIVERSIDAD POLITÉCNICA DE MADRID, DEPARTAMENTO DE MATEMÁTICA APLICADA, Madrid, Spain

Backgrounds

Most ecological theory has been developed for plants and animals. However, for the last years, technical progress on several fields, from computers to last generation DNA sequencers, has made it possible to collect large amounts of data on microbes at unprecedented rates. Microbial systems are also easy to sample massively and expand along orders of magnitude of environmental factors. All these facilities makes microbial communities excellent model systems to check general ideas on the function and structure of ecological communities and expand ecological theory.

Objectives

Most recent work on microbial communities describes spatial patterns, such as the species area relationship and beta diversity indexes, or take statistical approaches to describe snapshots of communities that are assumed to be at a steady state. Although temporal variation is fully appreciated and described for microbial communities, few attempts have been done yet to study the leading mechanisms driving community assembly in time. We will explore the potential of classic island biogeography theory to gain insights into the temporal dynamics and regional scale distribution of microbial communities.

Methods

A stochastic model formulation of the theory is used as a way to estimate an equivalent of effective colonization and extinction rates per microbial group, bridging the gap between empirical microbial ecology and theories of biodiversity organization in space and time.

Conclusions

We carried out a first attempt to describe microbial communities as the result of individual extinction/colonization stochastic events acting on an ensemble of bacterial populations belonging to a regional pool. The approach provided a powerful starting point to study temporal community re-assembly after environmental perturbations.

FEMS7-0764
Environmental Microbiology/Microbial Ecology /Microbial Communities

CLIMATE CONTROL OF REMOTE MICROBIAL DISPERSAL THROUGH ATMOSPHERIC AEROSOLS: A LONG-TERM STUDY IN THE CENTRAL PYRENEES (LTER-AIGUESTORTES)

E.O. Casamayor[1], *X. Triadó-Margarit*[1], *J. Caliz*[1], *R. Ortiz-Alvarez*[1]
[1]*Center for Advanced Studies of Blanes CSIC, Continental Ecology, Blanes, Spain*

Backgrounds

Dust coming from the large deserts on Earth, such as the Sahara, can travel long distances and be dispersed over thousands of square kilometers. Remote dust deposition rates are increasing as a consequence of global change and may represent a mechanism for intercontinental microbial dispersal. Remote oligotrophic alpine lakes are particularly sensitive to dust inputs and can serve as sentinels of airborne microbial transport and the ecological consequences of accelerated intercontinental microbial migration.

Objectives

Microbes are extremely abundant and ubiquitous on Earth, with a huge genetic and metabolic diversity and a large ability to quickly react to any change in the environmental conditions. They are therefore excellent sensors of environmental changes and one of the main actors in the ecosystems response. Our investigations carried out in the Aigüestortes National Park within the Spanish Long Term Ecological Research network (LTER), want to determine the role of terrestrial aerosols as a natural mechanism for global dispersal and ubiquity of microorganisms.

Methods

We applied high-throughput sequencing techniques (16S rRNA and 18S rRNA amplicon sequencing) to characterize the airborne microbial communities reaching the Central Pyrenees (NE Spain) along a long term study, and the planktonic microorganisms of the lacustrine Pyrenean district.

Conclusions

Overall, this study suggests that local and regional features may generate global trends in the dynamics and distribution of airborne microbial assemblages, and the diversity of viable cells in the high atmosphere is likely higher than previously expected.

Environmental Microbiology/Microbial Ecology /Microbial Communities

ISOLATION, CHARACTERIZATION AND SELECTION OF BACTERIAL ISOLATES FROM A SUPPRESSIVE SOIL WITH BENEFICIAL TRAITS TO PLANTS

C. Vida[1], A. de Vicente[1], S. Tienda[1], J.A. Gutierrez-Barranquero[1], F.M. Cazorla[1]
[1]Facultad de Ciencias- Universidad de Málaga, Microbiología, Málaga, Spain

Backgrounds

This study focused on the characterization and selection of bacterial strains obtained from a suppressive soil displaying antifungal activity against the soilborne phytopathogenic fungi *Rosellinia necatrix*. Bacterial profile from this suppressive soil were first obtained by 16S rRNA gene sequencing, revealing a significant increase in the bacterial class *Gammaproteobacteria*, especially in some antagonistic representatives of *Pseudomonas* spp.

Objectives

To obtain and characterize a collection of 246 bacterial isolates obtained from this suppressive soil, in order to identify new strains with antifungal activity against fungal phytopathogens.

Methods

To obtain the bacterial collection, we performed an isolation on a selective medium for *Pseudomonas*-like microorganisms. Further characterization tests were used in order to analyse the bacterial collection, including identification of the general metabolic profile of glucose, the profiling of antifungals produced, including both the putative production of antifungal compounds and lytic exoenzymes, and the evaluation of traits related with beneficial effects on plants.

Conclusions

A final selection of representative strains resulted in antifungal isolates belonging to the genus *Pseudomonas,* but also some representatives of the genera *Serratia* and *Stenotrophomonas.* These selected strains were tested for plant protection by an *in vivo* experiment using avocado and wheat plants challenged by the pathogen *R. necatrix*, showing all of them an antifungal ability and plant disease protection.
Pseudomonas-like strains isolated from suppressive soils constitute an excellent source for novel microbial biocontrol agents against soilborne fungal pathogens.

This work was supported by grant AGL2014-52518-C2-1-R. Carmen Vida and Sandra Tienda are supported by a PhD fellowship from the FPI program of the Spanish Government.

Environmental Microbiology/Microbial Ecology /Microbial Communities

ASSESSMENT OF THE PROKARYOTIC BIODIVERSITY OF THE SALTERNS OF MARGHERITA DI SAVOIA (ITALY) BY AMPLICON BASED NEXT GENERATION SEQUENCING ANALYSIS

L.R. Ceci[1], C. Leoni[2], M. Volpicella[2], C. Manzari[1], F. Bruno[1], P. Elisabetta[2], G. Bruno[1], P. Graziano[1,2]
[1]Institute of Biomembranes and Bioenergetics, CNR, Bari, Italy
[2]Department of Biosciences- Biotechnologies and Biopharmaceutics, University of Bari, Bari, Italy

Backgrounds

Marine salterns are excellent sites for studying the dynamics of the prokaryotic biodiversity at increasing salt concentrations. Metagenomics offers the most direct approach for reliably assessing the microbial diversity expecially for uncultivable prokaryotes.
Salterns of Margherita di Savoia (MdS) are located on the East-cost of South Italy. They are the largest salterns in Europe, with a yet unexplored microbiota composition.

Objectives

Defining the microbiota composition of the salterns of MdS in ponds with increasing salt concentrations.

Methods

eDNA purified from nine ponds with salt concentration in the 4.9-36% range was used for PCR amplification of the V5-V6 hypervariable region of the 16S rRNA gene. NGS of amplicon libraries was carried out by the Illumina MiSeq platform. Obtained reads were analyzed using the BioMaS software for taxonomic classification (Fosso et al., 2015, BMC Bioinformatics).

Conclusions

The microbiota composition of the MdS salterns resulted in a peculiar composition of prokaryotes, quantitatively different from that of other investigated salterns of the Mediterranean area. For example, Archaea are absent at low salt concentrations (4.9-8.4%) and reach their highest concentrations (30-35%) in the high-salinity ponds. In similar ponds of the salterns of Santa Pola (Spain) their presence has been estimated around 90%. Conversely, in the high-salinity ponds of the MdS salterns, the Eubacteria *Salinibacter* genus is the most represented genus.
This study is of particular interest, not only to define the microbiota composition in different salt concentrations, but also for better addressing future functional metagenomics analysis aimed at the identification of biotechnological useful extremozymes.

DIVERSITY OF SALMONELLA SPP. CIRCULATING IN WILD ENDEMIC LIZARDS IN NATURAL AND SEMI-URBAN ENVIRONMENTS

E. Gómez-Díaz[1], T. Ayats[2], J. Huertas[3], J. Figuerola[1], L. Santamaría[1], M. Cerdà-Cuéllar[2]
[1]Estación Biológica de Doñana, CSIC, Sevilla, Spain
[2]IRTA-CReSA, Research Center on Animal Health, Bellaterra, Spain
[3]IBE Institut de Biologia Evolutiva, CSIC-UPF, Barcelona, Spain

Backgrounds

Wild animal populations contribute significantly to the transmission, spread and persistence in the environment of a number of bacterial pathogens, such as *Salmonella*. However, little is known about the circulation and diversity of *Salmonella* in wild, free-living species.

Objectives

Here, we studied the occurrence and genetic diversity of *Salmonella* spp. from two lizard species (*Podarcis pityusensis* and *Podarcis lilfordi*) from the Balearic Archipelago, a touristic hotspot in the Mediterranean. These two lizards are highly abundant and distribute in dense populations that are in close contact with humans, providing a likelihood of human infection.

Methods

A total of 197 fecal samples were analyzed (4 populations and 2 years), and *Salmonella* detection was performed both by PCR and conventional culture methods. Isolates were characterized by serotyping and Multilocus Sequence Typing (MLST).

Conclusions

Overall, 46 samples tested PCR-positive. Among these, *Salmonella* was isolated from 41. There were not clear differences in prevalence between species or sexes or geographic structuring between semi-urban and natural areas. There was a wide diversity of subspecies and serovars, with isolates from all six subspecies (*enterica, salamae, arizonae, diarizonae, houtenae, indica*) and five serovars within supbsp. *enterica*. Together with this phenotypic diversity, a variety of MLST sequence types (ST) was found, with only three already described ST (508, 958, 2635) and up to 12 undescribed new ST. These findings illustrate the role of lizards as reservoir of *Salmonella* spp*.,* with some of them being pathogenic to humans, and highlight the need to closely monitor the wildlife-livestock-human interface in these touristic areas for disease prevention and wildlife conservation.

IS THERE A MICROBIOLOGICAL RISK IN RECREATIONAL ACTIVITIES WITH DROMEDARIES?

S. Vega[1], S. Sevilla-Navarro[1], M. Cerdà-Cuéllar[2], T. Ayats[2], C. Marín[1]
[1]Universidad CEU-Cardenal Herrera,
Departamento de Producción y Sanidad Animal- Salud Pública Veterinaria y Ciencia y Tecnología de los Alimentos, Alfara del Patriarca -Valencia, Spain
[2]IRTA, CReSA Research Center on Animal Health, Bellaterra, Spain

Backgrounds

Campylobacter and *Salmonella* are the main cause of food-borne enteritis in the European Union (UE). Wild animals can act as reservoirs and vehicles of transmission of these zoonotic agents. In Canary Islands (Spain) there is the most important population of dromedary camels (*Camelus dromedarius*) of the UE. These animals are exported to other countries and have direct contact with humans. Thus, there is a need to study their role in zoonotic bacteria dissemination.

Objectives

The aim of this study was determine the occurrence of *Campylobacter* and *Salmonella* in dromedary camels from Canary Islands and to study the genetic diversity of the isolates.

Methods

During February 2016, 54 camels were sampled in Tenerife (Canary Is.). Cloacal swabs were obtained for *Campylobacter* isolation, whilst faeces were collected directly from the rectum for *Salmonella* isolation. Samples were analysed according to ISO10272-1: 2006 (Annex E) for *Campylobacter* and ISO 6579: 2002 (Annex D) for *Salmonella.* Genetic diversity of the isolates was studied by pulsed field gel electrophoresis (PFGE).

Conclusions

None of the samples were *Campylobacter* positive. Three out of 54 camels (5,5%) were positive for *Salmonella* spp. All isolates belonged to serovar Frintrop and showed an identical or nearly identical PFGE profile (> 96% similarity).

Dromedaries from Canary Is. are therefore asymptomatic carriers of *Salmonella* spp. but not of *Campylobacter*. The presence of *Salmonella* in these animals may constitute a health hazard to humans. Biosafety procedures should be therefore implemented in animals to be transported through different countries and in recreational activities, to avoid zoonotic infection.

EFFECTS OF BACTERIAL INOCULATION ON THE RHIZOREMEDIATION POTENTIAL OF POPULUS CV. SKADO GROWING IN SOILS CO-CONTAMINATED WITH POLYCYCLIC AROMATIC HYDROCARBONS (PAH) AND TRACE METALS

A. Cerdeira-Pérez[1], B. Rodriguez-Garrido[1], Á. Prieto-Fernández[1], P.S. Kidd[1], M. Chalot[2]
[1]Instituto de Investigaciones Agrobiológicas de Galicia IIAG- Consejo Superior de Investigaciones Cie ntíficas CSIC, Soil Biochemistry, Santiago de Compostela, Spain
[2]Université de Bourgogne Franche-Comté, Laboratoire Chrono-Environnement, Montbéliard, France

Backgrounds

Polycyclic aromatic hydrocarbons (PAH) are one of the most ubiquitous persistent organic pollutants in soils with potential adverse effects on human health and the environment. Many sites are affected by co-contamination of mixtures of different PAH and toxic concentrations of trace metals. Rhizoremediation, which exploits the interactions between plants and their associated microorganisms to degrade organic compounds, is one of the more promising strategies for the treatment of PAH-contaminated soils.

Objectives

The aim of this study was to identify potentially useful plant-bacterial partnerships for application in the remediation of trace metal- and PAH- contaminated soils.

Methods

For this, several rhizobacterial and root endophytic strains were screened at a bench-scale in order to select those with highest potential to dissipate and/or mobilize different PAH compounds. Bacterial proliferation, degradation capacity and biosurfactant production were assessed in culture media. Molecular assays characterized bacterial strains for the presence of PAH ring-hydroxylating dioxygenase genes. Furthermore, greenhouse experiments based on bacterial inoculation of *Populus* cv. Skado growing on two substrates with organo-metallic contamination were carried out in order to identify those bacterial strains with greater plant growth promotion capacity. Plant tolerance, biomass production, nutritive status and stress enzyme activities were determined, as well as the effect of the plant-bacterial system on PAH dissipation and metal mobility.

Conclusions

On the basis of the results obtained several strains were identified presenting a combination of useful traits for use as bioinoculants in rhizoremediation techniques targeting PAHs, or which could be used in combination as a consortium in future research in this field.

DIVERSITY OF ADHERENT-MICROBIAL COMMUNITIES IN COLON MUCOSAL BIOPSIES FROM CHILEAN AND SPANISH ULCERATIVE COLITIS AND CROHN´S DISEASE PATIENTS

N. Chamorro Veloso[1], R. Rosselló-Móra[2], M. Hermoso[3], R. Vidal[1]
[1]Facultad de Medicina -Universidad de Chile, MICROBIOLOGY, Santiago, Chile
[2]Institut Mediterrani d'Estudis Avançats IMEDEA- CSIC-UIB,
Department of Ecology and Marine Resources, Esporles, Spain
[3]Facultad de Medicina -Universidad de Chile, Programa Disciplinario de Inmunología, Santiago, Chile

Backgrounds

Dysbiosis has been associated with changes in the individual's diet, antibiotic use and a number of clinical disorders, including inflammatory bowel diseases (IBDs). Mostly identified microbiome adhered to the mucosa has been made using short sequences (<300 nucleotides) difficulting clear affiliation at the genus or species level. In this study, we amplified 16S rRNA sequences belonging to biopsies of Chilean Ulcerative Colitis (UC), Crohn's Disease (CD) patients and control individuals using high quality reads (>300 nucleotides) for affiliation process

Objectives

To characterize the microbiota of colonic mucosa obtained from Chilean IBD patients and compare with previous studies performed in Spanish IBD patients

Methods

16S rRNA gene partial sequences were amplified from biopsies taken from 20 UC, 21 CD patients and 9 healthy subjects, by 454 GS FLX Plus System. The phylogenetic inferences from reads were grouped in OPU through ARB software

Conclusions

IBD patients can be classified in different groups according to their microbial composition. IBD1 group presented predominance in the *Bacteroidetes* proportion (40%) while IBD2 group showed a predominance in *Proteobacteria* (57%). Moreover, an IBD3 group exhibited *Actinobacteria* predominance, while IBD5 group, included only Chilean samples showing a *Proteobacteria* predominance (70%) with a large proportion of *Klebsiella oxytoca*. Furthermore, Chilean´s IBD and Spanish control samples were grouped together in IBD4, with a *Firmicutes* (65%) predominance characterized by Clostridia abundance. In conclusion, IBD patients are not distributed in a single homogenous group. In addition, Chilean IBD samples have a microbiota more similar to healthy patients.

NITROGEN REMOVAL PERFORMANCE AND MICROBIAL COMMUNITY OF A MULTISTAGE A/O BIOFILM PROCESS FOR LOW COD WASTEWATER TREATMENT

H. Chen[1], A. Li[1], F. Ma[1], C. Cui[1], H. Zhu[1], Q. Wang[1]
[1]Harbin Institute of Technology, State Key Laboratory of Urban Water Resource and Environment, Harbin, China

Backgrounds

Biological nitrogen removal has been widely applied in wastewater treatment for decades with various advantages. However, deficiency of organic carbon in low COD wastewater usually leads to deteriorative nitrogen removal and unstable biomass retention.

Objectives

A novel multistage A/O biofilm reactor was developed to improve the nitrogen removal from low COD wastewater in this study.

Methods

Polyurethane carriers with domesticated nitrification biofilm and denitrification biofilm were filled respectively in bench-scale reactor as multistage A/O mode to optimize the utilization of limited organic carbon. Key parameters were investigated to obtain optimal performance, and high-throughput sequencing technology was adopted to reveal the microbial community structure in biofilm process.

Conclusions

The results show that the optimal values of key parameters including nitrification liquid reflux ratio, hydraulic retention time and influent flow distribution ratio were 200%, 8 h and 2:1, respectively. Best ammonium and total nitrogen removal efficiency of multistage A/O biofilm process treating low COD wastewater could respectively reach 99% and 40%, while the effluent ammonium and total nitrogen were only 0.1 mg/L and 8 mg/L. Microbial community analysis in multistage A/O biofilm reactor showed that *Nitrosomonadaceae_uncultured* and *Nitrospira* were dominant responsible genera in nitrification biofilm, while genera with nitrate reduction ability including *Thauera*, *Flavobacterium* and *Pseudomonas* were dominant in denitrification. Functional microbial consortia in domesticated biofilm could steadily colonize and reproduce in the process along with a predominant nitrogen removal performance. Multistage A/O biofilm process shows promising performance for low COD wastewater treatment, which provides a choice for further application in practical conditions.

EXPRESSION OF THE PHOSPHODIESTERASE BIFA FACILITATING SWIMMING MOTILITY IS PARTLY CONTROLLED BY FLIA IN PSEUDOMONAS PUTIDA KT2440

W. Chen[1], *H. Qiaoyun*[1]
[1]*Huazhong Agricultural University, State Key Laboratory of Agricultural Microbiology, Wuhan, China*

Backgrounds

Flagella-mediated motility is an important capability of many bacteria to survive in nutrient-depleted and harsh environments. Decreasing the intracellular cyclic di-GMP (c-di-GMP) level by overexpression of phosphodiesterase enzyme BifA promotes flagellar-mediated motility and induces a planktonic lifestyle in *Pseudomonas* species. The mechanism that regulates the expression of *bifA* gene was poorly studied.

Objectives

The flagellar sigma factor, FliA control numerous genes other than those involved in flagellar biogenesis. The transcription of *bifA* in a *P. putida fliA* mutant decreased approximately two fold (Rodríguez-Herva *et al.*, 2010). Therefore, we hypothesized that the expression of BifA was putatively directly regulated by FilA and FliA possessed an ability to modulate intracellular c-di-GMP level via regulating BifA expression in *P. putida*.

Methods

Swimming motility assay, biofilm formation analysis and quantification of intracellular c-di-GMP were carried out to test the hypothesis.

Conclusions

The expression of BifA was partly controlled by FliA (σ^{28}) in *P. putida* KT2440. FliA deletion led to about twofold decrease in transcription of *bifA*. 5' race assay revealed two transcription start points in *bifA* promoter region, with the putative σ^{70} and σ^{28} promoter sequences upstream, respectively. FliA overexpression decreased the intracellular c-di-GMP level in a BifA dependent way, suggesting that FliA could modulate intracellular c-di-GMP level and BifA function was required for the modulation. Besides, FliA overexpression enhanced swimming ability of wild type strain, while made no difference to the *bifA* mutant. Our results suggest that FliA acts as a negative regulator to modulate c-di-GMP level via controlling transcription of *bifA* to facilitate swimming motility.

POPULATIONS DYNAMICS AND TRANSCRIPTOMIC RESPONSE OF PSEUDOMONAS AERUGINOSA TOWARDS ANTIBIOTICS IN 19 SPECIES PLANKTONIC AND BIOFILM MICROBIAL COMMUNITIES

Y.Y. Cheng[1], J.K.H. Yam[1], Z.J. Seng[1], L. Yang[1]
[1]Singapore Centre for Environmental Life Sciences Engineering SCELSE,
Singapore Centre for Environmental Life Sciences Engineering SCELSE, Singapore, Singapore

Backgrounds

Pseudomonas aeruginosa is an opportunistic pathogen responsible for a wide range of human and animal infections. *P. aeruginosa* is notorious for its antibiotic resistance and previous research has revealed several important mechanisms of this, including the activities of efflux pumps and biofilm formation. However, as a metabolically versatile bacterium, *P. aeruginosa* is able to adapt to various environments and often lives together with other microbial species. It remains largely unknown how *P. aeruginosa* adapt to antibiotic stress in a mixed-species community.

Objectives

To investigated the population dynamics and global stress response of *P. aeruginosa* towards tobramycin and colistin in 19 species planktonic and biofilm microbial communities.

Methods

We found that *P. aeruginosa* is able to gain fitness over other species in biofilm community while not in planktonic community, independent of the presence of antibiotics. RNA-seq based transcriptomic analysis showed that biofilm *P. aeruginosa* cells strongly induced the expression of quorum sensing regulated genes and stress response genes compared to planktonic *P. aeruginosa* cells in the 19 species communities without the presence of antibiotics.

Conclusions

Our study suggests that *P. aeruginosa* possess competitive advantage relative to other microbial species especially in biofilm mode of growth, which might lead to increase in its virulence and antibiotic resistance.

BOTTLENOSE DOLPHINS AND KILLER WHALES HARBOR A UNIQUE SKIN MICROBIOME THAT VARIES AMONG INDIVIDUALS

M. Chiarello[1], T. Bouvier[2], S. Villeger[2], C. Bouvier[2], J.C. Auguet[2]
[1]Université de Montpellier, UMR9190 MARBEC, Montpellier, France
[2]CNRS, UMR9190 MARBEC, Montpellier, France

Backgrounds

Marine animals host diverse and species-specific microbial communities on their skin that could play a major role for their health. However, most inventories of marine animals skin microbiomes have focused on corals and fishes, while the microbiome of cetaceans remains overlooked.

Objectives

Few studies have focused on wild or semi-captive cetaceans, making difficult to distinct intrinsic inter- and/or intraspecific variability in skin microbiomes from environmental effects. Assessing inter- and intraspecific variability of cetaceans skin microbiome in controlled conditions is also needed to better understand the differences with skin microbiome of other marine vertebrates and terrestrial mammals.

Methods

Here, using high-throughput sequencing, we assessed the skin microbiome of 8 individuals of two emblematic species, the bottlenose dolphin (*Tursiops truncatus*) and the killer whale (*Orcinus orca*), housed in captivity in controlled conditions (Marineland park, Antibes, France).

Conclusions

Using a set of complementary alpha- and beta-diversity indices, we show that *(i)* cetacean skin microbiome is distinct from the surrounding planktonic communities, *(ii)* the 2 cetacean species host different skin microbiomes, and that *(iii)* inter-individual variability of the skin microbiome was higher than intra-individual variability (*i.e.* between body parts), within each species. The predominant microbial clades on both species were *Gamma*- and *Alpha-proteobacteria*, *Actinobacteria* and *Firmicutes.* However, *Firmicutes*, and especially *Staphylococci*, were six times more abundant on dolphin skin than on killer whale skin.

Overall, the skin microbiome of those two Odontoceti cetaceans was more similar to that of the Mysticeti humpback whale than to microbiomes of fishes or terrestrial mammals.

Environmental Microbiology/Microbial Ecology /Microbial Communities

SOIL- AND PLANT-ASSOCIATED MICROBIAL COMMUNITIES AS DRIVERS FOR THE DECOMPOSITION OF MAIZE RESIDUES IN AN AGRICULTURAL SOIL

A. Chiba[1,2], *M. Schloter*[2], *S. Schulz*[2], *Y. Uchida*[1]
[1]*Hokkaido University, Graduate School of Agriculture, Sapporo, Japan*
[2]*Research Unit Comparative Microbiome Analysis, Department of Environmental Sciences, Neuherberg, Germany*

Backgrounds

Decomposition of plant residues is an important process in agricultural soils. The degradation process is strongly driven by microbes colonizing on plant surfaces as well as soil microbes. However, the interaction among microbiomes derived from soil and plants in relation to residue decomposition is not clearly understood.

Objectives

We evaluated the role of microbes from soil and plants during the degradation process of maize leaves by manipulating their diversities. We postulated that initial degradation processes are unaffected by the diversity of soil and plant microbiomes, however at later stages of litter degradation manipulated diversity will strongly impact the degradation process.

Methods

We prepared three soils, namely “original soil”, “inoculated soil” and “autoclaved soil”. The inoculated soil was an autoclaved soil with microbial cells extracted from the original soil, aiming to manipulate soil microbial diversities. We incorporated litter bags with fresh/sterile maize leaves into these soils. During 6 weeks incubation, the weight of the litter bags was measured. Soil microbial DNA was extracted from the soils and the litter, used for 16S rRNA gene quantification and community analyses.

Conclusions

As expected, the reduction of soil microbial diversity led to a breakdown of the litter degradation. This effect was more severe if sterile litter was added to soils with reduced diversity. In contrast, the degradation rate of sterile litter material applied to non-treated soils was comparable to systems where neither litter nor soils had been sterilized. In summary, the reduction of soil diversity reduced litter degradation rates, independent from the type of litter material.

BIODEGRADATION OF 2,4,6-TRINITROTOLUENE BY CITROBACTER SP. YC4 AND EVALUATION OF ITS CYTO-TOXICOLOGICAL EFFECTS

C.C. Chien[1], S.F. Wei[1], C. Ma[1]
[1]Yuan Ze University, Graduate School of Biotechnology and Bioengineering, Taoyuan, Taiwan R.O.C.

Backgrounds

The compound 2,4,6-trinitrotoluene (TNT) is a secondary explosive widely used for both military and civil purposes around the world. TNT is highly toxic and carcinogenic; therefore, the control of TNT contamination and its remediation is a critical environmental issue. Numerous studies have reported different remediation techniques for TNT-contaminated environments, including natural attenuation, physical or chemical processes, and biological remediation. Among them, bioremediation of TNT by microbial degradation is a very promising technique.

Objectives

The biodegradation products of TNT were evaluated for their cytotoxicity effects. *Citrobacter* sp. YC4 is able to grow in the medium with TNT as sole source of nitrogen. Resting cells and cell extracts of strain YC4 were used to study their ability for TNT biodegradation.

Methods

Cells of strain YC4 were grown in different media and examined for TNT degradation. The degradation products were evaluated for their cytotoxicity effects by WST-1-based cell cytotoxicity assay and comet assay.

Conclusions

Cells grown in the TNT media as sole nitrogen source was able to rapidly transform the compound, in contrast to cells grown in LB medium. The concentration of TNT was decreased from 100 ppm to 0 ppm within 10 hours in the solution containing TNT mixed with TNT-grown cells. Cytotoxicity of solution containing TNT was also decreased after incubated with TNT-grown cells.

Environmental Microbiology/Microbial Ecology /Microbial Communities

IDENTIFICATION AND CLONING OF ECTOINE BIOSYNTHESIS GENES OF AN INDIGENOUS MODERATE HALOPHILE BACTERIUM HALOMONAS SP. ISOLATE

C.C. Chien[1], *C.K. Chang*[1]
[1]*Yuan Ze University, Graduate School of Biotechnology and Bioengineering, Taoyuan, Taiwan R.O.C.*

Backgrounds

Ectoine (1,4,5,6-tetrahydro-2-methyl-4-pyrimidine carboxylic acid), an osmotic pressure compatible solute which serves as a protective substance helping organisms to counteract the external osmotic pressure, is one of the most commonly found osmolytes in nature. Ectoine-producing microorganisms are widely distributed in hyper-saline environments. Ectoine is currently used in biotechnology and cosmetics such as active ingredient in skin care and sun protection products.

Objectives

The aim of the present study was to isolate and characterize ectoine producing microorganisms from marine environment. The genes involved in the ectoine biosynthesis pathway were also studied.

Methods

Indigenous moderate halophile bacterium was isolated from marine sediments. Ectoine production by the isolate was evaluated with another three authentic *Halomonas* spp. (*Halomonas salina* BCRC 17875^T, *Halomonas variabilis* BCRC 17786^T and *Halomonas venusta* BCRC 17787^T) obtained from culture collection center as reference strains. The *ectABC* gene cluster was amplified by PCR for subsequently cloning and expression.

Conclusions

Halomonas sp. MT was isolated and identified according to its 16S rRNA gene sequence determination. The bacterium was able to produce significant amount of ectoine in the presence of osmotic pressure. Genes involved in ectoine biosynthesis (i.e. *ectABC*) in *Halomonas* sp. MT were amplified by PCR. The amplicon of entire *ectABC* gene cluster (ca. 3 kb) was cloned and sequenced. Heterologous expression of these proteins will be carried out in *Escherichia coli*. Salt tolerance and ectoine production by the recombinant *E. coli* will also be examined in this study.

ANALYSIS OF DORMANT CELL DYNAMICS WITHIN PSEUDOMONAS AERUGINOSA BIOFILM

K. Chihara[1], *S. Matsumoto*[2], *S. Miyagawa*[1], *S. Tsuneda*[1]
[1]*Waseda University, Life Science and Medical Bioscience, Shinjuku-ku, Japan*
[2]*Nagoya University, Medical, Nagoya, Japan*

Backgrounds

Existence of dormant cells within biofilms has been indicated as one of factors in chronic infections. Dormant cell, which suppresses cell division and is tolerant to antibiotics, is phenotypic variant of growing cell. To better understand dormant cell dynamics within biofilms, we constructed 3D Individual-based modeling biofilm simulator and predicted dormant cell formation against environmental stresses such as nutrient or oxygen depletion.

Objectives

In this study, a novel dormant cell detection system of *Pseudomonas aeruginosa* PAO1 was constructed. Our objective is to elucidate dormant cell dynamics within growing biofilms by comparing experimental results with simulation results.

Methods

To distinguish dormant cells from growing cells, CFP and YFP were fused at bacterial cytoskeleton FtsZ in PAO1 because FtsZ polymerizes at the middle of the cell during division. Using the constructed dormant cell marker strain, colony biofilm was formed and dormant cells localization was characterized with or without antibiotics.

Conclusions

When the biofilm thickness was under 30 μm, dormant cells localized at the top of the colony biofilm. In contrast, when that thickness was over 30 μm, they localized at the bottom of the colony biofilm. Expectedly, dormant cells survived within biofilm in spite of treatment by ofloxacin. These results suggest that dormant cell localization shifts depending on biofilm thickness with different nutrient and oxygen concentration profiles. We expected dividing cells at the bottom of early biofilm consume nutrient, and thus cells at the top which experienced nutrient depletion turned into dormant state, whereas dormant cells at the bottom of mature biofilm experienced oxygen limitation.

COMMUNAL METABOLISM OF METHANE AND THE RARE EARTH ELEMENT SWITCH

L. Chistoserdova[1], Z. Yu[2], M. Hernandez[3], S. Krause[2], J. Matsen[2], D. Beck[2], M. Lidstrom[2]
[1], SEATTLE, USA
[2]University of Washington, Chemical Engineering, Seattle, USA
[3]Institute of Ecology, Ecology, Xalapa, Mexico

Backgrounds

Metabolism of methane, a major contributor to climate change, is an important part of biogeochemical cycling of carbon. Methanotrophs consume methane for energy and carbon. While methanotrophy has been studied for the past hundred years as a metabolic feature of individual pure cultures, a concept of communal function in methanotrophy has recently emerged.

Objectives

We are investigating the mechanistic details of how and why methanotrophs share carbon with other species, and whether and what they gain in return.

Methods

We manipulated complex natural communities from lake sediment using methane as a sole source of carbon, to determine species persisting in methane-consuming communities (the top-down approach). We built synthetic communities of pure cultures of methanotrophs and non-methanotrophs and tested their behavior under a variety of conditions (the bottom-up approach). We sequenced multiple (meta)genomes and (meta)transcriptomes to gain insights into the genomic potentials and gene expression patterns.

Conclusions

Through microcosm manipulation and metagenomics we identified as key species active in methane consumption bacteria of the family *Methylococcaceae*. As the primary and most abundant satellite types we identified non-methanotrophic methylotrophs of the family *Methylophilaceae*. Two other persistent types were identified as members of Burkholderiales and Flavobacteriales. Through manipulation of synthetic communities followed by metatranscriptomics we identified at least one metabolic node for community cross-talk, two alternative methanol dehydrogenases, one requiring calcium, another requiring rare earth elements (REE), one of the first demonstrations of a biological function for REE. Methanol is thus a carbon compound the methanotrophs share with other community members, regulated by the REE switch.

MICROALGAL DIVERSITY FOSTERS STABLE BIOMASS PRODUCTIVITY IN OPEN PONDS TREATING WASTEWATER

D.H. Cho[1], R. Ramanan[2], H.S. Kim[1]
[1]Korea Research Institute of Bioscience and 6 Biotechnology KRIBB, Cell Factory Research Center, Daejeon, Republic of Korea
[2]School of Earth Science Systems- Central 21 University of Kerala, Department of Environmental Science, Kasaragod District, India

Backgrounds

It is established that biodiversity determines productivity of natural ecosystems globally. We have proved that abiotic factors influenced biomass productivity in artificial ecosystems i.e. high rate algal ponds (HRAPs), previously.

Objectives

The present study demonstrates that biotic factors, particularly microalgal diversity, play an essential role in maintaining stable biomass productivity in HRAP treating municipal wastewater by mutualistic adaptation to environmental factors.

Methods

Microalgal diversity, wastewater characteristics, treatment efficiency and several environmental and meterological factors was documented for two years. Multivariate statistical analyses reveal that microalgae in uncontrolled HRAPs adapt to adverse environmental conditions by fostering diversity.

Conclusions

Subsequently, five dominant microalgal strains by biovolume were isolated, enriched, and optimum conditions for high biomass productivity were ascertained. These laboratory experiments revealed that different microalgal strains dominate in different conditions and a consortium of these diverse taxa help in sustaining the algae community from environmental and predatory pressures. Diversity, niche or seasonal partitioning and mutualistic growth are pertinent in microalgal cultivation or wastewater treatment. Therefore, enrichment of selective species would deprive the collective adaptive ability of the consortium and encourage system vulnerability especially in wastewater treatment.

COMPARATIVE GENOME ANALYSIS OF SUBTERCOLA BOREUS, AN ACTINOBACTERIUM RETRIEVED FROM ANTARCTIC ROCKS, SOIL AND FRESHWATER

C. Yong-Joon[1], C. Ahnna[1], K. Ok-Sun[1], L. Jong-Ik[1]
[1]Korea Polar Research Institute, Unit of Antarctic K-route Expedition, Incheon, Republic of Korea

Backgrounds

The actinobacterium Subtercola boreus is psychrophilic species capable of growth at temperatures down to -2 ºC with an optimum at 15-17 ºC. This strain was first discovered in permanently cold groundwater but it was also found in several places at the Antarctica including rocks, terrestrial soil and freshwater.

Objectives

Here, we report the fully assembled genome sequence of S. boreus K300 to find out how this psychrophile can adapt to extreme environments. And the genomic structure and gene content of the type and 5 strains of this psychrophilic bacteria isolated from various Antarctic environments were analyzed and compared.

Methods

The type strain genome sequencing was completed by using hybrid assembly strategy with PacBio P6-C4 20 kb library and Illumina 250 bp paired-end library. Other strains were sequenced by Illumina technology only.

Conclusions

The genome sequence of the S. boreus type strain and the comparative analyses with other Subtercola strains provided a better understanding of psychrophilic adaptation and growth within different environments in this genus.

COMPLETE GENOME SEQUENCE OF SPHINGOBACTERIAL STRAIN SH-48, A PROTEORHODOPSIN-CONTAINING BACTERIUM ISOLATED FROM FRESHWATER IN KOREA

A. Choi[1], K. Baek[2], E.J. Chung[1], G.G. Choi[1]
[1]Nakdonggang National Institute of Biological Resources, Freshwater Bioresources Cullture Research, Sangju-si, Republic of Korea
[2]Nakdonggang National Institute of Biological Resources, Freshwater Bioresources Research, Sangju-si, Republic of Korea

Backgrounds

Proteorhodopsin (PR) was first discovered 10 years ago in uncultivated marine gammaproteobacteria of SAR 86 group. PR is a retinal-binding membrane protein belong to the largest family of microbial rhodopsins. PR is widely distributed in the oceanic environment and freshwater, but no bacteria with PRs have been isolated from freshwater so far.

Objectives

The main aim of the research was to analyze the first complete genome sequence of SH-48.

Methods

Genomic DNA was extracted using a DNeasy blood and tissue kit. Genome sequencing was performed using the PacBio RS II SMRT sequencing technology with a 20-kb insert SMRTbell library constructed. The bacterial genome was assembled *de novo* into one contig, with an average genome coverage of 114.78×, using the PacBio SMRT Portal (2.3.0) and the hierarchical genome assembly process. The data was then submitted to the Rapid Annotation using Subsystem Technology (RAST) server and the National Center for Biotechnology Information genome sequence database. Potential coding sequences were searched for using the Basic Local Alignment Search Tool (BLAST) against the Pfam and COG databases.

Conclusions

Strain SH-48 was isolated from the freshwater stream in Korea using dilution-to-extinction culturing. Phylogenetic analysis based on 16S rRNA gene sequences showed that strain SH-48 formed a distinct phyletic clade and was most closely related to species of the genus *Mucilaginibacter* (81.4 to 93.7%) of the Sphingobacteriia among the validly published species. Here, we present the first complete genome sequence of this strain, which consists of 5,650,162 bp with 35.4 GC content. The genome of strain SH-48 encodes many hydrolytic enzymes for utilizing mainly polysaccharides. The genome also revealed the presence of a proteorhodopsin-encoding sequence together with its retinal-producing pathway. This research provides a genetic basis for better understanding of Sphingobacteriia, as well as insights into the strategies adapted by a rhodopsin-containing photoheterotroph to thrive in the freshwater environment.

THE ASSOCIATION BETWEEN GUT MICROBIOME AND GENE EXPRESSION ON MENOPAUSE MOUSE MODEL

S. Choi[1], S.K. Shin[1], H. Yi[1,2]
[1]Korea University, BK21PLUS Program in Embodiment: Health-Society Interaction. Department of Public Health Sciences. Graduate School, Seoul, Republic of Korea
[2]Korea University, School of Biosystem and Biomedical Science, Seoul, Republic of Korea

Backgrounds

In the period of menopausal transition, the imbalance of estrogen causes obesity. The decreased energy expenditure in postmenopausal period may be linked with efficient energy-generating bacterial strains caused by the low level estrogen environment, but has not been examined.

Objectives

We aimed to compare the composition of intestinal bacteria and the accompanying change of host gene expression during menopausal transition.

Methods

Mouse with ovariectomy-operated(OVX) and sham-operated(SHAM) were prepared and the half of them were provided with high-fat diet. The microbiome in cecum and large intestine was analyzed using 16S rRNA gene sequencing and the gene expression of liver was measured using microarray. The correlation between bacterial abundance and gene expressions was calculated and statistically significant pairs were selected to create a network.

Conclusions

The results demonstrated that estrogen-level plays important roles in microbiota maintenance. The gut microbiome profile of ovariectomy mouse was very similar to control mouse with high-fat diet. The correlation analysis between 652 differentially expressed genes and 137 abundant bacterial species revealed 1160 statistically significant inter-kingdom interactions. The detailed meaning of the individual link in the network is under analyses to determine the metabolic pathway critically determined by the presence or absence of specific bacterial taxa. This study supported by the Cooperative Research Program for Agricultural Science & Technology Development (Project No. PJ010975) and by the National Research Council of Science & Technology (NST) grant (No. CRC-16-01-KRICT) by the Korean government.

EFFECT OF DIETARY PROCESSED-SULFUR ON GROWTH PERFORMANCE AND GUT MICROBIOTA IN CHICKENS

Y.J. Choi[1], S.S. Lee[1], C.D. Jeong[1], S.K. Kim[2], K.J. Yi[2], J.H. Kim[2]
[1]Sunchon National University, Animal Science and Technology, Suncheon, Republic of Korea
[2]Konkuk University, Department of Animal Science and Technology, Seoul, Republic of Korea

Backgrounds

Sulfur is essential for all animals because S-containing compounds, such as amino acids, hormones, B-vitamins, and co-enzymes, are required for normal metabolic, structural, and regulatory functions of all living organisms. Sulfur compound is highly toxic when directly ingested and causes side effects and thus often physical or chemical methods are used to eliminate harmful ingredients. Nevertheless, insufficient elimination of toxins leads to diseases in animals and thus special care is required.

Objectives

There is limited information about the effect of processed sulfur supplementation on the growth performance, especially correlation of gut microbiota. This study was carried out to investigate the dietary processed sulfur supplementation on the growth performance and gut microbial community in broiler.

Methods

A total of 180 day old Ross broiler chicken were used to investigate the effects of processed sulfur on growth performance and gut microbial community. The two dietary treatments, each with 3 replicates were basal diet and base diet plus the 0.2% (500 ppm) processed sulfur. Bacterial communities in the different regions of gastrointestinal tract of broiler chickens were analyzed by pyrosequencing approach to understand microbial composition and diversity. The DNA samples extracted from 4 different regions along the GIT were subjected to bacterial community analysis by pyrosequencing of the V1-V3 region of 16S rRNA gene.

Conclusions

Providing of 500 ppm sulfur decreased mortality rate and increased feed intake in finisher stage, resulting in weight gain and improving feed conversion rate to positively affect productivity enhancement. At the phylum level, *Firmicutes* was predominant in crop, gizzard and colon with control and treatment. Processed sulfur diet showed lower microbial diversity and quantity in GIT excluding crop.

EFFECTS OF PROBIOTICS ADDITION IN FATTENING PIGS FEED ON ODOR REDUCTION AND MICROBIAL COMMUNITY

Y.J. Choi[1], A. Biswas[1], S.S. Lee[1], C.D. Jeong[1], M.R. Lee[1]
[1]Sunchon National University, Animal Science and Technology, Suncheon, Republic of Korea

Backgrounds

Probiotics that have been widely marketed in animal industry and used as a replacer for antibiotic growth promoter It is known that probiotic are effective as an environment improvement alternative

Objectives

This study was conducted to know the effect of *Pediococcus acidilactici*, *Bacillus amyloliquefaciens*, and dry yeast on odor reduction potentiality and microbial community of fattening pig

Methods

Fermentation was carried out for 5 days at 37° C by solid-state fermentation method after inoculating each 5% of *Pediococcus acidilactici* DSM 20284^T (3.1x10^8 cfu/mL), *Bacillus amyloliquefaciens sub. plantarum* F2842^T (2.9x10^8 cfu/mL) and dried yeast (1.0x10^8 cfu/g) in sterilized wheat bran. A total of 176 fattening period pigs were used to investigate the effects of probiotic on odor reduction and microbial community. The two dietary treatments, one was control and other treatment was 0.2% fermented wheat bran with control. A total of 38 specimens, including Hydrogen Sulfide, ammonia, Volatile fatty acid (VFA), Indole and Skatole, were analyzed by HPLC and GC/MS at 30 days and bacterial community analysis were done by pyrosequencing

Conclusions

Results of this study revealed that the amount of Hydrogen Sulfide was 1,509 ppb in treatment and 1,950 ppb in control after 30th day. The amount of methyl mercaptan and Skatole at 30th day in treatment group were 5.85 and 0.06 ppb, respectively, compared to 9.05 and 0.08 ppb in the control group, respectively. At the phylum level Firmicutes was predominant in control and treatment. However, abundance of Firmicutes was higher in treatment than control. On the other hand, microbial diversity was higher in control than treatment.

SEASONAL EFFECT IN ABUNDANCE AND PROPERTIES OF PISTACIA TEREBINTHUS-ASSOCIATED COMMUNITIES FROM DRY AREAS

I. Cholakova[1], S. Thijs[1], E. Paredis[1], N. Weyens[1], L. Nacheva[2], A. Vassilev[3], J. Vangronsveld[1]
[1]University of Hasselt, Centre for Environmental Sciences, Diepenbeek, Belgium
[2]Fruit Growing Institute, Department of Propagation- Orchard Management and Biotechnology, Plovdiv, Bulgaria
[3]Agricultural University of Plovdiv, Department of Plant Physiology and Biochemistry, Plovdiv, Bulgaria

Backgrounds

Rhizosphere soil bacteria are beneficial for plants in an environment exposed to abiotic stress such as water shortage. Plant-associated bacteria can promote plant growth and assist their host to cope with osmotic pressures. However, environmental conditions might affect bacterial communities in their composition and abundance, and this may change their functional potential. In this context, it would be interesting to unravel the influence of seasons on the rhizosphere bacterial communities of trees in arid regions.

Objectives

The aim of this study was to investigate whether the abundance and functional properties of rhizosphere bacteria from *Pistacia* trees differ between a more humid spring season and a dry autumn season.

Methods

Soil samples from three different sites in an arid region of Bulgaria were collected to define soil properties and bacterial community composition. *Pistacia terebinthus*-associated cultivable bacteria were isolated from rhizosphere soil samples in two seasons – spring and autumn 2014. Besides the cultivable fraction, isolation of total DNA was performed from soil samples and used for Automated Ribosomal Intergenic Spacer Analysis (ARISA) and shotgun metagenomics sequencing.

Conclusions

Overall, in spring and autumn, high numbers of plant growth promoting (PGP)-isolates colonize the rhizosphere of *Pistacia*, which can help the tree to withstand the harsh conditions. The dominance of certain 16S phylotypes was found to differ between the soils. The functional properties of the microbial communities will be compared between the two seasons using shotgun metagenomics data analyses.

EFFECT OF EARLY-LIFE FORAGING IN DEVELOPMENT OF PIGLETS

R. Choudhury[1], A. Middelkoop[2], W.J.J. Gerrits[3], B. Kemp[2], J.E. Bolhuis[2], M. Kleerebezem[1]
[1]Wageningen University & Research, Host Microbe Interactomics- Animal Sciences, Wageningen, The Netherlands
[2]Wageningen University & Research, Adaptation Physiology Group- Animal Sciences, Wageningen, The Netherlands
[3]Wageningen University & Research, Animal Nutrition Group- Animal Sciences, Wageningen, The Netherlands

Backgrounds

Early-life and weaning are associated with dynamic changes of the gut microbiome in pigs. Early-life microbiome development is driven by exogenous (e.g., diet and environment) and endogenous (host derived) factors, and importantly modulates host physiology, which can persist throughout life. In nature, piglets start to forage with the sow already a few days after birth.

Objectives

Here, we aim to determine the effect of early-life foraging (pre-weaning access to solid feed) on growth, development and behaviour of piglets, their gut microbiome composition, and intestinal physiology.

Methods

Piglets were followed from birth until 6 weeks of age, and various samples (rectal swabs, blood, saliva, etc.) were collected at multiple time points. Next to the sow's milk, the treatment group was provided with a customised fibre-rich early-foraging diet from 2 days after birth, whereas the control group was only drinking sow milk. Physiological and behavioural measurements were collected during the pre- and post-weaning period. During the same period rectal swabs were collected to investigate community structure of the intestinal microbiome by 16S rRNA gene analysis. Moreover, a subset of piglets was sacrificed at weaning (at 28 days of age) and intestinal samples were collected, allowing the differential analysis of histological and molecular parameters in the experimental versus the control group.

Conclusions

By integrative data analysis, the study intends to provide insight into the relationship of early-foraging with pigs' welfare, health, and development. This knowledge can lead to sustainable husbandry regimes that mimic natural conditions for the production of healthier and more resilient pigs.

MARINE MICROBIAL INTERACTIONS SHOWCASED THROUGH EXOPROTEOMES

J.A. Christie-Oleza[1]
[1]*University of Warwick, School of Life Sciences, Coventry, United Kingdom*

Backgrounds

Microbial phototroph-heterotroph interactions propel the engine that results in the biogeochemical cycling of individual elements and, hence, studying the molecular basis of these key interactions is crucial for the understanding of marine systems. Cellular proteomics is a reliable tool to analyse how living organisms adapt to varying conditions, but the extensive datasets that are generated are swamped by processes from the central metabolism that occur independently to the extracellular environment.

Objectives

Here I present the advantages of analysing the extracellular proteome for studying the molecular processes that take place during microbial interactions and how proteins targeting specific cellular compartments can sometimes be found in the extracellular milieu.

Methods

High-throughput proteomics was used to analyse the exoproteome of an extensive array of co-cultured marine heterotrophic and phototrophic organisms.

Conclusions

The secreted fraction of the encoded proteome had a much higher incidence of lineage-specific proteins than the cytosolic fraction and exported proteins are largely uncharacterized to date compared to proteins from the cytosolic fraction. This suggests that the genomic and functional diversity of these organisms lies largely in the diverse pool of novel functions these organisms export to/through their membranes playing a key role in community diversification, e.g. for niche partitioning or evading predation. Furthermore, exoproteomes show i) a large number of transport systems giving information on the nutrients that are generated/targeted by each microbe within the co-culture, ii) an interesting array of strain-specific exoproteins involved in motility, gene exchange and mutualistic or hostile interactions, and iii) uncharacterised exoenzymes that require further characterisation.

DETERMINATION OF CR(VI) IN WASTEWATER USING MICROBIAL FUEL CELL-BASED BIOSENSOR OPERATED WITH EXIGUOBACTERIUM SP. YC210 AT THE ANODE

C.Y. Chen[1], M.C. Hsieh[2], S.T. Lin[2], Y.C. Chung[2]
[1]Hsing Wu University, Department of Tourism and Leisure, New Taipei city, Taiwan R.O.C.
[2]China University of Science and Technology, Department of Biological Science and Technology, Taipei city, Taiwan R.O.C.

Backgrounds

Cr(VI) is extensively used in electroplating, resistant alloys and leather tanneries. It is a toxic, carcinogenic and mutagenic chemical. The currently analytical methods for the Cr(VI) determination include atomic absorption spectroscopy, inductively coupled plasma mass spectroscopy, ion chromatography, and their combination with chromatographic techniques. These techniques exhibit high accuracy and selectivity, but they are usually tedious and expensive.

Objectives

In this study, we would like to develop a biological method to determine Cr(VI) in wastewater. A facultatively anaerobic, halotolerant, and moderately thermophilic bacterium, *Exiguobacterium* sp. YC210 was isolated and inoculated in a microbial fuel cell (MFC) to evaluate its feasibility as a biosensor or an early warning device for Cr(VI) determination.

Methods

Effects of coexisting cation ions (Zn^{2+}, Fe^{3+}, Cu^{2+}, Ni^{2+}, Na^{+}, Cr^{3+}), anion ions (Cl^{-}, $SO_4^{=}$) and pH values on Cr(VI) determination using MFC-type biosensor were evaluated. Also, Cr(VI) concentrations in five types of real wastewaters were measured by the biosensor and through standard colorimetric method.

Conclusions

Two regression equations for the Cr(VI) concentration and voltage output of the MFC-type biosensor were established. One is determined to be $y = -19.6\,x + 397.2$ with Cr(VI) concentrations ranged from 0 to 4 mg/L. The other equation was determined to be $y = -10.7\,x + 155.5$ with Cr(VI) concentration ranged from 4 to 20 mg/L. Effects of coexisting cation ions (< 45 mg/L), Cl^{-} (< 15 mg/L), and $SO_4^{=}$ (< 20 mg/L) on the performance of MFC-type biosensor were insignificant (p>0.05). The *Exiguobacterium* sp. biosensor for Cr(VI) determination could be fallen into a wide range of pH values (4-10). Compared with Cr(VI) concentrations measured through colorimetric method, the designed biosensor measurements in wastewaters were accurate and had low deviations (-1.8% to 3.2%). Thus, the developed MFC-type biosensor has the potential to be used as an early warning device to protect ecosystems.

METAGENOMIC ANALYSIS OF SOIL BACTERIA RESILIENCE IN A NEMATICIDE TREATED SOIL

M. Colagiero[1], L.C. Rosso[1], I. Pentimone[1], S. Convertini[2], A. Ciancio[1]
[1]CNR - Istituto per la protezione sostenibile delle piante, DISBA, Bari, Italy
[2]Reagri srl, -, Massafra Taranto, Italy

Backgrounds

Several agricultural practices affect soil bacterial diversity. Few data are available on the effects of chemical treatments such as nematicides.

Objectives

We aimed at studying the changes induced on soil bacteria by nematicides, through metagenomic analyses.

Methods

Six treatments were applied on greenhouse tomato infested by the nematode *Meloidogyne incognita* (Carovigno, Italy). They included 1,3-dichloropropene (1,3-D at 150, 200 or 250 l/ha), fenamifos (42 l/ha) and DMDS (300 kg/ha), with untreated parcels as controls. Soil (three replicates) was sampled at transplant and one month later. RNA was extracted and retrotranscribed, sequencing the hypervariable V3-V4 regions of the 16S rRNA gene on a MiSeq SystemÔ (Illumina). Contigs were assembled with PandaSeq and analyses performed with Qiime and STAMP.

Conclusions

A total of 4405 OTUs was identified in the first sampling. The alpha-diversity did not significantly differ among samples, with the exception of fenamifos-treated soil with a lower chao-1 index. Proteobacteria, Actinobacteria, Plancomycetes, Chloroflexi and Acidobacteria were mostly represented, with classes: Alphaproteobacteria, Actinobacteria, Phycisphaerae, Solibacteres and Acidimicrobiia. The predominant order was Rickettsiales, with Actinomycetales, Rhodospirillales, Sphingomonadales and Rhizobiales. Principal coordinate analysis showed samples were aggregated, apart of two controls. 4113 OTUs were found in the second sampling. Alpha-diversity was lower for 1,3-D at 150 and 200 l/ha than in control, but not significantly different at highest dose. Chao-1 index, accounting for rare taxa, was significantly higher in samples treated with 1,3-D at 200 l/ha. Data suggest that nematicides did not reduce the diversity of soil bacteria, which showed a resilient response.

MICROALGAL PREMATURE SENESCENCE PROVOKED BY CHEMICAL STRESS

M. Esperanza[1], M. Seoane[1], C. Rioboo[1], C. Herrero[1], Á. Cid[1]
[1]Universidade da Coruña, Bioloxía Celular e Molecular, A Coruña, Spain

Backgrounds

Organisms live in a constant struggle to cope with damaging agents. The inevitable accumulation of damage leads to the deterioration of cell components and functions. When damage accumulates irreversibly, cells can permanently arrest the cell cycle or trigger cell death programs. Furthermore, heterogeneity within the environment leads to nutrient patchiness and nutrients become depleted leading to cell death. This phenomenon is analogous to cultures grown in closed systems under laboratory conditions.

Objectives

Potential senescence of *Chlamydomonas reinhardtii* cells, as a response to a sublethal concentration of the herbicide atrazine, was studied.

Methods

Several senescence-related parameters were monitored: viability, reactive oxygen species (ROS) production, caspase activity, morphology of nuclei and the presence of auto-phagosomes. RNA-Seq technique was applied to obtain detailed quantitative transcriptomic profiling of algal cells exposed or not to atrazine, looking for similarities in the regulation of transcription.

Conclusions

Cell viability remained above the 96% for all conditions, ROS levels increased in all cultures with respect to 24 h-control, as well as caspase activity, cells with auto-phagosomes and alterations in the nuclei morphology. RNA-Seq technique displayed 27, with well-known function, differentially expressed genes between control cultures at 96 h and atrazine exposed cultures at 24 h. Many cellular processes were affected, but the most significant changes were observed in genes implicated in cell cycle. Results indicate that the production of ROS caused by exposure to atrazine during 24 h induces oxidative damage, possibly leading to the observed premature senescence in microalgal cells.

ACUTE TOXICITY OF OMEPRAZOLE ON THE MICROALGA TETRASELMIS SUECICA

M. Seoane[1], M. Esperanza[1], C. Rioboo[1], C. Herrero[1], Á. Cid[1]
[1]Universidade da Coruña, Bioloxía Celular e Molecular, A Coruña, Spain

Backgrounds

Omeprazole (OMP) is one of the most commonly used drugs worldwide. It belongs to a group of pharmaceuticals called proton pump inhibitors that act by irreversibly blocking the terminal stage of gastric acid secretion, inhibiting the gastric proton pump (H+/K+ATPase). Therefore, OMP decreases the amount of acid produced in the stomach and it is used for the treatment of gastro-intestinal disorders. Although it is daily consumed in high quantities and is commonly detected in waters worldwide, it is a poorly studied compound and relatively little is known about its ecotoxicity.

Objectives

The aim of this study was to evaluate the potential acute toxicity of increasing concentrations of OMP (1.6 to 2.8 ng cell^{-1}) on the marine microalga *Tetraselmis suecica.*

Methods

Several cytotoxicity biomarkers were analysed by flow cytometry after 24 h of exposure, completing a 12:12 h light:dark cycle.

Conclusions

Results showed that OMP caused a decrease in growth and autofluorescence, swelling of the cells, intracellular acidification and hyperpolarization of cytoplasmic and mitochondrial membranes. In addition, large amounts of reactive oxygen species (ROS) were generated which resulted in a decrease in the percentage of the viable population. However, the viable population showed an increase in the metabolic activity as a response to the stress. In conclusion, OMP may trigger receptors in unicellular organisms that regulate the proton flux in the cytosol. It disturbs pH homeostasis and provokes an early accumulation of ROS that results in a rapid cell death in cells cultured with the highest concentration assayed.

ISOLATION OF PSYCHROTOLERANT YEAST STRAINS WITH POTENTIAL FOR BIODEGRADTION OF PHENOL AND GLYPHOSATE

H. Cieslinski[1], A. Terebieniec[1], N. Filipowicz[1]
[1]Gdansk University of Technology, Molecular Biotechnology and Microbiology, Gdansk, Poland

Backgrounds

Nowadays, at a time of industrial development, the environmental pollution increase rapidly. Part of the pollution is an effect of intensive farming and pesticide overuse. The most common used agrochemical is glyphosate (PMG) - the active ingredient of Roundup, which is consider as possibly carcinogenic.

Another important water and soil pollution, according to its influence on human health, is phenol. The main sources of this hazardous compound are chemical industry and coal conversion processes.

Biological methods of these pollutants treatment base on biodegradation by microorganisms which are able to utilize compounds as a source of carbon needed to growth (for phenol) or to utilize carbon, nitrogen or phosphorus (for PMG).

Objectives

Isolation of psychrotolerant yeast strains from soil and water samples and testing their ability to organic pollutants degradation.

Methods

Microorganisms were isolated form soil and water samples collected from agricultural, industrial or peat-bog areas from Poland. Pure cultures were grown on YPD agar with ampicillin and chloramphenicol in 18^{o}C.

For nitrogen/phosphorus assimilation tests, isolates were cultured in liquid Czapek Dox Medium (CDM) with PMG at 4 mM and 2 mM concentrations as a sole nitrogen and phosphorus source respectively. For carbon assimilation test, isolates were cultivated in MSM medium supplemented with phenol at 500 – 2000 mg/l concentration. All strains were cultivated under 18°C.

Conclusions

The studies revealed that psychrotolerant yeast strains isolated from water or soil samples are excellent candidates for effective biodegradation of phenol and PMG. Isolated strains can be potentially used in waste water or soil treatments in temperate climate.

THE INTERACTION BETWEEN ENDOPHYTES AND SUGARCANE RESULTS IN CHANGES ON NITROGEN METABOLISM AND, RHIZOSPHERIC AND ENDOPHYTIC BACTERIAL COMMUNITIES

R. Freitas-Iório[1], M. Dimitrov[2], M. Cipriano[3], S. Andrade[4], E. Kuramae[2], A. Silveira[3]
[1]Agronomic Institute, Soil and Environmental Resource, Campinas, Brazil
[2]Netherlands Institute of Ecology, Microbial Ecology, Wageningen, The Netherlands
[3]Agronomic Institute, Soils and Environmental Resources, Campinas, Brazil
[4]University of Campinas, Plant Physiology Department, Campinas, Brazil

Backgrounds

Some endophytic bacteria have been used in different crops worldwide as plant-growth promoting bacteria. Nevertheless, the effects of these bacteria in sugarcane plants are not completely clear.

Objectives

The main goal was to evaluate the effect of sugarcane inoculation with six endophytic isolates in regards to the plant nutritional state, some aspects of nitrogen metabolism and its influence on endophytic and rhizospheric bacterial communities.

Methods

The endophytic isolates (*Burkholderia caribensis* IAC/BECa-088, *B. tropical* IAC/BECa-135, *Kosakonia radicitans* IAC/BECa-090 and 095*, Herbaspirillum* sp. IAC/BECa-152 and *Pseudomonas fluorescens* IAC/BECa-141) were inoculated on sugarcane seedlings and the foliar free amino acids levels and polyamine profiles, SHR5, GS1 and GS2 genes transcription, shoot mineral nutrition and, endo and rhizospheric bacterial communities were determined.

Conclusions

Our data revealed that the inoculation of all isolates was able to improve plant growth. The isolates changed the level of foliar free amino acids and polyamine profiles reducing the concentration of citruline, putrecine, glycine, alanine, glutamate, glutamine, proline and aspartate. SHR5 transcript levels in sugarcane leaves were reduced in some treatments, suggesting a successful sugarcane association with the endophytic strain *K. radicitans* IAC/BECa-095 and *P. fluorescens* IAC/BECa-141. All isolates impacted endo and rhizospheric bacterial communities, increasing the abundance of some families such as *Xanthomonadaceae*, *Burkholderiaceae*, *Methylobacteriacceae*, *Rhizobiaceae* and *Microbateriaceae*. The isolate *P. fluorescens* IAC/BECa-141 promoted the highest benefits in terms of plant growth probably due to its effective interaction, through changes in nitrogen metabolism and on bacterial communities at the rhizosphere and endosphere compartments.

Environmental Microbiology/Microbial Ecology /Microbial Communities

OCCUPANCY, VENTILATION AND USE OF INDOOR ENVIRONMENTS DICTATE THE MAKEUP OF THEIR MICROBIAL INHABITANTS

C. Ge[1], S. Huang[1], M. Canales[1], E. Cloutman-Green[1], L. Ciric[1]
[1]UCL, Civil- Environmental & Geomatic Engineering, London, United Kingdom

Backgrounds

As we are spending more time indoors, air quality within buildings is becoming a concern. Ventilation is used to maintain thermal comfort and dilute contaminants such as carbon dioxide, particulate matter and biological contaminants including microbes. However, higher occupancy and more air-tight buildings are leading to worse indoor air quality.

Objectives

The main objectives of the study were to: 1) measure levels number of physical and biological contaminants in different spaces in a university building; 2) assess whether levels of contaminants were correlated to occupancy; 3) assess whether microbial contamination is closely correlated to levels of any of the physical contamination parameters; and 4) assess what microbial taxa are present depending on occupancy and activity.

Methods

Four spaces with different ventilation strategies (e.g. natural, mechanical) and which are utilised in different ways (e.g. classroom, lecture theatre, office) were investigated. Repeat measurements of the following parameters were collected: occupancy, temperature, relative humidity, size-resolved particulate matter, carbon dioxide concentration, colony counts on a non-selective agar and colony counts on an agar selecting for common human pathogens. The measures for all parameters were standardised and correlations were investigated using Pearson's correlation coefficient.

Conclusions

Results indicate that total microbial contamination is closely correlated to occupancy and that the presence of different taxa is influenced by the activity taking place in the space as well as the ventilation strategy. Within the mechanically ventilated spaces, a close correlation between colony counts from air and particulate matter sized between 2.5 and 5 μm.

Environmental Microbiology/Microbial Ecology /Microbial Communities

USING METAGENOME BASED GENOME RECONSTRUCTION TO UNDERSTAND BACTERIAL AND ARCHAEAL ASSEMBLAGES IN THE SOUTHERN OCEAN

C. Matthew[1], *S. Vikram*[1], *T. Makhalanyane*[1]
[1]*Center for Microbial Ecology and Genomics- University of Pretoria, Genetics, Pretoria, South Africa*

Backgrounds

Microbial communities (Bacteria and Archaea) are ubiquitous across ecosystems and regulate key biogeochemical cycles. Due, in part, to difficulties related to the cultivation of 99% of microbes in the laboratory, little is known regarding precise mechanisms that allow microbial guilds to fulfill their ecological roles. Culture-independent analyses allow us to bypass this 'cultivation bottle-neck', and generate vast sequence data-sets which offer crucial insights into microbial metabolic potential. The Southern Ocean (SO) accounts for 40% of all oceanic carbon cycling. Evidence suggests that microbes (predominantly Archaea) are significant mediators in cycling of carbon, nitrogen and sulphur through chemolithoautotrophic pathways.

Objectives

To better understand the physiological roles of Bacteria and Archaea, we aim to reconstruct microbial genomes from SO metagenomes

Methods

Shotgun metagenome sequences were generated from samples recovered from the SO. These sequences were trimmed and filtered to remove low quality reads and then assembled using SPAdes. BLASTp was performed on translated contigs to assess functional potential and diversity of the metagenomes. Contigs were binned using composition dependent and independent binning algorithms to attain the best initial bins.

Conclusions

The assembly of the 6 data-sets produced ~38,780 contigs per sample (≥500 bp) which were used to bin 31 bacterial and archaeal genomes. Of these, 13 showed above 40% completeness. The BLASTp analysis revealed dominance of *Proteobacteria* in all 6 data-sets with a higher relative abundance of *Halobacteria* (MG*III* Archaea). Our analysis suggests that contrast to other marine environments where *Cyanobacteria* drive key ecosystem processes, *Proteobacteria* are the major functional guilds in this marine environment

COLD-ACTIVE PROTEASE PRODUCING BACTERIAL STRAINS DERIVED FROM SALMO TRUTTA MACROSTIGMA

D.N. Colak[1], M. Kacagan[2], S. Canakci[2], A.O. Belduz[2]
[1]Giresun University- Vocational School of Dereli, Department of Forestry, Giresun, Turkey
[2]Karadeniz Technical University- Faculty of Science, Department of Biology, Trabzon, Turkey

Backgrounds

Proteolytic enzymes are ubiquitous in occurrence, being found in all living organisms, and are essential for cell growth and differentiation. 60-65% of the industrial enzymes are belong to the protease family and mostly used in detergent industry, leather tannig, waste treatment, pharmacy exc. With the high activity and stability of proteases at low temperatures, the costs of industrial applications could be decrease significantly.

Objectives

In this work, the bacterial flora of *Salmo trutta macrostigma* was screened for cold active protease activity and industrial utility.

Methods

S. trutta macrostigma strains were collected from a cold stream of Balıkırmagi plateau (Duzkoy/Trabzon). The gastric mill and the intestine extract of the fish was cultivated at 37°C for 2 days in LB medium for bacterial growth. Single colonies were selected, isolated and 16S rRNA analysed. Bacterial isolates were incubated in LB medium with 1% of skim milk at 4°C, 8°C, 15°C, 25°C, and 37°C respectively. Protease positive strains were determined. 1% of azocasein was used for further activity assays.

Conclusions

Nine of the strains isolated from fish intestine was protease positive. Five of them belongs to the genus *Flavobacterium* sp., and 4 of them to *Bacillus* sp. All of the strains had exhibited the protease activity at 20-40°C, except for *Flavobacterium* sp. MT3 which showed the otimum protease activity at 8°C.

In this work 9 protease positive bacterial strains were isolated from *Salmo trutta macrostigma*, one of them had cold-active (4-25°C) protease activity. The protese of *Flavobacterium* sp. MT3 will be characterized and analysed for industrial applications.

CRYPTOCOCCUS SPP. PRESENT IN THE LUNG CORE MICROBIOME

M.F. Colom[1], E. Rubio-Portillo[2], D. Orts[3], E. Llorca[3], E. Revelles[1], J. Antón[4]
[1]Universidad Miguel Hernández, Producción Vegetal y Microbiología, Sant Joan d'Alacant, Spain
[2]Universidad de Alicante, Fisiología- Genética y Microbiología, San Vicente del Raspeig, Spain
[3]Hospital General Universitario de Elda, Sección Neumología. Servicio de Medicina Interna, Elda, Spain
[4]University of Alicante, Fisiología- Genética y Microbiología, San Vicente del Raspeig, Spain

Backgrounds

The use of the highly-throughput sequencing-based studies have led to the detection of microorganisms colonizing the lower respiratory tract of healthy individuals. Most of these studies focus on the description of the bacterial community while the fungal microbiome remains basically unexplored.

Objectives

Here, we explore the hypothesis that *Cryptococcus spp* yeasts are present in the human lower airways and they may cause cryptococosis, when there is a decrease in the host defenses or a local microbiome disruption.

Methods

Thirteen Brochioalveolar Lavage samples (BAL) were obtained by bronchoscopy in the General Universitary Hospital in Elda (Alicante. Spain). The samples were processed for DNA extraction (and for cultures and other cellular studies). The fungal Internal Transcribed Spacer (ITS) of the extracted DNA, was amplified by conventional PCR. The product was purified and a second seminested-PCR was performed with primers ITS4-86. The product was sequenced by the *illumina system*. Results of the massive sequencing were analyzed by QIIME 1.8.0 (Quantitative Insights Into Microbial Ecology) and the UNITE (User-friendly Nordic ITS Ectomycorrhiza) database was used for taxonomic assignments of sequences by BLAST.

Conclusions

Cryptococcus spp is a common member in the lower respiratory tract of all samples (100%) with a high prevalence of *C. neoformans* species. BAL samples showed to have more than 50 fungal species belonging to both phyla (*Basidiomycota* and *Ascomycota*) among which *Aspergillus* and *Candida* species were also detected.
This is a first evidence of the prevalence of *Cryptococcus* in the respiratory tract of the normal population.

DETERMINATION OF THE MICROBIAL COMMUNITY IN THE BROILER CHICKEN SOIL

A. Comte[1], *M. Diarra*[2], *T. Dumonceaux*[1], *E. Topp*[3], *J. Town*[1]
[1]*Agriculture-Agri-food Canada, Bioproduct and processing, Saskatoon, Canada*
[2]*Agriculture-Agri-food Canada, Guelph Research and Development Centre, Guelph, Canada*
[3]*Agriculture-Agri-food Canada, London Research and Development Centre, London- Ontario, Canada*

Background:

Enterobacteria are found in large numbers in poultry litter. Some of these bacteria could be potentially pathogenic and/or resistant to antibiotics.

Objectives:

The objective was to study the evolution of bacterial community**,** and to quantify the dominant bacteria in soil fertilised with litter from broiler chickens fed with or without antimicrobial agents.

Methods:

An agricultural soil was amended with litter from 36-day-old broiler chickens fed with diets supplemented with the commonly used antimicrobials monensin, chlorotetracycline, narasin, or virginiamycin. Soil samples were collected during 8 months for genomic DNA extraction, which was used as template for *cpn60* universal target amplification. The amplicons were purified by gel and pooled for sequencing. Operational Taxonomic Unit (OTU) identification was based on watered BLAST results. Abundant OTU and antimicrobial resistance genes (ARG) were quantified in soil samples using droplet digital PCR.

Conclusion:

Soil fertilised with litter from antibiotic treated birds showed decreased diversity over time compared to soil receiving litter from the control birds. Moreover, non-amended soil presented less bacterial diversity compared to litter-amended soils. All litter-amended soils were dominated by a microorganism with a 99.6% *cpn60* nucleotide sequence identity to *Escherichia coli*. Using ddPCR, we have shown that *E.coli and all resistance genes* were abundant in all litter-amended soil samples, particularly in soils amended with litter from virginiamycin-fed birds, and *E.coli* and ARG decreased over time. This study shows that bacterial community of agricultural soils can be changed when poultry litter is used as fertilizer and that such soils can be a reservoir of antibiotic various resistant genes.

Abundant OTU and antimicrobial resistance genes (ARG) were quantified in soil samples using droplet digital PCR.

Conclusions

Soil fertilised with litter from antibiotic treated birds showed decreased diversity over time compared to soil receiving litter from the control birds. Moreover, non-amended soil presented less bacterial diversity compared to litter-amended soils. All litter-amended soils were dominated by a microorganism with a 99.6% *cpn60* nucleotide sequence identity to *Escherichia coli*. Using ddPCR, we have shown that *E.coli and all resistance genes* were abundant in all litter-amended soil samples, particularly in soils amended with litter from virginiamycin-fed birds, and *E.coli* and ARG decreased over time.

This study shows that bacterial community of agricultural soils can be changed when poultry litter is used as fertilizer and that such soils can be a reservoir of antibiotic various resistant genes.

SOIL MICROBIOTA RESPIRATION ANALYSIS USING NEW OXYGEN-SENSITIVE MICROPLATES

J.L. Copa-Patiño[1], Á. Criado Fornelio[1], C. Verdú Expósito[1], T. Martín Pérez[1], C. Moracho Vilrriales[1], I. Heredero Bermejo[1], J. Soliveri de Carranza[1], J. Pérez Serrano[1]
[1]Universidad de Alcalá, Biomedicina y Biotecnología, Alcalá de Henares, Spain

Backgrounds

Usually respiration of soil microorganisms is monitored by measuring CO_2 efflux. Most of the current laboratory techniques employed for such purpose are cumbersome and difficult to adapt to micro-method format.

Objectives

Evaluate a second generation of microplates containing a new fluorophore covalently bound to the bottom of the well for laboratory microorganism respiration studies in pure culture or in soil samples.

Methods

Second-generation oxygen-sensitive plates Oxoprobics® OSMs capable of performing a highly sensitive measurement of oxygen content were evaluated for monitoring respiration in the course of axenic culture of microorganisms. Subsequently, either soil samples or their water extracts were used. However, the water extract procedure was much more convenient and therefore used in further experiments to study the respiration in presence of different chemicals.
Soil respiration curves generally showed no lag phase, starting by an exponential oxygen consumption phase and reaching a plateau after 8-10 h of incubation at 25 °C. In presence of streptomycin and penicillin, no reduction in soil respiration was detected. Kanamycin plus neomycin, thrimetroprim and 5-fluorocytosine exhibited limited inhibitory effects. In contrast, some chemicals like copper sulphate, amphotericin B, Dodine and Fosetyl, noticeably reduced fluorescence readings. Finally, insecticides and soil amendments were neutral or increased respiration.

Conclusions

Oxygen-sensitive microplates are reliable, convenient, and yield quantitative results. Moreover, the system is relatively inexpensive and amenable to automation. However, results obtained using soil water extracts were different from those derived from undisturbed soil aggregates or slurries studied under field conditions.

SPREAD OF VARIABLE ARSENIC TOLERANCE GENES AMONG ENTEROCOCCUS SPP FROM DIFFERENT HOSTS, ENVIRONMENTS AND GEOGRAPHICAL REGIONS (<1906-2015)

J. Mourão[1], A. Rebelo[2,3], A.R. Freitas[1], T.M. Coque[4], A. Almeida[2], L. Peixe[1], P. Antunes[1,5], C. Novais[1]
[1]UCIBIO/REQUIMTE. Faculdade de Farmácia. Universidade do Porto, Ciências Biológicas, Porto, Portugal
[2]LAQV/REQUIMTE. Faculdade de Farmácia. Universidade do Porto, Ciências Químicas, Porto, Portugal
[3]CISA- Centro de Investigação em Saúde e Ambiente. Escola Superior de Saúde- Politécnico do Port o, ATC Saúde Ambiental, Porto, Portugal
[4]Hospital Universitario Ramón y Cajal, Servicio de Microbiología, Madrid, Spain
[5]Faculdade de Ciências da Nutrição e Alimentação. Universidade do Porto, FCNAUP, Porto, Portugal

Backgrounds

Successful bacteria accumulate different genetic features shaping their evolution and fitness to diverse environments/hosts. Arsenic-compounds are widespread in nature and possibly contribute to selection of particular strains.

Objectives

To evaluate the dispersion of *arsA* genes among *Enterococcus* from several origins, geographical regions and temporal timeframes.

Methods

arsA (coding for arsenical-pump-driving-ATPases) were searched in GenBank *Enterococcus* genomes and used to construct a maximum-likelihood phylogenetic-tree. A PCR scheme+sequencing was developed to detect *arsA* alleles from all phylogenetic subgroups identified among 315 isolates (Portugal; human/animal/environment/food; 1996-2012). Na_2HAsO_4 susceptibility was evaluated by agar dilution (0,25 to 128mM; n=102 isolates).

Conclusions

Two major phylogenetic groups (A;B) and 5 subgroups (55-70% nucleotide identity; AI-GenBank-EFU15692.1, AII-EEU88411.1, BI-EOT39237.1, BII-SET88118.1, BIII-EOH82892.1; n=42 isolates) were detected. In all phylogenetic-subgroups *arsA* was distributed in different sources and/or species: *arsA*_AI-n=28 (human/animal/environment/food/feed; *E.faecalis-24/E.faecium-3*; Europe/North-America/Australia/Africa/Asia; <1906-2015); *arsA*_AII-n=13 (human/animal/feed; *E.faecalis*-13*;* Europe/North-America/Australia/Africa/Asia; 1951-2012); *asrA*_BI-n=6 (*E.dispar-1/E.malodoratus-1/E.avium-1/Enterococcus-3*; human/food; North-America; <1991-unknown); *arsA*_BII-n=7 (human; *E.faecium-1*/*E.raffinosus-1/E.devriesei*-1/*Enterococcus*-4; Europe; unknown date); *arsA*_BIII-n=2 (animal; *E.villorum-1/E.hermanniensis-1*; Europe/North-America; 1981-unknown). *arsA*_AI+*arsA*_AII were often associated (n=13). PCR+sequencing identified *arsA*-AI/AII/BII in 8% (n=26/315) of Portuguese *Enterococcus* also from diverse sources and species. Variable Na_2HAsO_4 phenotypes were observed: *arsA*_AI+*arsA*_AII (MIC=32-64mM/n=6); *arsA*_AI (MIC=4-8mM/n=2; 32-128mM/n=4); *arsA*_AII (MIC=0,5-2mM/n=7); *arsA*_BII (MIC=4mM/n=1); no-genes (MIC=0,5-2mM/n=78, MIC=8-128mM/n=4 suggesting the occurrence of new genotypes). *arsA* have been spread in the last 100-years among *Enterococcus* from diverse origins. The A/B phylogenetic groups seem to reflect diverse evolutionary pathways, with A-group including *E.faecalis/E.faecium* and B-group mainly other species. These data potentially reflect diverse genetic exchanges in bacterial communities including *Enterococcus* and other *Firmicutes* also carrying these *arsA* variants.

ARSENIC TOLERANCE GENES ARE FREQUENT AMONG SALMONELLA PIG-ASSOCIATED CLINICALLY-RELEVANT CLONES

J. Mourão[1], A. Rebelo[2,3], J. Machado[4], A. Almeida[2], L. Peixe[1], C. Novais[1], P. Antunes[1,5]
[1]UCIBIO/REQUIMTE. Faculdade de Farmácia. Universidade do Porto, Ciências Biológicas, Porto, Portugal
[2]LAQV/REQUIMTE. Faculdade de Farmácia. Universidade do Porto, Ciências Químicas, Porto, Portugal
[3]CISA. Centro de Investigação em Saúde e Ambiente- Escola Superior de Saúde- Politécnico do Port o, Saúde Ambiental, Porto, Portugal
[4]Laboratório Nacional de Referência de Infeções Gastrintestinais. Instituto Nacional de Saúde Dr. Ric ardo Jorge, Doenças Infeciosas, Lisboa, Portugal
[5]Faculdade de Ciências da Nutrição e Alimentação. Universidade do Porto, FCNAUP, Porto, Portugal

Backgrounds

Arsenic environmental contamination by anthropogenic activities, including in animal-farming management (e.g. coccidiostatics/pesticides/waste), may represent a long-term selective pressure driving the selection of multidrug-resistant (MDR) emergent *Salmonella* serotypes/clones. Diverse arsenic tolerance (AsT) mechanisms were described, although dispersion and association with a tolerance phenotype remains unknown in *Salmonella*.

Objectives

To study the occurrence of genes coding for arsenical efflux pumps and their implications in tolerance phenotypes in diverse *Salmonella* serotypes/clones.

Methods

284 *Salmonella* isolates (2000-2016; humans/foods/animal/environment) from 58 serotypes (including the most frequent: Enteritidis/n=16; Typhimurium/n=48; 4,[5],12:i:-/n=65; Rissen/n=15) were selected based in PFGE-type and different profiles of antibiotic-resistance or metal-tolerance (Cu/Ag/Hg/Te) (PMID-27118781). Screening of *arsB* and *acr3* was performed by PCR/sequencing. $MIC_{Na2HAsO4}$ were determined in aerobic and anaerobic atmospheres by agar dilution method.

Conclusions

A high frequency of AsT genes was found (150/284-53%) involving diverse serotypes (30/58-52%): *arsB* (25%-n=70; 8 serotypes) or *acr3* (29%-n=82; 24 serotypes). The *arsB* was almost restricted to the emergent pig-associated MDR “European clone” of *S*.4,[5],12:i:- (n=36/36-100%) and *S*.Typhimurium (n=25/25-100%). The *acr3* was highly dispersed, including in two emerging pig-associated serotypes *S*.Rissen (n=15/15-100%) and *S*.Derby (n=8/8-100%). Phenotypic assays showed higher $MIC_{Na2HAsO4}$ in isolates carrying *arsB* (MIC_{50}=>128mM) or *acr3* (MIC_{50}=8mM) than those without these genes (MIC_{50}=2mM) in both aerobic/anaerobic conditions. AsT isolates also carried frequently (n=105/150-70%; “European clone” and Rissen plus 9 serotypes) copper, silver ± mercury, tellurium tolerance genes. Occurrence of AsT, particularly among emergent MDR and copper/silver tolerant pig-associated *Salmonella* clones circulating in Europe, might contribute for their adaptation to food-animal farm environments contaminated with diverse metals and oxygen levels.

MARINE BIOMONITORING: PREDICTING BIOTIC INDICES FROM EDNA METABARCODING DATA USING SUPERVISED MACHINE LEARNING

T. Cordier[1], P. Esling[2], F. Lejzerowicz[1], J. Pawlowski[1]
[1]University of Geneva, Department of genetics and evolution, Geneva, Switzerland
[2]University Pierre and Marie Curie, IRCAM, Paris, France

Backgrounds

Monitoring diversity of benthic organisms is an important tool for environmental impact assessment of anthropogenic activities in marine environment. Traditional benthic monitoring involves the morpho-taxonomic identification of thousands of manually sorted macrofaunal specimens, which is extremely time-consuming and taxonomic expertise demanding. High-throughput sequencing of environmental DNA (eDNA metabarcoding) offers an alternative to describe biological communities. However, an important fraction of eDNA sequences are new to science or belong to species of unknown ecology, which strongly limits their use for inferring biotic indices.

Objectives

To overcome these limitations, we investigated the possibility of using supervised machine learning (SML) algorithms to build predictive models from eDNA metabarcoding data targeting groups that are not commonly used for benthic monitoring.

Methods

We tested our approach on benthic foraminifera, a group of unicellular eukaryotes known to be sensitive to organic enrichment associated with marine aquaculture.

Conclusions

Our study conducted on five salmon farms in Norway show that SML tools applied to foraminiferal metabarcoding data allow the building of accurate predictive models, leading to similar biotic indices values than the ones derived from macrofaunal inventories. Although the routine application of SML still requires some adjustments and validations, we argue that such approaches could be used to overcome and even bypass the cost and time demanding macrofaunal approach in future biomonitoring.

WASTEWATER EFFLUENTS BACTERIAL COMMUNITY INFLUENCE THE MICROBIOME AND THE RESISTOME OF THE RECEIVING WATER

G. Corno[1], Y. Yang[2], A. Di Cesare[1], D. Fontaneto[1], E. Eckert[1]
[1]CNR-National Research Council of Italy, Institute of Ecosystem Study - Microbial Ecology Group, Verbania, Italy
[2]Sun Yat-sen University, School of Marine Sciences, Guangzhou, China

Backgrounds

Wastewater treatment plants (WWTPs) are a hot-spot for the spread of antibiotic resistance genes (ARGs) into the environment. Several studies targeted the selection and persistence of ARGs in WWTPs applying different disinfection technologies. Still, little is known on the fate of resistances once they are spread into the environment with the treated effluents.

Objectives

This is the first study on the fate of bacteria and ARGs released from different WWTPs once in contact with the resident microbial communities of the receiving water bodies. The result of complex ecological interactions concomitantly acting on the newly formed mixed communities gives an overview and allows speculations on the potential risk of ARGs spread under different environmental conditions.

Methods

Experimental mixed communities were designed mimicking the impact of different (in size and disinfection) WWTP effluents on the communities of various receivers (lake, river). Bacterial abundance and phenotype was assessed by flow-cytometry and microscopy. Bacterial communities composition and their relative resistome (1208 different ARGs) were assessed by full-genome metasequencing.

Conclusions

The fate of the bacteria from the WWTPs depended by the disinfection applied but even more on the ecological stability of the microbial community of the receiving system. ARGs released into the environment could established in the newly formed communities and those already present into the resident community surprisingly increased especially when the introduction of WWTP effluents was limited (e.g. 10% of the final water volume). This study demonstrated how the impact of the WWTP effluents is heavily influenced by the ecological conditions of the resident microbial community.

ISOLATION AND CHARACTERIZATION OF FUNGAL STRAINS WITH CELLULOLYTIC ACTIVITY ON A 19TH CENTURY COLLECTION OF ART

C. Coronado Ruiz[1,2], *R. Avendaño*[1], *G. Conejo*[3], *E. Escudero*[2,4], *P. Chaverri*[2,4], *M. Chavarría*[1,2,3]
[1]*CeNAT-CONARE, Centro Nacional de Innovaciones Biotecnológicas CENIBiot, 1174-1200 San José, Costa Rica*
[2]*Universidad de Costa Rica, Centro de Investigaciones en Productos Naturales CIPRONA, 11501-2060 San José, Costa Rica*
[3]*Universidad de Costa Rica, Escuela de Química, 11501-2060 San José, Costa Rica*
[4]*Universidad de Costa Rica, Escuela de Biología, 11501-2060 San José, Costa Rica*

Backgrounds

The archive of the University of Costa Rica holds a 19th century French collection of drawings and lithographs in which the biodeterioration by fungi is notorious. Due to nutritional limitations in which these fungi grew up, it is believed that the isolated strains possess the ability to degrade cellulose.

Objectives

Our goal was to isolate and identify the fungal strains responsible for the biodegradation of the 19th century collection and determine their cellulolytic activity.

Methods

Fungi were isolated using potato dextrose agar (PDA) and carboxymethyl cellulose (CMC). Identification of fungi was assessed by DNA sequencing complemented with morphological analysis. Finally, assays for cellulolytic activity was conducted by using Congo red dye.

Conclusions

Twenty different species were isolated. By sequence analysis (ACT and ITS regions), 90% of all strains were identified correctly to the species level belonging mainly to the genera *Aspergillus, Trichoderma, Cladosporium, Penicillium, Calostilbe, Chaetomium* and *Arthrinium*. There was no register in the Gene Bank for the sequence of two samples; consequently, they were identified through morphological analysis as new species of the genera *Periconia* and *Coniochaeta*. Qualitative tests show that the fungus collection present important cellulolytic activity.

REGULATORS AND FACTORS INFLUENCING THE MOBILITY OF PLANT PATHOGENIC BACTERIA OF THE GENUS DICKEYA

N. Cotte-Pattat[1], *V. Utzinger*[2]
[1]*Université Claude Bernard Lyon 1, Biology, VILLEURBANNE, France*
[2]*INSA de Lyon, Biosciences, Villeurbanne, France*

Backgrounds

Bacteria of the genus *Dickeya* are causal agents of soft-rot diseases on various plants, including economically important crops. Most phytopathogenic bacteria are mobile and this ability contributes to plant colonization and virulence. *Dickeya* can move either by 'swimming' in a fluid environment, or by 'swarming' on a surface. While swimming is an individual cell behavior, swarming depends on remarkable collective behavior.

Objectives

Our objective was to identify the factors and regulators influencing the swarming and swimming motility of the *D. dadantii* strain 3937.

Methods

Using conventional media with low agar concentrations, *D. dadantii* 3937 showed only moderate mobility. Analysis of different growth conditions showed a major influence of the carbon source on swarming and swimming. It was previously observed that the *D. dadantii* motility greatly increased after inactivation of PecS, a repressor controlling various virulence factors in response to unknown condition(s). Thus, we analyzed the swimming and swarming motility of a collection of mutants containing an inactivated transcriptional regulator.

Conclusions

Easily metabolizable carbon sources are the most efficient sugars to induce swarming; they could bring enough energy for this process. Swimming was differently influenced depending on carbon sources, probably due to chemotactic responses to some of them (galactose, ribose, xylose…). In addition to PecS, several regulators were found to affect (up or down) the swimming and/or swarming motility. This ability is controlled by a complex set of regulators, in response to environmental conditions that could be encountered by *Dickeya* during the plant infection.

MICROBIOTA CHARACTERIZATION AND VOLATILE AND NON-VOLATILE LIPOPHILIC FRACTION ANALYSIS OF BITTO STORICO CHEESE PRODUCED IN SIX DIFFERENT ALPINE PASTURES.

P. Cremonesi[1], F. Turri[1], G. Gandini[2], G. Battelli[3], M. Severgnini[4], F. Pizzi[1]
[1]Consiglio Nazionale delle Ricerche, Institute of Agricultural Biology and Biotechnology, Milan, Italy
[2]Università degli Studi di Milano, Department of Veterinary Medicine, Milan, Italy
[3]Consiglio Nazionale delle Ricerche, Institute of Sciences of Food Production, Milan, Italy
[4]Consiglio Nazionale delle Ricerche, Institute of Biomedical Technologies, Milan, Italy

Backgrounds

The Bitto Storico is an alpine heritage cheese made with raw milk and produced during the summer season in the Orobic Alps (Central Alps, Northern Italy). The cheese-making process depends on local traditions: freshly milked cow's milk is added to fresh goat's milk (10-20%), then production starts immediately in the "calècc" (itinerant dairy). The use of feeds and silage for animal feeding and the use of probiotics during curdling are prohibited thus the organoleptic variability of the cheese depends on local bacteria that change according to pastures and environment. These conditions guarantee a variability of organoleptic characteristics, probably associated to different microbial communities, highly appreciated by consumers.

Objectives

The objectives were (i) the characterization of the microbial variability of the Bitto Storico cheese by Next Generation Sequencing, and (ii) the analysis of the volatile and non-volatile lipophilic fractions.

Methods

Samples were collected from 54 Bitto Storico cheeses produced in six different Alpine pastures, in three geographical areas (Val Gerola, Valli del Bitto, Valle Brembana), during 2015 summer season. Bacterial DNA was extracted using an optimized protocol and 16S rRNA gene amplicons on V3-V4 region analyzed by Miseq (Illumina). The lipophilic fraction was characterized by means of Solid Phase Extraction-Gas Chromatography-Mass Spectrometry (SPME-GC-MS), the fatty acid profile by the High Resolution Gas Chromatography (HRGC).

Conclusions

Preliminary results showed a microbial community mainly dominated by *Firmicutes* with a high abundance of *Streptococcaceae* and *Lactobacillaceae* and low presence of *Entrococcaceae*. The volatile metabolome displayed a variability consistent with the dairy products of raw milk.

Environmental Microbiology/Microbial Ecology /Microbial Communities

GLYCEROL METABOLISM INDUCES BIOFILM FORMATION AT THE AIR-LIQUID INTERPHASE IN LISTERIA MONOCYTOGENES

N. Crespo Tapia[1], M.W. den Besten[1], T. Abee[1]
[1]Wageningen University & Research, Food Microbiology, Wageningen, The Netherlands

Backgrounds

Listeria monocytogenes is a microaerophilic food-borne pathogen that can grow as a biofilm on the surface of food-processing equipment. Bacterial biofilms vary greatly in structure and characteristics, and can be influenced by a wide range of environmental conditions.

Objectives

Although motile aerobic bacteria have been described to form biofilms at the air-liquid interphase of cell cultures, to our knowledge, this type of biofilm has never been described in *L. monocytogenes*. In this study we report *L. monocytogenes* biofilm formation at the air-liquid interphase of aerobically grown cultures, and that this phenotype is specifically induced when the media is supplemented with glycerol as a carbon/energy source.

Methods

A link with aerobic glycerol metabolism was confirmed by the analysis of *L. monocytogenes*' performance under anaerobic conditions, where biofilm production was reduced to the same level as the non-supplemented control, and it was located at the bottom of the well. Planktonic growth performance, metabolic activity assays and HPLC measurements of glycerol consumption over time showed that glycerol utilization in *L. monocytogenes* is restricted to growth under aerobic conditions. Additional motility assays revealed the induction of aerotaxis in the presence of glycerol. Gene expression analysis will provide further insight in parameters involved in glycerol metabolic pathway(s), aerotaxis and biofilm formation.

Conclusions

We hypothesize that the formation of biofilms at the air-liquid interphase is dependent on glycerol-induced aerotaxis towards the surface of the culture, where *L. monocytogenes* has access to higher concentrations of oxygen, and is therefore able to utilize this compound as a carbon source.

DETECTION AND METABOLIC MONITORING OF MICROBIAL CONSORTIA IN BENTONITE CLAY

S. Crook[1], M. Hausner[1], M. Kroukamp[1]
[1]Ryerson University, Department of Chemistry and Biology, Toronto, Canada

Backgrounds

Extreme environments present unique challenges to microbiologists. One such example of an extreme environment is bentonite clay. This natural material, slated to serve as the primary environmental barrier in the Deep Geologic Repository for spent nuclear waste, has been well characterized both physically and chemically. However, the ultra-oligotrophic and hygroscopic nature of bentonite, along with low biomass have presented hurdles in characterizing the microbial communities present, especially in the realm of molecular tools. The metabolic products of sulfate reducers and other microbes could potentially have profound effects on the proposed DGR design by influencing rates of corrosion on surfaces integral to the containment of nuclear waste. Past studies have attempted to identify relevant bacterial and eukaryotic organisms which may affect the proposed DGR design. However, the presence of archaeal populations and the role they may play has yet to be investigated.

Objectives

This study seeks to identify microbial populations native to bentonite clay and characterize the metabolic properties of these organisms.

Methods

The presence of microorganisms was investigated through the use of both cultivation and DNA-based techniques. To characterize the metabolic properties of sulfate reducing archaea/bacteria and methanogens present, anaerobic serum bottles containing bentonite and selective media were inoculated with enrichments from a bentonite sample. Sulfate, sulfite, acetate and methane concentrations were monitored.

Conclusions

Given sufficiently favorable conditions, microbially driven processes appear to occur which could potentially affect the proposed DGR design. This research furthers the understanding of the role played by microorganisms in bentonite and other extreme environments.

[2]Università degli Studi di Torino, Dipartimento di Scienze Agrarie- Forestali e Alimentari, Grugliasco, Italy
[3]Università di Modena e Reggio Emilia, Dipartimento di Scienze della Vita, Modena, Italy
[4]King Abdullah University of Science and Technology,
Biological and Environmental Sciences and Engineering Division, Thuwal, Saudi Arabia

Backgrounds

The role of diet in shaping the gut microbiota was evaluated in different animal models, including insects. *Drosophila* flies host an inconstant microbiota among which acetic acid bacteria (AAB) are important components capable of modulating immune response and the insect development.

Objectives

We characterized the bacterial and AAB communities associated to the spotted wing fly *Drosophila suzukii*, an invasive pest, by studying the same insect population separately grown on fruit-based or non-fruit artificial diet.

Methods

Prevalence of AAB in the insect gut was investigated by specific PCR. AAB capability to colonize the gut was estimated by fluorescent *in situ* hybridization and recolonization experiments with green fluorescent protein (Gfp)-labelled strains. Bacterial communities of individuals reared on the two diets were evaluated by pyrosequencing, analyzing the V1-V3 region of the 16S rRNA gene.

Conclusions

AAB massively colonized the insect gut with infection rates of 90 and 92% in fruit-fed and artificial diet-fed individuals, respectively. 16S rRNA gene pyrosequencing showed a differentiation of the bacterial microbiota of guts from insects fed with the two diets. The exclusion of AAB-related OTUs from the analysis showed a lack of the clustering pattern, suggesting that the diet-based diversification of the community is primarily reflected on AAB components. AAB alpha-diversity was also influenced by diet. Data suggested an AAB role in the gut response of *D. suzukii* to diet modification.

[2]Faculty of Forestry- University of Zagreb, Department of Forest Genetics- Dendrology and Botany, Zagreb, Croatia
[3]Saints Cyril and Methodius University of Skopje, Faculty of Forestry, Skopje, FYR Macedonia
[4]WSL Swiss Federal Institute for Forest- Snow and Landscape Research, Department of Phytopathology, Birmensdorf, Switzerland
[5]Michigan State University, Plant Biology, East Lansing, USA
[6]West Virginia University, Division of Plant and Soil Sciences, Morgantown, USA

Backgrounds

Chestnut blight is a disease caused by the plant pathogenic fungus *Cryphonectria parasitica*, which induces bark lesions (cankers) on stems and branches of chestnut (*Castanea*) species. The pathogen is successfully controlled by a double-stranded RNA mycovirus *Cryphonectria hypovirus* 1 (CHV1), which reduces virulence and reproductive capacities of the fungus, a phenomenon called hypovirulence. If the virus is introduced naturally or artificially into an active canker caused by virulent *C. parasitica* strain(s), canker expansion ceases and the canker calluses resulting in a so-called healed canker. High prevalence of CHV1 in *C. parasitica* populations often results in the recovery of chestnut forests. Therefore, it is important that CHV1-infected fungal strains persist on chestnut trees over years.

Objectives

The aim of this study was to investigate the persistence of hypovirulent *C. parasitica* strains in completely healed, callused chestnut blight cankers.

Methods

Bark samples were collected in seven blighted chestnut stands (six in Europe and one in North America) from more than 100 healed bark cankers.

Conclusions

The frequency of hypovirulent *C. parasitica* strains in sampled cankers varied substantially between different populations. Virulent *C. parasitica* strains were more frequent than hypovirulent ones in healed cankers, which was unexpected because CHV1-infected strains are thought to promote canker healing. The relationship between virulent and hypovirulent fungal strains in healed cankers appears to be highly dynamic. We suspect that in some cases the loss of vigor by hypovirulent *C. parasitica* strains leaves a niche for virulent ones to re-invade the already healed cankers.

DIVERSITY OF EXTRACHROMOSOMAL REPLICONS IN BACTERIA OF THE GENUS PARACOCCUS (ALPHAPROTEOBACTERIA)

J. Czarnecki[1], P. Decewicz[1], M. Szuplewska[1], A. Pawłot[1], R. Lasek[1], E. Prochwicz[1], M. Puzyna[1], A. Brozio[1], K. Kotecka[1], P. Dymek[1], Ł. Dziewit[1], D. Bartosik[1]
[1]Institute of Microbiology, Department of Bacterial Genetics, Warsaw, Poland

Backgrounds

Genomes of many *Alphaproteobacteria* (including members of the genus *Paracoccus*) comprise numerous extrachromosomal replicons (ERs) of diverse properties and different evolutionary history. The ERs are divided into non-essential plasmids and essential chromids, which contain house-keeping genes of chromosomal origin and are necessary for the viability of their hosts.

Objectives

We aimed to identify and analyze replication systems (REPs) of all ERs occurring in 18 strains of *Paracoccus* spp. We examined phylogenetic relationships of the REPs and analyzed genetic content of individual replicons in terms of the presence of: (i) the core genes conserved in all *Paracoccus* spp. genomes, and (ii) adaptive genes important in the natural niches of the tested strains. We assumed to obtain valuable data on the content, properties, distribution and directions of horizontal transmission of ERs in the genus *Paracoccus*.

Methods

In silico sequence analyses (construction of phylogenetic trees, determination of the core genome, search for adaptive genes) were performed using standard on-line available bioinformatic tools. Standard genetic techniques were used to clone REPs of individual ERs in a form of shuttle plasmids.

Conclusions

We characterized over 50 ERs in *Paracoccus* spp. Majority of them contained *dnaA-like*, *repB* and *repABC* REPs. Most of the strains carried two large ERs, with *dnaA-like* and *repB* REPs, essential for normal growth of their host strains. Other replicons (including those with *repABC* replication modules) were neither conserved nor essential, which suggests their relatively recent lateral acquisition.

MICROBIAL GROWTH FACTORS AFFECTING THE EXOPOLYMER PRODUCTION BY RHODOCOCCUS OPACUS

M. Czemierska[1], *A. Szcześ*[2], *A. Jarosz-Wilkołazka*[1]
[1]*Maria Curie Skłodowska University, Department of Biochemistry, Lublin, Poland*
[2]*Maria Curie Skłodowska University, Department of Physical Chemistry - Interfacial Phenomena, Lublin, Poland*

Backgrounds

Microorganisms such as fungi, bacteria and yeasts are able to synthesise exopolymers with many biologically important properties. Particularly valuable is their ability to purify the water from dyes, heavy metals, and colloidal particles by flocculation. This process can be applied for the removal of the suspended particles, causing their aggregation and sedimentation. Addition of natural polymers to the solution significantly accelerates this phenomenon and makes it safe for human health and environment. Therefore, there are many studies about obtaining new products to find the most effective and relatively inexpensive source of biopolymers with flocculating activity.

Objectives

The flocculation efficiency of exopolymers depends on many different factors and is strictly correlated with culture growth conditions. Therefore, it is crucial to optimise bacterial growth factors to receive exopolymers with high flocculating activity and possibly by the most efficient methods of extraction.

Methods

The optimum culture conditions were determined using different variants of culture, such as carbon and nitrogen sources, salts addition and pH value of the medium. Supernatants obtained from *Rhodococcus opacus* culture broths were tested for the flocculating activity in the presence of kaolin suspension.

Conclusions

The synthesis of the exopolymers with flocculating activity by microorganisms depends on multiple factors such as carbon and nitrogen sources, the pH value of medium and salts addition to culture growth. Determination of microbial growth conditions allows to obtain the products with high flocculating activity.

EVALUATION OF PLANT GROWTH-PROMOTING EFFECTS AND ANTIBACTERIAL PROPERTIES OF ENDOPHYTIC BACTERIA ASSOCIATED WITH TOMATO PLANTS

S. Dahikar[1]
[1]Sanjivani Arts- Commerce and Science College- Kopargaon, Department of Microbiology, Kopargaon, India

Backgrounds

Endophytic bacteria are widely studied because of their plant-growth-promoting benefits. They use various direct and indirect mechanisms to promote plant growth.

Objectives

The objective of these experiments were to select and characterized endophytic bacteria isolated from tomato stems, and to investigate the plant growth-promoting effect to develop systems to improve plant health and crop productivity based on microbial inoculation and as a biocontrol agents of tomato bacterial pathogens.

Methods

This study was conducted to select and characterize endophytic bacteria isolated from healthy tomato stems and to test their ability to promote plant growth and suppress bacterial diseases. The isolates were analyzed for a number of different PGP traits: organic acids (OA), indole acetic acid (IAA), ACC deaminase, and siderophore production. The antibacterial properties of the isolated strains were determined against *Ralstonia solanacearum*, *Xanthomonas campestris, Pseudomonas syringae* and *Clavibacter michiganensis.*

Conclusions

In the present study, a total of 17 strains of endophytic bacteria were isolated from tomato roots namely *Microbacterium* sp., *Bacillus* sp., *Rhizobium* sp., *Rhodococcus* sp., *Agrobacterium* sp., *Rhizobium* sp. A high percentage of the isolated strains tested positive for the following PGP traits: 67% were able to produce OA, 83% IAA, 76% ACC deaminase, and 81% siderophores. Endophytic bacteria which show significant antibacterial activity against *R. solanacearum*. The present studies strongly suggest that the endophytic bacteria characterized in this study could be successfully used to promote plant growth and act as biocontrol agents in tomato plants.

MULTIDRUG RESISTANT CTX-M TYPE PRODUCING ESCHERICHIA COLI OF PHYLOGENETIC GROUP B2 IN INTESTINAL COLONIZATION OF HEALTHY PORTUGUESE CATTLE

J. Dantas Palmeira[1,2], *H. Ferreira*[1,2]
[1]*University of Porto, Laboratory of Bacteriology, Porto, Portugal*
[2]*UCIBIO, REQUIMTE, Porto, Portugal*

Backgrounds

Background: Intestinal colonization of food-producing animals with extended-spectrum beta-lactamase (ESBL) producers represents a public health concern. *Escherichia coli,* an important commensal of the intestinal tract of animals is responsible for the spread of antimicrobial resistance.

Objectives

Objective: This study aimed to the characterization of CTX-M-type ESBL and phylogenetic grouping of multidrug-resistant (MDR) ESBL-producing *Escherichia coli* in feces of healthy bovine from Portugal.

Methods

Material/methods: Selection of the isolates obtained from fecal samples of bovine in Portugal, was performed on MacConkey agar with antibiotics, with previous incubation in TSB. Susceptibility testing was achieved by disk-diffusion-method according to the CLSI. Presumptive identification was performed by CHROMagar-Orientation. ESBL-producers were screened by the double-disk-synergy-test. ESBL coding genes were screened by PCR. CTX-M-type producing *E.coli* isolates were selected for further study. Phylogenetic groups were determined by PCR.

Conclusions

Results/Conclusions: From 117 cattle fecal samples, 470 *Enterobacteriaceae* isolates were obtained, showing a total of 392 MDR isolates, 227 (48.30%) *Escherichia coli* isolates were ESBL-producers (EC-ESBL), from these, 223 were CTX-M-producers. The EC-ESBL-CTX-M gene profile was: *bla*$_{\text{CTX-M}}$Group1 (87%); *bla*$_{\text{CTX-M}}$Group9 (12.1%); *bla*$_{\text{CTX-M}}$Group1+*bla*$_{\text{CTX-M}}$Group9 (0.9%). Phylogenetic group A was prevalent with 150 (67.3%) of EC-ESBL-CTX-M, 61 (27.4%) B1, 9 (4%) B2 and 3 (1.3%) D.
Results show prevalence of *bla*$_{\text{CTX-M}}$ EC-ESBL (98.24%) presenting a MDR phenotype and phylogenetic group A colonizing these animals. Relevant phylogenetic group B2 isolates presenting *bla*$_{\text{CTX-M}}$ were detected. The presence of *bla*$_{\text{CTX-M}}$ EC-ESBL in animal intestinal colonization shows a reservoir of multidrug-resistant microorganisms relevant in environmental and community spread of CTX-M-type ESBL.

MULTI-DRUG RESISTANT (MDR) CTX-M-15-PRODUCING ESCHERICHIA COLI FROM INTESTINAL COLONIZATION OF HEALTHY PETS IN THE NORTH OF PORTUGAL

C. Araújo[1], J. Dantas Palmeira[1,2], H. Ferreira[1,2]
[1]University of Porto, Biological Sciences, Porto, Portugal
[2]REQUIMTE, UCIBIO, Porto, Portugal

Backgrounds

Spread of *Escherichia coli* MDR-ESBL (EC-ESBL) producers has become a serious global problem in terms of public health. Intestinal colonization of pets with ESBL producers is problematic and contributes to antimicrobial resistance dissemination.

Objectives

The aim of this study was detection of MDR ESBL-producing *Enterobacteriaceae* in intestinal colonization of healthy pets in Portugal.

Methods

Nine companion animal fecal samples were enriched in TSB. Selection was obtained in MacConkey agar with antibiotics. Antimicrobial susceptibility was determined by disk-diffusion-method by EUCAST. ESBL producers were detected by double-disk-synergy-test. Presumptive identification was done by CHROMagar orientation. EC-ESBL were selected for detection of *bla*$_{\text{CTX-M}}$ groups (group1 positives were screened for *bla*$_{\text{CTX-M-15}}$), phylogenetic groups and non-beta-lactam resistance genes were studied by PCR.

Conclusions

A total of 50 *Enterobacteriaceae* were selected showing high resistance profile: 82% resistant to amoxicillin, 42% to amoxicillin+clavulanic acid, 14% to cefotaxime, 58% to tetracycline, 56% to ciprofloxacin and 42% to sulphamethoxazole+trimethoprim. Thirty-nine (78%) isolates showed MDR profile. A total of 6 isolates were MDR-ESBL-producing *E. coli* (EC-ESBL), of these, 4 carried the *bla*$_{\text{CTX-M-15}}$ gene. Phylogenetic classification showed 2 EC-ESBL group A, 1 B1 and 3 D. EC-ESBL showed diversity of non-beta-lactam resistance genes: 2 ***aac6'Ib-cr***, 2 *qnrB*, 6 *parC*, 5 *gyrA* and 5 *tetA* genes.

The results substantiate the occurrence and ongoing spread of various ESBL-producing, multi-resistant *E.coli* in healthy pets. These animals can act as ESBL-producers reservoir for humans highlighting the idea that antibiotic resistance is a public health problem that needs to be managed in a one-health perspective, encompassing human and animal health.

DIVERSITY OF HALOPHILIC BACTERIA IN NAMAKDAN HYPERSALIN CAVE IN QESHM

M. Darabi[1], N. zamani[1], M. mehrshad[1], M.A. amoozegar[1]
[1]Tehran university faculty of science, microbiology, Tehran, Iran

Backgrounds

Namakdan Cave in Qeshm island Geopark; south of Iran, is the longest salt cave in the world with 6850m length. In persian, the word "namak" means salt or Sodium Chloride which is the main component of Namakdan salt dome. Caves are dark and nutrient-limited environments. Microbial processes occurring in the absence of light have generally been considered insufficient to support ecosystem-level processes. bacterial diversity in caves is still rarely investigated.

Objectives

In the present study bacterial diversity in Namakdan salt cave has been investigated by culture dependent methods.

Methods

Sampling was carried out in October and Physico-chemical variables (e.g. temperature, conductivity and pH) were measured in situ. The salinity and pH of the samples were 32.07% and 7.1. In order to isolate halophilic bacteria Marine agar medium with 10% salinity was used. Total of 70 isolate were separated. 16S rRNA gene amplification, sequencing and analysis was performed for selected isolates and it could recognize members of Firmicutus and Bacteroidets phyla in *Paenibacillus, Aquibacillus, Paraliobacillus, Bacillus, Aliifodinibius* genus that need at least 2% salinity in their culture media. The optimal temperature range for growth of this bacteria is 30 to 34°C. most of them are rod shape and the rest are coccoid.

Conclusions

The present study is intended to determine the genetic map of Namakdan salt cave which will help us to identify unknown halophilic bacteria community of this unique environment and also stable the position of this Geopark in UNESCO.

VISIBLE LIGHT ASSISTED PHOTOCATALYTIC DISINFECTION OF MDR ESCHERICHIA COLI USING DOPED ZINC OXIDE NANOCOMPOSITES

S. Das[1], *S. Tripathy*[1]
[1]*KIIT University, School Of Biotechnology, Bhubaneswar- Orissa, India*

Backgrounds

With supplies of fresh water diminishing and population increasing, water scarcity is set to become a major global problem. Emerging pollutants including multi-drug resistant(MDR) bacteria possess risk for public health. Conventional treatment methods have been proven ineffective as far as their economy and performance is concerned. This necessitate an immediate need for alternative disinfection technology. Photocatalysis using semiconductor nano-composites have gained attention in recent time. Photocatalysis involves metal oxides in presence of water, which when illuminated with light generates reactive oxygen species (ROS) which serves detrimental to pathogenic bacteria.

Objectives

To Check the effect of solar-photocatalytic disinfection (PCD) on MDR *Escherichia coli* (environment isolate) using doped ZnO, To understand molecular disinfection mechanism and bacterial reactivation post disinfection (PD) and checking efficiency of the process with real water systems.

Methods

Synthesis of metal doped ZnO using chemical co-precipitation route. PCD and process optimization. Effect of different ROS scavenger on the rate of disinfection. Lipid peroxidation assay, LIVE/DEAD staining, Potassium ion leakage, Electron microscopy and DNA damage analysis to confirm the disinfection process. Validation of PCD with real water samples.

Conclusions

Solar-PCD was perfectly achieved (with 500mg/L Doped ZnO) within 90 minutes. Membrane damage, intracellular ion leakage and DNA damage was found to be the key mechanism of disinfection with no reactivation of *MDR E. coli* till 7 days post disinfection. H_2O_2 was the key species involved in solar-PCD of MDR *E. coli*. The process is validated in real water samples collected from different sources and is expected to have potential in real world application.

GENOME SCALE RECONSTRUCTION OF AROMATIC HYDROCARBON DEGRADATION PATHWAYS IN MARINOMONAS FUNGIAE STRAIN AN44T AND THEIR COMPARATIVE ANALYSIS

S. Das[1], *S. Zachariah*[1], *J. Badhai*[1]
[1]*Institute of Life Sciences, Department of Biotechnology, Bhubaneswar, India*

Backgrounds

Oceans are the final sink for almost all known aromatic pollutants that are produced on land. Bacteria have evolved complex metabolic pathways via various genetic mechanisms for the degradation of diverse aromatic compounds, using them as carbon and energy source. Thus, the possibilities of identifying marine microbes with novel genetic and metabolic abilities to degrade aromatic compounds are immense. However, the limited availability of information on genomic organization and mode of regulation/regulatory networks involved in aromatic compound degradation and assimilation in marine bacteria has impeded their genetic manipulation for proper biotechnological applications.

Objectives

Elucidation of aromatic compounds degradation pathways in a marine bacterium *Marinomonas fungiae* strain AN44^T.

Methods

Methods include BLAST search against KEGG database and MetaCyc pathways web-server, and genome comparison using MUMer.

Conclusions

Genome based screening revealed the presence of two central pathways involved in aerobic degradation of 3, 4-dihydroxybenzoate and 3, 4-hydroxyphenylacetate, and four peripheral pathways involved in degradation of ferulate, *p*-coumarate, caffeate and quinate. The 3, 4-dihydroxybenzoate degradation pathway was encoded by a 9.85 kb single operonic cluster composed of 11 genes, whereas the 3, 4-hydroxyphenylacetate degradation pathway was encoded by a 31.3 kb operonic region composed of 30 genes. Comparative analysis shows certain degree of heterogeneity in the DNA sequence to their corresponding counterparts in other pathways, indicating different evolutionary origins. This study provides important genetic information on the plasticity and diversity of bacterial catabolic pathways for degradation of specific aromatic compounds.

COMPARTMENTALIZATION AND ACTIVITY OF CLASS 1 INTEGRONS AND INCP-1 PLASMIDS IN RIVER SEDIMENTS IMPACTED BY URBAN AND INDUSTRIAL ANTHROPOGENIC PRESSURE

M. De La Cruz Barron[1], X. Bellanger[1], L. Mathieu[1], H. Guilloteau[1], C. Merlin[1]
[1]Université de Lorraine, Laboratoire de Chimie Physique et Microbiologie pour l'Environnement, Nancy, France

Backgrounds

The accumulation of antibiotic resistance genes (ARGs) and mobile genetic elements (MGEs) in natural environments is being increasingly highlighted, especially for aquatic ecosystems. Since MGEs such as class 1 integrons and IncP-1 plasmids are genetic structures that capture or mobilize ARGs, they are currently used as a proxy for estimating the relative abundance of ARGs in various environments.

Objectives

The aim of this study was to determine the relative abundance and activity of class 1 integrons and IncP-1 plasmids in various compartments of the Orne River, namely raw water, suspended material and sediments, and to identify environmental reservoirs of ARGs.

Methods

Abundances of class 1 integrons and IncP1 plasmids were estimated by qPCR from community DNA extracts. Then, the activity of such MGEs was explored using highly sensitive bacterial biosensor assays reporting the transcriptional activity of genes involved in their mobility.

Conclusions

Both MGEs appeared statistically enriched in suspended materials and in the top layers of sediments (recent deposits) compared to raw water. In sediments, MGEs abundance decreases with depth, excepted for discrete layers exhibiting a 2-3 order of magnitude increase, clearly indicating the existence of MGEs reservoirs. For the vast majority of sediment samples, the abundance of MGEs evolved independently from the local content in organic or metal pollutants, even the local community structures. Considering the fact that the dissemination of MGEs largely involved replicative processes, we speculate that abnormally elevated levels of MGEs may also result from an active dissemination of these elements, which is currently being explored using biosensors assays.

[6]Icelandic Institute of Natural History- IS-600, Botany, Akureyri, Iceland
[7]Real Jardín Botánico-CSIC, Mycology, Madrid, Spain

Backgrounds

One key consequence of glacier recession, as effect of climatic change, is the creation of new habitats for colonization. In glacier forefields, primary succession occurs simultaneously in soils and rocks recently discovered offering a type of natural experiment in which temporal colonization dynamics can be analyzed.

Objectives

A chronosequence established at Breiðamerkurjökull Glacier forefield, was used as a framework to analyze primary microbial succession processes in subarctic regions. This outlet glacier stretches to southeast from Vatnajökull Glacier and has been dramatically retreating during the 20th century.

Methods

Soil samples from different succession stages were collected. Microbial community structure was analyzed by high-throughput amplicon sequencing. Potential microbial activity (microbial respiration, N mineralization) as well as different soil attributes were also measured in these samples.

Conclusions

Microorganisms play a fundamental role in the initial colonization of exposed soils after glacier ice retreat. They are the only colonizers at soils close to the glacier front and are functionally relevant in later successional stages. High-throughput amplicon sequencing of fungal and bacterial communities revealed that the structure of microbial communities from soils close to the glacier front considerably differed to that found in later successional stages. After a first abrupt change in community composition at the beginning of the succession, changes occur smoothly but showed a clear trend along the chronosequence. We found a significant decrease in soil pH, and a significant increase in the size of both, the soil organic matter and the organic and mineral N pools, in parallel with the succession process. Rates of microbial respiration and N mineralization also significantly increased with time of exposure after glacier retreat. Hence, our results demonstrate that primary succession along this chronosequence is accompanied by both a replacement of microbial taxa and changes in soil functionality.

METAGENOMIC ANALYSIS OF THE MICROBIOME IN THREE DIFFERENT BIOREACTOR CONFIGURATIONS APPLIED TO COMMERCIAL LAUNDRY WASTEWATER TREATMENT

T.P. Delforno[1], G.V.J. Lacerda[1], I.N. Sierra-Garcia[1], D.Y. Okada[2], T.Z. Macedo[3], M.B.A. Varesche[3], V.M. Oliveira[1]
[1]CPQBA, DRM, Paulínia, Brazil
[2]Division of Technology in Environment Sanitation, School of Technology, Limeira-SP, Brazil
[3]Engineering School of São Carlos - University of São Paulo,
Department of Hydraulics and Sanitation, São Carlos-SP, Brazil

Backgrounds

High concentrations of linear alkylbenzene sulfonate (LAS), an anionic surfactant, have been detected in the laundry wastewater. Thus, molecular biology tools are used to understand the taxonomies and pathways involved in anionic surfactant removal from biological reactors such as (fluidized bed (FBR), expanded granular sludge bed (EGSB) and up-flow anaerobic sludge blanket (UASB), focusing on new strategies for biodegradation.

Objectives

Therefore, this study characterized and compared three distinct biological reactors used for laundry wastewater treatment using whole genome shotgun metagenomics.

Methods

Three samples were collected from three different configurations of biological reactors (FBR, EGSB and UASB) applied to laundry wastewater treatment. The reactors were fed only with laundry wastewater diluted with a public water supply to obtain an influent LAS concentration of approximately 15 mg L^{-1}. Metagenomes were sequenced on the Illumina Hiseq platform and were analyzed using MG-RAST, STAMP and PAST software.

Conclusions

The EGSB and UASB reactors were more closely related based on taxonomic and functional profiles, likely due to similar granular sludge and procedures adopted to ensure anaerobic conditions. The EGSB and UASB reactors showed a predominance of methanogens and genes related to methanogenesis, with a prevalence of the acetoclastic pathway, in addition to the peripheral and central O_2-independent pathways for aromatic compound degradation. By contrast, FBR showed a dominance of aerobic microbiota and pathways for O_2-dependent aromatic compound degradation.Therefore, although the reactors showed similar surfactant removal levels, the microbial composition, functional diversity and aromatic compound degradation pathways were significantly distinct.

COMPARISON OF THE DISSEMINATION OF 16S RRNA METHYLTRANSFERASE GENES IN E. COLI FROM HUMAN AND NATURAL EFFLUENTS USING WHOLE GENOME SEQUENCING

J.F. Delgado Blas[1], C.M. Ovejero[1], A. Hoefer[1], W. Calero-Caceres[2], M. Muniesa[2], M.P. Garcillan-Barcia[3], F. De La Cruz[3], B. Gonzalez-Zorn[1]
[1]Faculty of Veterinary Medicine and VISAVET Complutense University of Madrid, Animal Health Department, Madrid, Spain
[2]Faculty of Biology University of Barcelona, Microbiology Department, Barcelona, Spain
[3]University of Cantabria, Institute of Biomedicine and Biotechnology of Cantabria, Santander, Spain

Backgrounds

The environment plays a critical role in the dissemination of antibiotic resistance genes. The comprehension of the human impact on the acquisition and evolution of these genes is essential to mitigate the burden of antimicrobial resistance (AMR). Whole genome sequencing (WGS) has demonstrated to be highly useful to reveal the epidemiological elements governing the spread of AMR.

Objectives

The aim of this work was to determine the human influence on the ecology of 16S rRNA methyltransferase genes, which confer high resistance to amynoglicosides, by comparing *E. coli* from natural and human effluents using WGS.

Methods

A total of 43 *E. coli* isolates resistant to amynoglicosides (25 from two waste water treatment plants and 18 from two Spanish rivers near Barcelona) were fully sequenced by Illumina technology (MiSeq). The consequent analysis was performed by the Center for Genomic Epidemiology services. The structure of the methyltransferase gene-carrying plasmids was obtained using PLACNET.

Conclusions

We have identified two *E. coli* sequence types (ST479 and ST632) highly disseminated in waste water, which harbored the methyltransferase gene *rmtB*. However, the isolates recovered from river samples belonged to diverse STs, and all of them carried the methyltransferase gene *armA*. Furthermore, sewage isolates only shared an IncFII plasmid, while river isolates had a common IncHI2 plasmid. PLACNET analysis critically contributed to understand the resistance gene dynamics in both natural and human environments. These results show the impact of the human activity, which forces the selection of specific genes and plasmids associated to certain STs.

Environmental Microbiology/Microbial Ecology /Microbial Communities

THERMOPHILES REMAIN ACTIVE IN DIFFERENT SOIL ENVIRONMENTS

J.A. Delgado[1], *E. Gómez*[1], *J.M. González*[1]
[1]*Institute of Natural Resources and Agrobiology of Seville IRNAS, Biogeochemistry- Plant and Microbial Ecology, Seville, Spain*

Backgrounds

Microbial activity at high temperatures on the soil surface has not received the importance it deserves. Recent research has shown the presence of thermophilic bacteria in soils, and the *Geobacillus* genus is the most characteristic representant. It has been proposed that in temperate soils these thermophiles can be found as vegetative cells and they can be potential participants of soil biogeochemical reactions. It must be considered that hight temperature events are frequently observed at medium and low latitudes, providing with temporal niches for thermophiles to grow in upper soil layers. Nevertheless, thermophiles must survive low temperature periods which are dominant at high latitudes.

Objectives

This study suggests that soil thermophiles remain active during long periods even at relatively low temperatures common in most soils.

Methods

To answer this question we will quantify the activity of these thermophilic cells in comparison with mesophiles in the same environments using molecular and physiological methods. Our results directly contribute to evaluate the behaviour of soil thermophiles in a variety of environments and conditions.

Conclusions

The relevance of soil thermophiles will be highlighted because they are able to contribute with highly significant activity profiles and low, but steady, maintenance strategies.

[3]UMR 7517- Université de Strasbourg/EOST- CNRS,
Laboratoire d'Hydrologie et de Géochimie de Strasbourg LHyGeS, Strasbourg, France
[4]UMR 7156 UNISTRA - CNRS- Université de Strasbourg,
Department of Microbiology- Genomics and the Environment, Strasbourg, France

Backgrounds

Chlorinated hydrocarbons are widespread contaminants in groundwater and subsurface ecosystems due to their massive use as industrial solvents in the last decades. Their hydrophobic properties have led to their accumulation and persistence in aquifers, while their high toxicity and carcinogenicity pose serious risks for human health and the environment. Microbial biodegradation of halogenated hydrocarbons represents a promising dissipation process for rehabilitating polluted sites, although it requires diagnostic tools relying on molecular biomarkers to evaluate degradation potential *in situ*.

Objectives

The BioDissPOL (Microbial biomarkers: applicability for diagnostic and monitoring of polluted sites) project, funded by ADEME, addresses how dissipation of chloroethenes is linked with functional and taxonomic microbial markers, with the aim to develop a widely-accepted framework to monitor natural attenuation at contaminated sites.

Methods

We collected groundwater biannually from 12 piezometers in a multi-polluted site to *(i)* assess degradation conditions based on physico-chemical parameters and *(ii)* quantify the extent of degradation using stable isotope analysis (CSIA), in order to *(iii)* link this information with copy numbers of functional genes and changes in microbial community profiles using next generation sequencing (Illumina MiSeq).

Conclusions

Significant changes in carbon isotope composition accompanied by decrease in perchloroethylene and increase in dichloroethene and vinyl chloride concentrations throughout the plume, demonstrated the occurrence of *in situ* biodegradation. Taxonomic and functional analyses identified the presence of dehalorespiring genera with functional genes involved in biodegradation of chloroethenes in groundwater. Taken together, our results highlight that preliminary evaluation of chloroethenes biodegradation provides valuable information to bioremediation strategies at contaminated industrial sites.

INVESTIGATION IN THE POTENTIAL ROLES OF VISCOSINAMIDES PRODUCED BY P. FLUORESCENS

S. Depayras[1], A. Merieau[1], M. Barreau[1], T. Kondakova[1,2], C. Barbey[1,3], M. Gallique[1], M. Feuilloley[1], N. Orange[1], C. Duclairoir-Poc[1]
[1]University of Rouen Normandy, Laboratory of Microbiology Signals and Microenvironment, Evreux, France
[2]University of Illinois, Cronan Lab- Department of Microbiology, Urbana, USA
[3]North committee, Seeds Innovation Protection Research Environment, Achicourt, France

Backgrounds

Biosurfactants are amphiphilic compounds exhibiting low toxicity and high biodegradability. Produced by a wide range of microorganisms, they are nowadays commonly used in pharmaceutical, food cosmetic and bioremediation industries. However few studies focus on the potential role of cyclolipopeptides (CLPs) unlike well-known rhamnolipids.

Objectives

We investigated here new potential roles of viscosinamides, CLPs produced by a clinical *P. fluorescens* strain MFN1032. We focused on their implication in colonization, virulence and cell-to-cell communication.

Methods

CLPs of MFN1032 were isolated and identified by RP-HPLC-MS. Then MIC and cytotoxicity assays were performed respectively on cutaneous strains and pulmonary cell line (A549). Meanwhile adhesion and biofilm development of MFN1032 were quantified by confocal microscopy. Moreover quorum sensing tests were realized using two biosensor strains detecting N-AcylHomoserine Lactones (NAHLs) production.

Conclusions

P. fluorescens MFN1032 produced abundantly viscosinamide A and poorly other viscosinamides. CLPs contributed in embedding the matrix but also take part in the escape of asocial cells out of microcolonies by motility alteration. Cell free supernatant promoted the lysis of pneumocytes emphasing the potential cytotoxicity of CLPs or other exoproducts. CLP extracts induced an alteration of the growth of Gram positive bacteria. However MFN1032 did not seem to produce NAHLs. Interestingly MFN1032 was able to communicate, when placed in proximity with biosensors, suggesting a potential new way of cell-to-cell communication. The chemical similarities between NAHL and viscosinamides and their low diffusibility let us suspect the potential implication of CLPs in this phenomenon.

IMPACT OF GASEOUS NO2 ON P. FLUORESCENS STRAIN IN THE MEMBRANE ADAPTATION AND VIRULENCE

T. Kondakova[1,2], S. Depayras[1], N. Merlet-Machour[3], H.J. Heipieper[4], C. Catovic[1], M. Barreau[1], M. Gallique[1], M. Feuilloley[1], N. Orange[1], C. Duclairoir-Poc[1]
[1]University of Rouen Normandy, Laboratory of Microbiology Signals and Microenvironment, Evreux, France
[2]University of Illinois, Cronan Lab- Department of Microbiology, Urbana, USA
[3]University of Rouen Normandy, COBRA UMR 6014, Evreux, France
[4]Helmholtz Centre for Environmental Research, Department of Environmental Biotechnology, Leipzig, Germany

Backgrounds

Nowadays air pollution is clearly increasing due to anthropogenic activity despite more drastic regulations. Among all air pollutants, nitrogen oxides, such as NO and NO_2, are predominant. Such compounds exhibit direct toxic effects on humans especially on lungs. However microorganisms are also exposed to them but their synergy with microorganisms on microbial virulence is still not stated.

Objectives

We studied the impact of one major air pollutant, the nitrogen dioxide, on an environmental strain of *P. fluorescens* MFA76a, mainly in terms of its adaptability and virulence factors.

Methods

MFAF76a was exposed in a home-made exposure system at 45ppm of NO_2. Afterwards growth kinetics, MIC assays and cultivability were observed as the membrane permeability. Meanwhile HPTLC/MALDI-TOF MS Imaging characterized the membrane lipids. Finally transcriptomic studies by RT-qPCR were performed on NOx detoxification gene and RND class efflux pump.

Conclusions

An increasing of membrane permeability and a decrease of one log in cultivability were observed after a two hour exposure at 45ppm of NO_2. Interestingly a lipidomic study confirmed the alteration in membrane lipid composition. Following exposure an glycerophospholipid, still uncharacterized, disappeared. However transcriptomic studies indicated an up-regulation in the expression of genes implicated in NOx detoxification (*hmp*) and RND class efflux pump (*mexEF-oprN* and *mexXY)*, also implicated in antibioresistance as confirmed by MIC assays.

[2]Università degli Studi della Basilicata, Ph.D school in Applied Biology and Environmental Safeguard, Potenza, Italy
[3]Università degli Studi della Basilicata,
European and Mediterranean Cultures. Architecture- Environment and Cultural Heritage, Matera, Italy

Backgrounds

The biodiversity of soil, due to variety of chemical and metabolic processes, has an important role in maintaining ecosystems in a functionally efficient state. Changes and dynamics of soil ecosystem allow a stabilization of the functional interrelationships between the various micro-organisms, the plants and the animal community.

Objectives

In this study physical, chemical and microbiological characteristics of the agricultural and forest soil areas were determined to assess dynamics and the evolution processes induced by environmental restoration procedures after an oil pipeline implantation.

Methods

Soil samples were collected from forest and agricultural areas in a Southern Italy farm, and analyzed for specific parameters and biological indicators, such as total biomass-C, organic-C, respirometric tests and microbial community composition. Soils were sampled ante-opera to use as control and after one and two years from oil pipeline implantation.
Agricultural and forest area samples showed an interesting diversification of the specific parameters for each sampling site, with significant changes of textural fractions, high values of pH and a remarkable bio-stimulation of germination and a strong enrichment of edaphic fauna.
The microbial community composition proved the presence of particular species, usually current in contaminated/strongly disturbed soils, involved in bioremediation/biodegradation natural process to restore optimal conditions.

Conclusions

The elevated intra-specific and functional biodiversity underlined the soil capacity to tolerate and withstand the disturbances with the presence and the adaptation of bacterial species able to perform certain functions in alteration conditions.

HPTLC CHROMATOGRAPHY AS IDEAL TOOL FOR SEPARATION A MIXTURE OF BACILLUS LIPOPEPTIDE EXTRACTS IN SITU

I. Dimkić[1], P. Ristivojević[2], T. Berić[1], T. Janakiev[1], I. Nikolić[1], Đ. Fira[3], S. Stanković[1]
[1]Faculty of Biology - University of Belgrade, Microbiology, Belgrade, Serbia
[2]Innovative Centre of Faculty of Chemistry Ltd.- University of Belgrade, Analytical chemistry, Belgrade, Serbia
[3]Faculty of Biology - University of Belgrade, Biochemistry and Molecular Biology, Belgrade, Serbia

Backgrounds

Bacillus species produce a wide array of biologically active molecules, including nonribosomaly synthesized lipopeptides. Bioautography is a valuable tool for the identification of bio-active compounds from complex mixtures.

Objectives

Detection of antimicrobials production by *Bacillus* species is important in determining its capability to be a good biocontrol agent.

Methods

Antimicrobial activity of lipopeptide extracts of five *Bacillus* spp. strains (SS-10.7, SS-12.6, SS-13.1, SS-38.4 and SS-27.2) was tested against *Pseudomonas syringae* pv. *aptata* from sugar beet, *Xanthomonas arboricola* pv. *juglandis* from walnut tree, and *Listeria monocytogenes*. HPTLC chromatography was used for simultaneous separation of complex mixtures of lipopeptide extracts and for determination of antimicrobial activity of separated components by agar overlay method. Standard compounds of iturin A and surfactin were used as positive controls.

Conclusions

For the inhibition of *Xanthomonas* and *Pseudomonas* iturin analog was responsible. The growth inhibition was not observed for surfactin standard. SS-12.6, SS-13.1 and SS-38.4 extracts exhibited the high inhibition zones, while extracts of SS-10.7 and SS-27.2 showed weak effect against all tested pathogens. The highest inhibition was recorded for extract of SS-12.6 within R_F values of 0.20 and 0.28 indicating synergism of several analogues of iturin. HPTLC bioautography identified the active components from a mixture of lipopeptide extracts in a very effective manner, *in situ* proving its potential for use in direct detection and determination of antimicrobials.

CORRELATIONS BETWEEN GUT MICROBIOTA, PHYSIOLOGY, XENOBIOTICS INTAKE AND ANTIMICROBIAL RESISTANCE GENES IN OBESE, OVERWEIGHT AND EUTROPHIC INDIVIDUALS.

V.L. Silva[1], S. Marjorie Raquel Anariba[1], T.O. Paula[1], F.M. Borges[1], A.B. Ferreira-Machado[1], J.A. Resende[2], C.G. Diniz[1]
[1]Universidade Federal de Juiz de Fora, Departamento de Parasitologia- Microbiologia e Imunologia, Juiz de Fora, Brazil
[2]Universidade Federal do Espírito Santo, Departamento de Farmácia e Nutrição, Alegre, Brazil

Backgrounds

As obesity is related to the gut microbiota (GM), studies on microbial ecology in obese individuals are needed. GM is considered an important reservoir of antimicrobial resistance genes (ARG). Little is known on GM and ARGs in obesity, considering the altered physiology and xenobiotics intake.

Objectives

This study aimed in a comparative screening and correlations between gut microbiota, physiology, xenobiotics intake and AGRs in obese, overweight and eutrophic individuals.

Methods

Fecal metagenome of 72 individuals classified according to their body mass index (BMI) was used as template for PCR targeting 59 different ARGs and evaluation of bacterial density by FISH. Anthropometric/nutritional characteristics, and xenobiotics intake were recorded for correlation analysis.

Conclusions

Among 27 ARGs detected, a cluster of 17 was observed in all groups suggesting a common core. In general, ARGs were observed mostly within obeses, followed by overweight and eutrophic individuals. Bacterial groups showed to be increased, in terms of relative density, among obese individuals. The ratio between ARGs and bacterial groups may suggest that AGRs were more related to enterobacteria. Positive correlations were observed between ARGs and BMI, calories and xenobiotics intake (especially use of sweeteners). Overall the results are in agreement with observations that GM is altered in obesity. However the altered physiology in obese individuals seems to be also associated to the increased xenobiotics intake and may interfere with GM towards antimicrobial resistance, as observed by the fecal metagenome and ARGs screening. Overweight individuals behave as an intermediary category between eutrophic and obese. Support: FAPEMIG, CNPQ, CAPES, PPGCBIO/UFJF.

SEQUENCE AND ACTIVITY-BASED METAGENOMICS APPROACHES TO DISCOVER INDUSTRIALLY-RELEVANT ENZYMES

M.A. Distaso[1], S. Wright[2], C. Coscolin[3], V. Tverezovskiy[2], M. Ferrer[3], T. Hai[1], P. Golyshin[1]
[1]Bangor University, School of Biological Sciences, Bangor, United Kingdom
[2]Bangor University, Biocomposites Centre, Bangor, United Kingdom
[3]Consejo Superior de Investigaciones Cientificas, Institute of Catalysis, Madrid, Spain

Backgrounds

In the modern industrial era the demand for suitable enzymatic biocatalysts to use as greener alternative to chemical synthesis is crucial. Enzymatic routes become a successful application when they contribute to an overall cost reduction, an increased product yield and lower volumes of wastewater streams and by-products. Uncultured microorganisms are an exceptional resource of powerful biocatalysts capable of performing a wide range of reactions and of accepting extensive collections of complex molecules as substrates.

Objectives

We report on the application of metagenomic screening methods for the recovery of biocatalysts of industrial interest to use in enzymatic processes.
This work was specifically aiming at finding (1) a methylation reaction for the enzymatic pathway to produce a potent weed control compound

Methods

The soil was enriched with lipophilic compounds resembling the target substrate for the enzymatic conversion. Consequently, total DNA was recovered and subjected to *de novo* sequencing and in *silico* annotation, which has yielded few candidate genes.

Conclusions

One of them from a representative of the phylum *Actinobacteria* appeared an efficient SAM-*O*-methyltransferase able to accommodate and methylate the moiety of our substrate molecule. Preliminary tests showed up to 30% of substrate conversion in a not yet optimized reaction environment.
Contextually, (2) functional screening of the fosmid libraries established from the same source identified two highly promiscuous lipases capable of hydrolysing the broader range of ester substrates than the most-active industrial prototypes.

Characterization and site directed mutagenesis studies are ongoing, with the potential to make these enzymes extremely useful in a number of biotechnological applications.

[3]University of Palermo,
Dept. of Biological- Chemical and Pharmaceutical Sciences and Technologies STEBICEF, PALERMO, Italy
[4]Istituto per l'Ambiente Marino Costiero IAMC, Istituto per l'Ambiente Marino Costiero IAMC, MESSINA, Italy

Backgrounds

The contamination of marine environments by hydrocarbons represents a global concern with consequences on ecosystems and human health. The removal of HC by physical and/or chemical methods is expensive and disrespectful of the environment. The use of HC degrading bacteria is a good alternative for environmental remediation (bioremediation).

Objectives

The Algerian coastline is exposed to several types of pollutions, including hydrocarbons. The aim was to explore the bioremediation potential of its contaminated harbors for the first time.

Methods

To identify the hydrocarbon degrading bacteria seawater samples were collected in Sidi fredj harbor (Algeria) and used to enrichment cultures on mineral medium supplemented with Algerian light crude oil. The isolates were characterized by biochemical tests and Gram straining. The taxonomic identification of the isolates was performed by ARDRA and sequencing of the 16S rRNA gene. The ability to grow on hydrocarbons and degradation abilities were analysed by GC-FID together with their emulsification capacity. The key catabolic genes involved in HC degradation were detected by PCR.

Conclusions

About twenty isolates were assigned to known hydrocarbonoclastic genera (*Alcanivorax, Halomonas, Marinobacter*) and generalist HC degraders (*Pseudomonas*), but also to *Bizionia* (class Flavobacteriia). The isolates grow on *n*-alkanes (C_{16} to $C_{24,}$ *Alcanivorax, Halomonas*) toluene and benzene (*Marinobacter*) and a show average oil emulsification capacity. The PCR and sequencing of catabolic genes confirmed the presence of alkane hydroxylase genes and degradation abilities analysis is in progress. Further characterization will allow us to identify the most interesting strains to perform bioremediation.

Environmental Microbiology/Microbial Ecology /Microbial Communities

REMOVAL OF ENVIRONMENTALLY-PERSISTENT, AND COMMENSAL, E. COLI STRAINS FROM DRINKING WATER BY SLOW SAND FITLER: PERFORMANCE AND MICROBIAL ECOLOGY

O. Domingo Fernandez[1], *G. Collins*[1]
[1]*National University of Ireland- Galway, Microbiology, Galway, Ireland*

Backgrounds

Slow Sand Filters (SSFs) provide a cost-effective and energy-efficient option for drinking water production. Decontamination is achieved by biological processes in SSF biofilm. SSFs also provide a fascinating environment to study the microbial ecology underpinning pathogen removal mechanisms. At the same time, recent studies detected *E. coli* strains persisting in cold soils, putting into question whether *E. coli* is a reliable indicator organism of faecal contamination.

Objectives

In this study, the objectives were to assess the *E. coli* retention capacity of SSFs and compare retention rates of an environmentally-persistent and a commensal *E. coli* strain. The impact of sporadic faecal contaminations on the structure of bacterial and protozoan communities was also investigated.

Methods

Nine laboratory-scale SSFs were operated for 210 days and several contamination events were simulated in six of the filters. Each event comprised dosing the influent with *E. coli* (10^8 cfu/100ml) and monitoring the concentration in the effluent to determine SSF rentention of the coliforms. No contamination spikes were applied to the three control SSFs. *E. coli*, total bacteria and total protozoa were quantified in sand biofilm samples by targeting *rodA,* and 16S and 18S rRNA, genes, respectively, in qPCR assays. Bacterial and protozoan community structure and diversity were determined using high-throughput sequencing of 16S and 18S rRNA genes.

Conclusions

Excellent retention was achieved, and retention rates of the environmentally-persistent and commensal strains were similar. Certain protozoan families were more abundant after *E. coli* spikes. Overall, faecal contamination events played a major role in determining SSF microbial community structure.

PROKARYOTIC ASSESSMENT IN GEOTHERMAL AND VOLCANIC ZONES IN ARGENTINA: METAL AND METALLOID RESISTANCES AND BIOTECHNOLOGICAL APPLICATIONS

E. Donati[1], F. Massello[1], A. Lima[1], A.B. Segretin[1], C. Castro[1], G. Willis Poratti[1], M. Hipperdinger[1], M.S. Urbieta[1]
[1]CINDEFI, Quimica, La Plata, Argentina

Backgrounds

Assessing microbial communities in extreme environments such as volcanic/geothermal zones, allows for the search of novel extremophilic microorganisms that can be of use in the development or improvement of biotechnological processes. Most microbial communities developed in such harsh environments have different heavy metal resistance strategies of importance in some technological applications as biomining but also in the bioremediation of metal(loid) polluted environments.

Objectives

Our aim was to investigate the microbial diversity of Copahue geothermal system with temperatures up to 90°C and pH values from 2 to 7 under aerobic and anaerobic conditions.

Methods

Three different approaches were used, enrichment to isolate autochthonous microorganisms able to grow in the presence of high metal(loid) concentrations, and two culture independent alternatives (amplification and sequencing of the complete 16S rRNA gene of the entire community and fluorescent *in situ* hybridization). In addition, such communities were used in biotechnological applications related to heavy metal bioremediation .

Conclusions

Bacteria (acidophilic species related to AMD) dominated the acidic areas of moderate temperature, while archaea prevail in high temperature ponds. In the water samples, the dominant prokaryotes were chemolithoautotrophic or mixotrophic, mainly sulfur oxidizers while in microbial biofilms photosynthetic species were the most important primary producers. In the case of the acidic river, Rio Agrio, also mainly sulfur oxidizing bacteria and archaea were found although some iron oxidizing microorganisms were also detected. Some microbial communities isolated showed the ability to precipitate metals even at very low pH values and to reduce hexavalent chromium to the less toxic trivalent chromium.

CULTIVATION-DEPENDENT AND INDEPENDENT APPROACHES FOR DETERMINING PROKARYOTIC DIVERSITY IN ACID MINE DRAINAGE

E. Donati[1], L. Benitez[1], A. Muñoz[1], C. Bernardelli[1], J. Plaza Cazón[1], M.S. Urbieta[1]
[1]CINDEFI, Quimica, La Plata, Argentina

Backgrounds

Sulfide ores usually rich in heavy metals are a potential source for acid mine/rock drainage (AMD/ARD) which can cause severe contamination of surface and groundwater, also impacting on soils and plants constituting a serious environmental problem. AMD/ARD are produced when metal sulfides –mainly pyrite- are exposed to air and water. Although the process can occur under abiotic conditions, microbial activity can highly increase the rate of acid drainage generation. In order to prevent and/or remediate AMD/ARD, the native microbial communities must be assessed. It is widely accepted that culture-independent methods have many advantages on the traditional isolation techniques for microbial community analysis. However, for determining the role and the impact of indigenous communities on certain processes –like AMD/ARD generation- the contribution of cultivation approaches cannot be discarded.

Objectives

The aim of this work was to assess the prokaryotic diversity on the acid drainages of the Pan de Azúcar mine (Jujuy, Argentina) and Amarillo River (Famatina Belt, La Rioja, Argentina).

Methods

Denaturating gel gradient electrophoresis (DGGE) and metagenomic were used to determine the structure of the microbial communities. Cultivation techniques were also used.

Conclusions

Based on such results cultivation techniques were used to isolate microorganisms, although only a limited number of the predicted species were obtained. In addition, the isolates were tested on samples of tailings from Pan de Azucar mine and on water samples from Amarillo River. The results of our study show a decisive role of the species isolated on the AMD/ARD generation and on the geochemical characteristics of both acid drainages.

PROMOTING BIOFILM DEVELOPMENT OF CATALYTIC BACTERIA FOR BOOSTING BIODEGRADATION OF DBT

P. Dorado-Morales[1], B. García[1], I. Martínez[2], E. Díaz[2], I. Lasa[1], C. Solano[1]
[1]Centro de Investigación Biomédica Navarrabiomed/ UPNA, Laboratory of Microbial Pathogenesis, Pamplona, Spain
[2]Centro de Investigaciones Biológicas. CSIC, Laboratory of environmental microbiology, Madrid, Spain

Backgrounds

Biofilms are structured communities of microorganisms that grow adhered to inert or living surfaces due to a self-produced exopolymeric matrix in which they are encased. Inside the biofilm, bacteria exhibit a superior tolerance to physicochemical insults and harsh reaction conditions. These properties that might have deleterious consequences in clinical settings, are of great interest in industrial and environmental biotechnology, such as in the field of biocatalysis of toxic compounds.

Objectives

The aim of this study is to evaluate whether genetically engineered bacteria forced to grow as biofilm communities, through either the production of a heterologous polysaccharide or the overproduction of their own exopolysaccharides, show improved metabolic capabilities. As a proof of concept, we have used the gram-positive bacterium *Rhodococcus erythropolis* IGTS8 that harbors the *dszABCD* genes, through which the model compound dibenzothiophene (DBT) is transformed into the sulfur-free 2-hydroxybiphenyl (2HBP) molecule. *Rhodococcus erythropolis* engineered bacteria that grow inside a biofilm might provide an improved biotechnological strategy for the removal of the recalcitrant sulfur of aromatic heterocycles present in fuels.

Methods

Genetic engineering of a *Rhodococcus erythropolis* strain able to desulfurinate DBT in order to promote biofilm development.

Genetic engineering of *dsz* cassettes to avoid bottlenecks in the conversion of DBT into 2HBP.

Analysis of DBT desulfurization efficiency through the quantification of DBT and 2HBP by HPLC.

Conclusions

Preliminary results show that genetic programming of *Rhodococcus* bacteria to form a biofilm through the overproduction of its own exopolysaccharides leads to an increase in the bioconversion of DBT into 2HBP.

Environmental Microbiology/Microbial Ecology /Microbial Communities

THE EFFECTS OF GROWTH CONDITIONS AND SECONDARY ENVIRONMENTAL STRESSES ON THE RESPONSE OF LISTERIA MONOCYTOGENES TO VISIBLE LIGHT

A. Dorey[1], *B. O'Donoghue*[1], *K. NicAogáin*[1], *C. O'Byrne*[1]
[1]*Bacterial Stress Response Group, Microbiology, Galway, Ireland*

Backgrounds

Research investigating the response of *L. monocytogenes* to visible light has identified the Lmo0799 protein in the sensing of visible light, and the activation of the SigB signalling cascade. Triggering of the σ^B signalling cascade leads to the transcription of the general stress response gene regulon via the activation of σ^B. Growth of *L. monocytogenes* in alternating periods of light and dark results in a ringed colony morphology, preventable by the deletion of *sigB* or *lmo0799* from the genome. The inhibitory effect of visible light on *L. monocytogenes* is due to accumulation of reactive oxygen species, and exposure to visible light induces a protective response against a challenge by ROS.

Objectives

The aim of our study is to elucidate the role of σ^B in the resistance of *L. monocytogenes* to visible light using transcriptomic and phenotypic experiments.

Methods

L. monocytogenes wild-type and Δ*sigB* deletion mutant cultured at 30°C or 37°C were challenged with visible light at exponential and stationery growth phases. Cells were pre-exposed to sub-lethal doses of environmental stresses to investigate cross-resistance between visible light and alternative stresses. RT-PCR targeted at σ^B-dependent genes was used to determine the optimum dose and exposure time for the activation of σ^B by visible light.

Conclusions

Our research shows that growth phase and temperature affect susceptibility of *L. monocytogenes* to visible light, with cells being more susceptible at exponential compared to stationery phase and at 37°C compared to 30°C, and the role of σ^B in the protective response. Some environmental stresses convey resistance to visible light.

Environmental Microbiology/Microbial Ecology /Microbial Communities

ANTIBIOFILM ACTIVITIES OF MULTIPURPOSE SOLUTIONS AGAINST SOFT CONTACT LENS BIOFILM MODELS

S. Dosler[1], *M. Tuysuz*[1]
[1]*Istanbul University- Faculty of Pharmacy, Pharmaceutical Mirobiology, Istanbul, Turkey*

Backgrounds

Contact lenses are important bio-medical substances with not only the correction of some eye defects but also the cosmetic characteristics. Especially the formation of biofilms with adherent bacteria is very important menace for whole eye health. Especially multi drug resistant *Pseudomonas aeruginosa* or methicillin resistant *Staphylococcus aureus* (MRSA) and *Candida albicans* strains which are the common pathogen bacteria and yeast, respectively, in eye infections.

Objectives

Because of their increasing resistance to antibiotics, the treatment of them is very difficult today, especially when they are being in biofilms. In this study, we investigated the in vitro activities of some multi-purpose lens solutions. (Bio-true, renuu, opti-free and all-in-one) and antibiotics (gentamycin, tobramycin and ciprofloxacin) against *P. aeruginosa*, MRSA, and *C. albicans* biofilms on two kind of soft contact lenses with time killing curve method at 6, 24 and 48 hours.

Methods

In vitro activities of iMulti-purpose lens solutions (Bio-true, renuu, opti-free and all-in-one) and antibiotics (gentamycin, tobramycin and ciprofloxacin) against *P. aeruginosa*, MRSA, and *C. albicans* biofilms on two kind of soft contact lenses were tested with time killing curve method at 6, 24 and 48 hours.

Conclusions

The most active multipurpose solution against *P. aeruginosa* and MRSA biofilms at 24 hours was opti-free fallowed by the bio-true and renuu, against *C. albicans* biofilms at 48 hours was renuu fallowed by the opti-free and bio-true. In addition, all studied antibiotics were active against *P. aeruginosa* and MRSA biofilms on soft contact lenses at 24 hours. According to our results, anti-biofilm activities of multipurpose lens solutions were various depending the chemical ingredients and contact time.

Environmental Microbiology/Microbial Ecology /Microbial Communities

MICROBIAL DYNAMICS AND SUCCESSION IN DRINKING WATER DISTRIBUTION SYSTEMS

I. Douterelo[1], *K. Fish*[1], *J. Boxall*[1]
[1]*Pennine Water Group- The University of Sheffield, Civil and Structural Engineering, Sheffield, United Kingdom*

Backgrounds

Biofilms formed on inner-pipe surfaces of drinking water distribution systems (DWDS) can affect the quality and safety of drinking water. Biofilm formation is a successional process beginning when free-living microorganisms attach to pipe surfaces, growing whilst modifying the pipe wall, generating extracellular polymeric substances that facilitate the incorporation of other microorganisms into the biofilm. The community characteristics for such succession are largely unstudied, particularly for representative DWDS conditions and mixed microbial communities.

Objectives

To study the initial succession of water infrastructure biofilm communities over three months of development under conditions fully representative of operational DWDS.

Methods

Biofilms were developed and monitored over a three month period in a full-scale experimental pipe loop facility at 16°C (average UK summer water temperature). Hydraulic conditions were controlled to simulate demand driven daily patterns. Biofilms were sampled using coupons removed at regular time intervals. Water physico-chemical parameters were analysed using discrete sampling. Bacterial and fungal communities were characterised using Illumina sequencing of 16S and 18S rRNA genes, respectively.

Conclusions

Bacteria were found to be the predominant taxa compared to fungi within the DWDS biofilms. Fungal communities did not experience substantial temporal changes. However, bacterial communities were observed to increase in complexity over the three-month period. Indicative of successional colonisation of the pipeline from primary and secondary colonisers to a more complex, maturing biofilm. We can conclude that biofilm formation is a highly dynamic process occurring in relative short-time periods, dominated by bacteria and influenced by internal and external factors.

HIGH THROUGHPUT SEQUENCING OF FULL-LENGTH SSU RRNA SEQUENCES FROM COMPLEX MICROBIAL COMMUNITIES WITHOUT PRIMER BIAS AND HOW IT AFFECTS OUR ABILITY TO STUDY MICROBIAL ECOLOGY

M.S. Dueholm[1], S.M. Karst[1], S.J. McIlroy[1], R.H. Kirkegaard[1], P.H. Nielsen[1], M. Albertsen[1]
[1]Aalborg University, Department of Chemistry and Biosciences, Aalborg East, Denmark

Backgrounds

The small subunit (SSU) ribosomal RNA (rRNA) genes have been used to study microbial diversity and evolution for the last 30 years. Today, databases containing full-length SSU rRNA reference sequences remain fundamental for many core tools in microbial ecology, such as community profiling using 16S/18S amplicon sequencing and *in-situ* studies based on fluorescence *in situ* hybridization microscopy. The quality of the data produced relies heavily on the reference databases used, and it is widely recognized that the current databases are underpopulated, ecosystem skewed, and subject to primer bias. This is a consequence of the present low-throughput, primer-based methods used to generate the sequences.

Objectives

We want to develop a method that allows high-throughput sequencing of full-length SSU genes without the use of conventional primers. Furthermore, we will examine how the access to comprehensive ecosystem specific SSU databases affect our ability to study microbial ecology.

Methods

We have developed a method which combines reverse transcription of environmental full-length SSU rRNA sequences and Illumina based synthetic long-read sequencing to obtain high quality, full-length SSU rRNA sequences in a high throughput manner.

Conclusions

In our initial trials, we obtained more than 40,000 high quality SSU rRNA sequences (> 1200 bp) representing all domains of life from five different ecosystems (human gut, soil, fresh water, anaerobic digestion and activated sludge), showing the general application and the throughput of the method. Here we describe how the method works and demonstrate how the access to comprehensive ecosystem specific SSU databases affect our ability to study microbial ecology.

Environmental Microbiology/Microbial Ecology /Microbial Communities

SOIL MICROBIAL DIVERSITY: A COMPARISON OF METAGENOMICS AND CULTUROMICS APPROACHES

C. Dumolin[1], *P. Vandamme*[1]
[1]*Ghent University, Biochemistry and Microbiology, Gent, Belgium*

Backgrounds

Novel insights in the tree of life revealed staggering numbers of uncultivated bacterial lineages. Harnessing this novel biotechnological potential requires prior cultivation. Although metagenomics studies are considered the gold standard for analyzing microbial diversity, large scale isolation and identification campaigns, i.e. ”culturomics “, may reveal organisms that went undetected via metagenomics. A combined approach, is therefore paramount to determine the microbial diversity and to exploit its biological functionalities.

Objectives

The aim of the present study was to determine the microbial diversity in an old-growth forest soil sample using both metagenomics and culturomics.

Methods

A plain soil sample of the Aelmoeseneie forest (Gontrode, Belgium) was collected. For metagenomic analyses, DNA was extracted using the Mobio Powersoil kit. Total DNA was sequenced on the Illumina HiSeq platform. The cultivable microbial diversity of the same soil sample is studied via an in-house developed culturomics pipeline, based on the automated picking of isolates and dereplication via MALDI-TOF MS. We aim to isolate and identify 25,000 bacterial isolates.

Conclusions

Shotgun metagenomic sequencing yielded >237,000 reads, correlating to a bacterial richness of >800 species. This diversity is dominated by *Proteobacteria* (55%), *Actinobacteria* (35%) and *Acidobacteria* (3%). *Proteobacteria* are mainly represented by *Alphaproteobacteria* with *Rhizobiales* (78%) and *Rhodospirillales* (7%) as main orders. *Actinobacteria* are dominated by the *Corynebacteriales* order (31%); interestingly, 8% of the total DNA sampled represented *Mycobacterium* reads. The culturomics analysis is ongoing; in summer 2017 half of the culturomics data, i.e. referring to the isolation and identification of about 12,500 isolates, will be available and presented.

Environmental Microbiology/Microbial Ecology /Microbial Communities

ANAMMOX FOR MAINSTREAM NITROGEN REMOVAL FROM WASTEWATER

M. Duran[1], *D. Foster*[1], *S. Muller*[1]
[1]*Villanova University, Civil and Environmental Engineering, Villanova, USA*

Backgrounds

Anaerobic ammonium oxidation (anammox), is the biochemical process whereby bacteria oxidize NH_4^+ to N_2 using NH_4^+ as the electron donor and NO_2^- as the electron acceptor. Anammox bacteria, discovered in the mid-1990s,[1] are fairly common in oxygen-limited natural habitats[2,3] and allow one-step conversion of NH_4^+ to N_2, thereby abbreviating the nitrogen cycle. Anammox offers a transformative alternative for NH_4^+ removal from wastewaters, as it requires 75% less oxygen than the traditional nitrification/denitrification process. In addition, it reduces emissions of the greenhouse gas N_2O by 90%.[4,5,6]

Although anammox has been applied for the treatment of warm and high-strength wastewaters [24,25] there are significant challenges preventing its wider application for NH_4^+ removal from wastewaters. A recent survey by Lackner *et al.* (2014) points out the difficulty of developing and retaining sufficient anammox biomass, due to the anammox bacteria's unusually slow growth rates.[7] In addition, current anammox applications require partial denitritation in order to supply NO_2^- per the anammox reaction. This has limited the current anammox technologies to sidestream NH_4^+ removal where approximately 500 mg-N/L is required.

Objectives

This objective of this study was to cultivate anammox suitable for mainstream NH_4^+ removal from wastewaters.

Methods

A bench-scale bioreactor (15 L effective volume) was operated for over one year with the anammox culture, obtained from a full-scale DEMON® reactor, growing on NH_4^+ concentrations typically seen in municipal wastewater, 50 mg-N/L.

Conclusions

The results indicate that the selected anammox culture consistently achieved over 90% NH_4^+ removal, showing that mainstream NH_4^+ from wastewater is feasible.

AROMATIC RING-HYDROXYLATING OXYGENASE-ENCODING GENES OF THE HYDROCARBONOCLASTIC MARINE BACTERIUM ALCALIGENES SP. QD168

R. Durán[1,2], F. Salvà-Serra[3,4], B. Barra[1,2], E. Moore[3,4], M. Seeger[1,2]
[1]Laboratorio de Microbiología Molecular y Biotecnología Ambiental, Departamento de Química- Universidad Técnica Federico Santa María, Valparaiso, Chile
[2]Center of Biotechnology, Universidad Tecnica Federico Santa Maria, Valparaiso, Chile
[3]Culture Collection University of Gothenburg CCUG, University of Gothenburg, Gothenburg, Sweden
[4]Department of Infectious Diseases- Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

Backgrounds

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous, toxic and recalcitrant environmental pollutants. Microbial degradation has been applied to remove these pollutants. The aromatic ring-opening is a key enzymatic step catalyzed by multicomponent aromatic-ring-hydroxylating oxygenases (ARHOs).

Objectives

The aim of this study was the identification of ARHO-encoding genes in the marine *Alcaligenes* sp. QD168 genome.

Methods

Bacterial strain QD168 was isolated after an oil spill from marine sediment of Quintero Bay, Central Chile. QD168 cells growth on various PAHs as sole carbon source was assessed. Strain QD168 genome was sequenced, assembled and automatically annotated by RAST, PROKKA and further analyzed through a curated search to predict ARHO α-subunits. A phylogenetic tree was constructed using amino acid sequences of α-subunit terminal oxygenases**.**

Conclusions

QD168 cells were able to grow on fluorene, naphthalene and phenanthrene as sole carbon sources. After the assembly, we obtained a 4.28 Mb draft genome (GC-content 56.4%). More than 30 α-subunit terminal oxygenase-encoding genes were identified. The bayesian tree clustered QD168 α-subunits with reference ARHO genes, identifying the presence of different terminal oxygenase classes. In conclusion, this study revealed the existence of a wide range of terminal oxygenase-encoding genes in *Alcaligenes* sp. QD168, reflecting its potential for bioremediation of aromatic compounds.

[2]Institut für Chemie und Biologie des Meeres, Umweltbiochemie, Wilhelmshaven, Germany
[3]University of Bremen, MARUM, Bremen, Germany

Backgrounds

Bioremediation of arsenic in marine systems represent a desirable technology, encouraging the search for novel microorganisms with these features. The shallow hydrothermal system off the Greek island Milos expels fluids of high temperature and salinity with extremely elevated arsenic concentrations, identifying this environment as an ideal natural laboratory to search for endemic microbes with bioremediation potential. Recent data indicate lipids as primary focus for microbial adaptation to these extreme conditions.

Objectives

This study focusses on a novel halophilic isolate from the Milos hydrothermal system, its membrane lipid adaptations under arsenic stress and its potential for bioremediation applications.

Methods

The bacterial isolate was physiologically characterized and identified by 16S rDNA gene sequencing. Arsenic precipitation was evaluated by scattering electron microcopy couple to energy dispersive X-ray spectroscopy for shape, size and elemental composition determination. Microbial lipids were extracted in the stationary growth phase and response to arsenic stress (20 mM) and increasing salt concentrations (2.5 to 20%) were investigated by high performance liquid chromatography coupled to mass spectroscopy.

Conclusions

A novel moderately halophilic bacterium (optimal growth at 5% NaCl), exhibits an unusual high As(V) tolerance (tested up to 20 mM) associated with generation of Mg-As-O rich particles, needle shape and size near to 100 nm length. pH dependent co-precipitation of Mg and As is suggested as bioremediation mechanism. Composition of intact polar lipids showed unique profiles, indicating saturation of methyl-branched fatty acids as adaptation to salt stress and a significant decrease of respiratory quinones under increasing arsenic stress.

UNRAVELING THE MECHANISMS OF HOST-INTERACTION IN THE MACROALGAL PATHOGEN NAUTELLA SP. R11

S. Egan[1], J. Hudson[1], M. Gardiner[1], N. Deshpande[2]
[1]University of New South Wales, School of Biological- Earth and Environmental Science, Sydney, Australia
[2]University of New South Wales, School of Biotechnology and Biomolecular Sciences, Sydney, Australia

Backgrounds

Macroalgae are essential for the functioning of temperate marine ecosystems, but their survival is under threat as a result of anthropogenic pressures and disease. *Nautella* R11 is recognised as one etiological agent responsible for the occurrence of bleaching disease in the red alga, *Delisea pulchra*. Previous work has suggested that bacterial quorum sensing (QS) is involved in regulating *Nautella* R11 virulence, yet there is a lack of knowledge of specific virulence mechanisms involved in this host pathogen interaction.

Objectives

To determine the role of the LuxR- type QS regulator RaiR in the regulation of *Nautella* R11 virulence and to identify the transcriptional response of this pathogen to the presence of its macroalgal host.

Methods

A *Nautella* R11 *raiR* gene deletion strain was created and assessed for its ability to cause bleaching disease in *D. pulchra* relative to the wildtype strain. We used a RNA-sequencing approach to assess the transcriptional response of both widtype and mutant strains in the presence and absence of the host.

Conclusions

Mutations in *raiR*, render *N. italica* R11 avirulent, suggesting this gene is important for regulating the expression of virulence phenotypes. We found that genes related to oxidative stress resistance, carbohydrate uptake and central metabolism are all upregulated in *N. italica* R11 in response to the macroalgal host and maybe play an important role towards the virulence of this opportunistic pathogen. Furthermore RaiR appears to regulate a subset of these genes, including those involved in phenylacetate degradation, galactose metabolism, oxidative stress response and also controls the expression of multiple phage proteins. Interestingly a large proportion of RaiR controlled genes were annotated as hypothetical or predicted function only, suggesting the presence of yet uncharacterised virulence mechanisms in this marine bacterium. The outcome of this research contributes to our greater understanding of the pathogenic traits mitigating microbial diseases in marine ecosystems.

OLIGOTYPING TO ANALYZE LAB SUCCESSION OF RDNA VARIANTS THROUGHOUT ATOLE AGRIO FERMENTATION

P. Elizaquivel[1], A. Perez-Cataluña[2], P. Carrasco[2], J. Espinosa[3], D. Reyes[4], C. Wacher[5], R. Aznar[6]
[1]Colección Española de Cultivos Tipo - Universidad de Valéncia, Microbiology and ecology, Paterna Valencia, Spain
[2]Universidad de València, Microbiology and ecology, Burjassot, Spain
[3]Universidad Juárez Autónoma de Tabasco, Unidad Sierra. Villahermosa, Tabasco, Mexico
[4]Universidad Autónoma Metropolitana Unidad Cuajimalpa, Departamento de Procesos y Tecnología, México- D.F., Mexico
[5]Universidad Nacional Autónoma de México, Departamento de Alimentos y Biotecnología- Facultad de Química, México D.F., Mexico
[6]Colección Española de Cultivos Tipo - Universidad de Valéncia, Microbiology and ecology, Burjassot- Valencia, Spain

Backgrounds

Atole agrio is a Mexican non-alcoholic beverage derived from fermented maize. Lactic acid bacteria (LAB) are commonly found as a major population in this product. Comprehension of microbial ecology of *Atole* and, in general, LAB fermented products, would help to the implementation of new food manufacturing processes and possible biotechnological applications of LAB strains.

Objectives

To track the intraspecific population dynamics of predominant genera, *Weissella* and *Lactobacillus,* throughout *Atole* fermentation using oligotyping as an annotation independent method.

Methods

Partial 16S rRNA gene sequencing (V3–V5) was obtained from DNA directly extracted from ten *Atole* samples, corresponding to 0h, 4h, 6h, 12h and 24h fermentation from each liquid and solid batches. A total of 63,952 reads with an average length of 528 bp were obtained and analyzed (41,613 for liquid fermentation and 22,339 for solid fermentation). Oligotyping was performed using the open-source software pipeline available at http://merenlab.org/projects/oligotyping/.

Conclusions

For *Lactobacillus,* two oligotypes (C and T) were found. Oligotype C predominated at the beginning of the fermentation, but decreased after 12h and imposed at the end of fermentation. On the contrary, oligotype T increased to the maximum at 12h and decreased throughout the end.

Regarding *Weissella,* two oligotypes (C and G) were found. Oligotype (C) predominated at the beginning of the process but dropped at 6h and raised again outnumbering oligotype G at the end of the fermentation. In both species, the predominant oligotype detected at the initial step became predominant at the end of the process; despite they evolved differently during the fermentation.

CO-CULTURE GROWTH BETWEEN COMMENSAL ESCHERICHIA COLI AND SEROTYPE O157:H7 ISOLATES REVEALS A COMPETITIVE EDGE FOR NON-PATHOGENIC STRAINS.

T. Ells[1], D. Albert[2], M. Ritchie[1], D. Mader[1], H. Eberl[3], G. Bezanson[1], M. Kalmokoff[1]
[1]Agriculture and Agri-Food Canada, Food Safety, Kentville- NS, Canada
[2]Acadia University, Department of Biology, Wolfville- NS, Canada
[3]University of Guelph, Department of Mathematics and Statistics, Guelph- ON, Canada

Backgrounds

Escherichia coli are common constituents of the mammalian enteric community. Serotype O157:H7 differs from commensal *E. coli* by its ability to produce shiga-like toxins and cause serious illnesses in humans. Although ruminants represent the primary reservoir for serotype O157:H7 it does not incite disease in these animals. Serotype O157:H7 can be isolated from beef and dairy cattle, but not all animals carry the pathogen and questions remain regarding its carriage.

Objectives

Examine the growth kinetics of a diverse collection of commensal *E. coli* and serotype O157:H7 isolates to elucidate potential interactions during competition for a similar niche.

Methods

E. coli isolates (~1000) were obtained from fecal samples from an experimental beef herd in Nappan, Nova Scotia. Isolates were initially screened by rep-PCR and then by PFGE. Growth kinetics for all representative pulsotypes as well as a 51 strain panel of O157:H7 isolates were assessed using impedance technology (RABIT). Competitive growth dynamics were evaluated between selected co-culture pairings of commensal versus serotype O157:H7 strains by end point enumerations on BCIG.

Conclusions

Fifty nine unique pulsotypes were identified among the commensal *E. coli* isolates. Monoculture impedance growth curves revealed these isolates generally had significantly higher growth rates (and a narrower range) than the panel of O157:H7 strains. Competition studies between selected commensals paired with each of 32 different O157:H7 isolates resulted in end point strain ratios favoring commensal strains by varying degrees. Although data suggest an advantage for commensal strains further studies are required to elucidate the impact of substrate variation on competition outcomes.

COMPARISON METHODS FOR THE EFFICACY TESTING OF OIL INDUSTRIAL BIOCIDES (LABORATORY EVALUATION)

I. Elmisurati[1], *H. Althalb*[2]
[1]*Libyan Petroleum Institute, Industrial &Production Chemistry, Tripoli, Libya*
[2]*Libyan Petroleum Institute, Industrial & Production Chemistryt, Tripoli, Libya*

Backgrounds

The disinfection efficacy of chemical biocides and the subsequent assessment of the metabolic state of the microorganisms can be evaluated by a variety of methodological approaches.

Objectives

The action of the bactericides was tested against planktonic sulphate reducing bacteria isolated from oil field. The ability of the planktonic SRBs to recover from the biocidal application was quantified by determining SRA (SO_4^{-2}) as the terminal electron acceptor in an aerobic respiration.

Methods

Most probable number (MPN) in terms of Time-kill test for culturable bacteria, fluorochrome-based assay by (DAPI) or (AO) with aldehyde and non aldehyde based biocides has been used to measure total bacterial count.

Biocide is incompatible with oxygen scavenger; however biocidal activity is lost upon addition of oxygen scavenger.

GM bacteria such as *Escherichia coli*HB101 pUCD607 and naturally occurring bacteria such as *Vibrio fischeri* has been used as a biosensors to detect toxicity of biocides.

Conclusions

Considerable variation is seen in the activity of the tested biocides with these bioluminescent strains, this assay may be useful not only in determining the concentration of biocides in oil-water system, but also in determining optimal biocide concentrations on a real-time basis.

A NOVEL STRAIN OF MODERATELY HALOPHILIC BACTERIA BELONGING TO GARICOLA GENERA ISOLATED FROM HISTORICAL FRESCOES

M. Enache[1], R. Cojoc[1], S. Neagu[1], I. Gomoiu[2]
[1]Institute of Biology Bucharest - Romanian Academy, Microbiology, Bucharest, Romania
[2]National Arts University Bucharest, Arts Conservation, Bucharest, Romania

Backgrounds

Moderately halophilic bacteria are spread in various media containing sodium chloride and other salts from negligible quantity until saturation. The genus *Garicola* was proposed in 2015 by Lo et al., based on the isolation of a novel strain from traditional Korean fermented shrimp. From the mural painting of Hurezi Monastery in Romania, building between years 1690 – 1693, were isolated several strains of bacteria able to grow on media with salt concentration until to 4M.

Objectives

This work deals with characterization of a moderately halophilic bacteria strain in order to propose it as a new species. On the other hand the methodologies for conservation of the mural paint in order to avoid the future development of microbial strains are considered.

Methods

The novel strain is characterized by proposed minimal standard for new taxa of moderately halophilic bacteria. The various biochemical tests were performed, G+C content, DNA-DNA hybridization test, 16S rDNA sequence, membrane lipid and protein profiles and other tests.

Conclusions

Preliminary results based on 16S rDNA investigations, BLAST analysis and some biochemical tests showed that novel strain is close related to *Garicola* genera. Considering all data obtained the strain is proposed as a novel species of this genus.

FRUCTOPHILIC LACTIC ACID BACTERIA: TAXONOMY, BIOCHEMICAL AND GENOMIC CHARACTERISTICS AND POSSIBLE APPLICATION

A. Endo[1], S. Maeno[1], J. Nakagawa[1], S. Salminen[2], L. Dicks[3]
[1]Tokyo University of Agriculture, Food and Cosmetic Science, Hokkaido, Japan
[2]University of Turku, Functional Foods Forum, Turku, Finland
[3]Stellenbosch University, Microbiology, Stellenbosch, South Africa

Backgrounds

Fructophilic lactic acid bacteria (FLAB) are a special group of lactic acid bacteria (LAB) found only in fructose-rich niches, which have been established recently. Their specific characteristics had not been well documented.

Objectives

Our research is to study their unique characteristics and adaptation to their habitat.

Methods

Biochemical and genomic characteristics of FLAB were studied. FLAB prefer fructose but not glucose as a growth substrate. External electron acceptors, e.g. pyruvate, support the growth of the organisms on glucose. Moreover, the presence of O_2 strongly enhances their growth, although they do not possess respiratory chain. All five species of the genus *Fructobacillus* and *Lactobacillus kunkeei* are classified in this interesting bacterial group. The genomic characterization of *Fructobacillus* spp. as compared to their phylogenetic relatives, *Leuconostoc* spp., revealed their unique genomic evolution, e.g. less CDS and poor systems in carbohydrate transport and metabolism. The *adhE* gene encoding bifunctional alcohol/acetaldehyde dehydrogenase, which is essential for regeneration of NAD in glucose metabolism of heterolactic metabolism, is missing in all *Fructobacillus* spp. They are the first organisms which lack *adhE* gene in the heterofermentative LAB group. FLAB are found in flowers and fruits and also major components of gut microbiota in insects consuming fructose rich diets, i.e. honeybees. Our preliminary study revealed that certain FLAB strains specifically inhibit the growth of European foulbrood pathogen, *Melissococcus plutonius*.

Conclusions

FLAB possess quite unique biochemical and genomic characteristics in LAB group, and this would be due to a regressive evolution during adaptation to their fructose-rich habitats.

ENTEROBACTERIACEAE AND ANTIBIOTIC RESISTANCES ON LEAFY GREENS

A. Erlacher[1], *M. Grube*[2], *G. Berg*[1]
[1]*Graz University of Technology, Institute of Environmental Biotechnology, Graz, Austria*
[2]*University of Graz, Institute of Plant Sciences, Graz, Austria*

Backgrounds

Plants live in close interactions with microbial communities that are essential for the performance and survival of the host. However, these diverse microbiomes of vegetables can also act as reservoirs for antibiotic resistances, opportunistic and emerging pathogens. Increased consumption, larger scale production and efficient logistics of vegetables are at risk for contamination with pathogens causing human disease.

Objectives

Therefore, a comprehensive understanding of microbial structure on food items is urgently needed.

Methods

Using next generation sequencing techniques including, sequencing of 16S rRNA amplicons, whole metagenome shotgun sequencing, and complementary FISH/CLSM analyses, we were able to shed light on the structural and functional lifestyle of enterobacteria on fresh produce.

Conclusions

We found general preference of *Enterobacteriaceae* to colonize vegetables as abundant, highly diverse and indigenous key taxa, which are highly sensitive responders to biotic stress. CARD analysis complemented with disc diffusion antibiotic sensitivity testing revealed an enrichment of antibiotic resistances on the phyllosphere. Here, efflux pump conferring antibiotic resistances were predominant, followed by fluoroquinolone and chloramphenicol resistance genes. Further, an interesting colonization behavior was observed, as enterobacteria selectively intrude foliage through bruises, vascular bundles or stomata. Microbial network analyses of lettuce root samples revealed loose microbiome structures indicating susceptibility to perturbation and potential pathogen infestation. Our studies provided important insights to understand the nature of potential human pathogens and occurrence of antibiotic resistances in plant-associated ecosystems.

LISTERIA MONOCYTOGENES MAINTAINS ITS VIRULENCE POTENTIAL WHEN IT IS TRANSMITTED ALONG THE MICROBIAL FOOD CHAIN

S. Ermolaeva[1], V. Pushkareva[1], J. Podlipaeva[2], A. Gudkov[2]
[1]Gamaleya Research Center of Epidemiology and Microbiology,
Department of Infections with Natural Foci, Moscow, Russia
[2]Institute of Cytology, Laboratory of Cytology of Unicellular Microorgaisms, St.Petersburg, Russia

Backgrounds

Unicellular predators including *Amoeba* spp and ciliates feed on bacteria and smaller protozoa and might control pathogenic bacteria in natural ecosystems. Some pathogens seem to develop mechanisms that protect them from protozoa. The same mechanisms might be involved in virulence for mammals and humans. The thiol-dependent haemolysin, Listeriolysin O (LLO) is a key virulence factor of Gram-positive pathogenic bacterium *Listeria monocytogenes*. LLO causes mortality and encystment of *Tetrahymena pyriformis* feeding on LLO-producing bacteria (Puhkareva & Ermolaeva 2010).

Objectives

To establish a *L. monocytogenes* ability to maintain its virulence potential when it is transmitted along the microbial food chain and the role of LLO.

Methods

Wild type and LLO-lacking *L. monocytogenes* and wild type and LLO-producing *L. innocua* strains were used to feed *T. pyriformis* strain GL. Then washed and gentamycin treated bacterium-containing *T. pyriformis* were used to feed *Amoeba proteus* strain LB1503/4/.

Conclusions

A. proteus when fed on *T.pyriformis*, which in turn was fed on LLO-lacking bacteria, corresponded to normal physiological parameters (motility, size, the number of pseudopodia) up to 72 h. Feeding on T.*pyriformis* fed on LLO-producing bacteria caused loss of pseudopodia in 24 h and amoeba destruction in 72 h with releasing alive bacteria. Therefore, (i) *L.monocytogenes* maintained its virulence potential when it was transmitted along the microbial food chain, and (ii) the fate of *A. proteus* fed on bacterium-carrying ciliates was determined by LLO production. Obtained results proved the role of protozoa as a Trojan horse and demonstrated how a pathogen can move along a food chain.

IN SITU STUDY OF IBERIAN PYRITE BELT HARD ROCK BIOFILMS BY FLUORESCENCE MICROSCOPY TECHNIQUES

C. Escudero[1], *M. Oggerin de Orube*[1], *R. Amils Pibernat*[1]
[1]*CBMSO-UAM, Virología y Microbiología, Madrid, Spain*

Backgrounds

Natural microbial communities are characterized by the co-existence of microorganisms in self-produced matrix named biofilms. This matrix is compounded by extracellular polymeric substances (EPS) that create an ideal microenvironment in which microorganisms can survive even in adverse conditions.

Subsurface is an extreme environment where there is no sunlight or oxygen and organic matter is scarce or no bioavailable. Life is limited to low energy anaerobic metabolisms and the principal energy source depends on the geochemistry of the system. For this reason, it is believed that microorganisms present a very low metabolic rate or remain in a latent state and, consequently, biofilms are not produced due to the energetic cost required.**Objectives**

IPBSL is a drilling project designed to characterize the Iberian Pyrite Belt (IPB) subsurface ecosystem, which is responsible of the extreme acidic conditions of Río Tinto basin. The aim of this study was to analyze, *in situ*, the biodiversity and the presence of biofilms in subsurface hard rock matrix.

Methods

Fluorescence *in situ* Hybridization (FISH), CAtalyzed Reporter Deposition-FISH (CARD-FISH) and Fluorescence Lectin Binding Assay (FLBA) were applied in rock samples of different depths.

Conclusions

CARD-FISH, which allows the identification of microorganisms due to the use of specific probes, has shown the existence of a high microbial biodiversity in the IPB subsurface. Besides, the combination of FISH techniques and FLBA reveal that most of these microorganisms are part of mixed biofilms. These results suggest that production of biofilms can be a good structural mechanism for microbial activity and survival in deep subsurface environments.

EFFECT OF AIR POLLUTION ON BACTERIAL COMMUNITIES ASSOCIATED WITH PLATANUS HISPANICA (LONDON PLANE) LEAVES

J. Espenshade[1], L. Mattens[2], S. Thijs[1], N. Weyens[1], J. Vangronsveld[1]
[1]Hasselt University, Centre for Environmental Sciences, Hasselt, Belgium
[2]University of Leuven, Department of Pharmaceutical and Pharmacological Sciences, Leuven, Belgium

Backgrounds

Many plant-associated bacteria have a positive effect on the host plant's health and growth by producing useful biomolecules. It is also hypothesized that when these bacterial communities are constantly exposed to air pollution, they will favour strains that have a higher tolerance against and possibly degrade some polluting compounds. In this study, we searched for plant growth promoting leaf-associated bacteria with laccase-like multicopper oxidase enzymes (LMCO), which reportedly have the potential to degrade polycyclic aromatic hydrocarbons (PAHs) from diesel exhaust.

Objectives

The aim of this study was to isolate endophytic bacteria from *Platanus* leaves and characterise them for traits related to degradation of air pollution and promotion of plant health.

Methods

Platanus leaves were collected inside and outside of the city of Hasselt, Belgium. Bacteria were isolated from pulverised leaf material exposed to diesel fumes. Isolated bacteria were genotyped and screened for ACC-deaminase and auxin production, phosphate solubilisation, PAH tolerance, and laccase-like enzyme activity.

Conclusions

Initial results indicate that the *Platanus* tree outside the city centre hosted a larger bacterial community than the trees close to roadways. However, trees that were more directly exposed to air pollution appear to not only host bacteria with a greater tolerance for diesel fumes but also a greater proportion of bacteria with plant growth promoting traits and potential LMCO enzymes.

Environmental Microbiology/Microbial Ecology /Microbial Communities

ISOLATION AND CHARACTERIZATION OF SHEWANELLA PUTREFACIENS GROUP FROM DISEASED WILD EELS AND FRESHWATER LAKE WATER

C. Esteve[1], *E. Alcaide*[1]
[1]*Universitat de València, Microbiología y Ecología, Burjassot, Spain*

Backgrounds

Shewanella putrefaciens group are commonly found in brackish/marine water and sediments where they are important in the process of organic matter turnover under hypoxic conditions. *Shewanellae* are also present in wild marine fish intestinal microbiota where they may have an antagonistic effect on bacterial pathogens. At present, the role of *S. putrefaciens* group as fish pathogen is only based on infections of freshwater farmed fish that are suffering from non-determined stress conditions

Objectives

There are two objectives: 1) to assess the role of *Shewanellae* as pathogens of the European eel fishery at present, 2) to determine the environmental conditions at the L´Albufera Lake that favor an outbreak of such disease.

Methods

Physico-chemical parameters of water (i.e. O_2 dissolved; temperature: pH; conductivity; salinity) were measured *in situ*. Isolation and counting of *Shewanellae* from fish and water samples were performed by culturing on general (TSA-1) and selective (SH30VA) media. Bacterial isolates were assigned to *Shewanella* species by using conventional tests, API 20E and 20NE strips (Biomerieux), and 16S rRNA sequencing. Statistical analyses (correlation and regression) were used. Virulence for eel of *Shewanellae* isolates was assessed by both intraperitoneal (IP) injection, and bath immersion (BI) challenges.

Conclusions

Shewanellosis at the European eel fishery is promoted by hypoxic conditions in the aquatic system. First, the rise of *Shewanellae* in lake freshwater is correlated with hypoxia as general rule. Second, this fish infection can be transmitted through the water.

Environmental Microbiology/Microbial Ecology /Microbial Communities

INCREASING BIOREMEDIATION CAPACITY IN HYDROCARBON POLLUTED SOIL MATRIX

C.O. Esuola[1,2,3], J. Trögl[2], M. Schlömann[1], O.O. Babalola[3], D. Tischler[1]
[1]Technical University Bergakademie Freiberg- Institute of Biosciences, Environmental Microbiology, Freiberg, Germany
[2]Jan Evangelista Purkyně University, Faculty of Environment, Ústí nad Labem, Czech Republic
[3]North-West University- Mafikeng Campus, Department of Biological Sciences, Mmabatho, South Africa

Backgrounds

Toxic, heavy metals and hydrocarbons are still employed in many industries which anthropogenically leak into the environment. More research efforts are still needed to elucidate the role of particular bacteria for effective bioremediation of hydrocarbon and metal polluted soils.

Objectives

To investigate and determine the rate at which both *Gordonia* sp. and *Rhodococcus* sp. are effective for biodegradation of high concentrations of petroleum hydrocarbons in contaminated soil under the influence of metal-stress.

Methods

Contaminated soil (500 kg) were collected from an rafirenry lagoon and prepared for the pot experiment. A total of twelve variants, each in four replicates, was realized. 500g of soil was weighed into each pot (48 pots). The soil without addition of bacteria served as the control. Aliquot sampling were collected from each pot from 0-49 days. Samples were analysed for dehydrogenase activity, respiration activity, dry weight, aliphatic hydrocarbon (C_{10}-C_{40}) degradation and metal mobility by sequence extraction and ICP-MS. Data were evaluated using confidence intervals (alpha=0.05) which allows pair comparisons of significance. Bioaugmentation, iron-stress and biocarrier (activated charcoal) enhanced dehydrogenase and respiration activity. The tested soil has a high concentration of Ca, Fe, Al, Mg. Other Trace elements, including As are also present at low concentrations. After 49 days, variant GR1; *Gordonia* sp. cultured in iron-contained bacteria salt media (BSM) added to soil, showed the highest degradation of the aliphatic hydrocarbons from ~80,000 mg/kg dry weight of soil to ~54,000 mg/kg.

Conclusions

Gordonia sp. and *Rhodococcus* sp. offer a biological degradation of industrially contaminated soil even under metal stress.

Environmental Microbiology/Microbial Ecology /Microbial Communities

MICROBIAL FUNCTIONAL DIVERSITY AND ENZYMATIC ACTIVITIES IN A POST-COAL MINING RECLAMATION LAND CHRONOSEQUENCE

O. Ezeokoli[1], R. Adeleke[2], C. Bezuidenhout[1], M. Maboeta[1]
[1]North-West University, Environmental Sciences and Management, Potchefstroom, South Africa
[2]Agricultural Research Council-Institute for Soil- Climate and Water,
Microbiology and Environmental Microbiology, Pretoria, South Africa

Backgrounds

The restoration of soil ecosystem functioning in disturbed lands is crucial for a meaningful post-disturbance land use sustainability. Microbial community diversity and activity in soils are robust indicators for assessing soil ecosystem health and functional plasticity. Previous soil health assessments of reclamation lands have been based on aboveground indicators which are rather conservative.

Objectives

In this study, soil microbial functional diversity and enzyme activities of a post-coal mining reclamation land chronosequence (0- 20 years) located in the coal-rich Highveld of Mpumalanga, South Africa were investigated in summer.

Methods

Functional diversity was determined using utilization profiles of 31 carbon substrates on Biolog EcoPlates. Activities of β-glucosidase, alkaline- and acid- phosphatases and urease in bulk soil were assayed.

Conclusions

Mean Shannon-Weiner index (H´) and evenness (J) were lower in the acidic chronosequence soils compared to undisturbed lands. Within chronosequence, differences in H´ and J were not significant ($P > 0.05$), with H´ inversely related to reclamation years and J increased between the first two years of reclamation. In general, enzymatic activities significantly differed ($P < 0.05$) between reclamation chronosequence and undisturbed lands. β-glucosidase activity (p-nitrophenol µg/g/h) ranged from 66.8 to 524.20, and from 409.79 to 693.83 in reclaimed and undisturbed soils, respectively. Urease activity increased with reclamation years and was lower in reclaimed lands. Similarly, alkaline phosphatase and acid phosphatase activities reflected gradients indicative of phosphorus availability and vegetation growth. Changes in functional diversity and enzymatic activities within the chronosequence suggests development of a functionally redundant microbial community driving nutrient cycling within the reclamation soil ecosystem.

Environmental Microbiology/Microbial Ecology /Microbial Communities

ENZYME ACTIVITIES AND MICROBIAL DIVERSITY IN SOUTH AFRICAN COAL MINE SOIL STOCKPILES

S.K. Mashigo[1,2], R. Adeleke[1,2], E. Obinna[1,2], C.C. Bezuidenhout[2]
[1]Agricultural Reasearch Council, Institute for Soil- Climate and Water, Pretoria, South Africa
[2]Environmental Sciences and Management, North-West University- Potchefstroom campus, North-West, South Africa

Backgrounds

The quality of stockpiled soils are important for a meaningful post-mining land reclamation. The topsoil layer is required to be removed and stockpiled separately from other overburden material stockpiles. Soil stockpiles are often stored for longer period of time and the removal and replacement of the soil layers with heavy equipment's are factors that affect soil quality from an agricultural- use standpoint.

Objectives

The study was undertaken in order to determine the possible impact of stockpiling on the functional and diversity of microbiota (bacteria and fungi) in stockpiled soils of coal mines.

Methods

Soil samples were randomly collected from three opencast coalmines stockpile soils at a depth of 0-20 cm ("topsoil") and >20 cm ("subsoil"). Unmined soil served as a control. The physical and chemical characteristics of the soils, including soil texture, bulk density, total organic carbon, and pH, were determined. Microbial community functions were determined using enzyme assays (β-glucosidase and urease). Microbial diversity was determined using PCR-denaturing gradient gel electrophoresis (DGGE).

Conclusions

The physical and chemical properties of unmined soils significantly ($P<0.05$) varied from that of stockpile soils. The enzymatic activities (β-glucosidase and urease) were higher in stockpiled soils than unmined soils. Densitometry analysis of DGGE snapshots revealed higher microbial diversity in unmined (control) soils. The results suggest that the stockpiling process negatively affects microbial diversity. The higher enzymatic activities in stockpiled soils suggest nutrient deficiency. Overall, these findings demonstrate that soil stockpiling process has potential negative effects on soil quality.

FEEDING THE BEAST TO KEEP THE BEAUTY! GENOME EVOLUTIONARY DYNAMICS OF ENDOSYMBIOTIC BACTERIA OF INSECTS

M. Fares[1], B. Sabater-Muñoz[1], C. Toft[2], D. Alvarez-Ponce[3]
[1]Instituto de Biología Molecular y Celular de Plantas, Abiotic stress, Valencia, Spain
[2]Universidad de Valencia, Genetics, Valencia, Spain
[3]University of Nevada- Reno, Biology, Reno, USA

Backgrounds

The interactions between biological entities and their role in evolution have enthralled scientists for decades, but the causes and consequences of such interactions remain poorly characterized. An open question is how does the selection-drift balance determine the fates of biological interactions.

Objectives

We searched for signatures of selection and drift in genomes of five endosymbiotic bacterial groups to determine the role of chance and necessity in the evolution of endosymbiotic genomes.

Methods

We identified signatures of selection in endosymbiotic genes using maximum-likelihood approaches. The effect of drift was determined through experimental evolution of *Escherichia coli* populations. The evolution of regulation was described through RNA sequencing.

Conclusions

Many genes in endosymbiotic bacteria exhibited stronger selective constraints than their orthologs in free-living bacterial relatives. Remarkably, most of these genes had no role in the host-symbiont interactions, but were involved in either buffering the deleterious consequences of drift or other host-unrelated functions, suggesting that they have either acquired new roles or their roles became more central in endosymbiotic bacteria. Experimental evolution of *Escherichia coli* under strong genetic drift revealed remarkable similarities in the mutational spectrum and genome reduction patterns to endosymbiotic bacteria of insects. Experimentally evolved lines showed a generalized de-regulation of the genome that affected genes encoding proteins involved in mutational buffering, regulation and amino acid biosynthesis, patterns identical to those found in endosymbiotic bacteria. Our results indicate that drift has shaped endosymbiosic associations through a change in the functional landscape of bacterial genes, and that the host had a small role in this shift.

[1]Instituto de Biología Molecular y Celular de Plantas, Abiotic stress, Valencia, Spain
[2]Queen´s University of Belfast, School of Biological Sciences, Belfast, United Kingdom

Backgrounds

Glycerol synthesis is key to central metabolism and stress biology in *Saccharomyces cerevisiae*, yet the cellular adjustments needed to respond and adapt to glycerol stress are little understood. Glycerol stress can result from an increase of glycerol concentration in the medium due to the *S. cerevisiae* fermenting activity or other yeast metabolic activities.

Objectives

Here, we determined impacts of acute and chronic exposures to glycerol stress in *S. cerevisiae*.

Methods

We subjected experimentally evolved *S. cerevisiae* populations to acute and chronic exposures to glycerol. We determined the effects of glycerol on *S. cerevisiae* fitness and identified transcriptomic alterations involved in the response and adaptation to glycerol.

Conclusions

Acute glycerol-stress led to a 50% decline in growth rate and altered transcription of more than 40% of genes. The increased genetic diversity in *S. cerevisiae* population led to an increase in growth rate and altered transcriptome when such population was transferred to stressful media containing a high concentration of glycerol. Evolution of *S. cerevisiae* populations during a 10-day period in the glycerol-containing medium led to transcriptome changes and readjustments to improve control of glycerol flux across the membrane, regulation of cell cycle, and more robust stress response; and a remarkable increase of growth rate under glycerol stress. Most of the observed regulatory changes arose in duplicated genes. These findings elucidate the physiological mechanisms, which underlie glycerol-stress response, and longer-term adaptations, in *S. cerevisiae*; they also have implications for enigmatic aspects of the ecology of this otherwise well-characterized yeast.

MARINE PROSPECTING OF CELLULASE GENES: CAN THE RED SEA BE ANOTHER ENERGY RESERVOIR?

S. Fatani[1], Y. Saito[1], K. mineta[1], T. Gojobori[1]
[1]King Abdullah University of Science & Technology KAUST, BESE, Thuwal Jeddah, Saudi Arabia

Backgrounds

Cellulase is a key player in biorefinery, especially for the utilization of plant biomass. In the Middle East in particular, biofuel is considered to be one of the important alternative energies to the crude oil. Then, an interesting question is raised if cellulolytic microbes can be found in the Red Sea. Moreover, the Red Sea is a unique environment with a high temperature and salinity.

Objectives

The aim of the present study is to know whether the Red Sea can be a source of cellulase-active microorganisms.

Methods

Although we, first, isolated 700 different bacterial strains from seawater, no cellulase-producing strains were obtained. Then, we isolated 369 different isolates from plankton fraction of sweater using 0.63 µm mesh, successfully obtaining two cellulase-active strains. We also identified two more cellulase-active strains out of 300 bacterial isolates that were collected from seaweeds bodies. Small subunit rRNA gene sequences suggested that one of the strains is related to Ascomycota fungus whereas the other three isolates belong to Firmicutes bacteria. We showed that the hydrolysis observed in those four strains was actually caused by cellulases secreted.

Conclusions

In conclusion, the Red Sea is rich in cellulase-producing microorganisms, most of which are probably present on the surface of cellulose containing organisms such as algae. Therefore, the Red Sea can be potential reservoir of energy that is worthwhile being exploited in the coming years.

THE INFLUENCE OF GEOGRAPHICAL ORIGIN AND SUBSTRATE PREFERENCES ON THE BIOCHEMICAL AND MOLECULAR GENETIC PLASTICITY OF BASIDIOMYCETE STRAINS - STECCHERINUM OCHRACEUM (PERS.) GRAY

T. Fedorova[1], O. Glazunova[1], K. Moiseenko[1], N. Shakhova[2], N. Psurtseva[2]
[1]Federal State Institution Federal Research Centre "Fundamentals of Biotechnology" of Russian Aca demy of Sciences, A.N. Bach Institute of Biochemistry, Moscow, Russia
[2]Komarov Botanical Institute of Russian Academy of Sciences, Laboratory of Fungal Biochemistry, St.Peterburg, Russia

Backgrounds

White-rot fungi as wood degraders are very important part of virtually all ecosystems. Studies of the physiological role and ecological adaptation mechanisms of white rot fungi attracted considerable interest of researchers in different areas. Basidiomycete *Steccherinum ochraceum* – is a species with great ecological amplitude. It occurs in different regions of Russia and in different climatic zones. *S. ochraceum* colonizes stumps, dead trunks and branches of various deciduous and seldom coniferous trees at different decay stages, but also could be found on living trees.

Objectives

The aim of our work was to examine genetic and biochemical diversity *S. ochraceum* strains from different geographic regions of Russia collected from different wood substrates.

Methods

The strains were obtained from Komarov Botanical Institute Basidiomycetes Culture Collection (LE-BIN). The phylogenetic diversity of *S. ochraceum* strains was examined by analyzing the nucleotide sequences of β-tub and *tef1α* gene and the nuclear ITS1-5.8SITS2 domain. Activity of enzymes was estimated for strains growing on liquid glucose–peptone medium and wood-supplemented growth medium.

Conclusions

Based on the concatenated dataset of all genes, the *S. ochraceum* strains were placed into three main clades correlating with lignocellulose-converting enzyme activity profiles of these strains: high oxidoreductase and low cellulose-converting activities; medium oxidoreductase and cellulose-converting activities; low oxidoreductase and high cellulose-converting activities. Thus, for the diverse *S. ochraceum* strains, there is a strong connection between the genotype and their lignocellulose-modifying activity profiles, but not with geographic origin of strains.

PRE-TERM BIRTH IS ASSOCIATED WITH DIFFERENT POPULATIONS OF VAGINAL MICROBIOTA COMPARED TO FULL-TERM BIRTH

C. Feehily[1,2], D.A. Crosby[3], F.M. McAuliffe[3], R.P. Ross[2], P.D. Cotter[1,2]
[1]Teagasc Food Research Centre, Food Bioscience, Cork, Ireland
[2]APC Microbiome Institute, University College Cork, Cork, Ireland
[3]Department of Obstetrics and Gynaecology- University College Dublin, National Maternity Hospital- Holles Street, Dublin, Ireland

Backgrounds

Bacterial vaginosis affects up to 30% of women worldwide and is associated with an increased risk of STI transmission, and adverse outcomes for pregnant women. There is a reported 2-fold increase of pre-term birth in women suffering BV during pregnancy. The condition is characterised by a shift in healthy populations of lactobacilli in the vagina towards a more mixed-species microbiota that mainly includes *Gardnerella vaginalis*, *Atopobium vaginae* and, *Prevotella* sp. amongst others.

Objectives

Our study aimed to examine the relationship between the vaginal microbiota and the onset of pre-term birth.

Methods

We recruited 30 pregnant women after 10 weeks gestation who were at risk of pre-term delivery and a further 21 pregnant women deemed not at risk. Using 16S amplicon sequencing on a MiSeq platform we compared the vaginal microbial composition between groups to determine any underlying microbial association with pre-term delivery.

Conclusions

Of the 9 women that subsequently delivered pre-term there were distinctly different patterns of lactobacilli populations compared with the microbiota found in full-term pregnancies. Specific groups of lactobacilli were only observed in the full-term cohort and absent in the pre-term cohort. There was no correlation observed between a BV state microbiota and gestational age at delivery.

RESPONSE OF A SALT MARSH BACTERIAL COMMUNITY TO SILVER AND COPPER NANOPARTICLES: IMPLICATIONS FOR PHYTOREMEDIATION PROCESSES

J. P. Fernandes[1,2], *A.P. Mucha*[1], *C. R. Gomes*[1,3], *C.M. R. Almeida*[1]
[1]*CIIMAR - Interdisciplinary Centre of Marine and Environmental Research, EcoBioTec, Porto, Portugal*
[2]*ICBAS/UP - Institute for the Biomedical Sciences Abel Salazar / University of Porto, ICBAS, Porto, Portugal*
[3]*FCUP - Faculty of Sciences of the University of Porto, Department of Chemistry and Biochemistry, Porto, Portugal*

Backgrounds

Silver (AgNP) and copper oxide (CuONP) nanoparticles are among the most used and their presence in estuarine environment is expected. It is known that salt marsh plants can take up metals in a process known as phytoremediation and that this process can benefit from the microbial activity around plant roots. Nevertheless, depending on its levels and forms, metals can be toxic to microorganisms, fact that can eventually compromise their contribution to the phytoremediation processes.

Objectives

Present work aimed to investigate the response of the microbial community colonizing *Phragmites australis* rhizosphere to AgNPs and CuONP contamination, evaluating the implications for phytoremediation processes.

Methods

One week experiments were carried out with medium (elutriate solution with the respective sediment) doped with Ag or Cu, either in ionic or NP form. Microbial community was characterized in terms of bacterial diversity, richness and community structure through ARISA, and metal uptake was evaluated in plant tissues, elutriate solutions and sediments by atomic absorption spectroscopy.

Conclusions

Overall, the presence of Ag or Cu and the form in which the metal was added to the medium clearly affected the bacterial community structure, despite richness and diversity were only affected by the presence of Cu. Regarding metal uptake, no Ag accumulation was observed and significant Cu uptake was observed only in roots tissues when Cu was added to the medium in ionic form.

The presence of both metals in either forms affected the bacterial community structure, which may cause disturbances in ecosystems function and compromise phytoremediation processes.

BIODEGRADATION OF PHARMACEUTICALS BY MICROORGANISMS ISOLATED FROM WASTEWATER TREATMENT PLANTS AND ESTUARINE SEDIMENTS

J. Fernandes[1,2], *P. Duarte*[2], *C.M. R. Almeida*[1], *M.F. Carvalho*[1], *A.P. Mucha*[1]
[1]*CIIMAR - Interdisciplinary Centre of Marine and Environmental Research, EcoBioTec, Porto, Portugal*
[2]*ICBAS/UP - Institute for the Biomedical Sciences Abel Salazar / University of Porto, ICBAS, Porto, Portugal*

Backgrounds

In the last years, concerns about the detection of pharmaceuticals in the environment have grown, being one of the most relevant topics in environmental research. Bioremediation, the use of natural biological processes for ecosystems recovery, can lead to a partial or total elimination of contaminants from the environment.

Objectives

This work aimed to investigate the biodegradation of two pharmaceuticals, paroxetine and bezafibrate, by microorganisms isolated from an estuarine environment and an associated WWTP.

Methods

For that, isolated strains derived from microbial cultures previously enriched with the selected pharmaceuticals were reunited in 5
consortia: two consortia derived from paroxetine enrichment under static conditions, of which one was obtained from estuarine sediment and the other from activated sludge from WWTP, and three consortia derived from bezafibrate enrichment, two under static conditions, in which one was obtained from estuarine sediment and the other
from activated sludge, and the last obtained from activated sludge microcosms under agitation conditions.

Conclusions

Results showed that despite different acclimation times, high removal efficiency of pharmaceuticals (> 97%) was observed in three of the five studied consortia. Moreover, consortia derived
from estuarine sediment demonstrated to be more efficient in removing both studied pharmaceuticals. In the case of paroxetine, microorganisms present in consortia were able to promote fluoride anion release. Complementary analysis will allow the identification of the isolated strains present in the consortia responsible for bezafibrate and paroxetine degradation.

This work emphasizes the potential of microorganisms from estuarine environment and associated WWTP, for application in bioremediation techniques for pharmaceuticals removal.

MICROBIAL DIVERSITY OF MINERO-MEDICINAL SULPHATED SPRING WATERS

C. Rodriguez[1], *M.C. De la Rosa Jorge*[2], *C. Pintado*[2]
[1]*University Complutense, Microbiology II, Madrid, Spain*
[2]*University Complutense Madrid, Microbiology II, Madrid, Spain*

Backgrounds

Mineral spring waters have been used since ancient times due to their health benefits. They present a complex biodiversity of microorganisms which depends on the water physicochemical characteristics. We have studied comparatively the microbial diversity and the chemical composition from 14 Spas and 22 Spanish natural springs classified as sulphated minero-medicinal waters, used in therapeutic treatments and balneotherapy.

This work has been done analyzing the data obtained for several years from multidisciplinary approaches with the participation of our research group and accomplished by the Mineromedicinal Waters Commission of the *Real Academia Nacional de Farmacia*.

Objectives

The main objectives have been: a) To compare the physicochemical characteristics of these sulphated waters in order to determine which are the parameters that regulate the biodiversity of these aquatic ecosystems. b) To study the microbial diversity, the sanitary quality indicator bacteria, pathogenic and those of ecological interest.

Methods

The sulphated springs studied come from different spas located throughout the Spanish geography (Albacete, Almería, Aragón, Castellón, Ciudad Real, Cuenca, Granada, Madrid, Navarra, Teruel, Valencia, Zaragoza). Culture, biochemical, optical and electron microscopy methods were used. Sensitivity and antibiotic resistance of opportunistic pathogenic strains was determined.

Conclusions

No pathogens nor faecal indicators were detected, in compliance with the Spanish regulations of drinking water. The populations were predominantly mesophilic and oligotrophic. Sulfate-reducing, proteolytic, amylolytic, cellulolytic, nitrifying and ammonifying bacteria, which contribute to water self-purification, were detected; also halophilic and iron bacteria and fungi. The large number of identified microbial species proves the great biodiversity of these waters.

THE ROLE OF CYCLIC DI-GMP DURING THE ESTABLISHMENT OF THE ENDOPHYTIC LIFESTYLE IN AZOARCUS SP. CIB

H. Fernández-Llamosas[1], *E. Díaz*[1], *M. Carmona*[1]
[1]*CIB-CSIC, Environmental Microbiology, Madrid, Spain*

Backgrounds

Azoarcus sp. CIB is a free-living facultative anaerobic β-Proteobacterium with a high metabolic versatility[1] and able to interact with plants as an endophyte[2]. Since the molecular determinants involved in plant-bacteria interactions are still poorly understood, there is much interest in studying the regulatory circuits controlling this process. Cyclic di-GMP (c-di-GMP) is a second messenger that regulates a large number of bacterial functions[3], but its role in the endophytic lifestyle of bacteria is still poorly known.

Objectives

Unraveling a new function of c-di-GMP in bacteria by measuring the effect of different c-di-GMP cellular levels in the endophytic lifestyle of *Azoarcus* sp. CIB

Methods

By cloning and expressing a heterologous c-di-GMP cyclase and phophodiesterase, we have generated recombinant CIB strains with higher or lower c-di-GMP levels, respectively, than the parental strain and that showed the expected phenotypes. Rice seedlings were in contact with CIB strains for ten days, and endophytes were recovered for CFU counting.

Conclusions

By artificially modulating the c-di-GMP levels in *Azoarcus* sp. CIB we have revealed that whereas an increase in c-di-GMP does not affect significantly the establishment of the bacteria inside rice roots, a decrease in c-di-GMP clearly decreased this interaction. This work provides new insights into the molecular basis of plant-bacteria interaction, and may contribute to engineer new strains with improved plant growth-promoting properties o for (endo)phytoremediation approaches

GENETIC DIVERSITY OF NEW SSDNA VIRUSES FROM POLAR ENVIRONMENTS

C. Fernandez-Linares[1], *A. Rastrojo*[1], *A. Alcami*[1]
[1]*Centro de Biología Molecular Severo Ochoa, Virología, Madrid, Spain*

Backgrounds

Viruses are the most abundant biological entities on earth and play a major role as regulators of microbial communities. However, the current knowledge about them is still scarce, especially about their adaptation mechanisms and evolution. In this work we have studied the diversity and genetic variability of the viruses in several freshwater lakes in polar zones, isolated areas with very low human influence and with a low zoogenic input.

Objectives

The objective of this project is the study of the classification and variability of small circular ssDNA viruses found in several Antarctic and Arctic lakes.

Methods

Water samples were subjected to tangential flow filtration to remove cellular organisms and to concentrate viral fraction. Then viral DNA was extracted using phenol-chloroform method and was amplified using MDA before sequencing. Both 454 and Illumina technology were used, obtaining both single and paired reads. The subsequent viral metagenome assembly was carried out with the SPAdes program. Circular topology was identified using an in-house script based on the Minimus2 program. Genemark was used to predict putative genes, removing contigs without any potential gene. Viral genomes were then clustered based on sequence homology using the MCL program.

Conclusions

A large number of viruses with high variability have been found, although a specific relationship between the different viral families and their Shannon index was not observed. We have identified a large number of new viral families by classifying the contigs based on sequence homology.

Environmental Microbiology/Microbial Ecology /Microbial Communities

STUDY OF ENZYMATIC ACTIVITIES AND BACTERIAL COMMUNITIES IN TWO FULL-SCALE MBR PLANTS TREATING WASTEWATERS FROM MUNICIPAL SOLID WASTES

J. Fernández-Navarro[1], L. Moreno-Mesonero[1], A. Zornoza[1], I. Amorós[1], J.L. Alonso[1], F. Muñagorri[2], C. Álvarez[2]
[1]Instituto Universitario de Ingeniería del Agua y Medioambiente, Universitat Politècnica de València, Valencia, Spain
[2]URBASER, URBASER, Madrid, Spain

Backgrounds

Municipal waste treatment generates wastewaters that have to be treated before their disposal. Membrane bioreactor systems (MBRs) are used for this type of complex wastewater treatment, because of their capacity of working at high concentrations levels of suspended solids and high cell retention times. However, this produces microbial matrixes with limited substrates which reduce the respiratory capability of bacterial communities.

Objectives

The study of enzymatic activities provide important information about the different metabolic processes occurring in the catabolism of proteins, carbohydrates, lipids, inorganic phosphorus assimilation and respiratory capacity of microorganisms.

Methods

Samples from activated sludge were collected monthly during fifteen months from two MBR systems. The enzymatic activities (phosphatases, lipases, glucosidases, proteases and dehydrogenases) were determined spectrophotometrically. The bacterial communities were identified by 16S rRNA gene amplicon sequencing. Multivariate analysis was used to reveal relathionships between the level of enzyme activities, volatile suspended solids (VSS), extracellular polymeric substances (EPS) and bacterial communities.

Conclusions

The activities of all the tested hydrolases were dynamic, showing diverse patterns of variation. Statistically significant relationships have been found between the population of microorganisms and the different enzymatic activities studied. Thus, the relative abundance of Firmicutes, Bacteroidetes and different classes of Proteobacteria has been associated with an increase in glucosidase, acid phosphatase and protease activities in the activated sludge of bioreactors. The simultaneous use of different enzyme activities is useful for the full evaluation of the biodegrading capacity of MBRs treating wastewaters from municipal solid wastes.

MICROBIAL HYDROLYTIC ENZYMATIC ACTIVITIES IN FOUR PILOT-SCALE SBR EXPERIMENTAL PLANTS UNDER ADDITION OF A METABOLIC UNCOUPLER

J. Fernández-Navarro[1], E. Ferrer-Polonio[2], I. Amorós[1], J.L. Alonso[1], J.A. Mendoza-Roca[2]
[1]Instituto Universitario de Ingeniería del Agua y Medioambiente, Universitat Politècnica de València, Valencia, Spain
[2]Instituto Universitario de Seguridad Industrial- Radiofísica y Medioambiental, Universitat Politècnica de València, Valencia, Spain

Backgrounds

Microbial growth of the active sludge is mainly generated by the organic matter present in the wastewater and the energy coming from the use of the dissolved oxygen as electron acceptor in the catabolism. This exponential growth becomes a problem in the wastewater treatment plants (WWTP) due to the expensive treatment of the biological sludge. For this reason, techniques for reducing the production of active sludge are studied, which do not imply a reduction in purification yields. The study of the microbial hydrolytic enzymatic activities (MHEA) offers on the one hand information about hydrolysis processes of the activated sludge and, on the other hand, valuable information useful to optimize conditions for a better process performance when a reduction of the sludge production is studied.

Objectives

To Monitor and evaluate the trend of enzymatic activities under different operating conditions when activated sludge is treated with TCS, a metabolic uncoupler agent used to reduce sludge production.

Methods

Samples from four SBR systems were collected weekly and MHEA were determined spectrophotometrically. MHEA were correlated with different F/M ratios, dissolved oxygen (DO) variations and TCS addition to the activated sludge.

Conclusions

TCS addition produces important variations of enzymatic activities, such as lipase, protease and acidic and alkaline phosphatase. Different concentrations of dissolved oxygen and F/M ratios have shown that both parameters are important for process control when sludge production is reduced. This indicates that the microorganisms are acclimatized to the presence of the metabolic uncoupler that produces improvements in organic matter removal performance.

Environmental Microbiology/Microbial Ecology /Microbial Communities

DEVELOPMENT OF AN AGAR-BASED RNA-SEQ ASSAY FOR STUDYING THE INTERACTOME OF NASAL STAPHYLOCOCCI STRAINS

G. Hermansen[1], *L. Jelsbak*[1]
[1]*Technical University of Denmark, DTU Bioengineering, Kgs Lyngby, Denmark*

Backgrounds

Staphylococcus aureus is well-known as a human pathogen but also lives as a commensal in the human nose in approximately one fifth of the population. Carriage is usually asymptomatic but the nasal cavities can function as reservoirs for infection e.g. during surgical procedures. The human nose hosts a multi-species community and it has previously been reported that *Staphylococcus epidermidis* strains can modulate *S. aureus* phenotypes. Intriguingly the cohabitation has been shown to result in inhibition of nasal colonization and biofilm formation of *S. aureus*. Even though some *S. epidermidis* products have been implicated in this inhibitory effect, a comprehensive understanding of the interactions between nasal Staphylococci isolates is needed.

Objectives

The aim of this study was to establish a robust method to map the transcriptome profiles of nasal *S. aureus* and *S. epidermidis* focusing on the differences between mono- and co-culturing.

Methods

Staphylococci strains were isolated from nasal cavities of healthy Danish individuals. A pair of *S. aureus* and *S. epidermidis* strains isolated from the same nose were used for a novel agar-based RNA-seq method enabling investigation of their interactome. The strains were grown on agar surfaces as mono- and co-cultures, respectively, and RNA was harvested after 24 hours of incubation. RNA-seq was performed and enables mapping of the expression profiles of the two nasal Staphylococci isolates.

Conclusions

Our preliminary results indicate this novel RNA-seq method can be applied to study interactions between *S. aureus* and *S. epidermidis* isolated from nasal swaps of a healthy Danish adult.

ASSESSMENT OF COASTAL WATER QUALITY IN WOBURN BAY, GRENADA WEST INDIES, 12.0°N, 61.6°W

N. Bartholomew[1], A. Lin[2], B. Javier[2], K. Farmer-Diaz[1], M. Matthew[1], M. McCai[3], A. Kraus[3], S. Kotelnikova[1]
[1]St. George's University, Microbiology and Immunology, St. Georges, Grenada
[2]St. George's University, Medical Student Research InstituteMSRI, St. Georges, Grenada
[3]St. George's University, Medical Research Student, St. George's Grenada

Backgrounds

This was a novel study that was performed to establish a water quality baseline in Grenada by tracking sources of pollution as a means to maintain environmental health. Pollution management influences Grenada's overall economic sustainability, which is dependent on the environment. Potential eutrophication of water, due to anthropogenic activities, may lead to the rise of opportunistic pathogens and possibly neurotoxic effects on marine and human populations.

Objectives

To assess the coastal water quality at Woburn Bay and to identify the sources of pollution in three marine and two river sites.

Methods

Throughout eighteen weeks, that spanned the wet and dry seasons, twenty biochemical parameters, as well as sample, temporal and spatial variations were documented. Points of pollution were identified based on site cross-correlation, t-test and temporal variation analysis

Conclusions

The documented coliform MPN was above the EPA limits and positively correlated with rainfall data. BOD_5 levels were over 50 mg/l at river sites. Possible sources of non-point fecal pollution were the watershed runoff, septic tanks and recreational yachts which are permanently parked in the Bay. A significant relationship between rainfall and ammonium discharge was documented. An increased level of organic matter, phosphate, ammonium, sulfides, copper, and iron in the marine waters which further enhanced microbial oxidation was as a result of the mangrove filtering capacity failure. As a result, increased heterotrophic bacterial MPN counts, turbidity, acidification and decreased oxygen concentrations were observed. A nearby rum distillery was identified as a major point sources of pollution, sedimentation and eutrophication in the bay.

Environmental Microbiology/Microbial Ecology /Microbial Communities

TRANSCRIPTOME AND SECRETOME OF SHORT RNAS IN BACTERIAL POPULATIONS

O. Ozoline[1], *A. Bykov*[1], *K. Shavkunov*[1]
[1]*Institute of Cell Biophysics RAS, Functional Genomics and Cellular Stress, Pushchino, Russia*

Backgrounds

Switching research from individual genes to large-scale analysis of transcriptomes revealed a huge amount of untranslated RNAs with poorly understood functions. The least studied are short RNAs, including those processed from tRNAs or produced from gene ends, though their regulatory potential has been recently elucidated.

Objectives

The goal of the study was to characterize the intracellular and extracellular fractions of short (11-14 nucleotides) RNAs, in particularly those derived from “promoter islands” suppressed by H-NS.

Methods

Fractions of short RNAs from cells of *E. coli* K-12 MG1655 and novel isolate of the *Paenibacillus* genus were obtained using mirVana™ miRNA Isolation Kit. Short secreted RNAs were purified from filtered LB medium using miRNeasy Serum/Plasma Kit (Qiagen). cDNA libraries were prepared using Ion Total RNA-Seq Kit v2 and sequenced with Ion Torrent PGM. Sequence reads were mapped to the genomes with Matcher algorithm.

Conclusions

In both bacteria intracellular fractions of short RNAs mainly contained fragments of tRNAs, rRNAs and small untranslated RNAs. The proportion of RNAs derived from the “promoter islands” of *E. coli* was lower than on average over the genome; however, their abundance in the extracellular fraction was twice higher. The distribution profile of the secreted RNAs across the genomes differed, as compared to their intracellular RNAs. Cooperative culturing of two microorganisms allowed detecting evident divergence between the sets of extracellular RNAs in pure and mixed cultures. Bacteria, therefore, secrete not only proteins and small signaling molecules, but also short RNAs, which may participate in cell-to-cell communications.

METAGENOMIC SNAPSHOT: MEASURING PATTERNS BY GEOGRAPHICAL LOCATIONS IN MARINE METAGENOME DATA USING NEWLY ADOPTED GENOTYPING-BY-SEQUENCING

H.J. Seong[1], C.Y. Hwang[2], H.H. Won[3], W.J. Sul[1]
[1]Chung-ang University, Systems Biotechnology, Anseong, Republic of Korea
[2]Korea Polar Research Institute, Division of Polar Biology and Ocean Sciences, Incheon, Republic of Korea
[3]Sungkyunkwan University- Samsung Medical Center,
Samsung Advanced Institute for Health Sciences and Technology, Seoul, Republic of Korea

Backgrounds

Dealing with huge quantity and high complexity of metagenomic data is a very difficult and time-consuming process. In addition, a new metagenomic approach is required to simply identify genetic variation.

Objectives

We demonstrated more effective metagenomic approach to analyze particular sequences related to restriction enzyme sites for targeting reduced numbers of genes than to estimate whole genome sequences.This approach was applied to analyze the marine metagenome by genotyping-by-sequencing (GBS) method, which was used to analyze plant genomes with large genome sizes.

Methods

Metagenomic GBS was demonstrated with marine epipelagic samples collected on 10 locations across from East Sea to Bering approximately 8000 km apart on July, 2013. These samples were processed by a restriction enzyme *Ape*KI and then sequenced by Illumina HiSeq, yielding 74.4 million reads. These restriction site-associated sequences were analyzed to characterize taxonomic diversity and functional profiling of microbial community directly. Moreover, metagenomic GBS reads were grouped, aligned, and Shannon entropy-analysis using UCLUST, MUSCLE, and in-house script from Oligotyping respectively. Entropy in sequence variation among sorted clusters by functional category was measured to evaluate their rate of SNPs variations.

Conclusions

Nucleotide and amino acid substitutions were discovered that indicate micro genetic diversity associated with evolutionary histories according to geographical patterns. Besides profiling microbial community and functional pathway, metagenomic GBS can analyze evolutional study based on nucleotide variation. GBS to metagenomic analysis was applied as a snapshot for understanding the highly dynamic ecosystem quickly to resolve budget and time-consuming issues with identification of micro genetic diversity through comparing each samples.

Environmental Microbiology/Microbial Ecology /Microbial Communities

ESTIMATING MICROBIAL COMMUNITY STRUCTURE USING METABOLIC NETWORKS

K. Takemoto[1]
[1]*Kyushu Institute of Technology, Department of Bioscience and Bioinformatics, Iizuka, Japan*

Backgrounds

Microbes interact with one another via metabolic interactions etc., and they compose ecological communities. It is important to untangle such ecosystems in medical and environmental sciences. In this context, microbial ecological networks are often studied. In general, such networks are estimated based on time-series data on species abundance, obtained from 16S rRNA data, for example. However, such estimation methods have fiscal constraints; moreover, they are not useful for understating microbial ecosystems at the molecular level, despite the importance of metabolite interactions in microbial ecosystems.

Objectives

Thus, I developed a novel method for estimating microbial community structure using metabolic network analysis: Estimator of COmmunity Structure based on MetabOlic networkS (ECOSMOS).

Methods

For this, I considered reverse ecology [R. Levy, E. Borenstein, Adv. Exp. Med. Biol. 751, 329 (2012)]. In particular, cooperative interactions (i.e., complementary support of nutrients) and competitive interactions (i.e., scramble for nutrients) are calculated based on nutrient metabolites identified using graph-theoretic algorithms. In addition to this, I used random matrix theory [S. Suweis et al. Nat. Commun. 6, 10179 (2015)], and evaluated ecological community stability based on the strength of interactions and species abundance.

Conclusions

ECOSMOS considers metabolic interactions between organisms, and it estimates ecological networks from at least one sample. I applied ECOSMOS to actual examples, and found interesting results. For example, the gut microbiota in healthy subjects were highly stable. Cooperation and stability of soil microbial community increase after environmental perturbations. ECOSMOS enhances our understanding of microbial ecological community. ECOSMOS is available from takemoto08.bio.kyutech.ac.jp/ecosmos-lite/

BACTERIAL TRANSCRIPTOME REPROGRAMMING IN NODULES OF PEA (PISUM SATIVUM L.) SYMBIOTIC MUTANTS

V. Zhukov[1], A. Afonin[1], A. Sulima[1], A. Zhernakov[1], I. Tikhonovich[1]
[1]All-Russia Research Institute for Agricultural Microbiology, Biotechnology, Saint-Petersburg - Pushkin, Russia

Backgrounds

Nodule bacteria can fix atmospheric nitrogen in symbiosis with legume plants. In nodules of some legumes, including pea (*Pisum sativum* L.), bacteria are terminally differentiated into organelle-like structures called bacteroids. The process of terminal bacteroid differentiation (TBD) implies cell enlargement, genome amplification and membrane permeabilization. Mutations in plant regulatory symbiotic genes may lead to defects in TBD. Analysis of such model systems using transcriptomics approach can help unravel the molecular bases of TBD.

Objectives

To describe the influence of plant mutations on expression of bacterial genes in case of abnormal TBD and to find possible new factors and components playing a role in this process.

Methods

To assess gene expression levels, we used 5'-MACE (Massive Analysis of cDNA Ends) technology developed by GenXPro GmbH (Frankfurt-am-Main, Germany), which involves sequencing of 5'-part of each transcript on Illumina HiSeq2000. The total RNA was extracted from the following sources: i) free-living culture of *Rhizobium legominosarum* bv. *viciae* RCAM1026, ii) nodules of wild type pea line SGE, iii) set of mutants in pea genes *sym33*, *sym40* and *sym26* obtained on SGE background, which demonstrate block on sequential stages of TBD.

Conclusions

Bacterial genes crucial to cooperative metabolism of micro- and macrosymbiont were identified, along with a number of multi-drug resistance genes possibly modulating the effects of NCR peptides (plant anti-microbial agents promoting TBD) in nodules.

RAMAN MICRO-SPECTROSCOPY BASED QUANTITATIVE ANALYSIS OF POLYPHOSPHATE ACCUMULATING BACTERIA IN FULL-SCALE DANISH WASTEWATER TREATMENT PLANTS

E. Fernando[1], M. Nierychlo[1], S. Mcilroy[1], F.A. Herbst[1], M. Wagner[2], M. Schmid[2], J.L. Nielsen[1], P.H. Nielsen[1]
[1]Center for Microbial Communities- Aalborg University, Chemistry and Bioscience, Aaborg Ø, Denmark
[2]University of Vienna, Department of Microbial Ecology and Ecosystem Science, Vienna, Austria

Backgrounds

Enhanced biological phosphorus removal (EBPR) process is an integral part of wastewater treatment, in terms of removal and recovery of phosphorus from recycled water. The typical polyphosphate accumulating organism (PAO) phenotypes such as the genera Candidatus *Accumulibacter* and *Tetrasphaera* are well-characterised in terms of their P – metabolism taking place under anaerobic/aerobic “feed”/”famine” cycles induced in the EBPR process. The quantitative aspects of phosphorus accumulation in the different PAOs are poorly understood, partly due to shortcomings in currently available quantitative chemical analyses methods.

Objectives

The aim of this work was to establish a Raman spectroscopy-based quantitative method to assess polyphosphate contents within PAO cells.

Methods

This study utilised a non-invasive and non-destructive Raman spectroscopy- based method to quantitatively evaluate intracellular polyphosphate contents of single PAO cells, defined by fluorescence in situ hybridization (FISH), from full-scale Danish EBPR plants.

The method was appropriately calibrated to allow absolute quantification of poly-P amounts within single PAO cells of the populations of Ca. *Accumulibacter* and *Tetrasphaera*. The content was analysed in different plants and in the different aerobic/anaerobic tanks. Most poly-P was accumulated in Ca. *Accumulibacter* cells but since *Tetrasphaera* in general was present in larger abundance, they seemed more important for the removal of P in most plants.

Conclusions

Raman micro-spectroscopy was successfully used to quantitatively characterise single PAO cells from full-scale plants and is very suitable for further studies on the ecology of PAOs.

ANTIMICROBIAL RESISTANCE PROFILES AFTER CONJUGATIVE EVENTS WITH AN ESCHERICHIA COLI ISOLATE FROM HOSPITAL EFFLUENT

C. Ferreira[1], D. Bogas[1], R. Linheiro[1], A.R. Varela[1,2], O.C. Nunes[2], C.M. Manaia[1]
[1]CBQF - Centro de Biotecnologia e Química Fina,
Universidade Católica Portuguesa- Escola Superior de Biotecnologia, Porto, Portugal
[2]LEPABE, Universidade do Porto- Faculdade de Engenharia, Porto, Portugal

Backgrounds

The dissemination of antibiotic resistance in the environment is an issue of growing concern in which the selection and horizontal gene transfer have important roles. While bacteria of human origin released into sewage already harbour plasmids encoding for antibiotic resistance, further contact with other sewage contaminants may promote the conjugative transfer of resistance traits.

Objectives

This study aims at understanding the influence of candidate stressors on the rate of conjugation as well as characterising the conjugative plasmidome.

Methods

The isolate *Escherichia coli* H1FC54 from hospital effluent was used as donor and the azide resistant *Escherichia coli* J53 as recipient strain. The nucleotide sequence of the conjugative plasmidome obtained with these strains in the presence of ceftazidime was determined. Conjugation assays were carried out in the presence of ceftazidime (10 mg/L), tellurite (0.5-5 µM), or arsenite (0.5-15µ M), and the resistance phenotypes, genotypes and plasmids profiles were determined.

Conclusions

Stressors did not lead to significant increase in the conjugation rates. Transconjugants acquired resistance to amoxicillin, ticarcillin, sulfamethoxazole and tetracycline. Distinct conjugative plasmidomes and variations in the acquired phenotypes were detected in different conjugation assays.
The nucleotide sequence of the conjugative plasmidome revealed the presence of an HI2 plasmid backbone with determinants of resistance to antibiotics (beta-lactams, (fluoro)quinolones, sulfonamides), tellurite and arsenite.
The variable composition of the conjugative plasmidome and the formation of cointegrates during conjugation are novel findings, which may bring interesting insights into the comprehension of the molecular and physiological mechanisms that underlie antibiotic resistance propagation in the environment.

EXTENDED-SPECTRUM-B-LACTAMASE PRODUCING ESCHERICHIA COLI IN HEALTHY UNIVERSITY STUDENTS OF PORTO PORTUGAL

R. Mota[1], M. Pinto[2], J. Palmeira[3], D. Gonçalves[4], H.M.N. Ferreira[5]
[1]University of Porto, Microbiology - Biological Sciences - Pharmacy Faculty, Porto, Portugal
[2]University of Porto, Microbiology- Biological Sciences - Pharmacy Faculty, Porto, Portugal
[3]University of Porto, Micribiology - UCIBIO - Pharmacy Faculty, Porto, Portugal
[4]University of Porto, Microbiology- UCIBIO- Pharmacy Faculty, Porto, Portugal
[5]University of Porto, Porto, Portugal

Backgrounds

Extended-spectrum-β-lactamases (ESBLs) are increasingly being reported colonizing humans. Antimicrobial resistance mechanisms are spreading not only in healthcare institutions but also in community.

Objectives

Our aim was the detection of ESBL and carbapenemase-producing *Enterobacteriaceae* in healthy young-adults of University of Porto.

Methods

Faecal samples of 30 students were analyzed in MacConkey agar with cefotaxime, ceftazidime and meropenem (2 mg/L). Antimicrobial susceptibility of representatives of different colony morphologies was studied according to the CLSI. Bacterial identification was performed by CHROMagar-orientation, API20E and ID32GN, and ESBL-producers were detected and/or confirmed by the double-disk-synergy-test and clavulanic-acid addition. Detection of *bla*$_{\text{TEM}}$, *bla*$_{\text{OXA}}$, *bla*$_{\text{SHV}}$, *bla*$_{\text{CTX-M-group-1/group-2/group-8/group-9/CTX-M-group-25}}$ and *tetA*-B, was performed by PCR. In isolates showing susceptibility reduction to carbapenems we searched for prevalent carbapenemases. In ESBL-producers, we searched for virulence factors and phylogenetic-groups. We addressed transferability of resistance and virulence genes by conjugation. Students colonized with ESBL-producers were followed up after 5 months.

Conclusions

Our study showed the presence of ESBL-producing-*Enterobacteriaeceae* in healthy young-adults. ESBL-producing *E. coli* were isolated from 2 students (6.7%). These isolates showed *bla*$_{CTX-M}$-group1 (n=1), *bla*$_{CTX-M}$-group9 (n=2), *bla*$_{TEM}$ (n=2), *bla*$_{SHV}$ (n=1) and *tetA* (n=2) genes, and specific virulence-factors *fimH* (n=3), *traT (*n=3), *fyuA* (n=2), *iutA* (n=2) and *cvaC* (n=1). Transconjugants acquired resistance and virulence genes. Carbapenem resistant *Pseudomonas* spp was detected colonizing one student. One of the students colonized with ESBL-producer remained colonized after 5 months. Results show that healthy young-adults can be a reservoir of ESBL-producers and that *E. coli* is the ESBL-producing species most often found in community, suggesting silent dissemination.

STUDYING BIOFILM FORMATION DYNAMICS IN REAL-TIME

M.D. Ferrer[1], J.C. Rodriguez[2], E. Buetas[1], C. Collantes[1], I. Vidal[2], A. Mira[1]
[1]Center for Advanced Research in Public Health, Genomics and Health Area, Valencia, Spain
[2]Hospital General Universitario de Alicante Spain, Microbiology, Alicante, Spain

Backgrounds

Several methods are available to study biofilms *in vitro*, but their applications are in many occasions limited by a low sensitivity, high labor intensity and/or long time lags to obtaining a result. In addition, a generalized weakness is the fact that results are observed only at a certain time ("end-point" methods), with the consequent loss of information.

Objectives

The aim of this study is to present and evaluate a reliable, labeling-free and rapid assay for quantifying mono- and multi-species biofilm formation in real time.

Methods

We performed impedance-based technology measurements in microtiter plates with gold electrodes using RTCA xCELLigence system (ACEA Biosciences).

Conclusions

Biofilm growth curves showed an S-shape as cells grew attached to the wells disrupting the electrical current. The effect of 10 antibiotics on biofilm formation dynamics of different clinical strains of *Staphylococcus aureus*, *S. epidermidis* and *Pseudomonas aeruginosa* has been studied. Antibiotic resistance patterns in biofilms were very different to those obtained by traditional methods. Complex biofilm formation of oral samples (saliva, tongue and plaque) have also been monitored. Biofilm formed was a multi-species biofilm of similar composition and abundance to the original inoculum and the patterns of biofilm growth were different between them. In summary, RTCA is able to quantify mono- and multi-species biofilms in real time. We propose the use of real-time measurements for shedding light on the biology of mono- and multi-species biofilm formation, including diseases of polymicrobial etiology, and for clinical applications like the selection of efficient antibiotic therapy in biofilm-forming pathogens.

EVIDENCE OF HELICOBACTER HEPATICUS PRESENCE IN WASTEWATER BY METAGENOMICS

I. Hortelano[1], Y. Moreno[1], R. Pérez-Santonja[1], M.A. Ferrús[2]
[1]Universitat Politècnica de València, Research Institute of Water Engineering and Environment IIAMA, Valencia, Spain
[2]Universitat Politècnica de València, Biotecnología, Valencia, Spain

Backgrounds

Non-*H. pylori Helicobacter* (NHPH) species produce gastric diseases in human, including gastritis and mucosa-associated lymphoid tissue (MALT) lymphoma.

H. hepaticus is the most studied NHPH specie, as it is related with liver and biliary tract diseases. Human intestine seems to be its primary colonization site; therefore, it could be present in fecal-contaminated water. *In vitro* isolation of NHPH is extremely difficult and this specie has never been isolated from environmental samples. Thus, only molecular culture-independent methods can be successful for detection.

Objectives

We have investigated the occurrence of *H. pylori* and NHPH in wastewater by genus specific PCR targeting 16S-RNA gene. Furthermore, a 16S rDNA -base metagenomics approach was developed.

Methods

Eight samples from the tertiary treatment effluent from a wastewater treatment plant were processed. DNA was amplified, submitted to genus specific PCR and subsequently sequenced. Positive samples were analyzed by metagenomics: the hypervariable V1-V3 region of the 16S rDNA was amplified and deep sequenced using an Illumina MiSeq platform. The analysis of the sequences was performed using the QIIME software.

Conclusions

Results obtained showed that 6 of the analyzed samples were positive for *Helicobacter* genus. After sequencing, two of the samples were positive for *H.pylori* and other two were positive for *H. hepaticus.* These results were verified by metagenomics analysis. Since our knowledge, this is the first time that *H. hepaticus* has been identified from wastewater.

This study has been supported by the Spanish Ministerio de Economía y Competitividad AGL2014/53875-R grant

EXPLORING THE INFLUENCE OF GEOGRAPHY AND THALLI LOCATION ON BACTERIAL COMMUNITIES ASSOCIATED WITH THE LICHEN RAMALINA FARINACEA

À. Figàs-Segura[1,2], E. G. Biosca[1], E. Barreno[2,3], N. Fierer[4,5]
[1]Universitat de València, Microbiología y Ecología, Burjassot, Spain
[2]Instituto Cavanilles de Biodiversidad y Biología Evolutiva, Botánica, Paterna, Spain
[3]Universitat de València, Botánica, Burjassot, Spain
[4]University of Boulder, Department of Ecology and Evolutionary Biology, Boulder- CO, USA
[5]University of Boulder, Cooperative Institute for Research in Environmental Sciences, Boulder- CO, USA

Backgrounds

The classical definition of lichen comprises the mycobiont (a fungus) and the photobionts (green algae and/or cyanobacteria) as the symbiotic mutualistic partners. However, recent studies have demonstrated that heterotrophic bacterial communities are additional partners, with lichens now considered as multi-species symbiosis. Nevertheless, still very little is known about the composition and diversity of these communities, and how they could vary across geography and/or the lichen structure.

Objectives

We aimed to explore the diversity and composition of the bacterial communities associated with populations of the lichen *Ramalina farinacea* from different geographical locations, as well as between ectolichenic and endolichenic fractions and along differentiated thallus parts.

Methods

Lichen thalli of *R. farinacea* from four different locations in Spain with Mediterranean climate, two in the Canary Islands and two in the Iberian Peninsula, were analyzed by multiplexed sequencing of the V4-V5 region of the *16S rRNA* gene.

Conclusions

Our results provide new insights into the diversity of bacterial communities associated with *R. farinacea* populations from different Mediterranean-climate areas, showing that the predominant phylum at the four locations was the *Proteobacteria,* particularly *Alphaproteobacteria*, the families *Acetobacteriaceae, Caulobacteriaceae and Methylocystaceae* and the genera *Beijerinckia* and *Sphingomonas* among others. Furthermore, the bacterial community composition appears mainly determined by geography since some taxa within the *Cyanobacteria* and *Firmicutes* phyla were more abundant in the *R. farinacea* populations from the Island than in those from the Peninsula. Also, the communities were distinct between ectolichenic and endolichenic fractions and among apical, middle and basal thallus parts. (PROMETEOII/2013/021 & VALi+d-BEFPI; BACTPLANT-UV-Research Support; FiererLab).

COMPARATIVE GENOMIC ANALYSIS OF FAECALIBACTERIUM PRAUSNITZII STRAINS ISOLATED FROM HEALTHY HUMAN GUT

C.B. Fitzgerald[1], A. Shkoporov[1], V. Velayudhan[1], A. Forde[1], C. Hill[1], P. Ross[1]
[1]APC Microbiome Institute, Microbiology, Cork, Ireland

Backgrounds

Faecalibacterium prausnitzii is a member of the *Ruminococcaceae* family and one of the most predominant members of human gut microbiome. *F. prausnitzii* has been shown to decrease significantly in patients with IBD. It has also been shown to possess direct anti-inflammatory activities in mouse colitis models. Despite its predominance and positive role in the healthy human gut, little is known about it's genomic organization, genetic diversity, and the phylogenetic links of this species with related genera inhabiting the human gut.

Objectives

The objective of this project was to perform complete/draft genomic sequencing of 12 *F. prausnitzii* strains and one closely related *Subdoligranulum/Gemmiger* strain. These strains were isolated from healthy human subjects and were analysed comparatively in conjunction with 10 previously sequenced genomes available from public databases.

Methods

A total of 12 strains of *F. prausnitzii* were isolated from anaerobic cultures of healthy human fecal samples. These strains were identified by a combination of phenotypic tests and 16S rRNA gene sequencing. Draft genome sequencing of all strains was accomplished using Illumina Hiseq platform. Two strains were also subjected to PacBio sequencing for gap closing. An array of bioinformatic and molecular techniques were used to identify core genome composition, phylogenetic relatedness of *F. prausnitzii* in context of the family *Ruminococcaceae*, mobilome, and other genetic features.

Conclusions

Preliminary analysis results suggest that human *F. prausnitzii* isolates demonstrate high level of genetic polymorphism and genomic shuffling. Plasmids, and inducible prophages were identified. The results from this project will greatly increase our understanding of *F. prausnitzii.*

RHIZOBIA BIOFERTILIZER-BASED INCREASE YIELD PRODUCTION IN CARROTS

J.D. Flores Felix[1], P. García-Fraile[2], E. Martínez-Molina[1], E. Velázquez[1], R. Rivas[1]
[1]University of Salamanca, Microbiología y Genética, Salamanca, Spain
[2]Academy of Science of the Czech Republic, Department of Microbiology, Prague, Czech Republic

Backgrounds

Modern agriculture has to solve the problem of feeding an increasing population in a World with limited resources. Dealing with this challenge requires the application of new technologies in the fields to improve the efficiency of the available resources. One example is the application of biofertilizers formulated with Plant Growth Promoting Rhizobacteria (PGPR).

Objectives

The aim of this study was to develop a bacterial biofertilizer for carrots with the capability to promote this crop yields under field conditions.

Methods

We selected the strain PEPV16, a bacterium with several PGPR mechanism (Flores-Félix et al., 2015). Then, we checked the capability of the GFP-labelled strain to colonize carrots' root surface, using a fluorescence microscope. To study the capability of the bacterial strain to promote the first plant stages, inoculated seeds were cultivated in water-agar plates overlaid with Whatman number 1 sterile paper. After 7 and 14 days, stem and root length was measured and the number of secondary root was counted. Field experiments were performed and statistical analyses using StatView program allowed us to compared the carrots production from plant inoculated with the strain PEPV16 and the positive (chemical fertilizer) and the negative controls.

Conclusions

The strain PEPV16 is able to produce indolacetic acid-like compounds, siderophores and solubilize phosphates. It increases inoculated seedlings aerial and root length, and the number of secondary roots. In field conditions, inoculated carrots show an increase in root weight, which produces an improvement in caliber of yielded carrots, and reduce the malformation in roots.

THE PLANT-BENEFICIAL ROOT-COLONIZER PSEUDOMONAS PROTEGENS CHA0 PERSISTS IN INSECTS THROUGHOUT DIFFERENT DEVELOPMENTAL STAGES AND CAN BE TRANSMITTED TO NEW HOST PLANTS

P. Flury[1,2], P. Vesga[1], A. Dominguez-Ferreras[1], D. Bär[1], C. Tinguely[1], J. Schneider[1], A. Taddei[1], R. Kleespies[3], C. Keel[2], M. Maurhofer[1]
[1]ETH Zürich, Phytopathology, Zürich, Switzerland
[2]University of Lausanne, Department of Fundamental Microbiology, Lausanne, Switzerland
[3]Julius Kühn-Institute JKI,
Federal Research Centre for Cultivated Plants- Institute for Biological Control, Darmstadt, Germany

Backgrounds

The discovery of insecticidal activity in root-colonizing pseudomonads, best-known for their plant-beneficial effects, raised not only questions about a possible application of this trait in pest control, but also about the ecological relevance of insects as alternative hosts for these bacteria. Since soil bacteria are limited in their inherent abilities of dispersal, insects as vectors might be welcome vehicles to overcome large distances.

Objectives

This study investigates whether *Pseudomonas protegens* CHA0 exhibits biocontrol activity against a root-feeding insect pest and whether insects could serve as a vector for dispersal of this plant-beneficial rhizobacterium.

Methods

In a pot experiment larvae of the cabbage fly were feeding on roots colonized by *P. protegens* CHA0-*gfp2*. Emerging adult flies were exposed to new, bacteria free plants, imitating the natural situation in which flies search for new host plants to deposit eggs. Bacterial numbers (in roots and insects) and insect survival were monitored. Persistence of *P. protegens* CHA0 in insects throughout different life-stages was further assessed in additional insect species and investigated by microscopy methods.

Conclusions

P. protegens CHA0 is able to persist in several insect species throughout different life-stages and can be transmitted from the roots of one plant to the roots of another plant by the cabbage root fly. Although, survival of the latter was not affected by CHA0, morphological defects observed in parts of adult flies indicate a negative impact of the bacteria on insect development. In summary, our results suggest that certain fluorescent pseudomonads can use insects as hosts and vectors.

DISULFIDE BOND-CONTAINING AJOENE ANALOGS AS NOVEL QUORUM SENSING INHIBITORS OF PSEUDOMONAS AERUGINOSA

J. Fong[1,2], T.H. Jakobsen[3], K.T. Mortensen[4], M.M. Salido Delos Santos[1], S.L. Chua[1], Y. Liang[1,2], C.H. Tan[5], T.E. Nielsen[1,3], M. Givskov[1,3]
[1]Singapore Centre for Environmental Life Sciences Engineering, Public Health and Medical Biofilm, Singapore, Singapore
[2]Nanyang Technological University, School of Biological Sciences, Singapore, Singapore
[3]University of Copenhagen, Costerton Biofilm Center- Department of Immunology and Microbiology, Copenhagen, Denmark
[4]Technical University of Denmark, Department of Chemistry, Copenhagen, Denmark
[5]Nanyang Technological University,
Chemistry and Biological Chemistry- School of Physical and Mathematical Sciences, Singapore, Singapore

Backgrounds

Infectious diseases are the direct cause of 16 million deaths annually. Among those, estimated 65% fatalities are associated with biofilm infections. QS inhibitors (QSI) have been proposed as a promising agent for controlling persistent infections, where deletion of one or more QS genes in *P. aeruginosa* result in lower virulence factors as compared to the wild type and render biofilm bacteria more susceptible towards antibiotic treatment.

Objectives

Identify and develop novel chemical scaffolds as potential quorum sensing inhibitors (QSIs) and antivirulence drugs for treatment of *P. aeruginosa* infections.

Methods

We performed screening of in-house chemical library and structural activity relationship (SAR) study to improve bioactivities to sub-micromolar range. The compounds were then tested against our QS bioreporter strains (*lasB, rhlA, pqsA-gfp*), as well as on QS-activated virulence phenotypes such as elastase, rhamnolipid and pyocyanin production. Lastly, we also tested the efficacy of compounds *in vivo* using mouse implant biofilm infection model.

Conclusions

Our SAR study indicated a novel benzothiazole derivative with IC_{50} value of 0.56 µM, which is one of the most potent QS inhibitors reported to date. The compounds were also able to reduce expression of QS-regulated virulence factors and clear *P. aeruginosa* infection in a mouse implant biofilm infection model. Altogether, the QSI activity of the synthesized compounds is encouraging for the further exploration of novel analogs in antimicrobial drug development. The results presented here, from high-throughput screening (HTS) to SAR studies, could provide important scaffolds for future chemical development, in both design and discovery of novel QSIs.

THE MICROBIAL ECOLOGY AND BIOGEOCHEMISTRY OF A NUCLEAR FUEL STORAGE POND

L. Foster[1], J. Pittman[1], K. Morris[1], D. Sigee[1], H. Muhamad Ali[2], R. Goodacre[2], J. Lloyd[1]
[1]University of Manchester, School of Earth and Environmental Sciences, Manchester, United Kingdom
[2]University of Manchester, Manchester Institute of Biotechnology, Manchester, United Kingdom

Backgrounds

The Sellafield site has several open spent nuclear storage ponds (SNFP) that are at various stages of decommissioning, including an alkaline pond containing spent fuel and sludge waste, which are to be retrieved. This pond is extremely inhospitable with significant levels of radioactivity and high pH (~11) due to the continuous purging of highly alkaline water. Despite these conditions the pond is known to experience seasonal microbial growth, described as “algal blooms”. The blooms reduce visibility in the pond, impacting on waste retrieval operations and potentially increasing both the cost and timescale of hazard and risk reduction. Currently there is little information about the organisms responsible for the blooms, what the triggers for the bloom are, or how the microorganisms colonise such an extreme environment.

Objectives

The aim of this project is to characterise the microbial community residing in this pond. Initial analyses of DNA extracted from the pond water samples revealed the presence of a cyanobacterium, *Pseudanabaena catenata*.

Methods

Cultures of *P. catenata* were exposed to 95 Gy of X-irradiation over a 5 day period to monitor the effect that ionizing radiation had on the growth of the organism. Cell pellets were analysed using FTIR to get a fingerprint of the metabolic activity in the irradiated cells.

Conclusions

P. catenata showed no change in growth yield when irradiated. However the cultures did show a significant reduction in the chlorophyll concentrations following the treatment. FTIR results indicate an increase in polysaccharides, which may significantly impact on the fate of radionuclides in the pond.

MICROBIAL DIVERSITY IN EXTREME SALINE ENVIROMENTS

M. Franze[1], *A. Cherkouk*[1]
[1]*HZDR, Institute of Resource Ecology - Biogeochemistry, Dresden, Germany*

Backgrounds

Rock salt formations are considered as potential host rock systems for the long-term storage of highly radioactive waste in a deep geological repository. To date, little is known about the habitat rock salt and the way of life of the microorganisms occurring there. Next to bacteria and fungi, extreme halophilic archaea are dominating this habitat. It is of interest to know what kind of microorganisms are living there, how active they are under repository relevant conditions and how these microorganisms can influence the safe storage of the waste.

Objectives

A combination of culture-dependent and -independent methods was used to investigate the microbial diversity in rock salt from potential host rock for nuclear waste disposal as well as saline soil samples from Arava Desert, Israel.

Methods

Culture-dependent: A specific portion of the two kinds of samples were incubated in three different sodium chloride concentrations of modified R2A resuscitation buffer and were spread on corresponding agar plates (37°C) to get isolates which were further characterized. Culture-independent: From two samples DNA was extracted, purified for PCR amplification of 16S rRNA genes and sequenced with Illumina MiSeq (RTL Genomics).

Conclusions

Halophilic microorganisms could be isolated from both kinds of samples. The soil sample isolates can be assigned to different archaeal genera *Natrinema*, *Halorubrum*, and *Halobacterium.* Bacterial isolates could be related to *Bacilli* such as *Halobacillus* and *Aquibacillus*. From rock salt samples different *Halobacetrium* species could be isolated. The obtained isolates could be further used for investigations, regarding their activity under repository relevant conditions.

ECOINFORMATIC DECODING OF THE RABBIT MICROBIOME

G. Funosas[1], F. Castro[2], R. Villafuerte[2], E. O. Casamayor[1], X. Triadó-Margarit[1]
[1]Centre of Advanced Studies of Blanes-Spanish Council for Research CEAB-CSIC, Integrative Freshwater Ecology Group, Blanes, Spain
[2]Institute of Advanced Social Studies IESA-CSIC, TRAMAS - Territorio- Ruralidad- Medio Ambiente y Sostenibilidad, Córdoba, Spain

Backgrounds

The gut microbiome is a current hot topic of research, not only directly related to diet and nutritional status studies but also because the close relationships with physiological and immunological responses in animals, proving to be a key factor in the host health status. We analyzed the gut microbiome in the wild European rabbit (*Oryctolagus cuniculus*), a keystone species for Iberian biodiversity,

Objectives

We aimed to determine the identity and structure of the gut microbiome and the factors that shape its composition. We hypothesized that the proportion of different microbial groups can be used as a proxy for host health status.

Methods

We applied high-throughput sequencing Illumina techniques (16S rRNA amplicon) to fecal rabbit samples. Factors such as captivity, diet, age, sex, host taxonomy and other biometric variables were analyzed. A set of healthy domestic rabbits was used to validate the health index.

Conclusions

Only diet and captivity status significantly shaped the microbiome composition. The highest diversity was found in wild rabbit whereas in many captive animals a consistent dominance by Escherichia-Shigella was observed. A significant negative correlation between relative abundances of Ruminococcaceae-Lachnospiraceae-Rikenellaceae and Enterobacteriaceae was found. The rabbit gut microbiome composition varied accordingly to the health status of the animals unveiling the ratio Ruminococcaceae/Enterobacteriaceae as a key parameter for healthy individuals.

MICROBIAL GRANULATION AT HIGH SALINITY: A STRESS INDUCED SURVIVAL STRATEGY?

M.C. Gagliano[1], T. Neu[2], U. Kuhlicke[2], D. Sudmalis[3], H. Temmink[3], C. Plugge[1]
[1]Wageningen University, Laboratory of Microbiology, Wageningen, The Netherlands
[2]Helmholtz Centre for Environmental Research UFZ, Department of River Ecology, Magdeburg, Germany
[3]Wageningen University, Sub-department of Environmental Technology, Wageningen, The Netherlands

Backgrounds

In the Upflow Anaerobic Sludge Blanket Reactor (UASB) technology, microorganisms auto-aggregate as a granular biofilm, forming a microbial ecosystem with a characteristic architecture. When saline wastewater is biologically treated in this system, the sodium concentration can negatively affect microbial aggregation and consequently the anaerobic process. On the other hand, microbial aggregation, with the production of extracellular polymeric substance (EPS), is described as a protective response to environmental stress. In this research, we analysed the structure of anaerobic granules in two UASB reactors treating low (5 g/L of sodium) and high (20 g/L of sodium) salinity synthetic wastewater.

Objectives

Identify granules components (extracellular polymers, microorganisms) to clarify the granule formation mechanism at low and high salinity, pointing out the role of the main microbial protagonists.

Methods

Fluorescence lectinbar-coding (FLBC) analysis coupled with Confocal Laser Scanning Microscopy (CLSM) revealed a completely different glycoconjugate composition at two different salinities. Fluorescence in Situ Hybridization (FISH), 16S rRNA analysis and Scanning Electron Microscopy (SEM) highlighted that the non-halophilic *Methanosaeta harundinacea spp.* was the dominant methanogen in both granules, constituting the main “builiding block” of the structure. Conversely, a completely different bacterial community between the low and high salinity reactors had developed.

Conclusions

Halotolerance in UASB reactors is facilitated by means of EPS/biofilm production. EPS glycoconjugate distribution and the ratio between the components in granules were influenced by the different salinity levels and the different microbial community members.

[4]National Research Council of Italy CNR, Institute of Agricultural Biology and Biotechnology, Pisa, Italy
[5]Justus-Liebig-University Giessen, Institute of Applied Microbiology, Giessen, Germany

Backgrounds

Plant seeds possess a complex microbiota which may play a crucial role in many aspects, such as preservation, germination, seedling development, plant growth and health. In particular, seed endophytic microbiota is gaining more and more consideration due to the fact that it may be vertically transmitted to ensure individual competitive advantages. The *Citrus* species, including *C. limon*, are one of the most economically important evergreen fruit crops in the world.

Objectives

i) Identification and characterization of microbial isolates from *Citrus limon* L. Burm. F. seed endosphere.
ii) Structure of *Citrus limon* L. Burm. F. seed endosphytic microbiota.

Methods

- Surface-sterilization of *Citrus limon* L. Burm. F. seeds.
- Strain isolation and phylogenetic characterization by 16S rDNA sequence.
- Next Generation Sequence (NGS) technology analysis of metagenomic DNA by pyrosequencing of 16S rDNA.
- Fluorescence In Situ Hybridization coupled with Confocal Laser Scanning Microscopy (FISH-CLSM).

Conclusions

Culture-dependent approaches allowed the isolation of several bacterial strains belonging to the genus *Staphylococcus* and several fungal strains belonging to the genera *Aspergillus, Quambalaria and Efibula* from seed endosphere. These results were supported by the detection of bacterial cells and micro–colonies in seed cryosections by FISH-CLSM. In particular, this analysis highlighted the presence of Firmicutes and other bacteria colonizing intercellular spaces. In addition, NGS-based characterization using metagenomic DNA from seed endosphere is being carried out in order to elucidate the microbiota structure.

ANALYSIS OF MALDI-TOF MS PROFILES OF ISOLATES RECOVERED FROM DIFFERENT DRINKING WATER SOURCES

B. Galofré[1], G. Saucedo[1], C. Vilaró[1], S. Fernández[2], D. Baquero[2], A.R. Blanch[3], F. Lucena[3], C. García-Aljaro[3], L. Sala-Comorera[3], D. Toribio[3], M.A. Ruvira[4], L. Rodrigo-Torres[4], M.C. Macián[4], D.R. Arahal[4], M.J. Pujalte[4], R. Aznar[4]
[1]Aigües de Barcelona- Empresa Metropolitana de Gestió del Cicle Integral de l'Aigua- SA, Direcció Qualitat Aigua - Laboratori de Microbiologia, Barcelona, Spain
[2]Cetaqua- Water Technology Center, Quality area, Barcelona, Spain
[3]Faculty of Biology. University of Barcelona, Department of Genetics- Microbiology and Statistics, Barcelona, Spain
[4]Spanish Type Culture Collection CECT, Department of Microbiology and Ecology, Valencia, Spain

Backgrounds

Rapid identification of bacteria can be approached by molecular techniques as an alternative to traditional culture methods. MALDI-TOF MS (matrix-assisted laser desorption/ionization-time-of-flight mass spectrometry) has proven as an easy-to-use, efficient, reliable and fast technique in routine clinical analysis. However, the commercial database for identification of environmental bacteria in drinking water laboratories is still very limited by the lack of a suitable mass spectra database. This work is part of the on-going project *Drinking Water Library*, which aims to generate a MALDI-TOF MS database useful for water laboratories and water treatment - distribution operators.

Objectives

Evaluation of the MALDI-TOF profiles for the identification of drinking water associated bacteria using the current commercial database.

Methods

Isolation of bacteria from bottled mineral water, mineral source water, drinking water treatment plant (DWTP) and distribution network by plating on R2A Agar and Water ISO media followed by incubation at 22ºC for up to 7 days. Isolates identification by MALDI-TOF using the current database. Profiles clustering of unidentified isolates and selection of cluster representatives.

Conclusions

A total of 1014 strains have been isolated and processed so far from bottled mineral water (307), mineral source water (349) and DWTP and distribution network (358). 44% of the isolates were identified at species level as belonging to 36 different genera, being the majority *Bacillus* and *Pseudomonas*. 56% remain unidentified at species level and clustered in 22 profile groups. Identification of cluster representatives will lead the selection of species to be included in the Drinking Water Library.

TAXONOMIC AND FUNCTIONAL DIVERSITY OF PHYLLOSPHERIC COMMUNITIES IN AN URBAN PARK (MILAN, NORTHERN ITALY)

I. Gandolfi[1], I. Rossi[1], S. Molinetti[1], D. Brambilla[1], S. Covino[2], R. Ambrosini[1], E. Padoa-Schioppa[1], M. Papacchini[3], D. Cappelletti[2], E. Federici[2], A. Franzetti[1]
[1]University of Milano-Bicocca, Dept. of Earth and Environmental Sciences, Milan, Italy
[2]Università degli Studi di Perugia, Dipartimento Di Chimica- Biologia e Biotecnologie, Perugia, Italy
[3]INAIL,
Dipartimento Innovazioni Tecnologiche e Sicurezza degli Impianti- Prodotti ed Insediamenti Antropici, Rome, Italy

Backgrounds

Plant-associated microorganisms have been suggested to play a role in air pollution mitigation, especially in urban areas. Particularly, epiphytic bacteria and fungi might be able to degrade atmospheric hydrocarbons. However, phyllospheric microbial communities are highly variable depending on several factors, e.g. tree species, leaf age, environmental conditions.

Objectives

In this work, temporal variability of epiphytic bacterial and fungal communities hosted by leaves of different tree species (*Magnolia grandiflora, Cedrus deodara, Platanus x acerifolia, Tilia x vulgaris)*, located in an urban park in Milan (northern Italy), was assessed during a year-long sampling campaign.

Methods

Bacterial and fungal communities were taxonomically characterized by Illumina high throughput sequencing of the hypervariable regions V5-V6 of 16S rRNA gene and of the ITS1-ITS2 regions, respectively. Functional biodiversity was assessed by whole metagenomic sequencing on a subset of samples. Culturable bacterial strains, both epiphytic and endophytic, were isolated on oligotrophic media and tested for biodegradation abilities towards PAHs.

Conclusions

Results revealed that each tree species hosted peculiar microbial populations. Temporal changes, which are related to seasonality, acted as a strong driver on biodiversity of microbial communities. Moreover, temporal differences were more marked in deciduous plants than in perennial plants. Whole metagenomic analyses indicated the presence of aromatic hydrocarbon degrading abilities, although at low coverages. Approximatively 7% of the isolated strains were able to degrade naphthalene and/or phenanthrene in laboratory cultures. It was therefore hypothesized that phyllospheric populations hosted by urban trees might play a role in the mitigation of hydrocarbon air pollution.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

MULTIPLE QUORUM-SENSING SIGNALS PRODUCED BY NITROBACTER N-ACYL-HOMOSERINE LACTONE SYNTHASE NWII

J. Gao[1], G. Zhuang[1]
[1]Research Center for Eco-Environmental Sciences- Chinese Academy of Sciences, CAS Key Laboratory of Environmental Biotechnology, Beijing, China

Backgrounds

The genome sequence showed that the nwi_0626 gene in *Nitrobacter winogradskyi* was predicted to encode LuxI homolog that is responsible for the synthesis of acyl-homoserine lactones (AHLs) as quorum sensing (QS) signals. Although the AHL-producing activity was confirmed in *N. winogradskyi*, the AHL synthase, LuxI/R QS system and the postulated QS in *N. winogradskyi* have not been proven.

Objectives

To investigate the potential AHL synthase from *N. winogradskyi*, we sought to identify the signal types that were produced by NwiI.

Methods

The *nwiI* gene of *N. winogradskyi* was confirmed to be a homoserine lactone synthase by heterologous expression in *Escherichia coli,* and we purified a novel AHL molecule with an unsaturated C10 acyl side chain generated by NwiI, as confirmed by the mass, nuclear magnetic resonance (NMR) and correlation spectroscopy (COSY) analyses.

Conclusions

To identify the signal types that were produced by the AHLs synthase in *N. winogradskyi*, we introduced *nwiI* into *E. coli*, which resulted in the synthesis of a series of AHLs with chain lengths ranging from C7 to C11. Five of the AHLs were identified as C7-AHL, C8-AHL, C9-AHL, C10-AHL and C10:1-AHL. A novel signal, 7, 8-*trans*-*N*-(decanoyl) homoserine lactone (C10:1-AHL), was identified in both *N. winogradskyi* and the recombined *E. coli*. Furthermore, this novel signal also triggered variances in the nitrification rate and the level of transcripts for the genes involved in the nitrification process. These results indicate that quorum sensing may have a potential role in regulating nitrogen metabolism.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

THE GOLLUM PROJECT: CHARACTERISING SUBTERRANEAN BACTERIAL COMMUNITIES IN DEPTH(S)

C.P. Garay[1]
[1]*Institute for Integrative Systems Biology I2SysBio, Theory, Paterna, Spain*

Backgrounds

The Somport tunnel (connecting Spain and France in central Pyrenees) crosses different rocks from the late Paleozoic ages, and includes several Facies. Its length, depth and diverse ecology make it a perfect site for extremophile ecology studies. In extreme environments, bacteria –and archaea- tend to be the main living organisms. Subterranean microorganisms have been described, but almost all reports refer to samples taken centimeters to few meters below the surface. In fact, many of those have a photoautotrophic metabolism. By contrast, the literature describing microorganism inhabiting the very inside of rocks are scarce. The few reports analysing the microbial diversity of rock inhabitants evidence, though, a rather high diversity of microbial taxa and metabolism pathways.

Objectives

Gollum goal is the identification and characterization of the microbial communities living in a range of different rocks throughout the length of the Somport tunnel, from the surface to the maximum depth (850 meters).

Methods

This is being accomplished through geochemical analysis and 16S amplicon and shotgun high throughput sequencing of the combined genomes in a given sample. Sampling different depths and rocks is achieved by collecting one-meter length cylinders of rock drilled along the tunnel, minimizing external contamination.

Conclusions

Taken together, these procedures allow determining with high precision the microbial composition of the Somport tunnel at different depths and on different mineral substrates. This pioneering study may serve as a platform for further geomicrobiology (e.g., biology) studies in already existing deep underground labs, nowadays mainly dedicated to low background physics experiments.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

NEW MICROBIAL SOURCE TRACKING MARKER BASED ON THE PREDICTED BACTERIOPHAGE CRASS GENOME

C. García-Aljaro[1], E. Ballesté[1], M. Muniesa[1], J. Jofre[1]
[1]University of Barcelona, Genetics- Microbiology and Statistics, Barcelona, Spain

Backgrounds

In the last decades considerable efforts have been devoted to the search of microbial source tracking markers in order to predict the associated health risks of fecally polluted waters, with no universal marker reported so far. A recent metagenomic study identified the genome of a bacteriophage referred to as crAssphage which was abundant and widespread in human faecal samples.

Objectives

To develop a quantification method to study the real abundance and prevalence of crAssphage in wastewaters of human and animal origins.

Methods

The presence of crAssphage was investigated in the DNA extracted from raw samples (total and viral DNA fraction) by qPCR using a TaqMan® assay. Primers and probe were designed from a 1331 bp fragment of the sequence of crAssphage (NC_024711.1) from a human sewage sample.

Conclusions

CrAssphage showed up to 10^8 GC/100 ml in all sewage samples from human origin in the total DNA and in the viral fraction. In animal wastewaters, 36% of the samples were negative for the presence of the phage and those showing positive results were between 3 and 2 log10 units (36%) lower than samples from human origin; the remaining showed 1 log10 units difference. The ratios between the numbers of crAssphage and indicators of general fecal contamination were higher in samples with human fecal contaminants. This study opens the door for further research to explore if different specific animal variants of crAssphage exist and whether other zones of the genome of crAssphage have better capability of discrimination of the source.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

COMMUNITY DIVERSITY AND NICHE STRUCTURES AFFECT DIFFERENTLY THE EVOLUTION OF SECRETED PROTEINS TO MAXIMIZE COMPETITION

M. Garcia-Garcera[1], *M. Touchon*[1], *E. Rocha*[1]
[1]*Institut Pasteur, Genomique Evolutive des Microbes, Paris, France*

Backgrounds

Microbes display a remarkable interaction with the environment, which relays on the secretion of a wide variety of proteins. These effectors, although costly, are essential for cooperation, foraging, shelter, microbial warfare, and virulence. With such variety of roles, one wonders whether the different environmental factors affect similarly the evolution of the secreted proteins.

Objectives

To evaluate this question, we have studied the effect of the habitat structure and the community composition in the evolution of the bacterial secretome, with special emphasis on proteins involved in antimicrobial activity and nutrient scavenging.

Methods

Using a comparative genomics approach, we have assessed the frequency and diversity of secreted proteins associated to each environment in more than 6000 publicly available metagenomic datasets. We have evaluated with general linear mixed models the relationships between environmental factors and the secretome, paying special attention to the habitat structure and community diversity.

Conclusions

We have found that highly unstructured habitats have selected proteins minimizing their diffusibility. This maximizes the benefit from the producer while limiting the access to non producers. This association is especially important for secreted proteins involved in foraging, as they tend to be, not only less diffusible in unstructured habitats, but also less abundant in environments with a great diversity. Bacteria living in such environments also tend to carry a higher abundance of antimicrobial tools, to clash against a potentially higher diversity of contestants.

AN EXPLORATION OF THE VIROME IN PATIENTS WITH ORAL LEUKOPLAKIA, PROLIFERATIVE VERRUCOUS LEUKOPLAKIA AND ORAL SQUAMOUS CELL CARCINOMA, AND ITS INTERACTION WITH THE MICROBIOTA

R. García-López[1], V. Pérez-Brocal[1], J.V. Bagan[2], A. Moya[3]
[1]Joint Unit of Research in Genomics and Health: Fundación para el Fomento de la Investigación Sanit aria y Biomédica de la Comunitat Valenciana FISABIO & Cavanilles Institute for Biodiversity and Evol utionary Biology University of València, Genomica y Salud, Valencia, Spain
[2]Universitat de València, Oral Medicine, Valencia, Spain
[3]Joint Unit of Research in Genomics and Health: Fundación para el Fomento de la Investigación Sanit aria y Biomédica de la Comunitat Valenciana FISABIO & Cavanilles Institute for Biodiversity and Evol utionary Biology University of València, Genetics, Valencia, Spain

Backgrounds

Proliferative verrucous leukoplakia (PVL) is a high-risk form of oral leukoplakia (OL), an oral lesion manifested as white hyperkeratotic plaques or warts in the human oral cavity, mainly detected in elderly women. Most PVL lesions derive in aggressive oral carcinomas, mainly oral squamous cell carcinomas (OSCC). Associations to alcohol and tobacco consumption have been discarded and, although no etiology has been confirmed for PVL, its multi-focal pattern and its high rate of recurrence hint on the involvement of an infectious agent, possibly of viral origin.

Objectives

In order to detect a potentially novel infectious agent, we studied the broad collection of viral DNA and RNA from viral communities, or virome, as well as the 16S profiles of the bacterial communities in patients with PVL, OL and OSCC.

Methods

Forty biopsies were used for the study, 10 from groups PVL, OL, OSCC, and Control. Both DNA and RNA were extracted independently for high-throughput sequencing, and the amplification of the 16S rRNA gene was carried out for bacterial composition assessments. The resulting sequences were quality-processed, filtered, assembled, identified and analyzed for taxonomic and functional profiling, depending on the set. Accessory sequences belonging to Fungi were also included in the cross-analysis of the interactions between the microbiome and the virome.

Conclusions

The detection of potential etiological agents in this thriving community is hindered by the interactions between its multiple relevant players but the virome still plays a relevant role in this bacteria-rich environment as it appears to contribute in modulating populations of preyed bacteria.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ASSESSMENT THE MICROBIAL COMMUNITIES ASSOCIATED TO MANILA CLAM BY MEANS OF 16S RRNA AMPLICONS

D. Gerpe[1], A. Lasa[1], S. Balboa[1], J. L.Romalde[1]
[1]CIBUS- Facultad de Biología. Universidade de Santiago de Compostela, Microbiology and Parisitology, Santiago de Compostela, Spain

Backgrounds

Clam culture represents an important economic activity in Galicia (NW Spain). All the existing studies analysed the bacterial communities using culture dependent methods, leading to an underestimation of the diversity. The introduction of the Next Generation Sequencing technologies opened a new era in the understanding the complexity of bacterial communities.

Objectives

To study the bacterial microbiota of Manila clam (*Ruditapes philippinarum*) through 16S rRNA amplicons analysis.

Methods

Samplings of the clams were carried out in summer and winter from two localities in the Galician coast. Different organs, including mantle, gills, gonads and hepatopancreas, were analysed separately. Gradient centrifugation step was performed to separate prokaryotic and eukaryotic cells. A commercial kit was employed for isolation of bacterial genomic DNA. V3/V4 region of 16S rRNA gene was amplified and sequenced at Sistemas Genómicos (Valencia, Spain) using Illumina paired-end sequencing technology.

Conclusions

In most samples analysed the main phylum was *Proteobacteria* except in mantle, gills and hepatopancreas in one of the locations where *Bacteroidetes*, Clamydiae or Tenericutes acquired more relevance. Moreover, *Firmicutes* and *Bacteroidetes* appeared in winter as the major phyla, while in summer were only detected as sporadic and very low abundant groups. Some genera as *Mycoplasma* and *Methylobacterium* appeared in high numbers in hepatopancreas and gonad respectively regardless the season. Uncultured bacteria belonging to the *Cythophagaceae* family was the major group in the mantle microbiota of clams from Redondela all over the year. *Vibrio* and *Pseudomonas* genera appeared in low representation when comparing with other studies based on culture dependent methods.

INFERENCE OF ECOLOGICAL INTERACTIONS IN MICROBIAL COMMUNITIES BY POPULATION TIME SERIES

C.M. Ghim[1]
[1]*Ulsan National Institute of Science and Technology UNIST, School of Life Sciences, Ulsan, Republic of Korea*

Backgrounds

With a view to controlling complex systems, the knowledge of interaction patterns among the constituent parts is essential. A recent surge of interest in microbiome research has led to massive efforts to identify microorganisms and their interactions in environmental settings, including human body. However, despite the promise metagenomic identification of microorganisms offers, reliable reconstruction of ecological interactions among those microbes is still lacking.

Objectives

We try to build a reliable mathematical inference platform to reconstruct ecological interaction networks from microbial time series, which will mark the onset of further analysis and prediction on the microbial population dynamics.

Methods

To this end, we use both empirical as well as synthetic population time series data with generalized Lotka-Volterra model. We quantitatively investigate the impact of both the quantity (duration) and quality (resolution) of the time series and evaluate the performance of various inference methods based on the accuracy and precision.

Conclusions

We evaluate the validity of the linear regression with regularization, direct integral method, and sparse linear regression for inferring interactions between microbes at the genus or higher level, and discuss applicability and limitations of each method.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

DETERMINATION AND DIVERSITY OF SMALL FILTERABLE MICROBIAL SPECIES IN FRESHWATER

L.A. Ghuneim[1], O. Golyshina[2], D. Jones[1], P. Golyshin[2]
[1]Bangor University, School of Environment- Natural Resources- and Geography, Bangor, United Kingdom
[2]Bangor University, School of Biological Sciences, Bangor, United Kingdom

Backgrounds

Small filterable microbial species (i.e. prokaryotes with size dimensions in the 'nano' range, of 50-400 nm which have the ability to physically pass filters with pore sizes 0.2-0.45 µm) are more common than originally thought. They are known by various other names such as: 'ultra-small', 'ultramicro', 'very small', 'small cells', 'nanooorgansims', and 'nanobes'. Their role in nutrient cycling and their identity remains largely unknown due to the inability to successfully isolate in vivo.

Objectives

The goal of this research is to determine the identity and function of these small cells, and how they interact with other community members.

Methods

Using the Conwy catchment as an exemplar, we were able to assess the microbial communities in both filtered (passed through a 0.22 µm filter) and unfiltered fractions of freshwater obtained from the Conwy River. Bacterial 16S rRNA clonal library (amplicon) was generated and de novo sequencing was used to establish a basic community profile.

Conclusions

The phylogenies generated from both amplicon and de novo sequencing show evidence of 'filterable' microbial species. Additionally the community profile showed there was incredible amount of diversity within the Conwy River. The existence of the possible small filterable cells coupled with high biodiversity is indicative of a dynamic community that garners further research in terms of species identification and their contribution to overall nutrient cycling.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

"CANDIDATUS TREMBLAYA PHENACOLA" PPER: A BETA-GAMMAPROTEOBACTERIUM CHIMERA

R. Gil[1], C. Vargas[1], S. López-Madrigal[2], D. Santos-García[3], A. Latorre[1], A. Moya[1]
[1]Institute for Integrative Systems Biology I2SysBio- Universitat de València, Evolutionary Genetics, Paterna Valencia, Spain
[2]INSA-Lyon- Université de Lyon, Biologie Fonctionnelle Insectes et Interactions, Villeurbanne, France
[3]The Robert H Smith Faculty of Agriculture- Food and Environment- The Hebrew University of Jerusalem, Department of Entomology, Rehovot, Israel

Backgrounds

Many insects rely on bacterial endosymbionts to obtain nutrients that are scarce in their highly specialized diets. The most surprising known endosymbiotic system belongs to pseudococcinae mealybugs, where the betaproteobacterium "*Candidatus* Tremblaya princeps" and a gammaproteobacterium maintain a nested endosymbiotic consortium. In the sister subfamily Phenacoccinae, a single beta-endosymbiont, "*Candidatus* Tremblaya phenacola", has been described. We recently detected the presence of a gammaproteobacterial *trp*B gene in "*Ca.* Tremblaya phenacola" from two *Phenacoccus* species, apparently representing one of the first recorded cases of horizontal gene transfer (HGT) in bacterial endosymbionts.

Objectives

In order to identify the extent of the putative HGT, and to better understand the evolutionary history of mealybugs' endosymbiotic systems, we sequenced the genome of "*Ca.* Tremblaya phenacola" PPER from *Phenacoccus peruvianus*.

Methods

Total DNA enriched in bacterial endosymbionts was paired-end sequenced with MiSeq, and assembled using SPAdes. Unions between contigs were confirmed by PCR. Annotation was done with Prokka plus manual curation. We performed a functional analysis by comparison with other *Tremblaya* genomes and using EcoCyc and KEGG databases. The CDSs taxonomic affiliation was determined with MEGAN and phylomizer. OrthoMCL was used to generate clusters of orthologous genes. Phylogenomic reconstruction were built with PhyloPhlAn.

Conclusions

This chimeric endosymbiont presents the same biosynthetic capabilities than other mealybug endosymbiotic consortia. While the complete set of rRNA genes of this strain place it as a betaproteobacterium of the *Tremblaya* clade, nearly half of its CDSs are taxonomically affiliated to Gammaproteobacteria, forming an unprecedented evolutionary collage. A nightmare for molecular taxonomists.

NATURAL OCCURRENCE OF SECONDARY BACTERIAL SYMBIONTS IN APHIDS FROM TUNISIA

R. Gil[1], S. Zouari[2], M. Reyes-Prieto[1], A. Salas Martí[1], P. Monfort Lanzas[1], A. Latorre[1], M. Ben Halima-Kamel[2]
[1]Institute for Integrative Systems Biology I2SysBio- Universitat de València, Evolutionary Genetics, Paterna Valencia, Spain
[2]Institut Supérieur Agronomique ISA- Université de Sousse Tunisie,
Cultures maraîchères conventionnelles et biologiques, Chott Mariem, Tunisia

Backgrounds

Aphids commonly face the attacks of numerous natural enemies, most notably Hymenopteran parasitoids, which are often used as biological control agents.

Many aphids harbor facultative symbionts, some of which confer protection against natural enemies. *Hamiltonella defensa* is known to provide resistance towards specific parasitoids. The degree of protection is greatly influenced by the presence of the lysogenic bacteriophage APSE. *Serratia symbiotica* and *Regiella insecticola* have also been involved in improving resistance to parasitoid wasps, albeit to a lesser extent.

Objectives

We intend to characterize different aphid species and populations from Tunisia for the presence of protective symbionts against *Aphidius transcaspicus*, a braconid parasitoid that has been selected as a biological control agent against the mealy plum aphid *Hyalopterus pruni*.

Methods

Aphids were field collected from natural populations in different locations of Tunisia. Total DNA was used for PCR amplification of symbiont 16S-23S RNA operon sequences and APSE. Amplicons were ABI-sequenced, and analyzed by BLAST to identify the bacterial species. Phylogenetic analyses were performed using Bayesian Inference with MrBayes v3.2.5 software.

Conclusions

Most analyzed populations present *Arsenophonus* sp., a widespread symbiont whose effects on aphid phenotypes are unknown. *S. symbiotica* and *H. defensa* have also been identified in several populations. All *H. defensa* strains detected possess the phage APSE-2, which has been associated with moderate protection against braconids in pea aphids.

EVIDENCE OF INTRASPECIFIC VARIATION IN N-ACYL L-HOMOSERINE LACTONES (AHLS) PRODUCTION BY ENVIRONMENTAL ISOLATES OF V. MEDITERRANEI

L. Girard[1], R. Lami[1], F. Vouvé[2], F. Lantoine[3], M. Suzuki[1], J. Baudart[1]
[1]Sorbonne Universités- Université Pierre et Marie Curie Paris 06- CNRS- Observatoire Oceanologique, Laboratoire de Biodiversité et Biotechnologies Microbiennes - USR 3579, Banyuls sur mer, France
[2]Université de Perpignan Via Domitia, Laboratoire B.A.E, Perpignan, France
[3]Sorbonne Universités- Université Pierre et Marie Curie Paris 06- CNRS- Observatoire Oceanologique, Laboratoire d'Ecogéochimie des Environnements Benthiques - UMR 8222, Banyuls sur mer, France

Backgrounds

Quorum sensing (QS) is a mechanism enabling bacteria to coordinate their genetic expression, behavior and physiological responses. A large panel of molecules named autoinducers (AI) are involved in these regulations, including AHLs (N-acyl L-homoserine Lactones). Many studies have revealed intraspecific variability of AHLs among members of the same *Vibrio* species (e.g. *V. fischeri*, *V. anguillarum*, *V. metschnikovii*, *V. splendidus*). However, despite current knowledge on the production patterns, little is known about the ecological processes that drive AHL production phenotypes in marine environment.

Objectives

The aim of this study was to assess the temporal dynamic of AHLs producing *V. mediterranei* isolates and to evaluate the impact of environmental variables on these phenotypic variations.

Methods

We investigated the capacity of *V. mediterranei* isolates, collected in Salses-Leucate Mediterranean lagoon, to produce AHLs fortnightly during Spring/Summer 2015 and 2016. The analysis of the *V. mediterranei* diversity was investigated by combining ERIC-PCR fingerprinting and phylogenetic analysis of *gyrB* sequences. The AHLs characterization was based on a biosensor based assays, HPLC fractionation and activity-screening prior to UHPLC-HRMS/MS analysis.

Conclusions

Our results revealed a temporal variation of *V. mediterranei* isolates with a succession of different AHL production phenotypes. Remarkably we observed a ERIC-PCR genotype of *V. mediterranei* able to produce a different set of AHLs, in identical culture conditions, over time. The possible interactions between environmental variables and *V. mediterranei* AHL production phenotypes will be discussed.

INACTIVATION MECHANISMS OF ENTEROCOCCUS FAECALIS BY SODIUM HYPOCHLORIDE, CHLORINE DIOXIDE AND ELECTRO ACTIVATED WATER

Z. Girgin Ersoy[1], Ö. Türkay[2], S. Barışçı[2], B. Çınar[1], S. Tunca Gedik[1]
[1]Gebze Technical University, Molecular Biology and Genetics, Kocaeli, Turkey
[2]Gebze Technical University, Environmental Engineering, Kocaeli, Turkey

Backgrounds

Chlorine based disinfectants are commonly used disinfectant agents in a variety of different application areas. There are numerous studies focusing on disinfectant dose and contact time for the removal of different microorganisms by using these agents. However, their mode of action on inactivation of microorganisms has not been comprehensively studied.

Objectives

Therefore, in this study, the effectiveness of three chlorine based disinfectants sodium hypochloride (NaOCl), chlorine dioxide (ClO_2) and electro activated water (EAW) were compared and their bacterial inactivation mechanisms were deeply investigated. *Enterococcus faecalis* was selected to reveal inactivation mechanisms of these disinfectants on a Gram positive bacteria.

Methods

For this purpose, supernatant analysis (determination of cell membrane integrity, measurement of potassium (K^+) leakage and measurement of conductivity) and cellular analysis (measurement of TTC-dehydrogenase activity, determination of DNA damage, SDS-PAGE analysis, measurement of lipid peroxidation and FTIR analysis) were carried out.

Conclusions

According to our results, EAW was the most effective disinfectant by killing bacteria in a very limited time even at low concentrations. All the disinfectants tested brought about DNA, protein and ion leakage due to disruption of cellular membrane; finally caused cell death because of breaking down the ion balance between inside and outside of the cell. Additionally, disinfectant agents could pass through the membrane and effect cellular structures such as DNA, proteins and lipids of the cell negatively. In conclusion, EAW is favorable agent amongst three chlorine based disinfectants due to its strong and environmental friendly character.

MECHANISMS OF ESCHERICHIA COLI AND ENTEROCOCCUS FAECALIS INACTIVATION BY POTASSIUM FERRATE

Z. Girgin Ersoy[1], S. Barışçı[2], N. Genel[1], H. Öztürk[3], Ö. Türkay[2]
[1]Gebze Technical University, Molecular Biology and Genetics, Kocaeli, Turkey
[2]Gebze Technical University, Environmental Engineering, Kocaeli, Turkey
[3]Kocaeli University, Environmental Engineering, Kocaeli, Turkey

Backgrounds

Ferrate (VI) has been used as a greener oxidant in water treatment with its dual effect (i.e. oxidation and coagulation character) for years. Besides its ability for chemical oxidation of organic substances, ferrate (VI) can also be used as a disinfectant agent for the removal of microorganisms. In recent years, some of studies used potassium ferrate in this manner, but the primary focus of these studies was to evaluate the effect of contact time and disinfectant concentration.

Objectives

For this reason, the scope of this study was to reveal the bacterial inactivation mechanism of potassium ferrate on a cellular scale. Because of their different membrane structures, *Escherichia coli* and *Enterococcus faecalis* were selected as a Gram positive and a Gram negative bacteria, respectively.

Methods

The inactivation mechanism of potassium ferrate (K_2FeO_4) on each microorganism was determined by supernatant analysis (determination of cell membrane integrity and measurement of potassium (K^+) leakage and measurement of conductivity) and cellular analysis (measurement of TTC-dehydrogenase activity, determination of DNA damage, SDS-PAGE analysis, measurement of lipid peroxidation and FTIR analysis).

Conclusions

The results showed that potassium ferrate killed both Gram positive and Gram negative bacteria in a short time by working on cellular membrane structures. On one hand, the disruption of cell membrane integrity caused leakage of cellular structures (such as DNA, protein…) and ions occurred. On the other hand, potassium ferrate damaged cellular structures directly. Using many different methods, this study provides the fundamental mechanism of Ferrate (VI) on bacterial inactivation.

FEMS7-2228

BEHAVIOR OF STREPTOMYCES SCABIES, MYXOCOCCUS XANTHUS AND RHODANOBACTER THIOOXYDANS CO-CULTIVATED ON POTATO SUBERIN

L. Giroux[1], *S. Lerat*[1], *C. Beaulieu*[1]
[1]*Université de Sherbrooke, Biologie, Sherbrooke, Canada*

Backgrounds

Suberin is a complex biopolymer found in various plant tissues such as the potato periderm. Suberin acts protective layer against pathogen. Bacteria cannot easily degrade suberin and its degradation was attributed to fungi for a long time. The common scab pathogen *Streptomyces scabies* was shown to be able to grow with suberin as a carbon source and to degrade it. A previous study demonstrated that some bacteria found in the potato soil could potentially be involved in suberin degradation. This proteomic study allowed the identification of lipases from *Myxococcus xanthus* and *Rhodanobacter thiooxydans* when a soil community was exposed to potato suberin.

Objectives

In a 60-days experiment, the capacity of *M. xanthus, R. thiooxydans* and *S. scabies* alone or in combination to degrade suberin was assessed.

Methods

The strains were grown in minimal media with suberin as the carbon source and sampling was done every ten days. Various enzymatic assays were performed to evaluate the enzyme production of the strains and TEM microscopy was performed to detect potential degradation.

Conclusions

Extracellular protein production decreases during the experiment but esterase activity of the supernatant was higher in the combination of strains. The strains survival was also assessed in the strains combination. The survival rate of *M. xanthus* was better when grown with the two other bacteria than alone and as for the *R. thiooxydans,* growth showed decline in the presence of the two other bacteria. The combination of the three strains performed better in most enzymatic assays suggesting greater capacity to degrade suberin.

CO-OCCURRENCE NETWORKS AND ASSEMBLY PROCESSES IN SOIL DENITRIFIER COMMUNITIES

M. Goberna[1], *S. Donat*[1], *E. Pérez-Valera*[1], *S. Hallin*[2], *M. Verdú*[1]
[1]*Centro de Investigaciones Sobre Desertificación, Ecología, Moncada, Spain*
[2]*Swedish University of Agricultural Sciences, Microbial Ecology, Uppsala, Sweden*

Backgrounds

Denitrifiers possessing *nirS* or *nirK* genes are thought to be ecologically distinct since they respond differently to soil abiotic factors. Furthermore, they could have different fitness associated with the costs of synthesizing heme- or Cu-dependant nitrate reductases. Thus, several assembly processes, ie. abiotic filtering, competition based on fitness differences or on limiting similarity, might simultaneously operate to structure the soil denitrifier communities.

Objectives

We aimed to unravel the ecological processes shaping the denitrifier communities before and after fire, which shifts resource availability and thus likely the strength of competition.

Methods

We analysed co-presence and mutual exclusion links in *nir*-based networks and quantified *nirS* and *nirK* before and during one year after an experimental fire.

Conclusions

Network analysis on *nirS* and *nirK* sequences revealed that co-presence links mostly occurred within the same *nir* variant, while exclusion links were equally distributed within and between *nir* variants. Under pre-fire conditions, co-presence *nirS-nirS* links occurred more often than expected by chance, reflecting the similar niche requirements of ecologically similar microbes. Mutual exclusion links, however, were overrepresented for *nirK-nirK* and *nirS-nirK*. While exclusion links between *nir* variants (*nirS-nirK*) can result from niche segregation, those within a single variant (*nirK-nirK*) suggest competitive exclusion based on limiting similarity that precludes the co-existence of functionally similar organisms. Fire erased the signals of competition between *nirK*-bearing microbes probably by reducing resource limitation, despite quantitative PCR revealed a significant increase in *nirK* copy numbers. Our results indicate that fire alters the relative contribution of assembly processes in shaping the communities of soil denitrifiers.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

THE RELEVANCE OF THERMOPHILES IN SOILS. AN ENZYMATIC APROACH

E. Gómez[1], *J. Delgado*[1], *J. González*[1]
[1]*IRNAS-CSIC, Biogeoquímica- ecología vegetal y microbiana, Seville, Spain*

Backgrounds

In the last years, the role of thermophilic microorganisms in soils is starting to be understood above all within an scenario of periodically changing temperature and other environmental conditions. Unexpectedly, the presence of these thermophiles has been confirmed in a wide range of environments. However, their presence and activity are scarcely understood. Extremophilic enzymes are known to be able to maintain their stability (and thus their function) under extreme conditions such as high temperature or dessication. These properties are attracting the interest on these enzymes as a source of new tools for biotechnology. In relation to the biogeochemical cycles of elements, the extracellular enzymatic activity is generally the limiting processe for the mineralization of polymers and recalcitrant organic matter by microorganisms.

Objectives

Evaluate the enzymatic activity by thermophilic microorganisms in soils in a variety of environments.

Methods

In this study, we used fluorogenic substrates to determine different enzymatic activities under different environmental and laboratory conditions.

Conclusions

Our data show that the activities of extracellular enzymes from thermophiles represent the maximum peak of activity in natural soils and sediments. These results suggest that the thermophilic enzymes could play critical roles in the precessing of organic mater in terrestrial environments. These findings contribute to the understanding of the ecology and functioning of microorganisms in soils, specially on arid and semi-arid environments. This is highly relevant in the current climate change framework when a rise of extreme high temperature and dessication events are expected.

CAROTENOID – PRODUCING BACTERIA – A CAUSE OF MURAL PAINTING BIODETERIORATION IN SOME ROMANIAN HISTORICAL MONASTERIES

I. Gomoiu[1], M.I. Enache[2], E.S. Neagu[2], I.M. Cortea[3], R. Radvan[3], L.R. Cojoc[2]
[1]National University of Arts Bucharest, Conservation and restauration, Bucharest, Romania
[2]Institute of Biology Bucharest of the Romanian Academy, Microbiology, Bucharest, Romania
[3]National Institute for Research and Development in Optoelectronics,
Center of Excellence for Restoration by Optoelectronic Techniques – CERTO, Magurele-Ilfov, Romania

Backgrounds

Carotenoids are widely distributed between extremophiles. Some halophilic bacteria produce carotenoids as adaptation to salt stress and, in the case of mural painting, their accumulation results in the modification of the original color, producing pink or red pigmentation.

Microclimate peculiarities of Hurezi and Humor monasteries and the presence of efflorescences offer favorable conditions for halophilic bacterial colonization and biodeterioration.

In the refectory of Hurezi monastery, pink pigmentation is visible on all walls and in Humor Monastery, it was identified up to the height of 0,5m in the pre-nave and up to 0,7m in the chamber tombs.

Objectives

The aim of present work is to highlight a new corroboration of scientific methods to identify carotenoid-producing halophilic bacterial strains involved in biodeterioration of mural paintings.

Methods

The pink pigmentation observed by naked eye was further analyzed by optical and scanning electron microscopy. Microbiological and molecular techniques were used for isolation and identification of carotenoid-producing bacteria. Carotenoid pigments were identified by FTIR (Fourier transform infrared spectroscopy) on samples of mortar, pictorial layer and on pure bacterial cultures.

Conclusions

The correlation of the laboratory data with those registered on the mural painting allowed the identification and attribution of pink biopigmentation to *Halobacillus naozhouensis.* The biopigmentation was put in evidence on most analyzed samples: mural painting, repaintings, infilling mortars clearly stating the presence of carotenoid pigments identified in the case of this halophilic bacterial strain.

STUDY OF POTENTIAL OF OIL DEGRADATION BY MICROORGANISMS ISOLATED FROM THE CASPIAN SEA REGION

A. Goncharova[1], T. Karpenyuk[1], Y. Tufuminova[1], A. Kalbayeva[1], S. Yergaliyeva[1], A. Platayeva[1], M. Zavorotnaya[1]
[1]al-Farabi Kazakh National university, Research Institute of Ecology problems, Almaty, Kazakhstan

Backgrounds

The basis of biotechnological purification of the environment from oil and petroleum products are biological products containing viable cells of hydrocarbon oxidizing microorganisms. The problem of creating effective and accessible microbial consortia to eliminate dangerous oil pollution is very relevant.

Objectives

We have studied the growth activity and biodegradation of petroleum hydrocarbons of local deposits by microorganisms-destructors allocated in the Caspian region.

Methods

Methods: fluorimetric method for determining of oil concentration, emulsification index was determined by Rosenberg method, BATH-test to determine the hydrophobicity of the cell wall, gravimetric and nephelometric methods for determining the growth of microorganisms on the 1 and 3% oil.

Conclusions

Based on the active growth of microorganisms on solid and fluid medium containing 1% oil (as a sole carbon source) were selected 57 cultures, which were measured for biomass growth, cell wall hydrophobicity, emulsification index and the percentage of oil degradation. We have selected cultures for which the percentage of oil degradation ranged from 91,1 ± 4,5; to 49,7 ± 3,5, emulsification index values ranged from 52.7% to 43.9%, the hydrophobicity growth varied from 46.1% to 6.7%, biomass was increased (in 10 days) from 200% and 3000%. Selected cultures after identification were assigned to the following genera: *Achromobacter, Ochrobactrum*, *Stenotrophomonas, Roseomonas, Rhodococcus, Sphingobacterim.* These organisms have a high potential of hydrocarbons degradation, comparable to the activity of the commercial product BK-Oil Buster, they are not antagonists to each other and can be used to create on their basis the consortiums for their further use in bioremediation.

IMPACT OF HOMOLOGOUS RECOMBINATION ON THE EVOLUTION PROKARYOTIC CORE GENOMES

P. Gonzalez-torres[1], F. Rodriguez-mateos[2], J. Anton Botella[3], T. Gabaldon[1]
[1]Centre for Genomic Regulation CRG, Bioinformatics and Genomics Program, Barcelona, Spain
[2]University of Alicante, Matemática Aplicada, Alicante, Spain
[3]University of Alicante, Physiology- Genetics- and Microbiology, Alicante, Spain

Backgrounds

Metagenomic and genomic studies carried out in recent years suggest that intraspecific homologous recombination (HR) could play an important role in the microevolution of many microorganisms, with this mechanism being sometimes the major evolutionary force. However, such studies are still scarce, focused only on few aspects or life style strategies and heterogeneous in terms of distribution over the prokaryote phylogeny.

Objectives

To assess whether HR may act as a prevalent mechanism in the evolution of core genomes, explore which factors determine its incidence and finally clarify HR effect on the microdiversity, adaptative events and generation of cohesive population structures within bacterial specie

Methods

Here we deal with this open question using an extensive study that involves 338 strains of 54 prokaryotic species covering a wide distribution of phylogenetic groups and life-styles. In order to elucidate the most relevant factors that determine the impact and distribution of HR, genomic and ecological elements that favour or hinder the horizontal transfer as restriction modification systems (RM), CRISPR-Cas systems or competence genes (com) were considered.

Conclusions

Life-style and ecology were the factors most associated with the distribution of HR events. HR exchange gene patterns showed a clear functional structuring according to different ecological strategies, adaptation processes, environmental pressure and fitness. In addition, competent species and those with great presence of MR systems exchanged greater events than the rest. HR contributes to the homogenization of core genomes and maintains cohesive population structures thus affecting significantly the microevolution of prokaryotic species.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

STUDY OF AIRBORNE BACTERIOPHAGES AND ANTIBIOTIC RESISTANCE GENES IN TENERIFE, CANARY ISLANDS, SPAIN

C. Gonzalez-Martin[1], N.M. Coronado-Alvarez[2], N. Teigell-Perez[1], R. Diaz-Solano[1], F.J. Exposito[3], J.P. Diaz[3], D.W. Griffin[4], B. Valladares[1]
[1]Instituto Universitario de Enfermedades Tropicales y Salud Pública de Canarias, Instituto Universitario de Enfermedades Tropicales y Salud Pública de Canarias, San Cristobal de La Laguna, Spain
[2]Hospital Universitario San Cecilio, Antimicrobial Research Laboratory. Infectious Diseases Department, Granada, Spain
[3]Grupo de Observación de la Tierra y la Atmósfera GOTA, Universidad de La Laguna, San Cristóbal de La Laguna, Spain
[4]St. Petersburg Coastal and Marine Science Center, United States Geological Survey, Florida, USA

Backgrounds

Dispersion of antibiotic resistance genes by bacteriophages is an important agronomic and public health issue. This type of viruses may transform innocuous bacteria into pathogens or modify their resistances to antibiotic-based treatments. Recent studies have identified the presence of bacteriophages in air samples collected from different environments, implicating the atmosphere as a limited, but important, source for the dissemination of antibiotic resistance genes.

Objectives

1. To detect, identify and analyze the presence of bacteriophages and associated antibiotic resistance genes in the atmosphere.
2. Analyze the relationships between the microbiological results and different clim atic variables.

Methods

Atmospheric samples were collected in an urban area of Tenerife, Canary Islands, Spain. After concentration and nucleic acid extraction, samples were screened for bacteriophage genomes (DNA and RNA phages) and antibiotic resistance genes. Climatic variables, such as the occurrence of African dust storms, seasonality, origin of the air mass and particle matter levels were analyzed and compared with the microbiology data to detect possible correlations.

Conclusions

Positive results were obtained for F – DNA bacteriophages (10%) and antibiotic resistance gene TEM (6.2%). No statistical relationships were observed between the microbiological data and the occurrence of African dust storms, the origin of the air masses or the PM values. F – DNA phages detection was significantly correlated with cooler seasons. This is the first study describing the presence of these viruses and antibiotic resistance genes in an outdoor urban environment in the Canary Islands, Spain.

FEMS7-2824
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

AIRBORNE VIABLE BACTERIAL COMMUNITY IN AN URBAN AREA IN TENERIFE, CANARY ISLANDS, SPAIN.

N. Teigell Perez[1], C. Gonzalez-Martin[1], R. Diaz Solano[1], F.J. Exposito[2], J.P. Diaz[2], D.W. Griffin[3], B. Valladares[1]
[1]Instituto Universitario de Enfermedades Tropicales y Salud Pública de Canarias,
Instituto Universitario de Enfermedades Tropicales y Salud Pública de Canarias,
San Cristobal de La Laguna, Spain
[2]Grupo de Observación de la Tierra y la Atmósfera GOTA, Universidad de La Laguna,
San Cristobal de La Laguna, Spain
[3]USGS, St. Petersburg Coastal and Marine Science Center, Florida, USA

Backgrounds

Despite their potential implications for human health, agriculture and other ecosystems, and their ability to survive long-range transport, information about airborne microorganisms is scarce. Dust storms are considered a long-range mechanism of dispersion for microorganisms. Due to the proximity of the Canary Islands to the African continent, the archipelago is commonly affected by Saharan dust intrusions.

Objectives

1. To study the viable airborne bacteria community in the atmosphere of an urban area in Tenerife.
2. Analyze the relationship between the microbiological results with climatic variables.

Methods

Atmospheric samples were collected in an urban area of Tenerife. Isolation and identification of viable bacteria was performed using culture followed by 16 rRNA PCR and sequencing. Climatic variables, such as the influence of African dust storms, seasonality, origin of the air mass and meteorological parameters (rain, temperature, humidity) were analyzed to determine possible correlations.

Conclusions

Fifty-three samples were collected and a total of 732 bacteria were isolated. *Bacillus* sp. (21.72%), *Arthrobacter* sp. (17.49%) and *Staphylococcus* sp. (11.48%) were the most common among the fifty-eight genera identified. Potential pathogens for animals and plants were detected. No significant correlation was noticed between climactic variables and microorganisms. However, isolates within Firmicutes and Actinobacteria phyla were more abundant during African dust days. Also, Gram-positive bacteria were predominant over Gram-negative. Gram-positive bacteria increased during African dust days while Gram-negative increased during non-dust days. This is the first study in the Canary Islands regarding the composition of airborne bacterial communities and their relationship with different environmental factors.

FUNGAL ENDOPHYTES ISOLATED FROM ARID PLANTS OF ANDALUCIA: PRODUCTION OF NEW ANTITUMOR AND ANTIFUNGAL ACTIVITIES BY THE ADDITION OF ADSORPTIVE POLYMERIC RESINS.

V. Gonzalez-Menendez[1], G. Crespo[2], N. de Pedro[3], C. Diaz[3], J. Martin[2], C. Toro[1], F. Muñoz[2], C. Justicia[2], F. Vicente[3], F. Reyes[2], J.R. Tormo[2], O. Genilloud[4]
[1]Fundacion MEDINA, Microbiology, Granada, Spain
[2]Fundacion MEDINA, Chemistry, Granada, Spain
[3]Fundacion MEDINA, Screening, Granada, Spain
[4]Fundacion MEDINA, Scientist Director, Granada, Spain

Backgrounds

Arid zones in Andalucía have native plant communities possessing distinctive characteristics to survive in special conditions that have led to the existence of a large number of poorly studied endemic plants. It is precisely this singularity which turns them into a potential source for the discovery of novel fungal symbionts, as well as host-specific endophytes not described yet. Addition of adsorptive polymeric resins in fungal fermentations has been described to promote the production of new secondary metabolites as a tool to consistently generate new compounds with potential biological activities.

Objectives

To evaluate the effects of addition of resins on our collection of fungal endophyte fermentations for the generation of new extracts with antitumor and antifungal activities.

Methods

A total of 346 fungal strains isolated from 54 selected plant species from these ecosystems were characterized morphologically as well as on the basis of their ITS/28S ribosomal gene sequences. The strains were grown in four different media in the presence and absence of selected resins according to our previous studies. Fermentation extracts were evaluated for the presence of induced cytotoxic activities against HepG2 cell line and antifungal activities against the human fungal pathogens *Aspergillus fumigatus* and *Candida albicans*.

Conclusions

Twelve compounds were purified by chromatographic techniques and identified as being the active secondary metabolites induced in the fermentations by the adsorptive polymeric resins. Our results also confirmed the biodiversity richness of the plants of Andalusian deserts as an untapped source of new host-specific fungal strains with the potential to produce new bioactive compounds.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ARSENIC RESISTANCE OF PLANT-MIOCROBES ASSOCIATION AS A TOOL TO RESTORED CONTAMINATED ENVIRONMENTS

N. Gonzalez[1], M. Diaz[1], R. Simarro[1], S. Garcia[2], M.A. Quijano[2], L.F. Bautista[3], J.F. White Jr[4], J. Lopez[1], M.D.C. Molina[1]
[1]Universidad Rey Juan Carlos, Department of Biology and Geology- Physics and Chemistry, Móstoles, Spain
[2]Universidad Politecnica de Madrid,
Departmento de Ingenieria Civil- Hidraulica y Ordenacion del territorio, Madrid, Spain
[3]Universidad Rey Juan Carlos, Department of Chemical and Environmental Engineering, Móstoles, Spain
[4]Rutgers- The State University of New Jersey, Department of Plant Biology, New Brunswick, USA

Backgrounds

Arsenic (As) is a highly toxic metalloid that accumulates in the environment as a result of natural and anthropogenic processes. The major form of As in aerobic soils is As(V), which is structurally a chemical analogue of phosphate and enters plant root tissue via phosphate transporters. Plants and microorganisms can play a vital role in arsenic species transformation. Reduction of As (V) to As (III) and biomethylation to mono or dimethyl arsenic, trimethylarsine oxide and volatile trimethylarsine, through the oxidation of organic matter or the utilization of As (V) as an electron acceptor, have been reported as detoxification mechanism. In addition, As (III) may form complexes with thiol compounds such as phytochelatins (PCs) and glutathione (GSH), in order to convert inorganic As into less toxic organic forms. The association of plant-microbiome (rhizosphere and endosphere) and their interactions have been recently considered as a Metaorganism with important ecological, phytotechnological and healthy environmental implications.

Objectives

The aim of this study was to identify the rizhosphere and endosphere microbial composition in a Mediterranean plant such as *Jasione montana* and extimate the minimal lethal As concentration of bacteria and fungi endophytes. We selected this plant for being able to live in highly contaminated soils with arsenic and behave like a resistant plant.

Methods

Jasione montana is a Mediterranean native terrestrial plant collected in the vicinity of the Mónica mine (NW Madrid, Spain), from As soil polluted (from 0.3 to 30 g kg^{-1}) by past mining activities. Bacterial rizosphere DNA from *J. montana* rizhosphere was extracted for metabarcoding sequencing Illumina. Bacteria and fungi from *J. montana* endosphere were isolated and exposed to an increasing gradient of As (V) to estimate the minimal lethal As(V) concentration of the microbial species. Arsenic speciation analysis was performed by high performance liquid chromatography-photo-oxidation-hydride generation-atomic fluorescence spectrometry (HPLC-(UV)-HG-AFS), to evaluate arsenic species transformation. Total arsenic concentration was determined by ICP-AES to detect the presence of unidentified arsenic species.

Conclusions

J. montana rizosphere showed a similar bacterial composition at all As concentration levels in soils, with 30 % of Actinobacteria, 20% of Proteobacteria and 10% of Acidobacteria. Endophytic bacteria as

Pantoea sp, *Kocuria rosea*, *Pseudarthrobacter oxydans, Arthrobacter siccitoleran*, and fungi as *Fusarium* sp, *Fusarium oxysporum*, *Umbelopsis isabellina*, *Mortierella lignicola* and *Curvuraria protuberata* strain were identified in *J. montana* with a minimal lethal As concentration of around 250 mM for bacteria and 50 mM for fungi.

Regarding arsenic speciation studies, reduction of As (V) to As(III) was detected, but not methylated species. However, between 20-40% of arsenic remained as unidentified species, probably due to their biotransformation to thiol compounds complexes, which cannot be detected with the analytical method applied.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

THE HIDDEN DYNAMICS OF THE RARE MICROBIAL BIOSPHERE IN COASTAL WATERS OF EASTERN AUSTRALIA

K.M.E. Goossen[1], J.P. Bowman[2], M.V. Brown[3], J. van de Kamp[1], L. Bodrossy[1]
[1]CSIRO Oceans and Atmosphere, Environmental Genomics, Hobart, Australia
[2]University of Tasmania, TIA - Research Institute, Hobart, Australia
[3]University of New South Wales, School of Biotechnology and Biomolecular Science, Sydney, Australia

Backgrounds

The roles rare microorganisms play in maintaining biodiversity and modulating biogeochemical processes such as carbon and nutrient cycling are not well understood.

Objectives

To address this, we analysed Illumina (Mi/Seq) based bacterial and archaeal 16S rRNA gene amplicon sequencing data from monthly time series.

Methods

Samples were collected from six depths at each of three coastal National Reference Stations (NRS) operated in conjunction with the Integrated Marine Observing System (IMOS). These stations are located in distinct bio-regions, ranging from sub-tropical to cool temperate, along Australia's eastern seaboard. Rare and abundant taxa were defined as having abundances below and above 0.1% of total reads of all samples per station, respectively.

Conclusions

The rare microbial taxa comprised approximately 98% of the total operational taxonomic units (OTUs) observed and 34% were shared amongst all three stations. At two stations the rare taxa increased in abundance in deeper waters compared with the surface samples. Rare and abundant taxa were classified as Persistent (>75%), Intermittent (25-75%) and Transient (<25%) based on their occurrence across all samples. During late winter one station showed a decrease of the abundant persistent OTUs over two years at ~ 30m depth, with a concomitant increase in the rare transient OTUs. Based on these criteria the rare biosphere displayed different patterns to the abundant taxa in relation to depth, season and latitude. We observed that rare taxa can increase in abundance when environmental conditions are advantageous sometimes replacing nominally abundant taxa, suggesting an important role in maintaining ecosystem functionality under fluctuating conditions.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

DETECTION OF BACTERIA ASSOCIATED WITH PM10 PARTICULATE MATTER IN MEDELLIN – COLOMBIA

D. Grajales[1], C. Zapata[2], O. Montoya[1], C. Moreno[1]
[1]Universidad Nacional de Colombia - Sede Medellín, Biociencias, Medellín, Colombia
[2]Universidad Nacional de Colombia - Sede Medellín, Geociencias y Medioambiente, Medellín, Colombia

Backgrounds

In recent years, particulate matter air pollution has increased in major cities worldwide and its effects have been directly related to health conditions.

Objectives

The aim of this research was to evaluate the presence of bacteria associated with particulate matter with aerodynamic diameter less than 10 micrometres and its correlation with meteorological variables.

Methods

In this study, a Hi-Vol air sampler was implemented to collect the PM10 particulate matter in two seasons of the year (Wet and Dry) at the MED-UNFM station of the Universidad Nacional de Colombia (Medellín, Colombia, South America). Environmental parameters such as concentration, temperature, humidity and wind speed were determined and the bacterial diversity associated with PM10 filters was evaluated using culture-dependent and molecular identification methods. Additionally, hemolytic activity was evaluated in the isolates identified

Conclusions

Molecular characterization analyses revealed the presence of predominant bacteria in both seasons, belonging to the phylum Firmicutes and predominant bacteria from the phyla Proteobacteria and Actinobacteria in dry seasons with species such as *Bacillus megaterium*, *B. pumilus*, *Escherichia hermannii*, *Arthrobacter gandavensis* and *Staphylococcus aerlettae*. Some of these species have been considered as possible human pathogens with possible antibiotic resistance. Sixty-two percent (62%) of the isolates had beta-haemolytic activity. Temperature and humidity increased the amount of bacteria captured in the PM10 filters. These results provide important information to understand the distribution of bacteria associated with different concentrations of particulate material in the air and are of interest because of their influence on the environmental health and air quality of the region.

MULTIDRUG-RESISTANT ESCHERICHIA COLI AND OTHER ENTEROBACTERIACEAE SPECIES DETECTED IN MARINE BIVALVES HARVESTED ALONG THE NORWEGIAN COAST

D. Grevskott[1], C. Smith Svanevik[1], M. Sunde[2], A.L. Wester[3], B.T. Lunestad[1]
[1]National Institute of Nutrition and Seafood Research, Contaminants and Biohazards, Bergen, Norway
[2]Norwegian Veterinary Institute, Bacteriology- Fish and Animal, Oslo, Norway
[3]Norwegian Institute of Public Health, Bacteriology, Oslo, Norway

Backgrounds

The mechanisms for development of resistance in bacteria residing in the coastal environment are far from elucidated. Bivalve molluscs filtrate large amounts of seawater daily, and retain smaller particles, including free and particle-bound bacteria. These bacteria may originate from humans and livestock animals either via sewage, by runoff from land, or representatives of the wild fauna, such as birds or marine mammals. Bivalves are therefore excellent indicators for faecal contamination by reflecting the load of *Escherichia coli* and other Enterobacteriaceae species present in the water column at a given location.

Objectives

The objective of this study was to examine for antibacterial resistance among *Escherichia coli* and other species in the Enterobacteriaceae family isolated from bivalve molluscs.

Methods

A total of 549 bivalve samples were examined applying the standardised Most Probable Number (MPN) EU-method (ISO-16643-3). The disc diffusion method of the European Committee on Antimicrobial Susceptibility Testing (EUCAST) were performed with 26 agents on all 199 isolates recovered. A selection of ten multidrug-resistant *E. coli* isolates were subjected to Whole-genome Sequencing (WGS). Multiple-locus Variable Number Tandem Repeats Analysis (MLVA) was applied on a selection of 30 resistant *E. coli* isolates in order to compare isolates from bivalves with community-acquired strains causing bacteraemia in humans.

Conclusions

Totally 75 (38%) of the isolates showed antibacterial resistance, and 9 (5%) were found to be multidrug-resistant, including resistance towards third-generation cephalosporins. This study demonstrates that bivalves represent an important tool for monitoring of antibiotic resistant *E. coli* and other Enterobacteriaceae species in the coastal environment.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

BACTERIAL BIODEGRADATION NETWORKS FOR POLYCYCLIC AROMATIC HYDROCARBONS REMOVAL IN POLLUTED SOILS

J. Vila[1], M. Tauler[1], S. Jiménez-Volkerink[1], M. Grifoll[1]
[1]University of Barcelona, Genetics- Microbiology and Statistics, Barcelona, Spain

Backgrounds

Bacterial metabolic pathways for the biodegradation of single polycyclic aromatic hydrocarbons (PAHs) by pure cultures are well established. The challenge now is to identify the actual *in situ* cooperative metabolic routes driving PAH removal in polluted environments, where these compounds are constituents of complex mixtures exposed to versatile microbial communities under diverse environmental conditions.

Objectives

In this study, we investigate the bacterial populations and processes involved in the transformation and eventual elimination of PAHs, oxy-PAHs and N-PAHs, in a creosote-polluted soil (PAH 8,500 ppm) from a historical site, amended with nutrients and incubated in aerobic conditions.

Methods

Depletion of substrates and formation of metabolites (GC-MS) is correlated with the dynamics of total and active phylogenetic groups (pyrosequencing of 16S rRNA genes and transcripts), and the abundance and expression (qPCR) of key functional genes (Ring Hydroxylating Dioxygenases, RHDs).

Conclusions

The stimulation of the natural communities resulted in a extensive removal of PAHs (96%). The initial fast removal of 2-3 ring PAHs was associated to members of *Pseudomonas* and *Pseudoxantomonas* harboring nah-like RHDs. Ketones and quinones were formed and transiently accumulated, being later degraded by alternative microbial populations. 4-Ring PAHs were removed by members of *Sphingobium,* unclassified *Gammaproteobacteria* and mycobacteria, the low relative abundance of the latter being compensated by their level of expression. Cometabolism played a key role, the resulting oxy-PAHs acting as metabolic nodes in complex metabolic networks. Analysis of RHDs was limited by the availability of primers and the knowledge of RHD diversity.

FEMS7-2764

BIODEGRADATION OF BENZ(A)ANTHRACENE AND CHRYSENE IN PAH-POLLUTED SOILS

S. Jiménez-Volkerink[1], J. Vila[1], J.M. Nieto[1], M. Grifoll[1]
[1]University of Barcelona, Genetics- Microbiology and Statistics, Barcelona, Spain

Backgrounds

Benz(*a*)anthracene (BaA) and chrysene (CHY) are 4-ring polycyclic aromatic hydrocarbons (PAHs) of known genotoxicity and carcinogenicity. Due to their low water solubility and chemical stability, they are resistant to extensive microbial degradation, being enriched in historically polluted sites. Although a few degrading bacterial strains have been reported, little is known about the microbial populations and interactions involved in the *in situ* biodegradation of these compounds in polluted soils.

Objectives

The general objective of this work is to obtain and thoroughly characterize BaA and CHY-degrading bacterial communities from a creosote-polluted soil, isolate their components, describe the functions involved, and, finally, confirm the modeled processes in polluted soils.

Methods

In a first phase we have assessed the biodegradation and microbial community shifts in sand-in-liquid soil microcosms spiked with BaA, CHY or benz(*a*)anthracene-7,12-dione, by using chemical (GC-FID) and molecular analyses (16S rRNA-PCR-DGGE).

Conclusions

The degradation kinetics of CHY, BaA and BaA-dione in the microcosms, suggested a cometabolic attack of BaA and CHY when together. Analogous populations could degrade BaA and BaA-dione, as they presented similar biphasic plots. DNA-based analysis did not reveal substantial changes in the structure of the total bacterial community; however, the further RNA-based analysis suggested a catabolic redundancy between different active phylogenic groups. The actual relevance of these phylotypes in polluted soils will be confirmed by mining pyrosequencing data, including total and active microbiome analysis, from a previous bioremediation assay.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

VIROME DIVERSITY IN TROPICAL WATER BODIES AND WATER CATCHMENTS IN SINGAPORE

X. GU[1], Q.X.M. Tay[2], N. Saeidi[1], S.G. Goh[1], K. Ariel[3], J. Thompson[4], K.Y.H. Gin[1]
[1]National University of Singapore, Department of Civil and Environmental Engineering, Singapore, Singapore
[2]Singapore-MIT Alliance for Research and Technology, Singapore-MIT Alliance for Research and Technology, Singapore, Singapore
[3]Nanyang Technological University, School of Material Science and Engineering, Singapore, Singapore
[4]Massachusetts Institute of Technology, Departments of Civil and Environmental Engineering, Cambridge, USA

Backgrounds

Viral metagenomics has developed increasingly in freshwater ecosystems. However, few studies focus on the geospatial distribution in the natural water bodies and the land use impacts on viral community. It is hypothesised that land use change will impact the characteristics of tropical water catchments and further influence virome distribution pattern. Metagenomics will be used to study the virome geospatial diversity in Singapore surface waters.

Objectives

This study seeks to understand the general distribution of virome abundance and diversity in water bodies and water catchments in Singapore and its correlation with land use. Emerging zoonotic viruses will be investigated. Besides, metagenomics data will be linked with qPCR in terms of human and plant related viruses.

Methods

A total of 38 samples were collected from 7 sampling sites (10 water bodies and 9 water catchments) during Northeast monsoon (Jan15) and inter-monsoon (Apr15). 200-ml of primary concentrate was followed by polyethylene glycol and Amicon ultrafiltration. The extracted viral nucleic acids were amplified with a random amplification protocol (Bibby and Peccia 2013) and were sent to SCELSE on Illumina Hiseq 2500 platform (2*250bp). After trimming and assembly, contigs were uploaded into Metavir pipeline for taxonomy annotation. Remapping was done by Novoalign to generate RPKM table for quantifying the virome.

Conclusions

- Overall, the majority of the annotated virome belongs to bacteriophage (65.5%).
- A higher Shannon-index virome diversity in water bodies was observed than in water catchments.
- PCoA analysis showed that land use (urbanized, agriculture and less impact areas) influenced the viral geospatial distribution community.
- 41 contigs found to have the lowest common ancestor affiliation to human viral pathogens. The most abundant human-related viruses belonged to *Hepatitis E viruses* and the second most abundant viruses were *Picobirnaviruses*.
- PMMoV RPKM analysis from metagenomics demonstrating the relative abundance and the proportion of reference-mapped reads is significantly correlated with qPCR ($0.588<r<0.879$, $p<0.05$).

CARBENICILLIN AND PENICILLIN TRIGGER PLANT RESPONSES ASSOCIATED TO THE PRODUCTION OF REACTIVE OXYGEN SPECIES

M. Gudiño[1,2], N. Blanco-Touriñán[1], V. Arbona[3], M.Á. Blázquez[1], F. Navarro-García[2]
[1]Instituto de Biología Molecular y Celular de Plantas CSIC-UPV, Vegetal Development, Valencia, Spain
[2]Universidad Complutense de Madrid - Facultad de Farmacia, Departamento de Microbiología II, Madrid, Spain
[3]Universitat Jaume I, Departament de Ciències Agràries i del Medi Natural, Castelló, Spain

Backgrounds

Antibiotics are considered nowadays bifunctional molecules working either as quorum-sensing signaling molecules as well as bacterial killing substances. The presence of antibiotics in soils could be due to the natural production by soil microorganisms as well as the result of anthropogenic activities. However, the impact of these compounds on plant physiology has not been thoroughly investigated.

Objectives

To evaluate the effect of several beta-lactam antibiotics (ampicillin, carbenicillin and penicillin) on the growth and development of *Arabidopsis thaliana* roots.

Methods

All essays were made with *Arabidopsis thaliana* seedlings grown in culture medium supplemented or not with 100 $\mu g \cdot mL^{-1}$ of carbenicillin, penicillin or ampicillin.

Conclusions

The exposure to penicillin and carbenicillin limited root growth and triggered the local endogenous production of ROS (reactive oxygen species) in roots, which caused an increase in the number of root hairs. Furthermore, carbenicillin-treated plants showed an altered pattern of the expression of genes involved in glucosinolate biosynthesis, and a modification of the levels of indole-glucosinolates. In summary, the presence of some beta-lactam antibiotics seems to interfere with the signaling pathways that plants use to interact with soil borne microbes.

MICROBIOLOGICAL ANALYSIS OF HEMODIALYSIS WATER AT THE UNIVERSITY TEACHING HOSPITAL OF YAOUNDE, CAMEROON

C. Gueguim[1], A. Ragon[2], H. Gonsu Kamga[3], F. Kaze Folefack[4]
[1]University of Yaoundé I, Microbiology, Yaoundé, Cameroon
[2]Hospital of Conception, Uro-Nephrology Laboratory, Marseille, France
[3]Microbiology Laboratory of the Hospital Center and the University Hospital of Yaoundé, Microbiologie, Yaoundé, France
[4]University of Yaoundé I, Néphrology, Yaoundé, Cameroon

Backgrounds

Rigorous control of the microbiological quality of water in hemodialysis services is important because the immune system of patients with chronic renal failure is weakened.

Objectives

To determine the microbiological quality of water for hemodialysis.

Methods

Twelve water samples were collected each month at different sites of the hemodialysis circuits **A** (inlet of filters), **B** (Outlet of filters) and **C** (outlet of the RO device) between July and October 2015 to be analyzed. The bacteria were isolated after filtration of 100 ml of water at each site through nitrocellulose membrane with 0.45 µm microporosity deposited on the surface of the *Tryptone Glucose Extract Agar* and then incubated at room temperature for 7 days. Pure bacterial isolates were identified by their cultural characters and marketed biochemical galleries. The colony count was well above the required international standards (>100 CFU / ml), a percentage of 83.3% (10/12) of non-compliance. Among the bacteria identified, nine (09) were Gram-negative bacilli including *Pasteurella haemolytica*, *Pseudomonas fluorescens, Pseudomonas paucimobilis, Aeromonas salmonicida* and *Klebsiella pneumoniae subsp ozaenae,* three (03) Gram-positive bacilli all *Bacillus sp* and six (06) Gram-positive cocci all of coagulase-negative staphylococci. The most frequently isolated bacterial genera were *Pseudomonas* (30.4%), *Staphylococcus* (26.1%), *Aeromonas* (13%), *Bacillus* (13%), *Klebsiella* (13%) and *Pasteurella* (4.3%).

Conclusions

In this study, the detection of a variety of bacteria in the hemodialysis water indicates the need for regular monitoring of the water for hemodialysis by the CHUY hemodialysis center to ensure a better quality of life for patients undergoing this treatment.

TRANSCRIPTIONAL AND PHYSIOLOGICAL CHARACTERIZATION OF KLEBSIELLA PNEUMONIAE BIOFILM DISPERSED BACTERIA

C. GUILHEN[1], N. CHARBONNEL[1], C. FORESTIER[1], D. BALESTRINO[1]
[1]Universite d'Auvergne, UMR CNRS 6023, Clermont Ferrand, France

Backgrounds

Surface-associated communities of bacteria, known as biofilms, play a critical role in the persistence and the diffusion of bacteria. Biofilm development includes adhesion of bacteria to the surface, formation of microcolonies, maturation with synthesis of an exopolymeric matrix, and dispersion. The final highly regulated step contributes to the dissemination of bacteria in the surrounding environment. Whereas the physiology of planktonic and sessile bacteria is exhaustively documented, very little is known about the properties of biofilm-dispersed cells.

Objectives

We aim to characterize bacteria released from *Klebsiella pneumoniae* mature biofilm.

Methods

Spontaneously biofilm dispersed bacteria were harvested in the effluent of a flow-cell device. Their specific properties were assessed using RNA-seq analysis and phenotypic characterizations (confocal microscopy observations, determination of enzymatic activities, etc.).

Conclusions

Dispersed bacteria were transcriptionally different from both planktonic (logarithmic and stationary phases) and sessile states (7 and 13 hours-old biofilms). In particular, dispersed cells overexpressed a large proportion of genes involved in translation, suggesting a high metabolic activity. This hypothesis was supported by determination of enzymatic activities linked to ATP biosynthesis. In addition, dispersed cells display enhanced abilities to form new biofilm compared to planktonic lifestyle cells, as measured by biomass determination and confocal imaging. Altogether, these data indicate that dispersed bacteria should be regarded as a unique stage in the bacteria lifecycle, transcriptionally different from the other states, with cells harboring mixed properties in between planktonic and sessile forms.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

SPATIAL ORGANIZATION OF MULTI-SPECIES MARINE BACTERIA IN BIOFILM

R. Guillonneau[1], *C. Baraquet*[1], *A. Bazire*[2]
[1]*Université de Toulon, MAPIEM EA 4323, La Garde, France*
[2]*Université de Bretagne Sud- UEB,*
Laboratoire de Biotechnologie et Chimie Marines LBCM- EA 3884- Institut Universitaire Européen de l a Mer IUEM, Lorient, France

Backgrounds

In marine environments, all surfaces submerged are rapidly colonized by bacteria and others microorganisms followed by macro-organisms. These complex communities of organisms formed on inert immersed surfaces have important environmental and economic ramifications. In order to find new antifouling strategies that are usually tested *in vitro* prior to field experiments, multi-species biofilms need to be developed to better apprehend their antifouling efficacy and to better understand mechanisms that govern organisms interactions within more complex biofilms.

Objectives

The aim of this study is to characterise adhesion and biofilm formation of different marine bacterial species, when they are inoculated alone or together and to understand what could be involved in their spatial organization in multi-strains biofilms.

Methods

Static and dynamic biofilm formation were studied to determine the pattern of biofilm formation using confocal laser scanning microscopy. Matrix components were observed using specific fluorescent probes. Bacteria-specific antibodies were used during multi-strains studies.

Conclusions

These marine bacterial strains, whose biofilm grew at different paces and shapes in artificial sea water, produced exopolymers such as eDNA, proteins and exopolysaccharides that can be different according to the strains. Some of them secreted inhibitory supernatants toward others. During multi-strains biofilms experiments, a specific spatial organization was observed with four of these bacteria. Very few studies deal with multi-species biofilm in particular in the marine environment context. This is one of the rare study performed with marine bacteria, whose aim is to understand bacterial spatial organisation within multi-species biofilm.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ACTIVE MICROBIAL INTERACTIONS INVOLVED IN NITROGEN FATE IN VERTICAL SUBSURFACE CONSTRUCTED WETLANDS TREATING URBAN WASTEWATER

M. Guivernau[1], C. Pelissari[2], C. Ávila[3], J. Garcia[4], P.H. Sezerino[2], F.X. Prenafeta-Boldú[1], M. Viñas[1]
[1]Institute of Agrifood Research and Technology IRTA, GIRO, Caldes de Montbui, Spain
[2]Federal University of Santa Catarina UFSC, GESAD, Florianópolis, Brazil
[3]Catalan Institute for Water Research ICRA, ICRA, Girona, Spain
[4]Technical University of Catalonia UPC, GEMMA, Barcelona, Spain

Backgrounds

Constructed wetlands (CW) are eco-friendly systems, engineered to treat different wastewaters, such as nitrogen enriched sewage. However, microbe-microbe interactions during nitrification/denitrification (NDN) process in the so-called "*nitrification aggregate*" of biofilms, have not been deeply assessed in CW.

Objectives

Two vertical subsurface flow constructed wetlands (VF-CW) treating urban wastewater, were implemented at pilot-scale to boost NDN process by i) unsaturated (UVF) and ii) partially saturated (SVF) configurations.

Methods

Operational Periods I-II (winter-summer) were characterized by a similar hydraulic loading rate and different organic and total nitrogen loading rates. Sand/gravel of top and bottom horizons of CW as well as water influent and effluent, were sampled in triplicate at the end of both periods. Active bacterial/archaeal populations were assessed through DNA/RNA-based 16S-Illumina MiSeq sequencing. Moreover, total/active bacteria, ammonia-oxidizing bacteria (AOB) and archaea (AOA), and typical denitrifiers (16S rRNA, *amoA* and *nosZ*-clade-I genes/transcripts, respectively) were quantified by (RT)-qPCR.

Conclusions

SVF-CW prompted proper redox conditions at bottom layer, that favored active nitrifying-denitrifying populations achieving a more efficient NDN process by increasing nitrogen removal rate concomitant with low nitrite/nitrate accumulation. Noteworthy, biofilm harbored a putative rather stable "*nitrification aggregate*", where AOA/AOB and nitrite oxidizers (NOB) were clearly influenced by seasonal environments linked to oxygen and ammonia limiting conditions. Although ammonia-oxidation was associated to both AOB (*Nitrosospira*) and AOA (*Nitrososphaeraceae*), AOB were clearly overcome by AOA in the more oxidative horizons. Interestingly, AOA were positively correlated with NOB phylotypes belonging to *Nitrobacter*, whilst AOB were negatively correlated with other NOB, *Nitrospira* ($n=6$; $r^2>0.80$ and $r^2>0.63$, respectively).

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

THE EFFECTS OF DIFFERENT ANTIBIOTICS ON EXPRESSION LEVELS OF USP, SFA/FOC AND CNF1 GENES IN A UPEC STRAIN

D. Gumus[1], F. Kalayci Yuksek[1], E. Yoruk[2], G. Uz[2], E. Celik[2], C. Arslan[2], E.M. Aydın[2], C. Canlı[2], M. Ang Kucuker[1]
[1]Istanbul Yeni Yuzyil University Medical Faculty, Medical Microbiology, Istanbul, Turkey
[2]Istanbul Yeni Yuzyil University Faculty of Arts and Sciences, Molecular Biology and Genetics, Istanbul, Turkey

Backgrounds

The association between environmental factors and bacterial gene expression are well known. The host is main environment for bacteria and they also expose many antibiotics during the treatment of infectious diseases.

Objectives

In this present study, our aim was to investigate possible changes in expression levels of three virulence genes [*sfa/foc* (S and F1C fimbria)*, cnf 1* (cytotoxic necrotizing factor) and *usp* (uropathogenic-specific protein)] in a uropathogenic *E. coli* standard strain (UPEC C7) within the presence of ciprofloxacin, nitrofurantoin and trimethoprim-sulfamethoxazole which are frequently used for the treatment of urinary tract infections.

Methods

The UPEC C7 strain was cultured in tryptic soy broth-TSB (control), TSB+ciprofloxacin (0.016 µg/ml), TSB+nitrofurantoin (3 µg/ml) and TSB+trimethoprim-sulfamethoxazole (0.047 µg/ml). Antibiotics were added according to their sub-minimal inhibition concentrations (MIC). Broth dilution method was used to determine MIC's of antibiotics.

Gene expression levels were determined by q-PCR. The results were evaluated by relative quantitation method to compare the gene expression levels. Tukey's post hoc-test was used for statistical analysis. Each experiment was replicated at least thrice.

Conclusions

We detected statistically significant differences in each gene expression levels for all antibiotics via relative quantification analysis. Fold changes in gene expression was found 0.65, 1.42 and 0.23 for sfa/foc gene; 0.01, 0.01 and 2.84 for cnf1 gene and 0.1, 0.01 and 0.01 for usp gene in the presence of ciprofloxacin, nitrofurantoin and trimethoprim-sulfamethoxazole respectively. In qPCR analysis, melting scores were ranged from 93% to 96%.

This investigation has suggested that antibiotics can play role as an environmental factor which may determine the pathogenicity of bacteria in vivo.

HUMAN PROTOZOAN PARASITE DIVERSITY IN WASTE AND TREATED WATER: AN ENVIRONMENTAL METAGENOMICS ANALYSIS

A. Gundogdu[1,2], A. Charyyeva[3], H. Kilic[1], U. Nalbantoglu[2,4]
[1]Erciyes University, Microbiology and Clinical Microbiology, Kayseri, Turkey
[2]Erciyes University, Genome and Stem Cell Center GENKOK, Kayseri, Turkey
[3]Erciyes University, Parasitology, Kayseri, Turkey
[4]Erciyes University, Computer Engineering, Kayseri, Turkey

Backgrounds

Water is a primary source for infections related to digestive system. Especially the consumption of water with insufficient treatment might give rise to the dissemination of the corresponding infectious agents.

Objectives

In this study, wastewater metagenomes of an urban area, a rural area , and a hospital in Turkey were studied using next generation sequencing and bioinformatics analysis, in order to profile the protozoan parasites threatening the human health.

Methods

Samples were collected from wastewater treatment plants before and after treatment and from a hospital's wastewater. Total DNA was extracted using commercial kits and shotgun DNA sequencing was performed using Illumina technology. Obtained metagenomes were filtered for human contamination, and a panel of 80 human parasite genomes were searched using short-read mapping. The total DNA length mapped to each parasite species was nomalized by the genome lengths and the sequencing depth to obtain the relative abundance.

Conclusions

To our knowledge, this is the first parasite profiling study in the environment. Since the treated water is piped to the nearest fresh water sources, the existence of human parasites poses a potential risk to the public utilizing the related natural resources. While the detected sequences belonging to clinically non-reported species might be attributed to the genomic similarities with other unfiltered eukaryotes, they might also stem from the migration of the corresponding protozoa due to the increasing refugee population. Special wastewater treatment eliminating the parasites might reduce the risk of potential transmission of these pathogens from the environment.

CONTRASTING MICROBIAL COMMUNITIES ALONG PH GRADIENT OF ACID MINE DRAINAGE OF MALANJKHAND COPPER PROJECT, INDIA

A. Gupta[1], A. Dutta[2], J. Sarkar[1], D. Paul[1], M. Panigrahi[3], P. Sar[1]
[1]Indian Institute of Technology Kharagpur, Department of Biotechnology, Kharagpur, India
[2]Indian Institute of Technology Kharagpur, School of Bioscience, Kharagpur, India
[3]Indian Institute of Technology Kharagpur, Department of Geology and Geophysics, Kharagpur, India

Backgrounds

Acid mine drainage is considered as extreme environments for life due to the presence of high concentration of sulfate and metals as a result of bio-oxidation of sulfidic ores. Hence, it becomes a model system for ecologist to understand the microbial composition and their role in biogeochemical cycling.

Objectives

In the present study, the prokaryotic assemblage was elucidated from unexplored acid mine drainage of Asia's biggest open cast, Malanjkhand copper project, India to infer their role in biogeochemistry.

Methods

To assess the composition and structure of microbial community and the environmental factors that shape them, 16S rRNA gene based amplicon sequencing, network analysis, clone library of functional genes involved in C and S cycles, taxon-specific and functional gene based qPCR and physicochemical analysis were performed on AMD sediment and water samples.

Conclusions

The physicochemical parameters showed that the samples were divided into two pH regime low (1.9<pH<4.0) and high (4.0<pH<6.0) with high sulfate concentration. The microbial diversity analysis of the two categorized pH regime showed a distinct microbial assemblages. The abundance of highly acidophilic group involved in Fe/S metabolism were found to be dominated in low pH samples. The qPCR analysis showed that low pH samples harbored less cell density in comparison to high pH samples. In spite of their distinct diversity, the microbial population showed similar physiological functions related to carbon fixation (*cbb*L) and sulfate reduction (*dsr*B) but with varied abundance. This study provides a better insight into microbial composition, their functional roles in biogeochemical cycling and prospect for its bioremediation.

FEMS7-0352
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

COMPARATIVE GENOMIC ANALYSIS OF NATIVE PSEUDOMONAS SYRINGAE PLASMIDS BELONGING TO THE PPT23A FAMILY REVEALS THEIR ROLE IN P. SYRINGAE EPIPHYTIC AND PATHOGENIC LIFESTYLES

J.A. Gutiérrez Barranquero[1], *A. de Vicente*[1], *F. Aprile*[1], *G.W. Sundin*[2], *F.M. Cazorla*[1]
[1]*Instituto de Hortofruticultura Subtropical y Mediterránea La Mayora IHSM-UMA-CSIC- Universidad de Málaga, Microbiología, Málaga, Spain*
[2]*Center for Integrated Plant Systems- Michigan State University, Department of Plant- Soil- and Microbial Sciences, East Lansing, USA*

Backgrounds

The pPT23A family of plasmids (PFPs) appears to be indigenous to the plant pathogen *Pseudomonas syringae* and these plasmids are widely distributed and widely transferred among pathovars of *P. syringae* and related species. PFPs are sources of accessory genes for their hosts that can include genes important for virulence and epiphytic colonization of plant leaf surfaces.

Objectives

Further understanding of the evolution of the pPT23A plasmid family and the role of these plasmids in *P. syringae* biology and pathogenesis, requires the determination and analysis of additional complete, closed plasmid genome sequences. Therefore, our main objective was to obtain complete genome sequences of PFPs from three different *P. syringae* pathovars and perform a comprehensive comparative genomic analysis.

Methods

In this work plasmid DNA isolation, purification by CsCl-EtBr gradients, and sequencing using 454 platform, were carried out to obtain the complete sequence of *P. syringae* plasmids. Different bioinformatic tools were used to analyze the plasmid synteny, to identify virulence genes (*i.e.* type 3 effectors) and to unravel the evolutionary history of PFPs.

Conclusions

Our sequence analysis revealed that PFPs from *P. syringae* encode suites of accessory genes that are selected at different levels (universal, interpathovar and intrapathovar). The conservation of type IVSS encoding conjugation functions also contributes to the distribution of these plasmids within *P. syringae* populations. Thus, this study contributes to unravel the genetic bases of the role of PFPs in different *P. syringae* lifestyles.

This work was supported by grants Proyecto de Excelencia, Junta de Andalucía (P07-AGR-02471; P12-AGR-1473) and by Michigan State University AgBioResearch.

GENOMIC ADAPTIVE STRATEGIES TO SEVERE METAL-STRESS IN TETRAHYMENA THERMOPHILA: CREATING NEW GENE ISOFORMS UNDER PRESSURE

P. de Francisco[1], A. Martin-Gonzalez[1], J.C. Gutierrez[1]
[1]Universidad Complutense UCM- Facultad Biologia, Microbiologia-III, Madrid, Spain

Backgrounds

High-level stresses can induce "genomic chaos" or genetic instability involving genome shattering and reorganization. The main reported genome alterations induced by stress are: mutations, epigenetics changes and gene copy number variations. *T. thermophila* has five metallothionein (MT) gene isoforms; 3 CdMT genes (*MTT1*, *MTT3* and *MTT5*) and 2 CuMT genes (*MTT2* and *MTT4*).

Objectives

During more than two years, cultures of the this ciliate have been exposed to increasing metal (Cd^{2+}, Cu^{2+} or Pb^{2+}) concentrations, achieving adapted strains to a maximum metal tolerated concentration. In addition, a knockout MTT1 strain (MTT1KO), a knockdown MTT5 strain (MTT5KD) and a double mutant strain (MTT1KO + MTT5KD) have been obtained.

Methods

From all these strains a MT gene copy number quantification has been carried out by quantitative-PCR.

Conclusions

The main conclusions from this study are: 1)- For the first time in ciliates and exclusively in the Cd-adapted strain, we have detected a fast and reversible increase of the copy number (≈ 5-fold) of the *MTT1* gene, involving an over-expression of this gene under extreme Cd-stress. 2)- *MTT5* gene is an essential gene because it is not possible to isolate a stable knockout strain, being the first time that a MT gene is considered as an essential gene. However, a MTT5KD strain has been obtained (copy number reduction of 1n-3n). 3)- In the genome of the MTT5KD strain the presence of two new *MTT1* gene isoforms (*MTT1a* and *MTT1b*) has been detected. Both are originated from homologous recombination between two original *MTT1* gene copies.

FEMS7-0782
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

COMPARISON OF BACTERIAL SUCCESSION ALONG THE CHRONOSEQUENCES OF TWO GLACIER FORELANDS OF THE HIGH ARCTIC

H. Gyeong[1], *M. Kim*[1]
[1]*Korea Polar Research Institute, Division of Polar Life Science, Incheon, Republic of Korea*

Backgrounds

Glacier foreland chronosequences offer a model setting for understating ecological succession. Bacterial succession is relatively poorly understood in glacier foreland soils of the High Arctic.

Objectives

We investigated the successional changes in bacterial community composition and diversity along the chronosequences of two glacier forelands (Austre Lovenbreen: AL and Bloomstrandbreen: BS).

Methods

The bacterial communities were analyzed using MiSeq sequencing of 16S rRNA gene. The ANOSIM analysis revealed that bacterial community compositions were significantly shifted along the chronosequences of both AL and BS glacier forelands.

Conclusions

There were directional trajectories in the relative abundance of some of the dominant bacterial phyla throughout succession. Bacteroidetes are more abundant at early successional stages and decreased towards later phases in both regions. Planctomycetes showed a contrasting changing pattern along the chronosequence with increasing relative abundance in AL and vice versa in BL. Bacterial diversity decreased significantly along BS chronosequence, whereas it remained unchanged in AL. Overall, our results indicate that bacterial community compositions were changed in a predictable way along chronosequences of both glacier forelands. However, bacterial diversity and phyla relative abundance showed different patterns along both glacier forelands. This discrepancy between two glacier forelands could be further explained by comparing local environmental conditions and vegetation dynamics in the future.

ISOLATION AND CHARACTERIZATION OF ELITE INDIGENOUS RHIZOBIA NODULATING PEA (PISUM SATIVUM L.) COLLECTED FROM DIFFERENT BIOCLIMATIC AREA IN TUNISIA

A. Hachana[1,2], *I. Hemissi*[1], *M. Bouraoui*[1], *S. Kouki*[1,2], *N. Abdi*[1], *B. Sifi*[1]
[1]*National Institute of Agronomic Research, Agricultural Sciences and Techniques Laboratory, Ariana, Tunisia*
[2]*National Institute of Agronomic- Carthage University, Science of crop production, Tunis, Tunisia*

Backgrounds

Legumes constitute a very important plant taxon. They play biological, ecological, agronomic and environmental roles Their capacity to fix the atmospheric nitrogen generates a double interest, economic by minimizing nitrate fertilizers applications, and ecological by limiting nitrogenous leakage Legumes contribute also to the improvement of biological balance of rotation in agricultural production systems In spite of their multiple interests, legumes areas in Tunisia are continuously regressing, leading a decrease in the production particularly in pea culture The extension of this culture is limited by its extreme sensibility to biotic and abiotic stresses and the absence of specific and efficient *Rhizobium* strains

Objectives

The objective of this study is the isolation and selection of elite indigenous rhizobia to improve the productivity of pea crop

Methods

In this study, indigenous *Rhizobium* strains were isolated from nodules of pea roots or directly from soil collected from different regions of Tunisia These isolates were morphologically characterized by the Gram test and the study of their growth in alkaline media The selected strains were also biochemically characterized for their assimilation of different carbonate substrates Then, they were screened for their ability to fix atmospheric nitrogen and solubilize inorganic phosphate in Pikovskaya medium and the potassium in Aleksandrov medium

Conclusions

The results obtained showed a large variability in the characteristics of *Rhizobium* strains and their performance for nitrogen fixation and phosphorus and potassium solubilisation in dependence on their origins This shows that the *Rhizobium*-pea symbiosis efficiency is largely dependent on the pedoclimatic conditions of the crop areas

FEMS7-2771
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

THE EFFECT OF NITROGEN FERTILISATION AND PLANT GENOTYPE ON THE FUNCTION AND COMPOSITION OF MICROBIAL COMMUNITIES IN THE RHIZOSPHERE OF FIELD GROWN BRASSICA NAPUS

C. Hale[1], *H. Schäfer*[1], *G. Teakle*[1], *G. Bending*[1]
[1]*University of Warwick, School of Life Science, Coventry, United Kingdom*

Backgrounds

Plant roots and adhering soil (the rhizosphere) host a diverse and active microbial community. The composition of bacteria and microbial eukaryotes, inhabiting the rhizosphere can have significant impacts on plant health through a range of direct and indirect interactions. A wide range of factors can potentially influence the distribution and abundance of microbial taxa in the rhizosphere.

Objectives

The aims of this study were to determine the roles of nitrogen (N) fertilisation and the genotype of *Brassica napus* in shaping the diversity, composition and function of microbial communities in the rhizosphere and surrounding bulk soil, and the implications for plant health.

Methods

Rhizosphere and soil samples were taken from field plots at the green bud stage. We used targeted amplicon sequencing to determine the structure of bacterial, protist and fungal taxa respectively. Furthermore we used PICRUSt, NEMAGuild and FUNGuild to predict whether the shifts in community composition impacted function.

Conclusions

Plant genotype had no significant effect in shaping the microbial community of the rhizosphere. N fertilisation significantly altered the soil microbial eukaryote communities, but had no significant effect on the bacterial soil community. Community composition of all groups were affected by N fertilisation in the rhizosphere. PICRUSt analysis indicated an increase in antibiotic genes in the low N rhizosphere communities. NEMAGuild analysis indicated an increase of nematode plant parasites in the rhizosphere of the high N treatment. FUNGuild analysis indicated an increase of pathotrophs in the rhizosphere, however N treatment had no effect on fungal functional guild in the soil or rhizosphere.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

THE ROLE OF QUORUM SENSING SIGNALS ON THE INTERACTIONS BETWEEN VIBRIO CHOLERAE AND CHIRONOMIDS MICROBIOTA

M. Halpern[1], *N. Atamna-Ismaeel*[1], *B. Hammer*[2]
[1]*University of Haifa, Biology and Environment, Haifa, Israel*
[2]*Georgia Institute of Technology, School of Biology, Atlanta, USA*

Backgrounds

Vibrio cholerae causes the fatal cholera diarrhea and is a natural inhabitant of aquatic ecosystems. We commonly isolate *V. cholerae* along with other bacterial species from all four life stages (eggs, larvae, pupae and adults) of chironomid insects. *V. cholerae* secretes Haemagglutinin/Protease (HAP) that degrades the gelatinous matrix of chironomid egg masses, likely acquiring nutrients and consequently preventing hatching. HAP is activated by Quorum Sensing (QS), a bacterial cell-cell communication process in which accumulation of extracellular chemical molecules (called autoinducers, AIs) triggers an intracellular signal transduction cascade.

Objectives

Our aim was to define the role of QS AI signals produced by chironomids microbiota on the production of HAP by *V. cholerae*, and to characterize the complex relationships of chironomids, *V. cholerae,* and other members of the egg mass microbial community

Methods

To study the role of QS signals we used *V. cholerae* bioluminescence reporter strains (QS-proficient O1 El-Tor wild type and QS-deficient mutants).

Conclusions

The results demonstrated that *V. cholerae* responds to AIs produced by other members of the chironomid bacterial consortium by expressing the *hapA* gene. The egg mass microbiota may use the degraded gelatinous matrix of the egg mass for their own growth. By doing so, these other species may in turn control the population levels of *V. cholerae* in the egg mass. So too *V. cholerae* supports the maintenance of endogenous bacteria in the egg mass by secreting HAP. Understanding *V. cholerae* QS in the insect system may help uncover the interactions between this pathogen and the human gut.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ABUNDANT MICROORGANISMS IN DIGESTERS OVERLOOKED BY AMPLICON SEQUENCING DUE TO PRIMER BIAS

L. Hao[1], R. Kirkegaard[1], M. Dueholm[1], S. McIlroy[1], J. Chenjing[1], M. Albertsen[1], P. Nielsen[1]
[1]Center for Microbial Communities, Department of Chemistry and Bioscience- Aalborg University, Aalborg Ø, Denmark

Backgrounds

Amplicon sequencing of the 16S rRNA gene is often applied to study the presence and population dynamics of uncultured bacteria in anaerobic sludge digesters. Such studies can give important information about novel bacteria and how they may play important roles in this complex engineered microbial system. However, primer bias can cause severe problems, and sometimes abundant and novel microorganisms may be completely overlooked.

Objectives

The microbiome in a full-scale mesophilic sludge digester at a Wastewater Treatment Plant (WWTP) was studied by amplicon and shot-gun sequencing, to investigate the influence of PCR primer choice.

Methods

Three primer-sets targeting V1-3, V3-4 and V4 region of the 16S rRNA gene, respectively, were used for amplicon sequencing, and the results were compared with the metagenomic data.

Conclusions

The results showed that the relative read abundance of some novel microbial phylotypes was seriously affected by the choice of primers. Microbial phylotypes affiliated to the candidate phylum Acetothermia demonstrated 2.3~6.7% relative abundance according to metagenomic analysis. This was, however, underestimated by two orders of magnitude when V1-3 and V3-4 primers were used. V4-primer mediated amplicon sequencing, nevertheless, demonstrated similar results to the metagenomic analysis, with 3.5~10.1% relative read abundance detected in various samples. The detection of several other candidate phyla was also significantly influenced by primer choice, including Cloacimonetes and Fermentibacter.

A survey was conducted on these overlooked microorganisms in digesters at 19 Danish WWTPs. The results showed that several of these phylotypes were among the most abundant bacteria in most digesters, indicating their significance to the digester performance.

MICROBE-MEDIATED PLANT-SOIL FEEDBACK AS A POSSIBLE DRIVER OF PRIMARY SUCCESSION

L. Harantova[1], E. Kuťáková[2], P. Kohout[1], P. Baldrian[1]
[1]Institute of Microbiology - Academy of Sciences of the Czech Republic, Ecology, Prague, Czech Republic
[2]Institute of Botany- Czech Academy of Sciences, Department of population ecology, Prague, Czech Republic

Backgrounds

Primary succession of plants is a fundamental ecological process, however, it is soil microorganisms that first colonize barren substrate. They change its physico-chemical properties, increase nutrient availability and facilitate plant establishment and growth. Plants in turn shape their associated soil microorganisms and modulate soil properties. This plant-soil feedback (PSF) affects subsequent performance and competitive ability of plants and can thus contribute to successional dynamics of plant communities.

Objectives

Using microcosm experiment, we studied soil microbial communities of three early- and three mid-successional plant species. Our main objective was to clarify whether early- and mid-successional species harbour different bacterial and fungal communities, what environmental factors mediate the differences, and how soil microbes contribute to PSF during successional transition.

Methods

Composition of soil bacterial and fungal communities was studied using next-generation sequencing of 16S and ITS amplicons. After one growth season, plant-soil feedback was assessed as plant performance in soil of their own as compared to soil from other five species.

Conclusions

Our results showed that soil microbial communities are both plant-species- and successional-stage-specific, with the effects being more pronounced in the case of fungi. Bacterial community composition is mostly driven by organic carbon content, whereas fungi respond also to soil pH and potassium. Early-successional plant species exhibited more positive plant-soil feedback than mid-successional ones.

POTENTIAL FOR EPIGENETIC MODIFICATIONS OF THE GENOME TO INFLUENCE VIBRIO VULNIFICUS VIRULENCE

V. Harwood[1], *J. Conrad*[1]
[1]*University of South Florida, Integrative Biology, Tampa, USA*

Backgrounds

BACKGROUND. The opportunistic pathogen *Vibrio vulnificus* is a natural bacterial inhabitant of coastal waters. No definitive virulence factors outside of a capsule have been identified, yet *V. vulnificus* strains display differential virulence. Epigenetic modifications such as DNA methylation can cause changes in gene expression, and may play a role in virulence. Three methyltransferases, which methylate DNA at specific sequences, have been identified in the genome of *V. vulnificus* CMCP6.

Objectives

OBJECTIVES: We hypothesize that (1) epigenetic regulation of gene expression, including DNA methylation, may contribute to a highly virulent phenotype, and (2) that environmental conditions influence gene expression via methylation patterns. Our objective was to sequence the methylome of *V. vulnificus* CMCP6 grown under varying conditions to identify modifications that may control gene expression, and to compare the methylome under varying environmental conditions.

Methods

METHODS. We sequenced the genome of *V. vulnificus* CMCP6 using single molecule real time sequencing (SMRT) in cultures grown in human serum (HS) or sterile natural seawater (SW). A *de novo* assembly of the genome was constructed and methylation was assessed using PacBio's modification and motif analysis pipeline.

Conclusions

CONCLUSIONS. The analysis revealed two distinct 6-methyladenine (6mA) motifs, GmATC and GGmAN$_9$TGGC/GCCmAN$_9$TCC, in both SW and HS treatments, and several other putative motifs. Two 4-methylcytosine (4mC) motifs (mCSN$_5$G and mCWGNNVNG) were detected in HS, but not SW cultures. Genes related to oxidative stress response had several methylation motifs, suggesting regulation by methylation. Further analysis and transcriptomic data will elucidate the effect of methylation on gene expression under varying environmental conditions.

INFLUENCE OF TRIPARTITE INTERACTIONS ON PHOSPHORUS ACQUISITION UNDER DROUGHT STRESS IN STERILIZED AND NON-STERILIZED SOILS.

L. Hassani Rezaei[1]
[1]*Department of Agriculture, Yadegar-e-Imam Khomeini(RAH) shahre rey Branch, Islamic Azad University, Tehran, Iran*

Backgrounds

Nitrogen fixers when used with arbuscular mycorrhizal fungi which improve absorption of nutrients from soil, increase N and phosphorus content of the plants particularly in low phosphorus soils.

Objectives

Comparison of phosphorus acquisition by alfalfa plants in the sterilized and non-sterilized soils under different moisture conditions.

Methods

The experiment was under green house conditions. Symbiotic association effects between VAM fungi, Rhizobium bacteria and alfalfa plants under 10, 15 and 22 percentage moisture levels was studied in sterilized and non-sterilized soils. The trial was laid out by factorial experiment in the form of Complete Randomized Block Design with 5 replications.

Conclusions

The main effect of moisture levels ,VAM inoculation and also Double interaction of rhizobium Î moisture level significantly increased Phosphorus uptake at 1% probability level in the both sterilized and non-sterilized soils. The main effect of rhizobium bacteria on phosphorus nutrition was significant in non-sterilized soil at 5% level but it wasnot significant in the other soil. The synergistic effect between VAM and rhizobium had not significant effect on mentioned parameter in the both soils. Double interaction of VAM Î moisture level and also triple interaction of VAM Î rhizobiumÎmoisture level became significant on phosphorus uptake at 1% level in the sterilized soil but they were not significant in the non-sterilized soil.

QUORUM SENSING IS INVOLVED IN ADHESION AND BIOFILM FORMATION OF SHEWANELLA WOODYI

M. HAYEK[1], *C. Baraquet*[1], *Y. Blache*[1], *M. Molmeret*[1]
[1]*University of Toulon, MAPIEM LABORATORY, Toulon, France*

Backgrounds

Quorum sensing (QS) or cell-to-cell communication is a process by which bacteria produce and detect signal molecules and thereby coordinate their behavior in a cell-density dependent manner. Two main QS systems can be distinguished: the acylhomoserine lactone (AHL) and the autoinducer-2 (AI-2). The sequenced genome of the marine bioluminescent *Shewanella woodyi* MS32 contains genes coding for these two main QS systems.

Objectives

The objectives of this work are to identify the QS communication systems present in *S. woodyi* and to determine its role in adhesion and biofilm formation.
The aim of this work is to find molecules that interfere with QS processes to inhibit adhesion and biofilm formation of *S. woodyi*.

Methods

In this study, we used the bacterial biosensor assay and the high resolution liquid chromatography mass spectrometry (LCMS) to identify the active QS systems and to specify the AHL (s) synthesized by *S. woodyi.* Luminescence Fluorescence and Crystal violet assay were also used to select molecules that inhibit adhesion and biofilm formation by interfering with the QS system of this bacterium.

Conclusions

For the first time, the active QS systems in *S. woodyi* and its role in adhesion and biofilm formation was determined. *S. woodyi* synthesizes an C8-HSL and the AI2 QS molecule. Some exogenous AHLs and other molecules known to have an effect on QS, can influence the luminescence of this bacterium, in particularly oxo and hydroxy derivatives, and reduce adhesion and biofilm formation. Mutation of putative QS genes should help determining the precise role of QS in biofilm formation.

AGRICULTURAL BIOSTIMULANTS DIFFERENTIALLY AFFECT THE BACTERIAL, FUNGAL AND ARCHAEAL COMMUNITIES OF SOIL: AN ILLUMINA SEQUENCING BASED-ANALYSIS

E. Hellequin[1], C. Monard[1], O. Klarzynski[2], M. Henriot[2], F. Binet[1]
[1]Universite de Rennes 1, CNRS-UMR 6553 Ecobio, Rennes, France
[2]Bio3G l'Agronome, research and development, Merdrignac, France

Backgrounds

To respond to the increasing demand for food and in the context of ecological transition, the use of agricultural biostimulants (BS) is becoming a common practice for sustainable agriculture. These BS can either be applied to plants or soils to enhance plant nutrition and growth. However, the mechanisms by which soil BS improve soil biological functioning and increase crop yields are still ignored. We thus focused our research on a soil BS, developed by the BIO3G Company to improve the degradation of crop residues, limit leaching of nutrients and release nutrients faster for the next crop.

Objectives

We hypothesize that changes in the microbial communities induced by the BS are responsible for the increase of crop residues mineralization. The objectives were to (i) determine the impact of BS on straw mineralization by soil microorganisms, (ii) identify whether the action was due to the inoculation of microorganisms and/or the stimulation of soil indigenous microorganisms, (iii) identify the soil microbial communities recruited in presence of BS.

Methods

Soil samples with straw were incubated with or without BS and the soil mineralization was monitored for 49 days. At the end of the incubation, changes in both microbial biomass and bacterial, fungal and archaeal diversity were determined by using a metabarcoding approach.

Conclusions

We demonstrated that the soil BS stimulated soil mineralization and increased the microbial biomass. Changes in bacterial and fungal community structures were observed due to the stimulation of soil indigenous microorganisms rather than an inoculation of specific microorganisms.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

NEW FUNGAL COMMUNITY WITH DISTINCT SPECIES COMPOSITION: FILAMENTOUS FUNGI ASSOCIATED WITH REED GALL INQUILINES

P. Heneberg[1], P. Bogusch[2], A. Astapenková[2], D. Šimčíková[1], A. Čmoková[3], M. Kolařík[3]
[1]Charles University, Third Faculty of Medicine, Prague, Czech Republic
[2]University of Hradec Králové, Faculty of Science, Hradec Králové, Czech Republic
[3]Charles University, Faculty of Science, Prague, Czech Republic

Backgrounds

Backgrounds: Monotypic stands of common reed (*Phragmites australis*) and the reed-gall-associated insect assemblages are distributed worldwide. However, fungi associated with these assemblages have never been characterized in detail.

Objectives

Objectives: We aimed to characterize the newly identified fungal community and perform a large-scale experimental verification of the infectivity of the species found.

Methods

Methods: Here we examined over 10,000 individuals of 14 species of immature reed gall inquilines from the order Hymenoptera collected at 34 sampling sites across Europe for the presence of fungal infections. We cultivated the fungi on basal as well as on selective media. To confirm their pathogenicity, the representative spectrum of newly identified strains was allowed to sporulate and the spores were inoculated on larvae of the eudominant reed gall inquiline, *Pemphredon fabricii*. We then counted the numbers of larvae, which died due to the infection or which managed to survive and fully develop to imagines, and recorded differences in a time needed to develop under fungal stress.

Conclusions

Conclusions: We found that the Hymenoptera occupying the reed galls serve as previously unknown microhabitat hosting abundant assemblage of filamentous fungi dominated by *Penicillium buchwaldii* and *Aspergillus pseudoglaucus*, but hosting also classical entomopathogenic species, such as *Lecanicillium attenuatum*. Fungal infections were an important driver of the abundance of reed gall-associated aculeate hymenoptera. Infections of generalist host species were more frequent than those of reed gall specialists, suggesting that suboptimal conditions decrease the immunocompetence of nonspecialized species, which only occasionally nest in reed.

OMICS APPROACH TO PROBE THE MECHANISM FOR INTERACTION BETWEEN CHLORELLA VULGARIS AND BACTERIA

J. Heo[1,2], D.H. Cho[1], H.S. Kim[1,2]
[1]Korea Research Institute of Bioscience & Biotechnology, Cell Factory research center, Daejeon, Republic of Korea
[2]University of Science and Technology, Green Chemistry and Environmental Biotechnology, Daejeon, Republic of Korea

Backgrounds

Over the past 20 years, people have studied the relationships between algae and bacteria from different perspectives, including the physical, biological, environmental and chemical processes involved. Recent studies on co-cultivation of algae with growth enhancing bacteria showed that bacteria enhance algal growth rate by at least 10%. Our previous studies have proved that selective infestation of growth promoting bacteria in the phycosphere of algae would lead to a cumulative increase in biomass and lipid productivity.

Objectives

The metabolomics study of interactive mechanisms between microalgae and bacteria could help improve algal biomass productivity in microalgae production processes. Moreover, the omics approach to study microbial ecology has transformed our understanding of microbial communities and their environment. In this study, the major objective is to examine the mechanism for interaction between *Chlorella vulgaris* and its associated bacteria.

Methods

Chlorella vulgaris OW-01 (NCBI accession number JQ664295) used in this study were isolated from wastewater. Axenic unialgal culture of *C. vulgaris*(ACV) were grown in BG11 medium for 14days (25℃, 150μmol/m²/s). After cultivation, the culture broth of ACV was filtered through a 0.2μm pore size bottle-top filter system. This filtered culture broth was utilized for microalgae growth-promoting bacteria cultures. Axenic *chlorella vulgaris* was co-cultured with bacterial metabolite fraction which were obtained from the bacterial culture supernatant.

Conclusions

This study suggests that the omics approach would help answer some basic questions on algal-bacterial association.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

CONDUCTIVITY RATHER THAN OXYGEN LEAKAGE DETERMINES ABUNDANCE AND COMPOSITION OF AMMONIA OXIDIZERS ON TYPHA LATIFOLIA ROOTS

E. Hernandez-del Amo[1], *G. Ramis*[1], *F. Gich*[1], *L. Bañeras*[1]
[1]*Universitat de Girona, Institute of Aquatic Ecology, Girona, Spain*

Backgrounds

Oxidation of ammonia in water and sediments is highly dependent on the availability oxygen. Emergent macrophytes, such as *Typha latifolia*, increase oxygen concentrations in the rhizoplane due to continuous oxygen leakage from roots, thus generating an aerobic microenvironment in close contact to the root surface. However, the impact of oxygen leakage on the abundance and diversity of nitrifiers has not been extensively quantified.

Objectives

The aim of this study was to quantify to what extent oxygen permeability on *Typha latifolia* roots affected the spatial distribution of ammonia oxidizing archaea (AOA) and bacteria (AOB) in an estuarine salinity gradient.

Methods

Oxygen leakage at different parts of root hairs was estimated as potential diffusion rates after measuring oxygen micro-profiles at the root surface. AOA and AOB diversity and abundance in root sections were inferred by barcode amplicon Illumina sequencing of the 16S rRNA gene, and quantitative PCR of *amoA* and 16S rRNA genes.

Conclusions

AOA and AOB abundances increased significantly in high conductivity areas (>10,000 mS/cm). The basal sections of root hairs contained a higher abundance of ammonia oxidizers, despite the low oxygen diffusion rates measured. Relative abundance of AOA was higher compared to AOB both in the root surface and the sediment adjacent to it. However, AOB/AOA increased in the root surface for some specific taxa. Overall, we were able to show that water conductivity and plant roots exerted a selection effect on ammonia oxidizers, although this effect may be limited to small portions of the root surface due to changes on oxygen leakage.

IN VITRO CELECOXIB SUPPLEMENTATION IMPACTS THE FUNCTIONAL CAPACITIES OF THE GUT MICROBIOTA

E. Hernandez-Sanabria[1], E. Heiremans[1], M. Calatayud Arroyo[1], B. Roman[2], S. Mangelinckx[2], L. Leclercq[3], J. Snoeys[3], T. Van de Wiele[1]
[1]Ghent University, Center for Microbial Ecology and Technology CMET, Gent, Belgium
[2]Ghent University, Department of Sustainable Organic Chemistry and Technology, Gent, Belgium
[3]Janssen Pharmaceutica NV, Janssen Research & Development, Beerse, Belgium

Backgrounds

Alterations on inflammatory pathways lead to aberrant expression of cyclooxygenase-2 (COX-2) in colon carcinogenesis (CRC). The efficacy of COX inhibitors (coxibs) for successfully reducing CRC recurrence further confirmed the key role of COX-2. Alas, continuous COX-2 inhibition may increase the risk of a cardiovascular event. Currently, little information is available on how inter-individual variations in colon microbiota impact coxib disposition and overall celecoxib disposition.

Objectives

This project evaluated the effect of clinical concentrations of celecoxib on the in vitro colon microbiota. We determined the baseline microbiota activities and metabolic response, to reveal whether microbial drug metabolism impacts the conversion process.

Methods

We conducted in vitro batch culture experiments, assessing the potential of human faecal microbiota for metabolising celecoxib. Faecal slurries from four volunteers were supplied with 100 mg/ml of celecoxib and anaerobically incubated for 16h, to simulate the transit time of the proximal colon. Short-chain fatty acids (SCFAs) were considered benchmarks of gut microbial functionality and determined by gas chromatography. Liquid chromatography-tandem mass spectrometry (LC-MS/MS) was used to determine celecoxib recovery. Total RNA was applied to perform qRT-PCR of the bacterial 16S rRNA gene and to evaluate the metabolically active population.

Conclusions

Our results indicate that celecoxib shifts in vitro fermentation, in a donor-dependent manner. Celecoxib significantly decreased total SCFA and butyrate ($P < 0.001$), but not copy number of 16S rRNA gene in all donors. Microbial-derived SCFA, such as butyrate, may fuel proliferation of cancer-initiated epithelial cells. This study will provide information about the microbiota interplay on the efficacy of colon-targeted coxibs.

CHALLENGE TO DISCOVER THE ANCIENT MICROBIOTA IN HOLOCENE SEDIMENTS OF THE EL PORTALON CAVE AT THE SIERRA DE ATAPUERCA (BURGOS) BY HIGH-THROUGHPUT SEQUENCING

M. Hernandez[1], D. Rodríguez-Lázaro[2], N.M. Quijada[1], G. Kay[3], A. Pérez Romero[4], C. Valdiosera[5], E. Iriarte[4], J.M. Carretero[4]
[1]Instituto Tecnológico Agrario de Castilla y Leon ITACyL, Laboratory of Molecular Biology and Microbiology, Valladolid, Spain
[2]University of Burgos, Department of Biotechnology and Food Science. Area of Microbiology, Burgos, Spain
[3]University of Warwick, Microbiology and Infection Unit- Warwick Medical School, Coventry, United Kingdom
[4]University of Burgos, Laboratory of Human Evolution, Burgos, Spain
[5]La Trobe University, Department of Archaeology and History- Faculty of Humanities and Social Sciences-, Melbourne, Australia

Backgrounds

The Archaeological Sites of “Sierra de Atapuerca” are located in the northeast sector of the Cenozoic Duero Basin, north-central Iberian Peninsula, very near to Burgos (Spain) and has been included in the UNESCO list of World Heritage Sites. It was occupied by hominids from the Early Pleistocene to modern man and it is continuously being excavated every year during a limited period of time in summer.

Objectives

The present study is focused on the microbial analysis of Late Pleistocene and Holocene stratigraphic levels of the El Portalón cave, in the Sierra de Atapuerca, by high-throughput sequencing. We have analysed samples from the Late Pleistocene levels (30.000 years BP) and throughout the Holocene, covering the Neolithic, Chalcolithic, Bronze Age and Roman period levels (6000 to 2.000 years BP).

Methods

Total DNA was extracted from sediments, taken special measures to avoid cross contamination. Libraries were prepared using TruSeq Nano DNA Library Preparation Kit (Illumina) and sequenced by synthesis using a MySeq platform. Quality-filtered sequences were analyzed by using Kraken for prokaryotic reads, and eukaryotic DNA by Blast algorithm and visualized using Megan.

Conclusions

Classical microbiological determination performed in some of the sediments allowed to grow bacteria corresponding to soil microbiota naturally present. Species as *Alteromonas* or *Pseudomonas* were generally present in the sediments. Besides, the DNA extraction yield highly compromised the results, and very diverse bacteria at low levels were identified, particularly those bacteria osmotolerant and facultative anaerobic in the different strata.

[7]Argonne National Laboratory, Biosciences Division, Lemont, USA
[8]University of Oregon, Department of Biology, Eugene, USA
[9]University of California Davis, Animal Science, Davis, USA

Backgrounds

Cyanobacteria are photosynthetic bacteria found in most types of illuminated environments. Their global biomass has been estimated to be ~3×10^{14} g carbon and their key role in global carbon and nitrogen cycling has been widely accepted. Despite the ecological importance and the significant efforts by the scientific community to advance our understanding of this important phylum, most of the research in this field is performed on pure cultures – which represent only a few percent of the organisms in an environmental sample. Very little is known about how members of the phylum cyanobacteria affect and respond to changes in complex biological systems.

Objectives

In the project presented here we selected photosynthetic consortia based on their culture maintenance condition and their collection site from a total of over 1,200 samples that are currently grown in our laboratories. We subjected these cultures to a diverse set of omics and imaging techniques to define the molecular processes that facilitate carbon and nitrogen sequestration by these phototrophic consortia and the individual organisms and interrelationships that contribute to them.

Methods

Methods used during this study included: 16S rRNA sequencing, metagenomics. metabolomics, metaproteomics, and FISH

Conclusions

Here we present first results from this study that was funded by the U.S. Department of Energy (DOE) as part of the FICUS Program at the Joint Genome Institute and the Environmental Molecular Sciences Laboratory, two User Facilities managed by the DOE Office of Science. We anticipate that this study will provide new insights into the growth requirements of the microorganisms that form phototrophic consortia, ultimately facilitating their isolation and axenic cultivation.

EXPLORING THE DRIVERS OF ANTIMICROBIAL RESISTANCE WITHIN THE ENVIRONMENT

J. Holden[1], E. Wellington[1], W. Gaze[2], L. Zhang[2], A. Singer[3], A. Mead[4]
[1]University of Warwick, School of Life Sciences, Coventry, United Kingdom
[2]Exeter University, Life Sciences, Truro, United Kingdom
[3]Centre for Ecology and Hydrology, Microbial Ecology, Wallingford, United Kingdom
[4]Rothamsted Research, Computational and Systems Biology, Harpenden, United Kingdom

Backgrounds

Persistent administration of antibiotics has placed enormous selective pressure on bacterial species. As a result, we have observed a significant rise in the number of antimicrobial resistant bacteria. Many resistance genes are located on mobile genetic elements and therefore resistant bacteria are capable of transferring genes conferring resistance to human and animal pathogens via horizontal gene transfer.
The (mis-)use of antibiotics alone is not solely responsible for the spread of antimicrobial resistance across bacterial populations. Effluent from hospital/communities, as well as agricultural runoff contain sub-lethal levels of antibiotics and resistant bacterial species; and whilst mitigation strategies are in place to reduce microbial load eg. wastewater treatment plants, these processes have been recently shown to positively select for resistant determinants that are released into the environment.

Objectives

Since bacterial communities are shaped by a complex array of evolutionary, ecological and environmental factors, it is important to take into account not only point sources, but also additional environmental variables when analyzing the drivers of antimicrobial resistance.
We aim to investigate the risk factors associated with the spread of antimicrobial resistance within the Thames catchment.

Methods

River sediment was collected from 69 sites within the Thames catchment. DNA was purified from each sediment and used for next generation sequencing data of resistance genes. GIS spatial data on land use, water quality analyses and rainfall data are used to predict the drivers of antimicrobial resistance.

Conclusions

Preliminary analyses suggest wastewater treatment plants as well as agricultural practices strongly influence the resistance loads within the Thames catchment.

HYPORHEIC ZONE: A HARBOUR FOR NOVEL MICROBIAL IBUPROFEN DEGRADERS

C.R. Njeru[1], M. Posselt[2], M.A. Horn[1]
[1]Leibniz Universität Hannover, Institute of Microbiology, Hannover, Germany
[2]Stockholm University, Department of Environmental Science and Analytical Chemistry, Stockholm, Sweden

Backgrounds

Presence of the widely used pharmaceutical Ibuprofen in effluents and receiving waters is attributed to inefficient removal by conventional wastewater treatment plants. Potential total removal via biodegradation in the hyporheic zones (HZ) of receiving rivers downstream of discharge sites has been hypothesized.

Objectives

A HZ downstream of an impacted river was evaluated for its performance in removal of ibuprofen using two sets of oxic HZ sediment microcosms spiked with ibuprofen only (5, 40, 200 and 400 µM), or ibuprofen and 1 mM acetate in batch experiments.

Methods

We applied oxic microcosm incubations coupled to amplicon imllumina sequencing and qPCR of 16S rRNA genes and transcripts to adress hitherto unknown microbes associated with the degradation of the model micropollutant ibuprofen.

Conclusions

Ibuprofen was completely removed in non-sterile relative to autoclaved sediments indicating microbial degradation. In refed microcosms, biodegradation occurred in the absence and presence of supplemental acetate within 24 hours following initial incubation of 11 and 16 days respectively. Carboxy- ,1-, 2-, and 3-hydroxy-ibuprofen were identified metabolites. The microbial communities involved were evaluated using Quantitative real-time PCR and time resolved triplicate amplicon Illumina MiSeq sequencing targeting 16S rRNA genes and transcripts. The analyses revealed similar copy numbers of 16S rRNA gene or transcripts between non-spiked controls and treatments. Increased relative abundances of the phyla *Proteobacteria*, *Acidobacteria* and *Actinobacteria* in treatments with compared to those without ibuprofen were observed. *Proteobacteria* was the dominant phylum with *Alpha-, Beta-* and *Deltaproteobacteria* being the most active as indicated by RNA based analyses. Hitherto unclassified species of *Acidobacteria* subgroup 6 and genera *Hyphomicrobium* and *Sphingomonadaceae* were linked to ibuprofen degradation.
Overall, the results unravel the HZ as a reservoir of hitherto unknown microbial communities associated with turnover and degradation of such micropollutants; a prominent ecological service in the natural self-purification of streams.

MICROBIAL CONTAMINATION OF CURRENCY NOTES AND COINS IN CIRCULATION IN UNITED ARAB EMIARTES (UAE)

I. Mukhtar[1], M.E.M. Mohamed[1], R.M.A. Hassan[1], A.K.S.A. Ibrahim[1], M. Magaogao[2], A. Hossain[2]
[1]Ras Al Khaimah Medical and Health Sciences University, Medicine, Ras Al Khaimah, United Arab Emirates
[2]Ras Al Khaimah Medical and Health Sciences University, Medical Microbiology and Immunology, Ras Al Khaimah, United Arab Emirates

Backgrounds

Currency notes and coins are items which are most frequently passed from hand to hand. Studies from different countries of the world have shown that currency notes and coins carry different bacterial and fungal species, including pathogenic strains.

Objectives

This study was designed to screen all 11 units of currency notes and coins in circulation in UAE for presence of bacterial species. In addition we also intended to determine the antibiotics resistance profile and biofilm forming potentials of selected dominant bacterial species isolated from currency notes and coins.

Methods

We screened a total of 55 currency notes and coins (5 of each units), which were collected from people engaged in various trades. Saline soaked sterile swab sticks were used to collect the bacterial samples from notes and coins, grown on blood agar and identified by standard microbiology procedures. Five dominant bacterial species of each note and coin were analyzed for antibiotic resistance by disk diffusion assay and biofilm production by crystal violet dye binding spectrophotometric assay.

Conclusions

The data obtained in this study indicates that UAE currency notes and coins carry antibiotic resistant, biofilm forming potential pathogens and may thus serve as a vehicle of transmission of these bacterial species. This is the first report of analyzing UAE currency notes and coins for carriage of bacteria.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

METAGENOMICS SURVEY OF LIMESTONE CAVE IN TAIWAN

B.M. Hsu[1]
[1]*National Chung Cheng University, Earth and environmental sciences, Chiayi, Taiwan R.O.C.*

Backgrounds

The limestone of Narro-Sky in Tainliao, Taiwan is of Pleistocene reef limestones interbedded in clastic layers that covered the Takangshan anticlines. Understanding how microbial relative abundance was changed in response to changes of environmental factors may contribute to better comprehension of roles that microorganisms play in altering the landscape structures.

Objectives

In this study, microorganisms growing on the wall of limestone, in the water dripping from the limestone wall and of soil underneath the wall were collected from different locations where the environmental factors such as daytime illumination, humidity, or pH are different.

Methods

Next generation sequencing (NGS) was carried out to examine the compositions and richness of microbial community. The metagenomics were clustered into operational taxonomic units (OTUs) to analyze relative abundance, diversities and principal coordinates analysis (PCoA).

Conclusions

Our results showed the soil sample has the highest alpha diversity while water sample has the lowest. Four major phyla, which are Proteobacteria, Acidobacteria, Actinobacteria, and Cyanobacteria account for 80 % of total microbial biomass in all groups. Cyanobacteria were found most abundantly in limestone wall instead of water or soil of weathering limestone. The PCoA dimensional patterns of each phylum showed a trace of microbial community dynamic, which might be affected by environmental factors. This study provided the insights to understand how environmental factors worked together with microbial community to shape landscape structures.

SURVEILLANCE AND EVALUATION OF THE INFECTION RISK OF ACANTHAMOEBA IN VARIOUS AQUATIC ENVIRONMENTS

B.M. Hsu[1]
[1]*National Chung Cheng University, Earth and environmental sciences, Chiayi, Taiwan R.O.C.*

Backgrounds

Acanthamoeba is one kind of free-living amoebae (FLA) which ubiquitous in various aquatic environments. Several *Acanthamoeba* species are pathogenic and host other pathogens such as *Legionella*, but the presence of *Acanthamoeba* and its parasites as well as the related infection risk are not well known.

Objectives

In this study, the surveillance and evaluation of the infection risk of *Acanthamoeba* in different aquatic environments was investigated. Water samples were collected from a river, intake areas of drinking water treatment plants, and recreational hot spring complexes in Taiwan.

Methods

A total of 140 water samples were tested for the presence of *Acanthamoeba* spp.. In addition, phylogenetic characteristics and water quality parameters were also assessed.

Conclusions

The pathogenic genotypes of *Acanthamoeba* T4 were abundant in the hot spring water. Taken together, *Acanthamoeba* contamination in recreational hot springs and drinking water source warrants more attention on potential legionellosis and amoebae infections.

[6]Ministry of Agriculture- Forestry and Fisheries, Department of Fisheries Post-Harvest Technologies and Quality Control, Phnom Penh, Cambodia
[7]Ministry of Health, National Centre for Malaria and parasites, Phnom Penh, Cambodia

Backgrounds

Intestinal microbiota has been extensively studied for many years, with associations between alterations in microbiota composition and several diseases firmly established. Surprisingly few data exist on associations between microbiota composition and micronutrient status. Also, most studies have been done in adults or infants, but rarely in schoolchildren. In Cambodia, malnutrition and micronutrient deficiencies are still common. We analysed data from a large intervention trial in Cambodian schoolchildren (FORISCA) for associations between microbiota and micronutrient status.

Objectives

The primary objectives of this study are to characterize the intestinal microbiota of Cambodian schoolchildren and possible associations with (micro)nutrient status. Secondary objectives include associations of microbiota composition with systemic inflammation, parasite infestation and scores on cognitive tests. Stability of microbiota along time has also been estimated.

Methods

In total, data was available on 450 schoolchildren (6 to 16 years old) from 16 schools at baseline and after 6 months of consumption of micronutrient-fortified rice (or placebo). Nutritional status indicators included anthropometry and biomarkers for iron, zinc and vitamin A status. Illumina sequencing of PCR amplicons of 16S rRNA coding genes have been performed on DNA extracted from stool samples.

Conclusions

Preliminary results suggest that microbiota composition is related to biomarkers of micronutrient status and cognitive test scores. Intestinal microbiota composition seems to evolve along time.

IDENTIFICATION OF REPRODUCTIVE MANIPULATOR BACTERIAL SPECIES IN PEST MITES OF ECONOMIC IMPORTANCE FOR CITRUS IN SPAIN

T. Pina[1], C. Marc[1], J. Cruz[1], B. Sabater-Muñoz[2], J. Josep[1], M. Hurtado Ruiz[1]
[1]Universitat Jaume I, Ciències Agraries i del Medi Natural, Castellon de la Plana, Spain
[2]Trinity College University of Dublin, Systems Biology and Abiotic Stress, Dublin, Ireland

Backgrounds

Citrus is an economic important crop threatened by several pests. Among them, *Tetranychus urticae* and *Panonychus citri* (Acari: Tetranychidae) are of special consideration. During the last years, our group has studied the genetic structure of *T. urticae* finding a relationship between genotypes and pesticides applications in citrus orchards. In addition, a sub-division of *T. urticae* populations was depicted between the main crop and the ground cover, highlighting the putative presence of plant-specialist *T. urticae* strains. Tetranychidae mites have been characterized for the presence of reproductive manipulator endosymbionts, like *Wolbachia*, *Cardinium*, *Rickettsia* and *Spiroplasma*. One of this species, *Wolbachia*, has been implicated in pesticide resistance of mites, being also of consideration to biotechnological control approaches (para-transgenesis). However, the distribution of these bacterial species and its relationship with mite population's genetic structure still deserves studies.

Objectives

Our main objective is to determine the presence of these four species in Spanish Tetranychidae populations on citrus orchards

Methods

After external surface sterilization, mite samples were screened by PCR with universal 16S primers, *Wolbachia* (wsp, fstZ in addition to 16S), *Cardinium*, *Rickettsia* and *Spiroplasma* specific primers. Samples were scored as positive in bacterial symbionts other than *Wolbachia*, *Cardinium*, *Rickettsia* or *Spiroplasma* if only amplified with universal 16S primers. PCR fragments were sequenced and aligned against Gene bank sequences of reference

Conclusions

Spanish Tetranychidae populations showed a differential *Wolbachia* infection level, with some populations showing additional bacterial species. The relationship between *Wolbachia* presence and host plant specialization of citrus mite populations deserves further research.

METAGENOMIC CHARACTERIZATION OF MICROBIOTA IN ECONOMIC IMPORTANT MITES OF CITRUS

T. Pina[1], B. Sabater-Muñoz[2], J. Jaques[1], M. Hurtado Ruiz[1]
[1]Universitat Jaume I, Ciències Agraries i del Medi Natural, Castellon de la Plana, Spain
[2]Trinity College University of Dublin, Systems Biology and Abiotic Stress, Dublin, Ireland

Backgrounds

Plant-organism interactions have been usually seen as a two component problem only. Over the few past years, bacterial endosymbionts of arthropods have been incorporated as a third part of this plant-arthropod interaction. The family Tetranychidae (Acari) comprises worldwide citrus pests as *Tetranychus urticae*. Due to its impact, interaction studies were started finding that plant defense response induced by *T. urticae* depended on citrus rootstock and/or cultivar. The implication of bacteria from the Acari microbiota in this plant-arthropod interaction still deserves research

Objectives

To ascertain the partners in this plant defense response variation, our objective is to determine the microbiota composition of different *T. urticae* populations, feeding on two citrus species used as main rootstocks of Clementine mandarins, and of other Acari of economic importance in citrus

Methods

Mites were sampled in citrus fields taking into consideration rootstock and variety. In addition, a *T. urticae* laboratory strain and its tetracycline-treated sister strain were also tested. After external surface sterilization, mite samples were subjected to total DNA extraction using Zymobiomics kit (Zymo) or by a Salting-out ('in house' protocol). The v3-v4 region of 16S rDNA was deep sequenced with MiSeq (Illumina) at 2x300bp cycle. Fastq files were processed and OTUs identified to determine bacterial diversity indexes. Finally, bacterial species were identified by blast homology

Conclusions

Mite populations in Spanish citrus present a complex microbiota. *Wolbachia* has been found mainly in *T. urticae* samples. Identified microbial assemblages are discussed by their implication in citrus-Acari interaction focused on biological control programs

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

BACTERIAL LEACHING OF MINERALS USING STREPTOMYCES

J. Hurtado[1], *D. Ugarte*[1]
[1]*Universidad Peruana Cayetano Heredia, Ciencias celulares y moleculares, Lima, Peru*

Backgrounds

Microorganism play a key role in arsenopyrite oxidation in natural and commercial processes. There are many organisms involved in the bacterial leaching operations. It has been shown the presence of actinobacteria in leaching enviroments.

Objectives

Demonstrate the use of Streptomyces in the bacterial leaching of arsenopyrite

Methods

Ten isolates of Streptomyces from arsenopiryrite, pyrite, polimetalic sulfides and magnetite from Peruvian mining zones have been characterized and they have been tested by growth on arsenopyrite tailings. Only two isolates were able to develop with this mineral. Streptomyces sp. E1 and Streptomyces variabilis AB5 leached 19.1 % and 15.5 % of arsenic present in tailings while, the control without inocula, only showed 2.5% of leaching.

Conclusions

This study demonstrated that Streptomyces is able to degradate arsenopyrite

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

FLAVONOIDS AND IAA CROSSTALK: COLONIZATION OF MAIZE ROOT BY ENDOPHYTIC FUNGI FUSARIUM CULMORUM SP. PZ

A. Hussain[1], *A. Mehmood*[1], *M. Irshad*[1]
[1]*Abdul Wali Khan University, Botany, Mardan, Pakistan*

Backgrounds

Molecular crosstalk between microbes and their host is the first step toward the establishment of any association. Plant roots release a variety of signal molecules to differentially treat the beneficial and harmful microbes.

Objectives

Current study focuses on the role of flavonoids and IAA as signals for molecular dialogue between endophytic fungus and maize root.

Methods

Endophytic fungi *Fusarium culmorum* sp. Pz was isolated from the roots of drought stressed *Asphodelus tenifolium* roots. Identity of the strain was confirmed by homology of the ITS region of 18 S rDNA sequence. Flavonoids and IAA were analyzed in fungal culture filtrate and exudate of maize root (with and without endophyte) by LC-ESI-MS/MS.

Conclusions

The strain was able to produce a number of phytostimulants and signaling compounds including indole-3-acetic acid (IAA), flavonoids and sugar. Its culture filtrate contained 33.2±0.8, 275.1±8.7 and 186.6±15.7 µg/mL of IAA, total flavonoids and sugar respectively. The strain effectively colonized in the roots of maize and subsequently enhanced growth of its host. Inhibition of flavonoids or IAA exudation by maize root effectively reduced colonization of the endophyte in maize root to 89% of the control. Similarly, colonization of root by endophyte with repressed flavonoids was reduced 62% of the control suggesting a flavonoids talk between the two partners. Suppression of IAA biosynthesis in the endophyte drastically affected its colonization in the maize root. It is concluded that a molecular crosstalk of maize roots and endophytic *Fusarium culmorum* sp. Pz is necessary for subsequent endophytic association between them.

INDUSTRIAL COATING SYSTEMS ARE A SPECIAL NICHE FOR BURKHOLDERIA STRAINS JEOPARDIZING CAR LACQUER PROCESSES

K. Huth-Herms[1], A. Sisman[1], J. Erhardt[1], A. Spielvogel[1], D. Oberschmidt[1], E. Uhlmann[1]
[1]Fraunhofer Institute for Production Systems and Design Technology, Microproduction technology, Berlin, Germany

Backgrounds

Microbial contaminations of water-based varnishes are a threat in industrial coating systems. Microorganisms of the genus *Burkholderia* are frequently carried over from pretreatment steps causing coating defects on surfaces during the final coating step. Despite regular and increased addition of biocides, microbial contamination leads to production downtime and financial losses.

Objectives

Four strains from the pretreatment (PT1, PT2) and coating (CT1, CT2) area were isolated. They were analyzed and compared to *Burkholderia cepacia* (DSM7288) regarding their growth behavior in different cultural and biocide conditions. All strains show an improved growth in minimal culture compared to carbon rich culture, with generation rates between 42 and 60 minutes. In addition, under such growth conditions the isolates from the coating systems formed significantly stronger biofilms than DSM7288. Interestingly, upon the addition of biocide the strain CT1 forms biofilms very fast and survives biocide concentration normally used in industrial settings.
The typical self-aggregation mechanism of *Burkholderia* could be confirmed for all isolated strains. Interestingly, under moving conditions the cells formed aggregates after only one hour of cultivation.

Methods

Microbial growth was examined by determining the optical density. Biofilmformation was detected by crystal violet staining. Aggregate formations was identified by microscopy and agar plate cultivation.

Conclusions

It is assumed that the aggregation mechanism is responsible for biofilm formation on the surface of coatings solids and not on the surface of the coating vessel. *Burkholderia* strains possess a fast adaptation system in order to survive harsh environmental conditions. Future work will aim to understand the genetic background of these changes.

[6]Federal Research and Clinical Center of Physical-Chemical Medicine, Federal Research and Clinical Center of Physical-Chemical Medicine, Moscow, Russia

Backgrounds

Bacterial competition between members of microbiome is often mediated by bacteriocins – small peptides produced by microorganisms which are capable to kill competitor strains or species. Bacteriocinogeny, i.e. an ability to produce bacteriocins, can give an evolutionary advantage to the strain-producer.

Objectives

In this work, we studied bacteriocin production activity of some species (*S. pneumoniae*, *S. pseudopneumoniae* and *S. mitis*) inside the mitis group of viridans group streptococci (VGS), which are frequent colonizers of the human nasopharynx. To estimate a bacteriocinogeny potential, we applied traditional culture-based methods as well as *in silico* searching of the bacteriocin-like peptides encoding genes across the genomes of the study strains.

Methods

Nine strains of VGS were inspected for the bacteriocin production by the deferred antagonism bacteriocin assay using *Staphylococcaciae* strains as indicators. A set of genes encoding potential bacteriocins was outlined by using of the web-resource BAGEL3 (http://bagel.molgenrug.nl/index.php/bagel3).

Conclusions

All strains under study were found to be active against *S. aureus, S. epidermidis* and *S. haemolyticus*. A thorough study of genomes showed that the ways of bacteriocin production by pneumococci might be more complicated than it was usually considered, due to the presence of some more putative bacteriocin-associated gene clusters in their genomes. However, we could not explain a high inhibition activity of at least one of three *S. mitis* strains based on the investigation of its genome.

This work was supported by the Russian Science Foundation (RSF) № 15-15-00158 grant.

ISOLATION OF NITROGEN FIXING BACTERIA ISOLATED FROM SOIL SAMPLES IN SOUTH KOREA AND CHARACTERIZATION OF ITS PLANT GROWTH PROMOTION

W.T. Im[1], *C. Gyumiin*[1]
[1]*National Hankyong University, Biotechnology, Anseong-si, Republic of Korea*

Backgrounds

Nitrogen (N) is an essential element for all living organisms, being a constituent of proteins, nucleic acids, and many other biomolecules. The largest pool of nitrogen in the biosphere is atmospheric dinitrogen (N_2). The input of N_2 into the biogeochemical nitrogen cycle occurs by reduction of N_2 to two ammonia molecules (NH_3) by nitrogen fixing bacteria.

Objectives

This study focused on the isolation and characterization of nitrogen fixing bacteria from the plant rhizosphere of various soil samples in Anseong and Pocheon province, South Korea, and investigate their effects on plant growth.

Methods

50 strains were isolated using nitrogen free agar from paddy soil and ginseng cultivating soil and were identified 16S rRNA gene sequencing. Two plant growth promoting, nitrogen-fixing bacterial strains, *Mesorhizobium plurifarium* EMML 409^T and *Burkholderia choica* Gsoil 652, were selected based on their growth curves in seven different media.

Conclusions

Their plant promoting abilities in the early growth phase were studied in cabbage (*Brassica campestris* subsp. *napus*). When the plant seedlings were treated with these strains, their fresh weight, dry weight and root length were increased.

COLLATERAL SENSITIVITY NETWORKS ENABLE TARGETED THERAPEUTIC STRATEGIES AGAINST DRUG RESISTANCE IN PSEUDOMONAS AERUGINOSA

L. Imamovic[1], M. Hashim Ellabaan[1], M. Ana[1], S.M. Søren Molin[1], H.K.J. Helle Krogh Johansen[1], S. Morten[1]
[1]Denmark, Technical Universisty of Denmark, Lyngby, Denmark

Backgrounds

Development of drug resistance in a serious challenge for success of drug therapies. Treatment strategies incorporating critical vulnerabilities induced by antimicrobial resistance development could have a great utility in clinical treatments. Previously, we and others reported the vulnerabilities of drug resistant cells (collateral sensitivities) of Escherichia coli. Applying same principles in a major cystic fibrosis pathogen, Pseudomonas aeruginosa, could significantly improve the treatment outcome.

Objectives

The aim of this study is to evaluate systematically phenotypic and genotypic adaptive changes that emerge as a consequence of drug resistance evolution in P. aeruginosa.

Methods

We performed experimental adaptive evolution in media that resemble the chemical composition of CF lungs for PAO1 and DK2 strains. Antibiotic resistant strains were selected during 10-day passage supplemented with clinically relevant antibiotics. To underline the genetic basis for collateral sensitivity and resistance, genomes of resistant strain were sequenced on a MiSeq platform.

Conclusions

Drug resistance development limits the successful application of many available anti-pseudomonal drugs. Studying drug resistance evolution may thus hold the key to understanding how the current therapeutics may change upon subsequent side effects. The drug deployment based on collateral sensitivities might integrate several factors important in the treatment of CF, such as 1) presence of heterogeneous population, 2) immunomodulatory properties 3) presence of other pathogens. Furthermore, identifying the genetic link to drug resistance has a high relevance in treatment of chronic infections.

FEMS7-0388

CHARACTERISATION OF TWO NEW SOIL-DWELLING PSEUDOMONAS ISOLATES ABLE TO BREAK-DOWN AIR POLLUTANTS

V. Imperato[1], S. Thijs[1], Ł. Kowalkowski[2], Y. Douwen[1], R. Carleer[1], J. Van Hamme[3], S. Gawronski[2], N. Weyens[1], J. Vangronsveld[1]
[1]Hasselt University, Centre for Environmental Sciences, Diepenbeek, Belgium
[2]Warsaw University, Department of Life Sciences, Warsaw, Poland
[3]Thompson Rivers University, Department of Biology, Kamloops, Canada

Backgrounds

Air pollution is considered as the world's largest single environmental health threat. It is clear that more effective pollution control measures need to be taken. Since airborne contaminants are regularly carried by rain into the soil, we hypothesise that soil microorganisms might play a significant role in an effective air pollution control.

Objectives

We tested soil bacteria for their ability to degrade common airborne pollutants.

Methods

We sampled soil in the world's first oil field, Bóbrka (Poland). For the *in situ* cultivation, we used innovative miniature diffusion chambers, each approximately inoculated with a single environmental cell. Consecutively bacteria were purified, tested for diesel-degradation, toluene degradation with GC-MS, and ability to produce VOCs for plant growth promotion. Presence and expression of catabolic genes (oxygenases) directly involved in the PAHs degradation pathway were evaluated with degenerate primers, and followed by draft genome sequencing.

Conclusions

Soil bacteria of diverse phylotypes were isolated for their high potential to degrade diesel. We found 14 new *Pseudomonas* sp. carrying naphthalene dioxygenase genes, 2 of them were selected for whole genome sequencing. Preliminary data on GC-MS showed a disappearance of 40 µg L^{-1} toluene from the air phase in 5 days. Further genome-mining will elucidate which other pathways are involved to degrade toluene and related PAHs.
Bacteria dwelling in heavily contaminated soils appear to be able to degrade airborne pollutants. Two of the isolated strains will be further tested in controlled cuvette-experiments to explore their potential to mitigate air-pollution and improve environmental quality in function of human health.

BIOLOGICAL NITRIFICATION INHIBITION BY RICE ROOT EXUDATES IN TWO DIFFERENT SOILS OF URUGUAY

G. Illarze[1], *P. Irisarri*[1]
[1]*Facultad de Agronomía, Plant Biology, Montevideo, Uruguay*

Backgrounds

Rice crop is an important source of greenhouse gases, mostly CH_4, but also of N_2O. Nitrous oxide in soils is originated mainly by the microbial processes of denitrification and nitrification. Recently the first evidence of biological nitrification inhibition (BNI) by root exudates was reported and it varied with the plant cultivar.

Objectives

The objective of this work was to check and compare the BNI potential of the roopt exudates of two rice cultivars, El Paso 144 and INIA Tacuarí, and to evaluate their inhibitory effect on the activity and abundance of bacteria and archeae NH_4^+ oxidizers.

Methods

This effect was tested in two soils that differed in their organic matter content, among other characteristics.With the bioassay using a *Nitrosomonas europea* recombinant strain, the BNI effect of both cultivars was verified. The cultivar Tacuarí presented higher BNI and in the microcosm assay the BNI effect was higher than the produced by the synthetic nitrification inhibitor DCD, in the soil with lower organic matter content. The *amo*A copy number of archeae, quantified with qPCR, was not affected by the root exudates addition, while that of bacteria decreased.

Conclusions

These rice cultivars BNI activities should be assayed in the field as a N_2O mitigation strategy.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ISOLATION AND CHARACTERIZATION OF ANTAGONISTIC BACILLUS STRAINS FROM THE RHIZOSHPERE OF TOMATO AS POTENTIAL BIOCONTROL AGENT AGAINST FUSARIUM OXYSPORUM F. SP. LYCOPERSICI

M. Jangra[1], *S. Sharma*[1], *S. Sharma*[2]
[1]*Indian Institute of Technology-Delhi, Centre for Rural Development and Technology, New Delhi, India*
[2]*Indian Institute of Technology-Delhi, Department of Biochemical Engineering and Biotechnology, New Delhi, India*

Backgrounds

*Fusarium*wilt is one of the most important diseases of tomato. In India, it causes 45% of yield losses. Its current control includes use of chemical fungicides. These chemicals have harmful effects on the environment and human health. As an alternative different biocontrol agents, can be used which is *Bacillus* that is known to have antagonistic activity against various plant pathogens.

Objectives

The objective of the present work was to isolate and characterize *Bacillus* strains from tomato rhizosphere with antagonistic activity against *Fusarium oxysporum* f. sp. *lycopersici* for application as biopesticides.

Methods

A collection of 49 *Bacillus* isolates were obtained from the rhizosphere of the unhealthy tomato plant on the basis of morphology on Hichrome Bacillus agar. Dual plate assay was used to observe the efficacy of all the isolates against pathogen. Antifungal properties like production of biofilm, hydrolytic enzymes, ammonia and hydrogen cyanide were studied.

Conclusions

One isolate was selected on the basis of analysis of the antifungal compounds involved in their antagonistic activity. It exhibited deleterious effects like production of protease, ammonia and hydrogen cyanide. This isolate was capable of producing indole acetic acid (IAA), a plant growth promoting trait and possesses higher ability for biofilm formation (35%) in microtitre plate assay. The isolate was identified as *Bacillus cereus* based on the analysis of the 16S rRNA gene sequence. Since, *Bacillus* isolates exhibited several traits beneficial to the host; they may be used to develop new safer and effective formulations as an alternative to chemical fungicides.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

EVALUATION OF SUITABILITY AND SAFETY IN COMMERCIAL PROBIOTICS FOR ANIMAL FEEDING

S.E. Jeong[1], C. Byung Hee[1], K. Hye Rim[1], J. Che Ok[1]
[1]Chung-Ang University, Life Science, Seoul, Republic of Korea

Backgrounds

Because the wide use of antibiotics as animal feed additives leads to more concerns about widespread of antibiotic resistance genes, the use of antibiotics as growth promoters was prohibited in Korea. A variety of commercial probiotics using microorganisms have been developed as alternatives of antibiotics. However, product description about microbiological compositions is not often in accordance with their contents in products. In addition, pathogen contamination in commercial probiotics also have not been extensively investigated.

Objectives

The aim of this work is to verify the suitability and safety of commercial probiotics produced in Korea as animal feeding.

Methods

Bacterial 16S rRNA genes of fifty commercial products of twenty-six brands were amplified and sequenced using 454 high-throughput pyrosequencing and raw data generated were processed and classified using RDPipeline (http://pyro.cme.msu.edu). Potentially pathogenic bacterial sequences from the raw data were found by BLASTN searches using 16S rRNA gene sequences of pathogens that are toxic to human and livestock (chicken, cattle, and pig) derived from the PHI (Pathogen Host Interaction) database.

Conclusions

Bacterial community analysis indicated that bacterial compositions of some probiotic products were similar with labeled information; however, some differences were also observed in other products. Potentially pathogenic sequences classified as *Pseudomonas aeruginosa*, *Burkholderia cenocepacia*, and *Escherichia coli* at a 97% sequence similarity criterion were approximately 2% of the total sequencing reads. The *regA*, toxin A regulatory gene, of *P. aeruginosa* was detected from some commercial products by PCR. Thus, strict regulation and quality control in the production of probiotics as commercial products may be necessary.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

SCREENING AND IDENTIFICATION OF HIGHLY EFFICIENT NITROGEN FIXING BACTERIA FROM AGRICULTURAL LAND SOILS TO UTILIZE AS BIO-FERTILIZER

S.H. Jeong[1], J. Kim[1], S.S. Lee[1]
[1]Kyonggi University, Life science, Suwon, Republic of Korea

Backgrounds

Fertilization of agricultural area is required for improving of yield of the crop by using microbial nitrogen metabolism.

Objectives

This study is to screen and identify the highly efficient free-living nitrogen fixing bacteria *Cedecea* sp. MK7 from agricultural soils. Moreover, *Cedecea* sp. MK7 improves the growth and yield of the plant.

Methods

Soil sampling was performed from Mun-kyeong and Yeon-cheon, South Korea. Ashby's media were used for isolation of nitrogen fixing bacteria. Isolates were analyzed to confirm nitrogen fixation activity by acetylene reduction assay (ARA). Among the nitrogen fixation bacteria, high efficient bacteria *Cedecea* sp. MK7 applied to perennial ryegrass pots for evaluating the plant growth. For the control, only water was applied to the plant. After growing plant, dry weight of plant and length of shoot was determined between experimental group and control group. Dry weight of the experimental group was heavier three-fold in response to control pot experiment. The length of the stem was 1.4-fold longer than the control.

Conclusions

From acquisition results, we confirmed the effects of nitrogen fixation bacteria on plants. Furthermore, we will study auxin, siderophore producing ability and phosphate solubilizing activity of bacteria. Nitrogen fixation bacteria can contribute on the agricultural industry.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

IDENTITY OF MICROORGANISMS RESPONSIBLE FOR FOAMING IN ANAEROBIC DIGESTERS FOR BIOGAS PRODUCTION

C. Jiang[1], S.J. McIlroy[1], L. Hao[1], B. McIlroy[1], M. Nierychlo[1], P.H. Nielsen[1]
[1]Center for Microbial Communities, Department of Chemistry and Bioscience, Aalborg, Denmark

Backgrounds

Anaerobic digesters (ADs) are commonly implemented at wastewater treatment plants for the conversion of surplus sludge to biogas. Foaming is a major operational problem in these systems where hydrophobic microbial cells are thought to stabilize foams. It is still not clear which organisms are specifically responsible for such events. It may be bacteria coming with the surplus sludges, e.g. *Microthrix* or *Gordonia*, or some that actively grow in the ADs.

Objectives

The objective of this study was to identify putative foaming-forming microorganisms in ADs.

Methods

Amplicon sequencing targeting the 16S rRNA gene was applied for analyses of the microbial communities of full-scale AD plants with and without foaming and, where possible, compare the communities of the bulk sludge and the foaming layer. Fluorescence *in situ* hybridization (FISH) was applied to further investigate putative foam formers.

Conclusions

Identification of potential foam forming organisms based on surveys was difficult attributed to the complexity of these systems. A focus on foaming incidents in individual plants was more successful. During a foaming episode at one plant, the bacterial community structure showed substantial variation between the top foaming layer and digester sample. Members of the A6 phylotype (phylum Chloroflexi), a novel phylotype classified to the family Ruminococcaceae (Firmicutes), and vadinBC27 wastewater-sludge group (Bacteroidetes) displayed relatively higher abundances in top foaming layer, which was confirmed with FISH for the former two. Members of the A6 were abundant in other plants with foaming issues and may be key organisms responsible for foaming in Danish systems.

FEMS7-1479

A NOVEL ARSENATE RESPIRING BACTERIUM ALKALIPHILUS SP. IMB: ISOLATION, CHARACTERIZATION, AND FUNCTION

C. jing[1]
[1]*Research Center for Eco−Environmental Sciences- Chinese Academy of Sciences, State Key Laboratory of Environmental Chemistry and Ecotoxicology, Beijing, China*

Backgrounds

Arsenic (As) redox transformation mediated by As(V)-respiring microorganisms plays an important role in regulating As speciation and mobility in the environment. The importance of As(V)-respiring bacteria in As geochemical cycling in the Hetao Plain, a typical area with geogenic As in China, motivated our study.

Objectives

The objectives of this study are 1) to isolate and characterize an As(V)-respiring bacterium in the Hetao Plain, and 2) to explore the As(V) respiration mechanism and effect of the isolate.

Methods

The soil sample was collected in the Hetao Plain, China. Standard protocols were followed to isolate and characterize the As(V)-respiring bacterium including TEM and synchrotron-based STXM. Batch incubation and flow-through column experiments were used to explore the effect of the isolate on the As mobility.

Conclusions

A novel As(V)-respiring bacterium, *Alkaliphilus* sp. IMB, was isolated from soil in the Hetao Plain, China. Strain IMB is Gram-positive, spore-forming, and rod-shaped. High similarity of 16S rRNA gene sequence was found between IMB and *Alkaliphilus oremlandii* strain OhILAs, with DNA-DNA relatedness of 44.3%. The 16S rRNA gene sequence and DNA-DNA hybridization results showed that the isolate was a new strain of the genus *Alkaliphilus*. A partial *arrA* gene sequence was amplified. An assay for As(V) reductase activity and STXM results showed that strain IMB could reduce As(V) to As(III) by a respiratory reductase mostly located at the outside of the cell membrane. Our batch and column experiments highlighted the importance of IMH in liberating As from a As-laden industrial solid waste.

[3]Institute of Catalysis- Consejo Superior de Investigaciones Científicas CSIC, Biotecnología de Sistemas, Madrid, Spain
[4]Università degli Studi di Torino, Department of Agricultural- Forest and Food Sciences, Turin, Italy

Backgrounds

The HIV infection is characterized by an early depletion of the mucosal associated lymphocytes Th17 and a disruption of the mucosal integrity. The HIV-gut associated bacterial community is significantly different from the healthy subjects showing an altered structure with an increment of gram-negative bacteria and a dysbiotic metabolism. The changes into the microbiota composition are related with the HIV inflammation

Objectives

The aim of the study is to integrate different “omics” data, retrieved from a cohort of HIV+ infected subjects, to describe in a holistic manner the HIV-gut associated community applying a multivariate statistical analysis.

Methods

Clinical data as well as metagenomes, metatranscriptomes and metabolomes from fecal samples were retrieved from a cohort of 54 HIV+/Control subjects. Ecological networks were estimated by means of the “sparcc” software. Functional networks were estimated using the R package “KEGG graph. Finally a Bayesian network from all the “omic” data was created (R package bnlearn), using as seed the results retrieved form the generalized linear models (R package“glmnet”). All the plots and network statistics were calculated using the R package Igraph.

Conclusions

The Bayesian modeling showed that the disruption of the mucosal associated lymphocytes might lead to an establishment of a dysbiotic microbiota that is functionally adapted to oxidative stress. The decay of the expression of genes related to the butyrate production and the proliferation of gram-negative bacteria were associated to inflammation parameters. Finally, species and pathways that are statistically increased into the HIV+ bacterial communities resulted into important hubs that maintain the stability of the dysbiotic community.

METAGENOMICS REVEALS ANTHROPOGENIC IMPACT ON BACTERIAL DIVERSITY OF WESTERN BALKANS GLACIAL LAKES SEDIMENTS

M. Malešević[1], N. Mirković[1], J. Lozo[2], J. Begović[1], K. Novović[1], B. Filipić[3], G. Vukotić[2], M. Miljković[1], M. Kojić[1], B. Jovčić[2]
[1]Institute of Molecular Genetics and Genetic Engineering, Laboratory for Molecular Microbiology, Belgrade, Serbia
[2]Faculty of Biology - University of Belgrade, Chair of Biochemistry and Molecular Biology, Belgrade, Serbia
[3]Faculty of Pharmacy, Department of Microbiology and Immunology, Belgrade, Serbia

Backgrounds

Potential vanishing of Balkans glaciers due to climate change could endanger existing glacial lakes, which points the need for conservation and biodiversity studies of this ecological niche. It is well recognized that unexplored ecological niches and their microbial communities metabolic potential could be a gold mine of secondary metabolites with importance for biotechnology, medicine and pharmacy.

Objectives

Our primary goal was to assess the biodiversity of bacterial communities of sediments from selected Western Balkans glacial lakes and to reveal the anthropogenic impact on those communities.

Methods

Sediment samples were collected from three glacial lakes the Plav lake (located in town of Plav, high anthropogenic activity), the Black lake (recreational site, medium anthropogenic activity) and the Donje Bare lake (remote lake with minimal anthropogenic activity). Chemical composition of sediments was determined by standard chemical procedures. DNA extraction from each sediment sample was performed using a MoBio UltraCleanTMSoil DNA isolation kit. 16S rDNA metagenome libraries were generated with the 454 Life Sciences GS-FLX Titanium platform.

Conclusions

Organic compounds that are product of anthropogenic activities were most abundant in Plav lake. A number of bacteria from families and genera that could be coupled to anthropogenic impact were also found only in the sediment from the Plav lake, or had the greatest representation comparing to other sediments. Prevalence of bacteria that are typical for low human impacted area was the highest in Donje Bare lake. Anthropogenic impact was shown to be important for shaping the sediment communities, beside the biological and biogeochemical factors.

EVOLUTION AND STABILITY OF COOPERATION IN GROWING POPULATIONS OF PSEUDOMONAS PUTIDA KT2440

H. Jung[1], B. Felix[1], W. Karl[2], L. Matthias[2], F. Erwin[2]
[1]Ludwig-Maximilians-University, Microbiology, Martinsried, Germany
[2]Ludwig-Maximilians-University, Statistical and Biological Physics, Munich, Germany

Backgrounds

The development of bacterial populations crucially depends on social interactions between cells such as competition and cooperation (West et al. (2007) *Annu. Rev. Ecol. Evol. Syst.* **38**, 53). For example, production of a public good by a cooperator can support growth of a population. However, non-producing individuals that benefit from the public good without paying the costs for its production have a selection advantage over the cooperator. As a consequence, the cooperator frequency may decline, and the entire population may destabilize.

Objectives

We set out to predict and experimentally test conditions leading to an increase in cooperator frequency in bacterial metapopulations growing in liquid culture.

Methods

Experiments were performed with two strains derived from *Pseudomonas putida* KT2440: a constitutive producer of the iron-chelating siderophore pyoverdine and a corresponding non-producer. The rate and the metabolic costs of pyoverdine production as well as the benefit of pyoverdine for growth under iron limiting conditions were experimentally determined. The parameters were used to formulate a mathematical model that predicts the growth dynamics of metapopulations consisting of groups with a random distribution of initial producer frequencies.

Conclusions

Both mathematical model and experiment agree well in demonstrating a transient increase of the global producer frequency due to competing inter- and intra-group processes during growth. Our results show that cooperation can evolve in a native microbial system due to demographic noise across a metapopulation.

ISOLATION AND CHARACTERIZATION OF CONFLUENTIMICROBIUM NAPHTHALENIVORANS NS6T, A NAPHTHALENE-DEGRADING BACTERIUM

H.I. Jeong[1], H.S. Jung[1], K.H. Kim[1], S.E. Jeong[1], C.O. Jeon[1]
[1]Chung-Ang University, lifescience, Seoul, Republic of Korea

Backgrounds

The investigation of bacteria responsible for biodegradation of polycyclic aromatic hydrocarbons (PAH) is of great interest in a sea-tidal flat contaminated with crude oil.

Objectives

The purpose of this study was to isolate and characterize bacteria responsible for PAH degradation from a contaminated tidal flat.

Methods

A slurry type enrichment system with naphthalene as a sole carbon and energy source was established for the isolation of PAH-degrading bacteria.

Conclusions

A new naphthalene-degrading bacterium, designated *C. naphthalenivorans* NS6^T, was isolated from sea-tidal flat sediment contaminated with crude oil. Degradation tests revealed that strain NS6^T had a great degradation ability for naphthalene in tidal flat sediment. In addition, the degradation tests using ^{12}C- and ^{13}C-naphthalene showed that salicylate, gentisate, and $^{13}CO_2$ were detected as metabolites or products of strain NS6^T, suggesting that strain NS6^T mineralizes naphthalene to $^{13}CO_2$ completely via the gentisate pathway. The genome of strain NS6 was completely sequenced for the better understanding of its naphthalene biodegradation properties, indicating that the genome consisted of a circular chromosome and three plasmids. We found that a plasmid, pNS6002, contains a gene cluster without salicylate 5-hydroxylase probably involved in naphthalene degradation although strain NS6^T metabolizes naphthalene via the gentisate pathway, suggesting that strain NS6^T may convert salicylate to gentisate via a different enzyme system. Instead of salicylate 5-hydroxylase, the plasmid harbors three genes annotated as cytochrome P450, hydroxymethylglutaryl-CoA lyase, and formyl-CoA trasferase, probably converting salicylate to gentisate. In this study, we will characterize the three genes and discuss their functions in naphthalene biodegradation of strain NS6^T.

PHOTOTROPHIC BIOFILMS IN CUEVA DEL TESORO, RINCON DE LA VICTORIA, MALAGA, SPAIN

V. JURADO[1], H.M. MARIONA[2], H. BERNARDO[1], S.J. CESAREO[1]
[1]INSTITUTO DE RECURSOS NATURALES Y AGROBIOLOGÍA DE SEVILLA- CSIC, Agroquímica- Microbiología Ambiental y Conservación de Suelos, SEVILLA, Spain
[2]UNIVERSIDAD DE BARCELONA, FACULTAD DE FARMACIA, BARCELONA, Spain

Backgrounds

In the last few years Cueva del Tesoro has been investigated regarding the need to control phototrophic biofilms colonizing cave speleothems.

Objectives

Cleaning of caves should be preceded by an inventory of species and testing of treatment protocols due to the fact that biocides have important negative effects in some caves.

The green biofilms in this cave were uncommon and presented some characteristics worthy of study. These communities were triggered by the artificial lighting which is located in selected places along the visitor´s trail. The assemblages were mainly composed of Cyanobacteria (*Friedmannia* sp., *Nostoc* sp., *Phormidium* sp., *Gleocapsa*-like members, etc.) Chlorophyta (*Friedmannia* sp., *Chlorella* sp., *Choricystis* sp.), Rhodophyta (*Cyanidium* sp.), and Bacillariophyta (*Diadesmis contenta*). Some locations develop abundant populations of the bryophyte *Eucladium verticillatum*.

Moreover, three novel bacterial species are being studied: *Acinetobacter thesauricus*, *Bacillus thesauricus* and *Paracoccus speluncae*; and two new fungal species were described: *Aspergillus thesauricus* and *Aspergillus baeticus*

Methods

We tested three cleaning methods: i) Mechanical cleaning with liquid nitrogen, ii) Cleaning with sodium hypochlorite and iii) Cleaning with hydrogen peroxide. The most effective method was hydrogen peroxide which was further used by the restoration company carrying out the works. In addition, a remodelling of the lighting system and installation of new LED lamps in more appropriate places were suggested.

Conclusions

Cueva del Tesoro revealed to harbour a rich biodiversity which suggests that in addition to cleaning and control of the biofilms, some actions are needed to preserve this cave and its microbial diversity.

TOWARDS DEFINING ESSENTIAL METABOLIC PATHWAYS AND REGULATORY FACTORS INVOLVED IN VIBRIO HARVEYI ADAPTATION IN MARINE ENVIRONMENTS

V. Kaberdin[1,2,3], *I. Montánchez*[1], *A. Hernández Plágaro*[1], *C. Parada*[1], *M. Orruño*[1,3], *I. Arana*[1,3]
[1]*Universidad del País Vasco UPV/EHU, Immunology- Microbiology and Parasitology, Leioa, Spain*
[2]*IKERBASQUE, Basque Foundation for Science, Bilbao, Spain*
[3]*PiE-UPV/EHU, Research Centre for Experimental Marine Biology and Biotechnology, Plenzia, Spain*

Backgrounds

The genus *Vibrio* encompasses a large group of bacteria ubiquitously present in aquatic ecosystems. Previous work has shown that *Vibrio* species possess a high capacity to survive under severe stress conditions including starvation, drastic temperature shifts and solar radiation.

Objectives

Vibrio harveyi was used as a model organism to study the temperature-dependent adaptation of this marine bacterium to starvation under conditions mimicking its natural environments.

Methods

Advanced microscopy along with cell plating techniques and highthroughput gene expression analysis were employed to monitor viability, physiological state as well as morphological and gene expression changes taking place during *V. harveyi* persistence in seawater microcosms.

Conclusions

These experiments revealed that, besides a gradual decrease in size and morphological changes, prolong (> 3-6 days) incubation in seawater at 20-30^{o}C led to a profound decrease in gene expression affecting the central carbon metabolism, major biosynthetic pathways and energy production. The above changes were accompanied by a concomitant increase in expression of genes closely involved in lipid degradation, recycling of amino acids and ancillary mechanisms important for sustaining iron homeostasis and cell resistance to the toxic effect of reactive oxygen species. Furthermore, RNA-seq and microarray data also suggested that some of the adaptation steps apparently involved small regulatory RNAs (e.g. GcvB) known for their essential roles in bacterial responses to stress. Based on the experimental data obtained, we defined the putative mechanisms and major factors likely contributing to the main physiological, phenotypical and gene expression changes that occur during *V. harveyi* adaptation in natural aquatic systems.

THE EFFECTS OF INSULIN AND GLUCOSE ON EXPRESSION OF GENES IN E. COLI MAR OPERON

D. Gumus[1], F. Kalayci[1], E. Yoruk[2], G. Uz[2], A. Bayraktar[2], P. Koseoglu[2], Y. Ofluoglu[2], B. Daylan[2], M. Ang Kucuker[1]
[1]Istanbul Yeni Yuzyil University Medical Faculty, Medical Microbiology, Istanbul, Turkey
[2]Istanbul Yeni Yuzyil University- Faculty of Arts and Sciences, Molecular Biology and Genetics, Istanbul, Turkey

Backgrounds

Microbes and their host environment is always linked dynamically to each other. Host environmental factors are known to modulate virulence factors, antibiotic resistance and growth rate of commensal bacteria.

Objectives

In this study we aimed to investigate the effects of insulin and glucose, as environmental factors, in host on expression of *acrA, acrB, marA, marR, ompF* and *tolC* genes in mar operon in a standard *E. coli*.

Methods

The standard *E. coli* SPC105 strain was cultured in tryptic soya broth (TSB) with or without insulin (20µIU and 200µIU) and/ or glucose (0.1%). Total RNA isolations were performed after 24 hours incubation at 37^0C. Gene expression levels were determined by quantitative PCR. The results were evaluated by relative quantitation method to compare the gene expression levels with 16S rRNA gene expression level. Tukey post hoc-test was used for statistical analysis. Each experiment was replicated at least thrice.

Conclusions

Expression of *acrA* gene was shown to be decreased in the presence of 200µIU insulin. Expression of *marR* gene decreased in 200µIU insulin, 0.1 % glucose+200µIU insulin and 0.1% glucose added TSB. The decrease in *acrA* and *marR were found to be statistically significant.* On the other hand there were no statistically significant difference on expression levels of *acrB, marA, tolC* and *ompF* genes between control medium and insulin or glucose added TSB. In qPCR analysis, melting scores were ranged from 92% to 98%.

It can be suggested that host factors which put together the environment of bacteria in a host may influence the gene expressions associated with antibiotic susceptibilities.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ARSENIC BIOREMEDIATION FROM WATER BY MULTI-METAL RESISTANT PAENIBACILLLUS JAMILAE ISOLATED FROM URANIUM RICH SUBSURFACE SOIL

D. Kalita[1], S.R. Joshi[1]
[1]North Eastern Hill University, Department Of Biotechnology And Bioinformatics, Shillong, India

Backgrounds

Arsenic contamination is a major health problem of northeast India. The Bengal delta plain consisting of the Ganga–Padma–Meghna–Brahmaputra river basin covering West Bengal, North-east of India and Bangladesh is reported as a highly arsenic-affected alluvial basin in the world with 112 to 657 µg/L in groundwater. Approximately 6.3% drinking water samples had arsenic concentration above the WHO recommended permissible limit of 50µg/L.

Objectives

The current investigation was undertaken to screen the microbial adherence, structure, composition and hydrophilic ligands of exopolysaccharide of Arsenic resistant *Paenibacillus jamilae* and their application to bioremediation.

Methods

A metallophilic bacterium, *Paenibacillus jamilae* isolated from the subsurface soil of Domiasiat and characterized by morphological, biochemical and molecular approaches. Was evaluated for arsenic resistance for its use in bioremediation purposes. The exopolysaccharide of the bacterium was tested for various microbial adherence properties along with the sugar and ligands characterization.

Conclusions

The bacterium showed strong and positive affinity towards the adherence property in the PAT and SAA test. The bacterium was found hydrophilic in nature with the index of 18.25 and 24.01 in adherence test and contact angle measurement respectively. The GC-MS and FTIR chromatogram showed presence of sugar molecules and hydrophilic functional groups, having capability to bind metals insurface.The structure and composition of the exopolysaccharide was inferred by SEM images.In batch culture experiment, *Paenibacillus jamilae* removed87% of arsenic from the synthetic Bangladesh groundwater.

The properties of the bacterium,*Paenibacillus jamilae* can be exploited for bioprospecting for bioremediation of arsenic and other metals from wastewater and groundwater.

BACTERIAL COMMUNITY STRUCTURE OF THE PACIFIC OCEAN ALONG A TRANSECT FROM ALASKA TO THE ANTARCTIC PENINSULA VIA THE KOREAN PENINSULA

I. Kang[1], *S.J. Yang*[2], *J.C. Cho*[1]
[1]*Inha University, Dept. of Biological Sciences, Incheon, Republic of Korea*
[2]*ChunLab Inc., Seoul, Republic of Korea*

Backgrounds

Bacterial assemblages play crucial roles in biogeochemical cycles in marine environments.

Objectives

In this study, bacterial community structure of the Pacific Ocean was analyzed to better understand the influence of environmental parameters on the composition of marine bacterial assemblages.

Methods

A total of 80 surface seawater samples were collected onboard ARAON, the ice-breaking research vessel. Thirty samples were obtained during a cruise from the Korean Peninsula to Alaska, USA. Another 50 samples were collected during a subsequent cruise from the Korean Peninsula to the Antarctic Peninsula. After removing large-sized particles and organisms, free-living bacteria of water samples were collected onto 0.2-μm pore-sized membrane filters, which were used for DNA extraction. Bacterial community structure was analyzed by pyrosequencing of 16S rRNA gene sequences amplified from extracted DNA samples.

Conclusions

The results showed that bacterial assemblages of surface water of the Pacific Ocean were dominated by *Alphaproteobacteria*, *Gammaproteobacteria*, *Bacteroidetes*, and *Cyanobacteria*. The SAR11 and SAR86 clades were prevalent in nearly all samples. The genus *Prochlorococcus* was abundant in oligotrophic areas of low-latitude regions but nearly undetectable in high-latitude regions. The Arctic96BD-19 (ZD0405) clade of the *Gammaproteobacteria*, NS groups of *Bacteroidetes,* and the marine *Roseobacter* clade of the *Alphaproteobacteria* were more abundant in high latitude regions. Ordination analyses based on beta-diversity indices and environmental parameters showed that the community structure of free-living bacteria of the Pacific Ocean changed according to oceanic provinces and was largely influenced by temperature, chlorophyll concentration, and salinity.

THE METRO SYSTEM MAY MODULATE THE SKIN MICROBIOME AND RESISTOME BY ITS ENVIRONMENTAL EXPOSURES AND INNER- AND INTERCITY TRAFFIC FLOWS

K. Kang[1,2], J. Li[1,2], G. Panagiotou[1,2]
[1]Leibniz Institute for Natural Product Research and Infection Biology - Hans-Knöl, Systems Biology and Bioinformatics, Jena, Germany
[2]The University of Hong Kong, The School of Biological Sciences, Hong Kong, Hong Kong S.A.R.

Backgrounds

Skin functions as the primary interface between the human body and the external environment, therefore great attention is given to the disinfection of high-density urban environments to limit the spread of pathogens. Yet, we have little understanding of how the built microbiome varies within urban environments and what factors drive the diversity and risk of pathogenicity therein.

Objectives

Hence, we established a metagenomic study regarding human interactions with public transit systems, and built a dynamic and global view of the microbial community and its potential health risks shaped by the traffic.

Methods

We used shotgun metagenomic sequencing to profile the palm microbiome after contact with handrails within the Hong Kong Mass Transit Railway (MTR) system. Our sampling has covered different times (AM vs PM commute), over the course of 3 days and targeted distinct lines (8) which serve different urban centers in the city.

Conclusions

Intraday sampling time was identified as the primary determinant of the variation and recurrence of the community composition, whereas human-associated species and clinically important antibiotic resistance genes (ARGs) were captured as PM signatures. Line-specific signatures were notably correlated with line-specific environmental exposures and civic characters, and losing their discriminatory power over time in the operating hours. For instance, high uniqueness was observed in the most topologically isolated line, which runs by a polluted river. The aquatic species and indicator organisms for sewage could also be identified as signature species of this line, in AM communities in particular. The only cross-boundary line appeared as an outlier in most analyses including the community diversity and dissimilarity. This line had the 2nd highest abundance of clinically important ARGs and community-wide dissemination potential, and the greatest intraday increments in the abundance of ARGs and clinically important ARGs (33.5% and 24.1%), suggesting a potential cross-boundary ARG transmission, especially tetracycline resistance.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ISOLATION OF UNCULTURED ANAEROBIC BACTERIAL SPECIES FROM FECES OF KOREAN ADULTS

W. Kang[1], N.R. Shin[1], D.W. Hyun[1], P.S. Kim[1], H.S. Kim[1], J.Y. Lee[1], E.J. Tak[1], H. Sung[1], J.W. Bae[1]
[1]KyungHee University,
Department of Life and Nanopharmaceutical Sciences and Department of Biology, Seoul, Republic of Korea

Backgrounds

Although studies on human gut microbial community based on next-generation sequencing techniques have been actively conducted recently, most of bacterial members in the human gut microbiota remain unculturable and have not been given a valid name. Expanding the availability of the human gut bacterial species by isolating and preserving will greatly contribute to improvement of insight into host-microbial interaction and development of therapeutic strategy focusing on the indigenous symbiont.

Objectives

The objective of this study was cultivation and characterization of taxonomic position of bacterial species resident in the human intestinal tract that have never been isolated.

Methods

Fecal samples from six Korean adults were homogenized and diluted in phosphate-buffered saline. The diluted solutions were spread onto Gifu-Anaerobic Medium supplemented with vitamin B solution, Trypticase-Soy Yeast-extract Agar and Brain-Heart Infusion agar media and were incubated for 3 days at 37 °C in an anaerobic chamber.

Conclusions

Five strains (2 strains of *Parabacteroides* sp., a strain of *Bacteroides* sp., *Anaerostipes* sp. and *Blautia* sp.) of novel bacterial species candidates were identified from the pure cultures by 16S rRNA gene sequence.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

IN VITRO ACTIVITIES OF COLISTIN IN COMBINATION WITH DORIPENEM, DOXYCYCLINE AND RIFAMPIN AGAINST MULTI-DRUG RESISTANT ISOLATES OF PSEUDOMONAS AERUGINOSA AND ACINETOBACTER BAUMANII

E. Karaaslan[1], S. Dosler[2]
[1]Bezmialem University- Faculty of Medicine, Medical Microbiology, Istanbul, Turkey
[2]Istanbul University- Faculty of Pharmacy, Pharmaceutical Mirobiology, Istanbul, Turkey

Backgrounds

Pseudomonas aeruginosa and *Acinetobacter baumannii* are nonfermentative Gram negative bacilli which are two of the leading causes of life threatening nosocomial infections and also public health threat. Besides causing infections with high mortality and morbidity rates, these two organisms are intrinsically resistant to most antibiotics and also excellent at developing new resistance mechanisms. During these times of antibiotics pipeline, developing combination therapies against these bacteria have become crucial.

Objectives

To test the effectiveness of combination therapies against clinically isolated and multi drug resistant strains of *P. aeruginosa* and *A.baumannii*.

Methods

Total 51 clinical isolates (23 *P. aeruginosa* and 28 *A.baumannii*) initially screened for the assessment of their resistance against colistin, doripenem, doxycycline, gentamicin, ciprofloxacin, ceftazidime, rifampin with broth microdilution assay. According to their resistance profiles 20 isolates (10 *P. aeruginosa* and 10 *A.baumannii*) were selected and colistin-doxycyclilne, colistin-doripenem and colistin-rifampin combinations were tested with checkerboard method. Also on select isolates, time kill curve experiments were carried out.

Conclusions

According to MIC values, all isolates were resistant to almost all antibiotics except for colistin. In combination studies, synergistic effects were mostly seen with colistin-doxycycline against *P. aeruginosa* (90%) and *A. baumonii* (60%), followed by the colistin-doripenem combinations (30%). In TKC studies, synergism was observed with almost all expected combinations especially with colistin-doxycycline and colistin-doripenem, even at 1/4xMIC values were used ın combinations.

FEMS7-1100
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

EVALUATING COMPOUNDS FOR ABILITY TO REDUCE UREOLYTIC ACTIVITY IN ANIMAL MANURE SLURRY

H. Karring[1], J.J. Sigurdarson Gade[1], S. Svane[1]
[1]University of Southern Denmark,
Department of Chemical Engineering- Biotechnology and Environmental Technology, Odense, Denmark

Backgrounds

Utilizing pig manure slurry as fertilizer in agriculture presents the challenge of controlling the microbiologically driven conversion of urine-derived urea to ammonia (NH_3) and the following volatilization of NH_3. Fertilizer nitrogen lost as NH_3 causes significant environmental and economic problems e.g. decreasing fertilizer value and deposition of excess nitrogen in the environment.

Objectives

The objectives of this study are to develop a medium-throughput bacterial and enzyme assay for screening compounds for anti-ureolytic activity and identify a method for reducing urea hydrolysis in manure slurry.

Methods

The assay relies on the absorbance change of a pH-indicator as a result of the change in pH caused by ureolytic NH_3 production. The absorbance was recorded with a plate reader and used to evaluate the ability of 60 compounds to reduce urea hydrolysis. The chemicals were screened at different concentrations for ability to reduce the ureolytic activity of both *K. pneumonia* and purified jack bean urease. Some of the compounds which displayed anti-ureolytic effect were further tested on pig manure slurry and the ureolytic activity quantified by the Kjeldahl method.

Conclusions

Using 96-well plates for the assay allows for the simultaneous triplicate test of 8 compounds at three different concentrations. A third of the tested compounds were found to have an effect against ureolytic bacteria while app. 20% worked against jack bean urease. A few compounds investigated in this assay showed reduction of ureolytic activity in pig manure slurry.

FEMS7-2458
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

EFFECT OF DIFFERENT HONEY TYPES AND THEIR COMBINATIONS WITH ESSENTIAL OILS ON BACTERIAL BIOFILM FORMATION AND QUORUM SENSING

L.A. Zsadon[1], E.B. Kerekes[2], C. Vágvölgyi[2], J. Krisch[1]
[1]University of Szeged- Faculty of Engineering, Institute of Food Engineering, Szeged, Hungary
[2]University of Szeged- Faculty of Science and Informatics, Department of Microbiology, Szeged, Hungary

Backgrounds

Biofilm formation represents a serious problem by lowering the shelf-life of foods thereby affecting food quality and safety. Quorum sensing (QS) is known to be crucial for biofilm formation. By targeting QS, the growth of bacteria is not influenced which would lead to selection pressure and to development of resistance.

Objectives

The aim of the present study was to test the effect of different honey types and honey-essential oil combinations on the QS of two pigmented bacteria.

Methods

Honey from acacia, linden, sunflower and silk grass were tested in different concentrations for their anti-QS and anti-biofilm forming effect on *Chromobacterium violaceum* 85 WT and *Serratia marcescens*. Honey solutions were supplemented with essential oils (EOs) of marjoram and clary sage at different concentrations and their effect was also evaluated. Pigment production of these bacteria is under QS regulation therefore, violacein and prodigiozin were extracted and quantified. Besides pigment production, changes in the culture cell numbers were also determined. Biofilm formation was investigated by crystal violet assay.

Conclusions

Results show that with low concentrations of honey solutions the QS could be inhibited without any change in the colony cell number. Also the inhibitions of QS lead to the disruption of biofilm formation. In general, addition of EOs enhanced the effect of honey solutions from which sunflower honey proved to be the most efficient in both tests. In conclusion, each tested honey proved to be good anti-QS and anti-biofilm forming agent which effect could be synergistically increased with the addition of the tested EOs.

THE ROLE OF MINERAL SCAFFOLDS IN BIOFILM DEVELOPMENT AND ANTIBIOTIC RESISTANCE

A. Keren-Paz[1], V. Brumfeld[2], Y. Oppenheimer-Shaanan[1], I. Kolodkin-Gal[1]
[1]Weizmann Institute of Science, MOlecular Genetics, Rehovot, Israel
[2]Weizmann Institute of Science, Department of Chemical Research Support, Rehovot, Israel

Backgrounds

Bacterial multicellular communities, called biofilms, have tremendous impact on human life and health. In biofilm, the bacteria are protected from environmental insults and assaults, and their attachment to different hosts is improved. Moreover, biofilm can be up to 1,000 times more resistant to antibiotics than planktonic (free-living) bacteria.
The molecular mechanisms supporting biofilm resistance are poorly understood. Organic extracellular matrix production, the hallmark of biofilm formation, has been extensively studied, and its role in cell–cell and cell–substrate adhesion is well established. However, the possible existence of **mineral scaffolds** providing rigidity to bacterial biofilms has been largely neglected.

Objectives

We recently discovered that controlled deposition of a calcium carbonate scaffolds can structurally support morphogenesis of bacterial colonies in both Gram-Negative and Gram-positive bacteria. In this study, we characterize the contribution of those calcite scaffolds
to biofilm development and antibiotic resistance.

Methods

To study this novel aspect of biofilm development, we propose a new method to analyze spatio-temporal accumulation of minerals within biofilms using MicroCT X-Ray.

Conclusions

We propose a central role of biomineralization molecular pathways in biofilm formation, and show that genetically manipulating or chemically inhibiting enzymes catalyzing crucial steps in biomineralization has a dramatic effect on biofilms of different bacterial species. Furthermore, we examine the contribution of enzymes involved in biomineralization to antibiotic resistance of pathogenic and beneficial biofilms, and demonstrate that chemical interference with those proteins can overcome antibiotic resistance within biofilms.

Our overall research sheds light on a novel aspect of biofilm development and suggests novel targets for anti-biofilm drugs.

MICROBIOTA DIVERSITY AND JEJUNUM MORPHOLOGY IS NOT AFFECTED BY HIGH-DOSE VOLATILE OIL COMPOUNDS

J.C. Kesselring[1], V.A. Sattler[2], I. Schantl[3], N. Reisinger[4], K. Teichmann[4]
[1]Biomin Holding GmbH, FD G2P, Getzersdorf, Austria
[2]BIOMIN Research Center, GutOmics, Tulln, Austria
[3]BIOMIN Research Center, FD G2P, Tulln, Austria
[4]BIOMIN Research Center, Cell Biology, Tulln, Austria

Backgrounds

Organic chemical compounds from plants are gaining popularity as growth promoting agents in animal husbandry. Among the suggested modes of action, antimicrobial effects were described.

Objectives

A feed additive containing the volatile oil compounds L-menthol, D-carvone and carvacrol was fed in high dose (up to 10x recommended dose) to weaned piglets and broilers to assess potential effects on the microbiota diversity and gut morphology.

Methods

Jejunum and colon digesta as well as mid jejunum were sampled for microbiota assessment and for the appraisal of gut morphology. Total genomic DNA was extracted with the QIAamp DNA Stool Mini Kit (Qiagen, Germany) after lysozyme pretreatment and bead-beating. The V3 region of the 16S rRNA gene was amplified and analyzed by DGGE. For evaluation of the gut morphology, paraffin embedded tissue (mid-jejunum) was stained with the Periodic Schiff Assay staining method and evaluated under a light microscope.

Conclusions

On average broiler jejunum samples had 26 ± 4.1 dominant bands and piglet colon samples had 35 ± 3.6 dominant bands in their DGGE profiles. Cluster analysis showed that the phytogenic additive did not have any influence on the bacterial diversity of dominant members of the broiler jejunum microbiota or the piglet colon microbiota. There was no significant effect of any treatment on villus length, crypt depth, V:C ratio and total goblet cell number per villus compared to the untreated control.

The phytogenic feed additive did not negatively affect any of the tested parameters, confirming its safety for the target species even in high dose.

FEMS7-0752
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

DIVERSITY OF ANTIBIOTIC RESISTANCE GENES IN GRAM-NEGATIVE BACTERIA FROM AQUATIC ENVIRONMENTS IMPACTED BY HOSPITAL AND HOUSEHOLD WASTEWATER

F.A. Khan[1], B. Söderquist[2], J. Jass[1]
[1]The Life Science Center - Biology, School of Science and Technology- Örebro University, Örebro, Sweden
[2]School of Medical Sciences, Faculty of Medicine and Health- Örebro University, Örebro, Sweden

Backgrounds

Enterobacteriaceae and non-fermentative Gram-negative rods such as *Acinetobacter* and *Pseudomonas* species are one of the major causes of nosocomial infections. Most clinically significant Gram-negative bacteria harbor plasmids with antibiotic resistance genes (ARGs) that are mobile due to horizontal gene transfer. There is growing evidence that ARGs are ubiquitous in natural aquatic environments.

Objectives

The main objective was to evaluate the repertoire of ARGs in a Gram-negative bacterial population from a hospital, wastewater treatment plant (WWTP), recipient river, and lake in Sweden, and to identify the possible route of dissemination into the environment.

Methods

Selective coliform agar was used to grow and enrich for Gram-negative bacteria from the water samples. High-throughput quantitative PCR was performed to compare the diversity of ARGs in Gram-negative bacteria from river and lake impacted by household and hospital wastewater.

Conclusions

The genes conferring resistance to aminoglycosides, fluoroquinolones and tetracycline were ubiquitous in all sites tested, while macrolide and multidrug efflux pumps were not found upstream or in the recipient lake. Class A and C β-lactamase genes were present in all the sites, however, metallo-β-lactamase genes (*bla*$_{IMP}$ and *bla*$_{VIM}$) were present in the hospital wastewater but not in the WWTP. Interestingly, *bla*$_{VIM-1}$ was found in the river receiving wastewater from WWTP. Additionally, the Class D β-lactamase genes were found at all sites except upstream in the river suggesting they originate from the city wastewater. Further analysis of ARGs in the community is needed to assess route and mobility of ARGs in the environment.

A UNIQUE APPLICATION OF MICROBIAL PEROXIDASES FOR RECALCITRANT PLASTIC WASTE DEGRADATION

N. Khatoon[1,2], *I. Ali*[3]
[1]*Duke university USA, department of environmental engineering, durham, Pakistan*
[2]*Quaid i azam university, department of Microbiology, Islamabad, Pakistan*
[3]*quaid i azam university, microbiology, islamabad, Pakistan*

Backgrounds

Polymeric compounds become challenging due to their persistent nature when released into the environment as a waste. Oxidative enzymes play significant role in biodegradation of recalcitrant materials. Fungi are important among microorganisms for production of extracellular enzymes

Objectives

Bodegradation of the recalcitrant polymer by catalytic oxidation through microbial peroxidase is novel approach for clean aquatic environment

Methods

Maximum enzyme production from indigenous isolates was observed 8.76µl/100ml by using vertyl alcohol as inducer. Statistical analysis (ANOVA) indicate the significance of enzyme production model and components on the basis of F value and P value <0.05 for rate of peroxidase activity. A band of 46 KDa was observed for lignin peroxidase. The Fourier transform infrared (FTIR) spectroscopy of enzyme treated plastic films revealed the structural changes as compared to control (without enzyme treatment. The significant change was observed in peak at wavelength 7866.09 cm^{-1} which attributes to C-H bonding. Application of enzyme on different substrate (polystyrene, polypropylene, polyvinyl chloride) indicates the different level of degradation. The structural changes on the on the surface and crakes and hole clearly showed degradation occur.

Conclusions

Peroxidase enzymes have the potential for biodegradability of recalcitrant plastic waste and can be used for plastic waste treatment at large scale.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ANALYSIS OF MICROBIOTA ON OCTOPUS VARIABILIS IN SOUTH KOREA

B.S. Kim[1], J.J. Lee[1], T.Y. Kim[1]
[1]Hallym University, Life Science, Chuncheon, Republic of Korea

Backgrounds

Octopus variabilis is one of popular seafood as a healthy food in South Korea. However, it can cause food poisoning when ingested as raw material.

Objectives

Analysis of microbiota on *O. variabilis* can improve the understanding of food poisoning risk and the management of product.

Methods

A total of 38 *Octopus variabilis* samples were collected from four sites in November and August. The microbiota on *O. variabilis* was analyzed by the Illumina Miseq based on 16S rRNA gene, and the quantification of bacteria was performed by real-time PCR. In addition, we analyzed the difference of microbiome between artificial infected model by *Vibrio vulnificus* and non-infected model.

Conclusions

The diversity of microbiota was higher in summer samples than that in winter samples. Bacteroidetes was predominant phylum in summer samples, whereas Proteobacteria was predominant in winter samples. *Coenonia* and *Mycoplasma* were dominant genera in summer samples, whereas *Burkholderia* and *Psychrobacter* were dominant genera in winter. The difference of microbiota among sampling regions was also detected. In infected experiment, the proportion of *V. vulnificus* was increased only at room temperature. However, the proportion of *V. vulnificus* was similar along storage time at 4℃, and the functional genes of microbiome were shifted similar between infected and non-infected model along time. These results indicate that the indigenous microbiota on *O. variabilis* can protect the colonization of *V. vulnificus* during storage at 4℃. Results in this study will help to understand the food poisoning caused by octopus ingestion and the management of product.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

GENOME SEQUENCING AND COMPARATIVE GENOMICS OF THE ORGANOPHOSPHORUS PESTICIDES-DEGRADING BACTERIUM, SPHINGOBIUM SP. EP60837

B.Y. Kim[1], *C.M. Lee*[2], *S. Yang*[1]
[1]*ChunLab- Inc., Bioinformatic institute, Seoul, Republic of Korea*
[2]*National Institute of Agricultural Sciences- RDA, Metabolic Engineering Division, Jeonju, Republic of Korea*

Backgrounds

Organophosphorus pesticides, which are highly poisonous and cause serious concerns over food safety and environmental pollution, are still widely used for pest insect control. Environment-friendly bioremediation is increasingly important in agriculture.

Objectives

The bacterium, designated EP60837, which showed the high activity of degradation of organophosphorus pesticides, including ethoprophos, cadusafos and chlorpyrifos, was isolated from agricultural soil in Korea,The bacterium, designated EP60837, which showed the high activity of degradation of organophosphorus pesticides, including ethoprophos, cadusafos and chlorpyrifos, was isolated from agricultural soil in Korea,

Methods

Here, we performed complete genome sequencing using PacBio RSII system and bioinformatic analysis. Also comparative genome analysis of *Sphingobium* sp. EP60837 with closely related strains was done.

Conclusions

The genome of strain EP60837 consists of two chromosome and two plasmids. An array of genes related to the degradation of pesticides was identified by whole genome analysis. The genome sequence of the strain EP60837 provides basic information for wider exploitation of bioremediation of organophophorus pesticides contaminated soil with soil microorganism

TRANSCRIPTOME ANALYSIS OF HALOARCHAEOBIUS SP. HME9146 IN RESPONSE TO SALT AND TEMPERATURE STRESS

H. Kim[1], H. Kang[1], I. Cha[1], K. Joh[1]
[1]Hankuk University of Foreign Studies, Department of Bioscience and Biotechnology, Yongin, Republic of Korea

Backgrounds

Solar salterns are artificial ponds for the production of salt from seawater and can be found halophilic archaea. The haloarchaea are dominant and survive from high salinity and temperature by intense sunlight in solar salterns.

Objectives

In this research, we performed RNA sequencing (RNA-seq) to investigate the transcriptome of a halophilic archaeal strain *Haloarchaeobius* sp. HME9146 in response to salt and temperature stress.

Methods

The strain *Haloarchaeobius* sp. HME9146 was isolated from a solar saltern in Republic of Korea. The RNA samples were extracted from strain HME9146 grown under different salt (2.5 M NaCl or 4.0 M NaCl) and temperature (30 ℃ or 45 ℃) conditions. The four samples were designated A (30 ℃ and 2.5 M NaCl), B (30 ℃ and 4.0 M NaCl), C (45 ℃ and 2.5 M NaCl) and D (45 ℃ and 4.0 M NaCl), and sequenced using the Illumina HiSeq 2500 platform.

Conclusions

The comparison of A and B samples by RNA-seq reveal that 962 genes were up-regulated and 897 genes were down-regulated by salt stress at 30 ℃. The comparison of C and D samples reveal that 3 genes were up re-regulated and 18 genes were down-regulated by salt stress at 45 ℃ (>2 folds). The comparison of four samples revealed that genes involved in lipid homeostasis and acetoin catabolism were down-regulated under high salt concentration in both temperature conditions (30 ℃ and 45 ℃). In addition, a considerable proportion of the significantly differently expressed genes identified in this study are novel. These data provide a crucial resource that may determine specific response to salt and temperature stress in *Haloarchaeobius* sp. HME9146.

COLLAPSE OF HUMAN SCALP MICROBIOME NETWORK IN DANDRUFF AND SEBORRHEIC DERMATITIS

H.J. Kim[1], T. Park[2], W.J. Sul[1]
[1]Chung-Ang University, Department of Systems Biotechnology, Anseong, Republic of Korea
[2]Amorepacific R&D center, Safety Research, Youngin, Republic of Korea

Backgrounds

Human scalp accommodates diverse bacteria and fungi that influence health condition. Some scalp commensal microorganism are widely known cause of most scalp diseases. However, there is still controversy regarding the microbial species responsible for dandruff and seborrheic dermatitis.

Objectives

We questioned i) whether there was any difference between diseased scalps and normal scalps with respect to their microbial community structure and diversity, and ii) whether the bacterial and fungal network collapsed in diseased scalps compared to normal scalps. In this work, we investigated the difference in the scalp microbiome of three different groups, namely normal (n=45), dandruff (n=28), and seborrheic dermatitis (n=29), in Korea.

Methods

Scalp microbiota were sampled, and the bacterial 16S rRNA gene and fungal ITS1 region were characterized using Illumina MiSeq platform.

Conclusions

PCoA revealed appreciably distinct bacterial and fungal communities among normal and disease groups. The disease status was the major factor used to separate bacterial (ANOSIM; R = 0.382; P = 0.001) and fungal communities (R = 0.548, P = 0.001) from different groups. We used SPIEC-EASI to construct a correlation network among the microbiome resident on the scalp. As a result, the disease groups showed a smaller and less complex network of bacterial and fungal communities than the normal group, suggesting that the healthy scalp microbiota stability had collapsed. Our results will not only provide insight on finding the key-stone species associated with scalp diseases but will also suggest shift in microbial communities.

SCREENING AND ISOLATION OF HIGH EFFICIENCY MARINE BACTERIA TO DEGRADE CRUDE OIL

H.S. Kim[1], J. Kim[2], S.S. Lee[1]
[1]Kyonggi University, Biological engineering, Suwon, Republic of Korea
[2]Kyonggi University, Life Science, Suwon, Republic of Korea

Backgrounds

The crude oil spill accident sometimes occurred in the ocean. And then, spilled crude oil made serious occurred pollution in ocean and coastal area. Crude oil spill was very common in the marine habitats which effect on the marine. The pollution was mainly remediated by natural remediation such as evaporation, spreading, dispersion.

Objectives

To date, oil-degrading bacteria were focused in biological remediation of crude oil pollution.

Methods

This study is to screen high efficient bacteria among 125 marine bacteria strains. Through crude oil degrading test for 2 weeks with Bushnell Hass (BH) media in 28°C, pH 7.0 and aerobic condition (150 rpm shaking incubator), we identified high efficient 5 strains such as *Gordonia* sp. Co 17, *Albirhodobacter*, *Rhodococcus*, and *Microbacterium*.

Conclusions

To determine the optimal condition for crude-oil degradation, highest efficiency bacteria *Gordonia* sp. Co 17 degraded average 84.0 % of n-alkanes (C_8 to C_{32}) for 7 days and PAHs and cyclo- compounds during 14 days through GC-FID and GC-MS analysis. From microscopic observation, the strain *Gordonia* sp. Co 17 was found in the oil phase in the degradation test, but they were not emulsified. *Gordonia* sp. Co 17 is tolerance up to for 8 % (w/v). The *alk*B gene known as alkane hydroxylase is important enzyme for alkane degradation pathway, it was confirmed in *Gordonia* sp. Co 17 by PCR. Based on the study, the *Gordonia* sp. Co 17 could be a potential strain for the effective remediation on the crude oil pollution in the ocean and coastal area.

SEDIMENTITALEA TODARODIS SP. NOV., ISOLATED FROM THE GUT OF A JAPANESE FLYING SQUID

H. Kim[1], D.W. Hyun[1], J.Y. Lee[1], P.S. Kim[1], T.W. Whon[1], W. Kang[1], N.R. Shin[1], E.J. Tak[1], H. Sung[1], J.W. Bae[1]
[1]Kyung Hee University,
Department of Life and Nanopharmaceutical Sciences and Department of Biology, Seoul, Republic of Korea

Backgrounds

The studies of bacterial luminescence systems and quorum sensing using *Vibrio harveyi* and *V. fischeri* have considerably expanded our knowledge of microbial interactions in squid. However, symbiotic interactions between gut microbes and animals in cephalopods have received little attention.

Objectives

This study focused on identifying novel microorganisms in the gut of Japanese flying squid which may affect host physiology, either beneficially or detrimentally, and engaged in interactions with other gut microbes to modify the physiologic effects of marine environments on squid.

Methods

The gut of a Japanese flying squid, *Todarodes pacificus*, collected from the East Sea of Korea, was used as a source of bacterial isolation. We performed phylogenetic, physiological, biochemical, chemotaxonomic and genotypic characteristics of the isolate and its reference strains.

Conclusions

A novel Gram-negative, motile, aerobic and rod-shaped *Alphaproteobacterium*, designated strain KHS03^T, shared 97.4 % sequence similarity of the 16S rRNA gene with type strain of genus *Sedimentitalea*. Strain KHS03^T grew optimally at 25 °C and pH 7 in the presence of 1–2 % (w/v) of NaCl. The major cellular fatty acid was $C_{18:1}$ *ω7c* (82.5 %). The primary isoprenoid quinone was ubiquinone-10. Polar lipids comprised diphosphatidylglycerol, phosphatidylcholine, phosphatidylethanolamine, phosphatidylglycerol, an unidentified aminolipid and two unidentified lipids. The genomic DNA has 59.9 mol% G+C content. DDH showed that the isolate shares 17.1 % ± 2.3 % (17.0 % ± 1.9 %) genomic relatedness with *S. nanhaiensis* NH52F^T. Here, we suggest that strain KHS03^T is a novel species of the genus *Sedimentitalea*, for which the name *Sedimentitalea todarodis* is proposed.

COMPARATIVE ANALYSIS OF SKIN MICROBIAL COMMUNITY BETWEEN YOUNG AND OLD WOMEN

J.J. Kim[1], H. Kim[2], T. Park[2], S. An[2], H.J. Kim[1], W.J. Sul[1]
[1]Chung-Ang University, Department of Systems Biotechnology, Anseong-si, Republic of Korea
[2]Amorepacific R&D center, Safety Research team, Yongin, Republic of Korea

Backgrounds

Skin is the largest organ in human body with diverse microbial community and influenced by multiple factors such as sex, age, skin surface pH, sebum content, and stratum corneum hydration, especially age is an important factor because other factors vary with it. However, relationship between age and skin microbiome is not yet understood.

Objectives

The purpose of this study is to investigate differences in the skin bacterial community and examine predictive functional profiling for the young and old group.

Methods

A total of 73 samples were recruited from young group (n=48) and old group (n=25) of Chinese women, and 16S rRNA gene sequencing was performed using Illumina MiSeq platform. Phylogenetic Investigation of Communities by Reconstruction of Unobserved States (PICRUSt) was used to predict metagenome functional contents.

Conclusions

PCoA shows that the bacterial communities of the young group and old group were appreciably distinct. *Chryseobacterium*, *Propionibacterium* and *Enhydrobacter* were dominant in both young and old groups. *Sphingomonas* and *Bacteroides* were more abundant in young group while *staphylococcus* was relatively more in old group. The phylogenetic diversity of skin bacterial communities was higher in the young group than the old group while variation in each group was higher in the old group. Bacterial communities of the two groups were also distinguished in predictive functional profiling and metabolism. From these results, we suggest that differences in bacterial communities and predictive functional profiling across ages will be the cornerstone of therapeutic and cosmetic application associated with human skin aging.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ECO-FRIENDLY PILOT PLANT-SCALE BIOLOGICAL TREATMENT OF MARINE WASTEWATER FROM LAND-BASED FISH FARM BY HIGH EFFICIENCY MARINE BACTERIA AND MARINE SEDIMENT

J. Kim[1], S. Jeong[1], S. Kim[2], S.S. Lee[1]
[1], Life Science, Suwon, Republic of Korea
[2], Environmental energy engineering, Suwon, Republic of Korea

Backgrounds

Saline wastewater in high concentration is difficult to be biologically treat. It is helpful to reduce cause of the red-tide in the long-term. However, it is required for eco-friendly and effective ways.

Objectives

This study is to apply the pilot plant-scale effective biological treatment of high salinity effluents from land-based fish farm.

Methods

We applied high efficiency NH_3-N removal strain, *Bacillus* sp. KGN1, and PO_4^{3-}-P removal marine strain, *Vibrio* sp. KGP1 to pilot plant-scale biological treatment system with eco-friendly marine sediment. The pilot plant-scale biological treatment consists of an influent tank in 2.5 m^3, an SBR reactor in 4.5 m^3 and an effluent tank in 2.5 m^3 with auto-control system. Using the pilot plant-scale SBR system with marine bacteria and sediment for treatment of marine wastewater from the land-based fish farm improved the treatment performance as indicated by averagely 69.8% R.E. of COD_{Cr} (Influence: 129.1 mg/L, effluence: 39.0 mg/L), 92.7% R.E. of NH_3-N (influence: 5.4 mg/L, effluence: 0.4 mg/L), 73.1% R.E. of T-N (influence: 7.8 mg/L, effluence: 2.1 mg/L), 62.5% R.E. of T-P (influence: 1.6 mg/L, effluence: 0.6 mg/L) at the optimal operation conditions (4h/cycle; 10 min influent period, 2 h 50 min aeration period, 0.5 h settlement, 0.5 h idle& effluent; HRT, 6h; solids retention time (SRT), 12 d). Bacterial community in the eco-friendly marine sludge of the SBR tank was traced change of diversity.

Conclusions

Our system proposed efficient and eco-friendly biological treatment of saline wastewater.

RISK FACTOR OF RENAL IMPAIRMENT IN PATIENTS WITH GENITOURINARY TUBERCULOSIS

E.J. Kim[1,2], J.J. Kim[1], J. Kim[1], H. Seong[1], S.J. Lee[1], W.Y. Jeong[1], Y.C. Kim[1,2], I.Y. Jung[1,2], D.H. Oh[1,2], S.J. Jeong[1,2], N.S. Ku[1,2], J.Y. Choi[1,2], Y.G. Song[1,2], J.M. Kim[1,2]
[1]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Republic of Korea
[2]AIDS research Institute, Yonsei University College of Medicine, Seoul, Republic of Korea

Backgrounds

Genitourinary tuberculosis (GUTB) is a common form of extrapulmonary tuberculosis. Because it leads renal calcification and ureter stricture during healing process, it may have deleterious effects on renal function. Therefore, we investigated to risk factors of renal impairment in GUTB patients.

Objectives

In total, 56 patients with GUTB (51.8% male, mean age 53.2 ± 17.2 years) were enrolled in the study. Renal impairment was developed in 14 (25.0%) patients and end stage renal disease in 4 (7.1%). In univariate analysis, old age (p = 0.011), microscopic hematuria (p = 0.005), proteinuria (p = 0.008), chronic kidney disease (p = 0.003), cardiovascular disease (p = 0.044) and diabetes (p = 0.012) were significantly associated with decreased renal function. In multivariate analysis, microscopic hematuria (odds ratio (OR), 14.334; 95% confidential interval (CI), 1.116-176.152, p =0.038) and old age (OR, 31.748; 95% CI, 2.090-482.189, p =0.013) were independent risk factors of renal impairment in GUTB patients.

Methods

A retrospective cohort study was conducted at a tertiary hospital in South Korea. Patients (>18 years) with GUTB were collected between January 2005 and December 2015. Analysis was performed to identify risk factors associated with renal impairment developed after treatment. Renal impairment was defined as glomerular filtration rate less than 60 ml/min/1.73 m^2.

Conclusions

Microscopic hematuria and old age were independent risk factors of renal impairment in GUTB patients. Therefore, in GUTB elderly patients with microscopic hematuria, regular follow-up of renal function should be needed during and even after the end of treatment.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

MICROBIAL COMMUNITY STRUCTURE AND ITS ECOLOGICAL FUNCTION IN PERRENIALLY ICE-COVERED LAKES OF THE MCMURDO DRY VALLEYS, ANTARCTICA

O.S. Kim[1], M. Kwon[1], J. Lee[1], M. Kim[2], S.G. Hong[2]
[1]Korea Polar Research Institute, Unit of Antarctic K-route Expedition, Incheon, Republic of Korea
[2]Korea Polar Research Institute, Division of Polar Life Sciences, Incheon, Republic of Korea

Backgrounds

Perennially ice-covered lakes in the McMurdo Dry Valleys are chemically stratified with depth and have distinct biological gradients. Despite the long-term studies on these unique environments there remains a paucity of data on microbial community structure and its ecological function in the water columns of these lakes.

Objectives

We investigated bacterial diversity in five different ice-covered Antarctic lakes targeting 16S rRNA genes and ecological function at different depths in Lake Fryxell by metagenomics.

Methods

16S rRNA gene-based pyrosequencing for microbial community structures and shotgun metagenomics by Illumina technology were carried out.

Conclusions

Distinct communities were present in each lake, paralleling the unique biogeochemical characteristics of each environment. Certain bacterial lineages were confined exclusively to a specific depth of each lake. Additionally, we present the metagenomic results to implicate the microbial ecological function in Lake Fryxell.

FEMS7-1517

SURROUNDING ENVIRONMENT SHAPES GUT MICROBIOME OF FISH AND POSSESS DISTINCT COMPOSITIONAL CHARACTERISTICS FROM OTHER VERTEBRATES

P.S. Kim[1], J.B. Lee[2], M.S. Kim[1], T.W. Whon[1], D.W. Hyun[1], J.H. Yun[1], N.R. Shin[1], M.J. Jung[1], J.W. Bae[1]
[1]Kyung Hee University,
Department of Life and Nanopharmaceutical Sciences and Department of Biology, Seoul, Republic of Korea
[2]National Fisheries Research & Development Institute, Dokdo Fisheries Research Center, Pohang, Republic of Korea

Backgrounds

Gut microbiota contribute to host organism by beneficial effects such as metabolism, immune response as well as ethological aspect. On the one hand, host organisms also select their commensal microbiota that provides advantages to survival or fitness of host. In recent studies, gut microbiota is determined by various factors including diets, habitat, and host phylogeny. So far, the discoveries that suggested with host-microbe interactions and co-evolutionary histories of vertebrate, yet unveiled in the gut microbiota of most of vertebrate species are uncharacterized. Species diversity on fish is greater than any other group of vertebrates and nearly half the total number of vertebrate species, therefore gut microbiota study of fish species attempt us to the dilatational views to understand the entire vertebrate gut microbiota.

Objectives

In this study, we investigated bacterial communities of distal gut and luminal contents from different habitats among more than 230 fishes that can be representatives of 70 species.

Methods

All samples were collected across streams, lakes and sea. Metagenomic DNAs from gut and luminal fluid of each fish species were extracted and then the V1-V3 region of 16S rRNA gene amplified and sequenced by high-throughput NGS technology.

Conclusions

Network-based analysis and beta diversity plots based on Unifrac distances show surrounding environmental features influences bacterial communities of fish. Additionally, fish gut microbiota clustered differently with other vertebrate gut microbiota. Thus, this study suggests deep knowledge to understand unrevealed host-gut microbe interaction in fish and surrounding environments, which can provides circumstantial clue for trends of co-evolution in vertebrate and commensal microbes.

GENOMIC RECONSTRUCTION AND METATRANSCRIPTOMIC ANALYSIS REVEAL CARBON-CYCLING BY BACTERIA ASSOCIATED WITH PHYTOPLANKTON BLOOMS IN AN ANTARCTIC POLYNYA

S.J. Kim[1], J.G. Kim[2], S.J. Park[3], J.H. Gwak[2], M.Y. Jung[2], S.K. Rhee[2]
[1]Korea Institute of Geoscience and Mineral Resources, Geologic Environment Research Division, Republic of Korea
[2]Chungbuk National University, Department of microbiology, Cheongju, Republic of Korea
[3]Jeju National University, Department of Biology, Jeju, Republic of Korea

Backgrounds

Polynyas in the Antarctic Ocean are regions of intense primary production, largely by *Phaeocystis antarctica.*

Objectives

Comparative analysis of data from different phases of bloom (peak and decline) and from sea ice-covered ocean provides fundamental insights into the ecology of key heterotrophs associated with phytoplankton blooms in these Antarctic polynyas.

Methods

We sampled Antarctic waters during three cruises (2011 to 2014) and analyzed DNA and mRNA to identify key heterotrophic bacteria active during peak and decline phases of polynya blooms.

Conclusions

Genome reconstruction and comparative metatranscriptomic analyses revealed that *Polaribacter* and Ant4D3 clades were dominant in peak phase and their transcriptional activities were high. Contrastingly, genome binning showed that *Bacteroidetes* and *Gammaproteobacteria* were highly abundant during decline phase. High transcriptional activity for genes in *Polaribacter* encoding metabolism of *P. antarctica's* storage glucan, chrysolaminarin, was found. Transcript abundances in *Gammaproteobacteria* (Ant4D3, SUP05 and SAR92) also indicated widespread utilization of compatible solutes produced by phototrophs. Populations within the SAR92 clade showed transcriptional activity for utilization of both polysaccharides and low molecular weight organic matter; this may account for this clade's abundance both in peak and decline phases. Versatility of *Gammaproteobacteria* associated with large genome size may contribute to their dominance in eutrophic polynya waters, while the SAR11 clade was abundant only in a control site (sea ice-covered oligotrophic ocean). Our results provide insight into niches of key heterotrophic populations engaged in C-cycling and succession of bacterioplankton in Antarctic waters.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

VAGINAL MICROBIOTA UNDER THE INFLUENCE OF HOST GENETICS AND ITS HEALTH EFFECTS

G. Ko[1], J. Si[1], H. Yu[1], J. Sung[1]
[1]Seoul National University, School of Public Health, Seoul, Republic of Korea

Backgrounds

Recent studies on the various subtypes of vaginal *Lactobacillus* among different ethnic groups suggested host effects on the vaginal microbiota. While the vaginal ecosystem is maintained through mutualistic relationships between the host and the vaginal bacteria, the effect of host genetics on the vaginal microbiota has not been well characterized.

Objectives

The objective of this study is to investigate the effect of host genetics on vaginal microbiota and their association with both vaginal and non-vaginal health conditions such as obesity.

Methods

Here, we examined the heritability of vaginal microbiota and their association with obesity in 542 Korean females, including 222 monozygotic and 56 dizygotic twins.

Conclusions

As expected, the vaginal microbiota significantly varied depending on host menopausal status and bacterial vaginosis, with which the abundance of both *Lactobacillus* and *Prevotella* was strongly associated. Host body mass index (BMI) was also significantly associated with the diversity of vaginal microbiota. Subsequent candidate gene analysis showed that genetic variants of interleukin-5 were strongly associated with the abundance of *Prevotella* sp. Finally, high-fat diet increased the diversity of vaginal bacteria including *Prevotella* in mice, and the transfer of vaginal microbiota promoted metabolic endotoxemia.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

DISTINCT SUBSTRATE CONSUMPTION PATTERNS IN THE MARINE BACTERIUM ALTEROMONAS MACLEODII DURING DEGRADATION OF MACROALGAL POLYSACCHARIDES

H. Koch[1], T. Schweder[2], A. Dürwald[2], M. Simon[1], M. Wietz[1]
[1]University Oldenburg, Institute for Chemistry and Biology of the Marine Environment, Oldenburg, Germany
[2]E.M.A. University of Greifswald, Department of Pharmaceutical Biotechnology, Greifswald, Germany

Backgrounds

Marine phototrophs perform 50% of the global net primary production, forming the basis of the marine carbon cycle. In phototrophic macroalgae, a major fraction of the fixed CO_2 is converted to polysaccharides that serve as storage compounds but also represent important substrates for marine heterotrophic bacteria.

Objectives

To get deeper insights into the bacterial degradation of macroalgal polysaccharides, we studied the globally distributed *Alteromonas macleodii*, a specialist in polysaccharide utilization by encoding a variety of carbohydrate-active enzymes (CAZyme). In this study, we perform physiological and transcriptomic analyses of *A.macleodii* strain 83-1 grown on the macroalgal polysaccharides laminarin, pectin and alginate as sole energy and carbon sources.

Methods

To analyze the effect of mixed substrates on the metabolism of *A.macleodii* 83-1, we incubated the culture in medium containing a mixture of these polysaccharides mimicking natural systems where several polymers occur in concert.

Conclusions

The incubation experiments revealed two distinct growth phases relating to substrate preferences. In the first growth phase laminarin was completely consumed and cells grew to maximum density. In the second phase alginate and pectin were used simultaneously, however without detectable net growth. To identify the molecular mechanisms causing these distinct phases transcriptomic and proteomic analyses are underway. Using comparative genomics, we furthermore show that *A.macleodii* 83-1 and closely related strains have a distinct CAZyme repertoire comparable to other polymer degrading specialists like Flavobacteria.Overall, our results indicate that *A.macleodii* exhibits remarkable genetic and physiological adaptations to complex polymer degradation, a process of great importance in the marine carbon cycle.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

EFFECTIVENESS OF DIFFERENT DISINFECTANTS ON BIOFILM LAYER GENERATED BY MULTI-DRUG RESISTANT MICROORGANISMS

E. Kocoglu[1], B. Guler[2]
[1]Istanbul Medeniyet University School of Medicine, Department of Microbiology, Istanbul, Turkey
[2]Abant Izzet Baysal University- Institute of Health Sciences, Department of Microbiology, Bolu, Turkey

Backgrounds

The major problem with infections caused by multidrug-resistant microorganisms is that treatment options are inadequate. Biofilms cause an increase in morbidity and mortality in patients having nosocomial infections.

Objectives

The aim of this study was to compare the effectiveness of five different disinfectants in different concentrations on biofilm layer formed by multidrug resistant microorganisms.

Methods

For the study, strains isolated from patients having nosocomial infection were used. Enterococcus faecalis ATCC 29212 strain was used as positive control, and Staphylococus aureus ATCC 25923 strain known not to form biofilm as negative control. Sterile stainless steel rods measuring 0.1 mm x 10 mm were used as a model for biofilm formation, and sterilized polystyrene microplates were used as a plastic surface model. Biofilm formation on the model was provided. The biofilm layers were exposed to concentrations of orthophthaldehyde (OPA) 0.55%, sodium hypochlorite 500 and 5000 ppm, iodine 10%, ethyl alcohol 60 and 70%, and citric acid 10 and 30% for 3, 5 and 15 min. The experiments were repeated twice for each contact time, temperature and test condition. A 5 log reduction in the number of microorganisms was accepted to be effective for disinfectant.

Conclusions

OPA, sodium hypochlorite, and ethyl alcohol were found to be effective on the biofilm layer. While the concentration of 10% iodine was found to be ineffective in 3 and 5 min, it was found to be effective when exposed for 15 minutes. Citric acid were found to be ineffective both on the strains forming biofilm layer, on the positive control strains and on the strains that did not form biofilms. According to our findings citric acid in the concentrations used in the experiment has no disinfectant activity in the presence of biofilm, and Iodine requires at least 15 minutes of contact time for efficacy on biofilm layer.

CHANGES IN FATTY ACIDS COMPOSITION IN SACCHAROMYCES CEREVISIAE CELLS PROTECTED BY RESVERATROL UNDER ETHANOL STRESS

I. Kolouchová[1], O. Maťátková[1], J. Masák[1], T. Řezanka[2]
[1]University of chemistry and technology Prague, Department of Biotechnology, Prague, Czech Republic
[2]Czech Academy of Sciences, Institute of Microbiology, Prague, Czech Republic

Backgrounds

Saccharomyces cerevisiae is one of the most useful yeasts used in biotechnology. It is utilized in ethanol production as well as in winemaking. During the fermentation process, S. cerevisiae is subjected to high ethanol stress, which influences the metabolisms of the cells as well as the biomass growth.

Objectives

The research is focused on *S. cerevisiae* protection by known antioxidant resveratrol as a modulator of ethanol stress. Two traditional biotechnological yeast species of *S. cerevisiae* were exposed to different ethanol and resveratrol concentrations.

Methods

The determination of fatty acid profile (by GC-MS with SP-2380 column), lipid peroxidation products (as TBARS) and changes in the activity of superoxide dismutase were used to determine the degree of ethanol induced cell damage and the resveratrol protective properties.

Conclusions

The results showed that resveratrol has not only the ability to mitigate the impact of ethanol on yeasts, but also to improve their ethanol tolerance.

PHYLOGENY AND ENVIRONMENTAL FACTORS DETERMINE METABOLIC ACTIVITIES OF SOIL ACTINOBACTERIA

J. Kopecky[1], Z. Kamenik[2], J. Novotna[1], M. Sagova-Mareckova[1]
[1]Crop Research Institute, Epidemiology and Ecology of Microorganisms, Prague 6, Czech Republic
[2]Institute of Microbiology of the AS CR- v.v.i., Laboratory of Fungal Genetics and Metabolism, Prague 4, Czech Republic

Backgrounds

A complex and structured soil environment provides a variety of resources supporting adaptation, and the microenvironments, where sharing the local gene pool may lead to evolution of site-specific traits.

Objectives

The study was conducted to explore locally specific relationships determined by soil chemistry and vegetation to phylogeny, metabolite profiles and antibiotic activity of cultivable actinobacteria at the sites of their isolation.

Methods

A set of 336 actinobacteria were isolated at ten soil sites, phylogenetically characterized by sequencing the genes for 16S rRNA and the beta-subunit of DNA-dependent RNA polymerase (*rpoB*). The strains were cultivated in submerged culture and the spent media were used to determine the inhibitory activities against *Kocuria rhizophilla*, *Escherichia coli*, and *Saccharomyces cerevisiae*, directly or after solid-phase extraction. In the solid-phase extracted fractions, the profiles of low-molecular weight metabolites were determined by reversed-phase HPLC with UV-VIS diode array detection.

Conclusions

Strains of actinobacteria isolated from the individual sites differed in their phylogeny. The differences were related to soil organic matter contents, but not to soil pH. Activities against the testing strains were related to the *rpoB*-based phylogeny. The profiles of low-molecular-weight compounds differed reflecting both soil organic matter contents and pH at the isolation sites. The relationships of the strains antibiotic activities and profiles of low-molecular weight metabolites to their phylogeny suggested phylogenetic differentiation as the main mechanism determining the strain properties.

INTERPLAY OF PATIENT MICROBIOME AND HOSPITAL ENVIRONMENT AT INTENSIVE CARE UNIT

K. Koskinen[1,2], M. Mora[1], M.R. Pausan[1], S. Duller[1], C. Högenauer[1], R. Krause[1], C. Moissl-Eichinger[1,2]
[1]Medical University of Graz, Department of Internal Medicine, Graz, Austria
[2]BioTechMed Graz, -, Graz, Austria

Backgrounds

Hospital-acquired infections (HAIs) are a serious problem worldwide. Patient groups most often affected are premature babies, elderly, and patients suffering from immunodeficiency, at intensive care units in particular. The risk is not only related to invasive procedures or inadequate hygiene, but infection can also be transferred directly from patient to patient, via surfaces, equipment and personnel.

Objectives

We conducted a pilot study of one ICU patient (suffering from pneumonia, mechanically ventilated) to recognize the microbial communities, transfer, and significance in the patient's well-being. For consecutive seven days, we sampled the patient skin, trachea, stomach and stool, and environment near the patient.

Methods

16S rRNA gene-based microbial community composition was correlated with clinical parameters, such as fraction of inspired oxygen and arterial oxygen partial pressure.

Conclusions

(Opportunistic) pathogenic bacteria were discovered in patient and environment. However, community structures were distinct in different sampling locations: the patient skin was dominated by *Staphylococcus*, *Anaerococcus* and *Corynebacterium*, stomach aspirate by *Citrobacter*, stool by *Bacteroides*, *Lachnoclostridium*, and *Roseburia,* and tracheal secretion by *Neisseria*, *Gemella*, and *Mycoplasma*. Interestingly, tracheal microbiome shifted on days of poorer oxygenation. Additionally, more diverse tracheal microbiome significantly associated with higher partial pressure of oxygen in arterial blood, suggesting that tracheal microbiome was connected to level of oxygenation. Human skin associated bacteria and (opportunistic) pathogenic bacteria *Acinetobacter*, *Pseudomonas* and *Burkholderia* were detected also in environment. The community structure of environmental samples altered daily reflecting the effect of disinfection, but patient microbiome stayed more constant. During the whole study, environment carried more diversity than patient samples.

CHARACTERIZATION OF THE ANAEROBIC DEGRADATION OF PHENANTHRENE BY A NOVEL SULFATE-REDUCING BACTERIAL ENRICHMENT CULTURE

I. Kraiselburd[1], T. Bruls[2], R.U. Meckenstock[1]
[1]University of Duisburg-Essen, Biofilm Centre, Essen, Germany
[2]Genoscope Institute of Genomics of the Atomic Energy and Alternative Energies Commission, CEA, Paris, France

Backgrounds

Polycyclic aromatic hydrocarbons (PAHs) are widely distributed contaminants that produce hazardous effects on human health. In PAH-contaminated sites, oxygen is rapidly depleted. Thus, microorganisms able to use these compounds as a carbon source in the absence of molecular oxygen are crucial for their consumption.

Objectives

The aim of this work is elucidating the mechanisms for the anaerobic degradation of phenanthrene by a novel sulfate-reducing enrichment culture (TRIP) obtained from the Pitch Lake in Trinidad-Tobago, the world largest natural asphalt lake.

Methods

The metagenome of the TRIP culture was sequenced and annotated at the Microbial Genome Annotation & Analysis Platform, Genoscope. The analysis of the metagenome sequences included a phylogenetic binning of bacterial genomes followed by a metabolic network reconstruction. Genes potentially involved in the degradation of phenanthrene were identified based on sequence similarity to genes previously characterized for PAHs degradation.

Conclusions

Five bacterial draft genomes were reconstructed from the metagenome sequences of the TRIP culture. These include two bacterial strains belonging to the *Desulfobacteraceae* family of delta proteobacteria, a putative *Paludibacter*, a *Spirochaeta* and a previously unclassified bacterium. Synteny and phylogenetic studies demonstrated that the members of the *Desulfobacteraceae* family are closely related to the naphthalene-degrading delta proteobacterial strain NaphS2. Two gene clusters encoding the subunits of a carboxylase enzyme potentially involved in the activation of phenanthrene were identified in one of the *Desulfobacteraceae* species (the more abundant operational taxonomic unit of the TRIP culture), suggesting this organism has a major role in phenanthrene degradation.

[4]Christian-Albrechts-University,
Institute for Experimental Medicine- Division of Systematic Proteome Research & Bioanalytics, Kiel, Germany
[5]Heinrich-Pette-Institute, Leibniz Institute for Experimental Virology- Virus Genomics, Hamburg, Germany
[6]University of Hamburg, Biocenter Klein Flottbek- Molecular Plant Genetics, Hamburg, Germany

Backgrounds

Microalga belonging to the chloro- and charophyta are of high relevance for the global carbon cycling and it is well-known that they are associated with a microbiota. However, it remains unclear, if the associated microbiota is specific for the microalga strains and which role individual bacterial taxa play.

Objectives

Here we provide experimental evidence that chlorophyte (*Chlorella saccharophila, Scenedesmus quadricauda*) and charophyte (*Micrasterias crux-melitensis*) microalga are associated with unique and specific microbial populations.

Methods

Deep metagenome sequencing, binning approaches, secretome analyses in combination with RNA-seq data implied fundamental differences in the gene expression profiles of the microbiota associated with the different microalga.

Conclusions

Our findings indicate that the transcriptionally most active bacteria with respect to key genes commonly involved in plant-microbe interactions in the chlorophyta belong to the phylum of the α-Proteobacteria. In contrast, in the charophyta microbiome bacteria affiliated with the phylum of the Bacteroidetes showed the highest gene expression rates. We furthermore show that effector molecules known from plant-microbe interactions as inducers for the innate immunity are already of relevance at this evolutionary early level.

PROFILING AND CONTROLLING THE MICROBIOME OF MICROALGAE IN MASS CULTIVATION PROCESSES

L. Krug[1,2], A. Erlacher[2], T. Cernava[1,3], G. Berg[2]
[1]Austrian Centre of Industrial Biotechnology, Petersgasse 14, Graz, Austria
[2]Institute of Environmental Biotechnology, Petersgasse 12, Graz, Austria
[3]Roombiotic GmbH, Petersgasse 12, Graz, Austria

Backgrounds

Under stressful conditions, the microalga *Haematococcus pluvialis* is capable to accumulate large amounts of the highly valuable carotenoid astaxanthin and is therefore cultivated in large photobioreactors.

Objectives

In mass cultivation, *H. pluvialis* often co-occurs with microorganisms that inhibit and disturb biomass formation and need therefore to be controlled.

Methods

The co-cultivated microbiome was studied in two individually performed mass cultivations by targeting specific taxonomic markers. Co-cultivated microalgae, including *Chlorella*, *Scenedesmus* and *Ochrophyta*, were detected as contaminants already in starting inoculums and could be linked to a substantial reduction of *H. pluvialis* biomass production. In particular, these contaminations accounted for more than 40% of the total eukaryotic biomass in large-scale photobioreactors. By using diazine derivatives we were able to achieve promising results to suppress eukaryotic shares. Illumina HiSeq 16S rRNA gene sequencing revealed a heterogeneous co-occurring prokaryotic community. In two self-contained processes, including reactor upscaling, *Runella*, *Sediminibacterium*, *Sphingomonas* (*Bacteriodetes*) and *Prosthecobacter* (*Verrucomicrobia*) were highly abundant in the first run, while a second analyzed process was dominated by *Comamonadaceae* (*Proteobacter*) and *Flavobacteria* (*Bacteriodetes*). Network analyses revealed reactor-specific cluster formation with 60% unique OTUs. Confocal laser scanning microscopy coupled with LIVE/DEAD staining uncovered a dense biofilm-like colonization behavior within algae aggregates.

Conclusions

The high abundance of co-occurring bacteria potentially positively complements the algae fitness and growth, with antagonistic potential towards unwanted contaminants. Further understanding of the abundant co-occurring microbiome can lead to new biotechnological solutions for contamination prevention and increased biomass yield.

FEMS7-2252
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

TOXICITY REDUCTION AND PROTEOMIC ANALYSIS DURING DEGRADATION OF SELECTED XENOESTROGENS BY FILAMENTOUS FUNGUS UMBELOPSIS ISABELLINA.

M. Krupiński[1], *T. Janicki*[1], *J. Długoński*[1]
[1]*University of Lodz, Department of Industrial Microbiology and Biotchnology, Lodz, Poland*

Backgrounds

Numerous pollutants have a harmful effect on the organism through affecting the endocrine system homeostasis. Due to their common use, it is necessary to develop methods for elimination of xenobiotics with endocrine properties from environment. An important compounds of these contaminants are: **4-*t*-octylphenol** (4-*t*-OP), **4-cumylphenol** (4-CP) and **technical nonylphenol** (*t*-NP).

Objectives

The work is a part of research involving identification and characterization of biological systems allowing the reduction of the toxic activity of xenobiotics through their biodegradation. The purpose of the project is acquiring the knowledge about the proteomic background of the xenoestrogens biodegradation (4-*t*-OP, 4-CP, *t*-NP) and obtaining detailed information on the toxic properties of intermediates formed during these processes.

Methods

The assessment of potential toxic properties of biodegradation products was analyzed using bioassays, in which the level of toxicity is tested based on a specific response bioindicators (bacteria, algae, crustaceans, protozoa). Because of the differences in organisms susceptibility to various chemical agents, in this project a battery of tests composed of species representing the various trophic levels of the biological chain were used. In the present work, a proteomic analysis of *U. isabellina* exposed to a tested xenobiotics was conducted using two-dimensional gel electrophoresis (2-DE) followed by MALDI-TOF/TOF identification to reorganize major proteins involved in the biodegradation pathways.

Conclusions

Our results show that the xenobiotics degradation by *U. isabellina* were accompanied by a decrease in the toxicity. Moreover, we observed change in protein expression during incubation of fungus with xenoestrogens, which provides potential evidence for the identification of biodegradation proteomic biomarkers.

DIVERSE PATTERNS OF BACTERIAL ORGAN FORMATION DURING EMBRYONIC DEVELOPMENT IN LYGAEOID BUGS (HETEROPTERA: LYGAEOIDEA)

S. Kuechler[1], Y. Matsuura[2], R. Koga[3], K. Dettner[1], T. Fukatsu[3]
[1]University of Bayreuth, Animal Ecology II, Bayreuth, Germany
[2]University of the Ryukyus,
Functional Genomics Group- Tropical Biosphere Research Center- COMB, Okinawa, Japan
[3]Bioproduction Research Institute AIST,
Symbiotic Evolution and Biological Functions Research Group, Tsukuba, Japan

Backgrounds

Many hemipteran insects are associated with specific intracellular symbionts housed in symbiotic organs, called bacteriomes. A minor group of true bugs (Heteroptera), especially members of the superfamily Lygaeoidea, also exhibit numerous bacteriome-associated symbiotic systems. The structure and localization of the bacteriomes as well as the symbionts therein offer extensive variations. Overall, six structurally different symbiotic systems have been identified and described within the Lygaeoidea so far.

As described for other intracellular bacteria, endosymbionts of lygaeoid bugs are transferred to the next generation by maternal transmission, usually by integration of the symbionts into eggs during oocyte development. However, detailed processes of symbiont colonization into the developing symbiotic organs have not been studied in most lygaeoid bugs and we almost know nothing about the molecular mechanisms of such an orchestrated phenomenon at the host-symbiont interface.**Objectives**

In order to elucidate bacteriome formation in five lygaeoid species with distinct types of symbionts and symbiotic organs, we analyzed spatio-temporal symbiont dynamics in embryonic development using confocal laser scanning microscopy.

Methods

After collection and fixation of insect embryos at regular time intervals, we traced symbiont relocation and bacteriome development by whole-mount fluorescence *in situ* hybridization (wFISH) in combination with symbiont specific probes.

Conclusions

Comparative analyses of symbiont colonization patterns revealed that symbiont activity as well as the formation of the bacteriomes during embryogenesis are quite diverse in the species corresponding to each symbiotic system characterized in mature insects. Therefore, we propose different developmental mechanisms have independently evolved for bacteriomes of lygaeoid bugs after acquisitions of novel intracellular symbionts.

[7]University of Turku, Department of Paediatrics, Turku, Finland
[8]K.E.M. hospital, K.E.M hospital research centre, Pune, India
[9]Smt. Chandibai Himathmal Mansukhani College, Department of Microbiology, Thane, India

Backgrounds

Microbial colonization in the human intestine begins during fetal development which is further influenced by conditions at birth and host genetics. *FUT2* (fucosyl transferase-2) secretor status and birth mode are key determinants of the compositional development of gut microbiota, as documented in western pediatric population. In view of the strong impact of environmental conditions, data from western population may not be valid for different geographical locations; such interactions and effects on the gut microbiota composition in non-western populations remains poorly understood.

Objectives

A comparative study was designed to understand whether alterations of *FUT2* secretor state and birth mode alter gut microbial composition in Finnish and Indian children.

Methods

Blood and fecal samples were collected from 99 children (Age: 13-14 years; Finnish=52, Indian=47) and characterization of the gut bacterial community was carried out using PCR-DGGE and 16S rRNA gene sequencing. Single Nucleotide Polymorphism (SNP) analysis was carried out to determine the *FUT2* SNP rs601338 by genotyping the exonic region of the gene.

Conclusions

The gut microbial composition varied between Finnish and Indian population. *FUT2* secretor state and birth mode had a significant impact upon a number of specific bacterial taxa, patterns of which differed in the two populations. Outcomes of this study highlight the need for exploring and assessing other confounding factors, which may improve our understanding of such interactions/associations in the non-western population, especially in the under-explored and heterogeneous population like India.

IDENTIFICATION OF A HEAT STABLE BETA-LACTAMASE, WHICH IS PRODUCED BY BACILLUS CEREUS INACTIVATES PENEM

R. Kuwana[1], R. Yamazawa[1], T. Yamashita[2], K. Honke[2], K. Ito[1], H. Takamatsu[1]
[1]Setsunan University, Pharmaceutical Science, Hirakata, Japan
[2]Kochi University, Center for Innovative and Translational medicine, Kochi, Japan

Backgrounds

Antibiotics are used for the medical care, the domestic animals growth, and the control of health administration. Some antibiotics exposed in the environment are stable and keep the activities, which potentially causes the potential ecological and human health issue. The penem antibiotics, which are hardly to be degraded, are frequently used in Japan.

Objectives

In order to reduce the antibiotics pollution, we aimed to isolate soil bacteria that produce meropenem digestion enzymes.

Methods

We screened *Bacillus* strains that can digest the meropenem from Biological Resource center in Japan and the soils. We found three natural isolates, SUBC1002, SUBC1008, and SUBC1010. We analyzed that they are included in *B. cereus* group.

Conclusions

The MICs of meropenem were 2.5, 3.3, 3.4 mg/l, respectively. We found that the supernatant of *B. cereus* strains after the heat treatment at 80 ℃ was also effective to degrade the meropenem. We resolved the proteins included in the supernatant of *B. cereus* strains by SDS-PAGE and found major two bands with the molecular mass of 28-kDa and 33-kDa bands. We determined their amino acid sequences by LC-MS/MS. The 28-kDa protein corresponded to the *B. cereus* 5/B/6 beta-lactamase II. The 33-kDa protein corresponded to the *B. cereus* 5/B beta-lactamase I. These beta-lactamases belong to the different protein family and highly conserved among *B. cereus* group. These results suggested that some beta-lactamases produced by *B. cereus* strains potentially digested the meropenem.

REVEALING OF LANM FUNCTION AND MOLECULAR-GEOECOLOGY IN FUSARIUM WILT PATHOSYSTEM

D.R. Kim[1], S.W. Hong[2], Y.S. Kwak[2]
[1]Gyeongsang National University, Plant Medicine, Jinju, Republic of Korea
[2]Gyeongsang National University, Applied Life Science, Jinju, Republic of Korea

Backgrounds

Crop production is prone to damage inflicted by various plant pathogens. For example, Fusarium wilt which is caused by *Fusarium oxysporum*, is difficult to control because the pathogen produces chlamydospores that survive in soil for many years. *Streptomyces* is a widely-known biocontrol agent that can colonize in the rhizosphere or phyllosphere, which may relate to disease control mechanisms. As a mechanism in the disease suppression system, *Streptomyces* species may act as an agent in specifically suppressing diseases in a long-term crop monoculture system.

Objectives

Fusarium wilt is known to severely affect strawberry cultivation fields and *Streptomyces griseus* S4-7 has been discovered as a representative suppressive strain. The *Streptomyces* secretes diverse forms of antibiotic and other valuable secondary metabolites, but generates only a few lantibiotics.

Methods

Total 7 lantipetide biosynthesis genes in *S. griseus* S4-7 eliminated by homologus knock-out protocol (pKC1132). LanM of *S. griseus* S4-7 showed unique biological properties that differ from other lantibiotics and specific *lanM* gene was detection in soil samples of three locations with qRT-PCR.

Conclusions

Lantibiotics constitute a group of sulfur-peptide with antibiotic properties and heat-stable compounds. Among 7 of lantipeptides, only tsrD, lanA and lanA mutants lost their antifungal activity against Fusarium wilt pathogen. To be suppress soil of strawberry Fusarium wilt takes a minimum of 7 years monoculture, and the *lanM* gene may be used to diagnose whether Fusarium wilt conducive or specific suppressive soil.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

SYMBIOTIC MICROBIOCENOSIS PROTECTION OF INDIVIDUALS AGAINST COMMUNICATING RELATIVELY PATHOGENIC MICROBES ON EXAMPLE OF CANDIDA

V. Lakhtin[1], M. Lakhtin[2], S. Afanasiev[2], A. Bajrakova[2]
[1]G.N. Gabrichevsky research Institute for Epidemiology & Microbiology, Moscow, Russia
[2]G.N. Gabrichevsky research Institute for Epidemiology & Microbiology, Medical Biotechnology, Moscow, Russia

Backgrounds

Human superorganism possesses communicative biotope microbiocenoses. In many cases mixed infections involve eukaryotic pathogens of genera *Candida.* We established principles of communicating microbial “bodies” contracting lectins of human probiotic microorganisms from the same biotopes. Probiotic lectins imitate probiotics and function as metabolomebiotics. The system *Candida-Lactobacillus* characterizes urogenital biotope. Interactions between pools of *Candida* species and *Lactobacillus* species reflect mutual communications.

Objectives

Proposal of the human symbiotic microbiocenosis strategy against pathogenic *Candida*.

Methods

Behavior and reactivity of *C.albicans, C.krusei, C.tropicalis* and *L.acidophilus, L.brevis, L.casei* from intestinal and urogenital biotopes were studied in cultural suspensions in microplate or on agar in the presence of soluble or disc-sorbed symbiotic bacterial lectins (SBL: bifidobacterial and lactobacillar lectins, BL and LL). Biofilms were evaluated using treatment with violet dye followed by its extract detection in visible light region. Leader strains in pools were calculated using our method of ranging biofilms.

Conclusions

1.The following *Candida* species communicative niches criteria were fulfilled. 1.1.Fungi possessed different panels of the utilized carbohydrates. 1.2.Specific landscapes of residual fungal communicative bodies depended on sorbed acidic BL or LL types. 1.3.Opposite and dissonant influences of BL and LL in doses less than 1 mkg/ml towards 48-h-suspension cultures of *Candida* non-albicans were registered. 2.Two identified leader strains of probiotic-like lactobacilli influenced specie-depended distribution of *Candida* on ability to biofilm forming. 3.BL and LL imitated counteractive niches of probiotic bacteria. 4.The data argue the choice and realization of the personal microbiocenosis protective strategy which uses leader symbiotic strains and SBL to alter fungal niches and, as a result, to increase effectiveness of antifungal treatments. Results indicate that SBL participate in antipathogen synergistic mosaic multipointed directed attacks together with leaders as a coupled network of reactions against development of *Candida* infections. Results indicate simplification of prognostic and diagnostic evaluations of communicating niches of yeast like fungi *in vitro*.

PROBIOTIC LECTINS: MICROBIOCENOSIS FUNCTIONAL ORGANIZERS

M. Lakhtin[1], V. Lakhtin[1], S. Afanasiev[1], A. Bayrakova[1], V. Aleshkin[1]
[1]G.N. Gabrichevsky research Institute for Epidemiology & Microbiology, Medical Biotechnology, Moscow, Russia

Backgrounds

Communication relationships between microbes in human biotope microbiocenoses are characterized by contribution of many factors. Among them probiotic microorganisms serve the one of key protectors of biotopes. We isolated probiotic lectins (PL, proteins recognizing carbohydrates and their derivatives) and their systems (PLS), characterized preparations of lectins of lactobacilli and bifidobacteria (LL and LB) – cell ingredients of probiotics Acilact, Bifidin, others.

Objectives

Summary of functional features of PLS perspective for effective regulation of human biotope microbiocenoses.

Methods

Intestinal and urogenital *Candida* and *Lactobacillus* species strains were from collection of microorganisms of G.N.Gabrichevsky Research Institute for Epidemiology & Microbiology. Behaviors of microbial cultures (monocultures, *Candida--Lactobacillus* mixtures, microbes in the presence of soluble or disc PL) were studied using microbial cultural suspensions in microplate or on agar. Acidic and alkaline preparations of standardized LB and LL were used. Biofilms were evaluated using violet dye. Leader strains were calculated using comparable ranging method proposed by us.

Conclusions

PL function as PLS which recognize and deliver glycoconjugates (GC such as metabiotics, therapeutics and prebiotics), reveal features of probiotics (antifungal and antibacterial synergism LL and LB to antibiotics and other antimicrobials, imitation of probiotic nishes counteracting the pathogens, cofunctioning to macrophage and to lymphocyte protective systems). PLS function as metabolomebiotics (acting in accordance to the system direction “Probiotic network—Own human network”), a part of Quorum sensing in microbiocenoses and human Cross-Talks involving own protective recognition systems. PLS and GC reveal properties of cofunctioning at the level of biofilm forming (eukaryotic, prokaryotic, mixed; microbial and human; clot-dissolving, destruction and lysis, early and late alterations). Results indicate that PLS are natural multifunctional new key effectors of any human biotope microbiocenosis. The data on structure-function of PLS can serve the guide for diagnostics and prognostics of microbial ecology and microbial communities events; construction of multistrain probiotics, synbiotics and symbiotics.

ANTIBIOTIC-RESISTANT ESCHERICHIA COLI STRAINS OBTAINED FROM BACTERIA PRESENT IN ORGANICALLY-AMENDED METAL CONTAMINATED SOIL

I. Alkorta[1], C. Garbisu[2], O. Garaiyurrebaso[1], I. Álvarez-Rodríguez[1], F. Blanco[2], I. Martín[2], A. Lanzén[2]
[1]Byophysics Unic UPV/EHU- CSIC, Biochemistry and Molecular Biology, Bilbao, Spain
[2]NEIKER, Conservation of Natural Resources, Derio, Spain

Backgrounds

Organically-amended and metal contaminated soils have been reported as reservoirs of mobile genetic elements (MGEs). Through horizontal gene transfer, MGEs can provide bacteria with a variety of advantageous traits such as, for instance, antibiotic and/or heavy metal resistance. Likewise, resistance to heavy metals and to antibiotics can be associated due to co-resistance or cross-resistance mechanisms.

Objectives

Here, we investigated the presence of plasmids and integrons in metal contaminated mine soil amended with organic wastes, as well as the physiological traits of antibiotic-resistant *Escherichia coli* transconjugants obtained from bacterial communities present in the abovementioned soil.

Methods

Mobilizable IncQ and conjugative IncP-1 plasmids, as well as class 1 integron integrase *intI1* sequences, were detected in soil by PCR-Southern blot hybridization. Through exogenous isolation, antibiotic resistances were captured in *E. coli* transconjugants, which then displayed a multi-resistant phenotype.

Conclusions

Genome sequencing of some of the transconjugants failed to identify novel genes; nonetheless, we identified one missense mutation in the genome of *E. coli* which could be responsible for the observed resistance to aminoglycosides. On the other hand, *E. coli* transconjugants displayed an altered fitness, as reflected by the values of some physiological traits such as growth rate, gyrase activity, RNA:DNA ratio, carbon substrate utilization and biofilm formation. It was concluded that organically-amended metal contaminated soils are a critical reservoir of MGEs harbouring antibiotic resistance genes, with concomitant implications for the dissemination of antibiotic resistance.

HIGH-THROUGHPUT SEQUENCING ANALYSIS OF MICROBIAL COMMUNITIES ASSOCIATED TO CARPET-SHELL CLAM

A. Lasa[1], D. Gerpe[1], S. Balboa[1], J.L. Romalde[1]
[1]CIBUS- Facultad de Biología. Universidade de Santiago de Compostela, Microbiology and Parasitology, Santiago de Compostela, Spain

Backgrounds

To date, the studies analysing the bacterial communities associated to bivalves, especially to clams, are focused on the culturable fraction, thus leading to an underestimation of the diversity. The recent introduction of high-throughput sequencing technologies would allow a deeper understanding of the bacterial communities complexity.

Objectives

The present study includes the analysis of the total bacterial community associated to carpet-shell clam (*Ruditapes decussatus*) using 16S rRNA amplicons.

Methods

Samplings of the clams were carried out in summer and winter from two different localities. Different organs (mantle, gills, gonads and hepatopancreas) were analysed separately. The bacterial genomic DNA was obtained and amplified using a set of primers designed for the amplification of the V3/V4 region of 16S rRNA gene. The subsequent amplicons were sequenced at Sistemas Genómicos (Valencia, Spain) using Illumina paired-end sequencing technology.

Conclusions

The analysis of the 16S rRNA amplicons of all the organs taken together and throughout the two samplings, revealed that the major fraction of the sequences belonged to *Proteobacteria*, *Actinobacteria*, *Spirochaetae*, *Bacteroidetes*, *Firmicutes* and *Tenericutes* phyla. Considering all organs, *Proteobacteria* was the most abundant phylum but it showed variations in some organs, being less abundant in the mantle or the hepatopancreas. Bacterial groups that are predominant in the culture-dependent methods, such as *Vibrio* or *Pseudomonas*, were detected but as minor representatives. On the other hand, many genera that are absent using the classic methods were identified including *Caedibacter*, *Endozicomonas* or *Ricketsiella*, together with large groups of uncultured bacteria from different families.

TOTAL AND POTENTIALLY ACTIVE RHIZOSPHERIC MICROBIOMES OF MELOJO OAK

A.V. Lasa[1], A.J. Fernández-González[1], P.J. Villadas[1], N. Toro[1], M. Fernández-López[1]
[1]Estación Experimental del Zaidín-Consejo Superior de Investigaciones Científicas, Microbiología del Suelo y Sistemas Simbióticos, Granada, Spain

Backgrounds

Melojo-oak (*Quercus pyrenaica* Willd) is a key tree species of Mediterranean forests with high landscape value in Iberian Peninsula. However, these forests show an advanced stage of degradation and their distribution area has been seriously reduced mainly due to historical human activities and harsh summer conditions typical of Mediterranean regions. In fact, it is regarded as a relict species in Sierra Nevada National and Natural Park. Previous works have suggested that better understanding of plant microbiome, especially of those active microbial members, could be helpful in the development of successful tools for improving plant fitness.

Objectives

The main goal of our work was to study the composition and structure of total and potentially active prokaryotic communities inhabiting melojo-oak rhizosphere, and to identify major bacterial players in order to develop microbiome-based approaches for future afforestation tasks.

Methods

Whole *Q. pyrenaica*'s rhizospheric prokaryotic microbiome and its corresponding active members were studied through 454 pyrosequencing of 16S rDNA and rRNA-derived amplicons. We also calculated the rRNA:rDNA ratio for each core microbiome taxa to get more insights into their potential contribution to the oak rhizosphere environment.

Conclusions

Our results revealed that active bacterial communities are as rich and highly diverse as DNA-based populations. In spite of being composed by nearly the same taxa, the relative abundance patterns differ to a great extent among both studied libraries (rRNA and rDNA). Furthermore, the uncoupling between potential activity and abundance observed for some OTUs showed that the most abundant bacterial taxa are not necessarily the most active.

FEMS7-2054
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

NITRITE DYNAMICS IN THE SEINE RIVER, FRANCE

A. Laverman[1], *T. Cazier*[2], *C. Roose-Amsaleg*[2], *V. Rocher*[3], *M. Raimonet*[2]
[1]*Universite de Rennes 1, UMR 6553 ECOBIO, Rennes, France*
[2]*Universite Pierre et Marie Curie, UMR 7619 Metis, Paris, France*
[3]*SIAAP, Direction du Développement et de la Prospective, Paris, France*

Backgrounds

In the Seine River, France, nitrite concentrations exceed the European norm (0.6µM). Nitrite is produced and eliminated by ammonia oxidizers (AO) and nitrite oxidizers (NO), respectively in the oxic water column.

Objectives

The aim of this study was to get insight in the role of pelagic nitrification in the origin and persistence of elevated nitrite concentrations downstream of Paris.

Methods

To this end, we determined the potential for AO and NO oxidation in the water column and the two main WWTP outlets of the Seine River. In addition to this the key players in ammonia and nitrite oxidation, the ammonia and nitrite oxidizing microbes, were enumerated at the same sites with qPCR.

Conclusions

We showed that the pelagic ammonia and nitrite oxidation potentials were similar whereas nitrite oxidizers outnumbered ammonia oxidizers. The low levels of ammonium in the water column are efficiently oxidized by ammonia oxidizing archeae. However, the relatively low nitrite oxidation rates was in contrast with high numbers of NO. This discrepancy is most likely due to mixotrophic and or heterotrophic growth of *Nitrobacter*, the dominant species in the water column. Rather alternative metabolism of NO than high abundance of pelagic NO in the highly anthropogenic impacted river explains the persistence of nitrite along the Seine River.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

VIRUSES IN SURFACE WATER AND SEWAGE IN SERBIA

G. Lazic[1], S. Lazic[1], D. Lupulovic[1], P. Knezevic[2], T. Petrovic[1]
[1]Scientific Veterinary Institute "Novi Sad", Department for virology, Novi Sad, Serbia
[2]Faculty of Sciences- University of Novi Sad, Department of Biology and Ecology, Novi Sad, Serbia

Backgrounds

Republic of Serbia does not implement surveillance for the presence of pathogenic human and animal viruses in surface and drinking water, neither is the established methodology of these studies in any institution in Serbia.

Objectives

The aim of the study was detection and molecular characterization of human and animal viruses in surface water and sewage in Vojvodina Province of Serbia.

Methods

The latest methods for concentration of viruses and nucleic acids extraction in surface water and sewage were used in this study. The presence of DNA and RNA viruses was tested by real-time PCR (qPCR) and reverse transcription real-time PCR (RT-qPCR) assays. Molecular characterization was done by Sanger`s sequencing of genome parts of detected viruses.

Conclusions

Human and animal viruses are present in surface water in Serbia. We tested a total of 108 samples of surface and municipal sewage in different seasons, from 2012 to 2014. The analysis of the partial viral genome of detected HAdV from 6 out of 42 positive samples were classified as HAdV group F (types 40 and 41). HEV genotype 3, PAdV type 5 and BPyV type 1 were confirmed in three samples originating from surface water and sewage. The presence of viruses in surface water and of urban sewage reflects the infectious status of the population, and also constitutes a significant risk to the human and animal health in the area that gravitates to that surface water.

Acknowledgments: This work is conducted within the project TR31084 funded by the Serbian Ministry of Education, Science and Technological development.

COLD STRESS INDUCED BIOFILM FORMATION OF LISTERIA MONOCYTOGENES STRAINS

B. Lee[1,2], *T. Bernardi*[1], *M. Herbraud*[3]
[1]*Biofilm Control, R&D, Saint-Beauzire, France*
[2]*GenXPro, R&D, Frankfurt am Main, Germany*
[3]*INRA, Microbiology, Theix, France*

Backgrounds

Listeria monocytogenes can efficiently survive even in extreme conditions where many other bacteria cannot withstand. Under the assumption that biofilms in food premises leads to food contamination of *L. monocytogenes*, studies have primarily compared the effect of temperature on biofilm formation by growing the bacteria at different temperatures most frequently from 4°C to 37°C and showed that *L. monocytogenes* strains are able to survive at low temperature and form biofilms. However, it is still difficult to directly compare the quantity of biofilms formed at different temperatures since the optimal growth temperature around 37°C involves higher cell growth and enzymatic activities involved in cellular physiology, even though various stress factors including low temperature are known to trigger biofilm formation of *L. monocytogenes*.

Objectives

In this study, we used 22 *L. monocytogenes* strains, of diverse origins and molecular serotypes, to investigate (i) effect of incubation temperatures on cell surface property and its influence on biofilm formation and (ii) effect of cold stress on biofilm formation by comparing biofilms formed upon cold stress and after cold adaptation.

Methods

We applied crystal violet staining to quantify the total biomass and an innovative technique called BioFilm Ring Test® to measure early step of biofilm formation, namely ‘adhesion’ to surfaces. To confirm the biofilm formed at different conditions, we employed scanning electron microscopy.

Conclusions

We confirmed that cold stress enhanced the biofilm formation of all 22 strains. However, there was no correlation between cell surface characteristics and total biomass or adherence of *L. monocytogenes*.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ANNUAL MONITORING OF GEOSMIN-PRODUCING CYANOBACTERIA AND STREPTOMYCES AND THEIR LINKS TO THE ODOROUS COMPOUNDS IN THE NAKDONG RIVER

C.S. Lee[1], H.S. Oh[2], H.M. Oh[2], C.Y. Ahn[2]
[1]Nakdonggang National Institute of Biological Resources, Bioresources Culture Collection Division, Sangju, Republic of Korea
[2]Korea Research Institute of Bioscience and Biotechnology, Cell Factory Research Centre, Daejeon, Republic of Korea

Backgrounds

Geosmin has an earthy-musty odor and now becoming an important issue in drinking water sources. Both cyanobacteria and actinobacteria were regarded as its microbial source. Levels of geosmin and its seasonal fluctuations have been studied in many freshwater ecosystems, yet there is limited information for the relationships with its microbial sources.

Objectives

The aims of this study was to monitor the concentration of geosmin and to investigate potential relationships between the odorous compound and its microbial sources.

Methods

During April 2014 to March 2015, an odorous compound, geosmin, has been investigated at a water intake tower on the Nakdong River using both the multiplex quantitative PCR(qPCR) and solid phase microextraction(SPME)-gas chromatography(GC). The highest concentration of geosmin was found during June 2014 over 100 ng/L in water, where levels of cyanobacteria and cyanobacterial geosmin-coding gene(*geoA*) were highest as about 40,000 cell/mL and 5,000 copy/mL during the same period. In addition, *Streptomyces*-specific *geoA* gene was also found more than 1,000 copy/mL from the same sample of June 2014. Sequencing analysis of *geoA* genes showed that both *Anabaena* and *Streptomyces* were a major microbial components. However, relatively low amount of geosmin was detected as about 20 ng/L in September 2014, where its microbial source was identified as *Streptomyces.* Statistical analysis indicated that there was a significant relationship between the level of geosmin and cyanobacteria during spring and summer. During autumn and winter, the level of *geoA* and geosmin compound were correlated with the occurrence of *Streptomyces.*

Conclusions

The results suggested both cyanobacteria and actinobacteria could effect on the outbreak of geosmin in the freshwater.

NOVEL SPECIES MICROBULBIFER ECHINI ISOLATED FROM THE DIGESTIVE TRACT OF HELIOCIDARIS CRASSISPINA

J.Y. Lee[1], P.S. Kim[1], J.W. Bae[1]
[1]Kyung Hee University, Dept. of Life and Nanopharmaceutical Sciences and Dept. of Biology, SEOUL, Republic of Korea

Backgrounds

The purple sea urchin *Heliocidaris crassispina* is known as algae eater. Algae is composed of specific polysaccharide that difficult to digestive.

Objectives

Investigate commensal bacteria that reside in digestive tract of *H*. *crassispina* is necessary for understanding digestion ability of algae polysaccharide.

Methods

To investigate algae degrading associated specific bacteria in gut of *H*. *crassispina*, we detached gut from *H*. *crassispina* and homogenized it. Bacteria isolation was performed using culture dependent method. Total 110 colonies were selected and were identified by 16S rRNA gene sequencing.

Conclusions

Among them, one bacterium, novel *Microbulbifer* species that was considered as algae associated bacteria was identified. Novel *Microbulbifer* species designated as strain AM134^T belonged to the genus *Microbulbifer* in family *Alteromonadaceae*. Strain AM134^T shared high 16S rRNA gene sequence similarity with *Microbulbifer epialgicus* F-104^T (98.90 % similarity). Strain AM134^T grew optimally at 30 ˚C, in the presence of 2 % (w/v) NaCl and at pH 7. The DNA-DNA hybridization analysis showed the strain shared less than 27 % genomic relatedness with *M. epialgicus* F-104^T. The G+C content of genomic DNA was 56.1 mol%. The major respiratory quinone was identified as ubiquinone-8 (Q-8). The major cellular fatty acids were summed feature 8 ($C_{18:1}$ *ω6c* and/or $C_{18:1}$ *ω7c*) and $C_{16:0}$. The results of the phylogenetic, phenotypic and genotypic analyses suggest that strain AM134^T represents a novel species in the genus *Microbulbifer*, for which the name *Microbulbifer echini* is proposed, where the type strain is AM134^T (= KACC 18258^T = JCM 30400^T).

KOREAN-DIET RAPIDLY ALTERS THE HUMAN GUT MICROBIOME

N. Lee[1], *M.D. Kim*[1], *E.J. Song*[1], *M.Y. Lim*[1], *Y.D. Nam*[1]
[1]*Korea Food Research Institute, Research Group of Gut Microbiome, Seongnam-si- Gyeonggi-do, Republic of Korea*

Backgrounds

Diet is a major factor driving the composition and metabolism of the intestinal microbiota. We prepared two diets that varied according to their primary food source: a Korean diet, which was rich in cooked rice, kuk (soup), kimchi, side dishes (fermented soy and vegetables); and a Western diet, which was wheat, meat, eggs and fruits.

Objectives

The aim of this study was to investigate the dietary effect of diet composed Korean style (n=5) or Western style (n=5) on gut microbiota composition during 2 week.

Methods

The stool samples were obtained weekly for next-generation sequencing of the 16S rRNA gene (V3-V4 region). The sequences were denoised and further filtered using QIIME software.

Conclusions

Although Western-diet has temporarily increased microbiota diversity during the first week, we observed the reduced microbial diversity between baseline and diet-associated gut microbiota from both diets. To identify the relationship between 15 clinical biomarkers and abundance of microorganism in species level, performed statistical analysis. In Korean- diet, the *Prevotella copri* and *Bacteroides coprophilus* showed the positive correlations with weight change and insulin change, respectively. In Western-diet, the *Bacteroides ovatus* and *Catenibacterium mitsuokai* showed the negative correlation with glucose change. As a result, Korean-diet and Western-diet can alter gut microbial communities in a rapid, diet-specific manner.

ESTABLISHING A LABORATORY MODEL OF DENTAL UNIT WATERLINE BIOFILMS USING A CDC BIOFILM REACTOR

H.Y. Yoon[1], S.Y. Lee[1]
[1]Gangneung-Wonju National University, College of Dentistry, Gangneung, Republic of Korea

Backgrounds

Water supplied through dental unit waterlines (DUWLs) is often contaminated with bacteria. However, it is challenging to obtain adequate waterline samples for studies of the formation and removal of biofilms.

Objectives

In this study, we established a laboratory model to reproduce DUWL biofilms, using a CDC biofilm reactor (CBR).

Methods

Bacteria obtained from DUWLs were filtered and cultured in R2A liquid medium for 10 days, and were subsequently stored at −70 °C. This stock was cultivated in R2A liquid medium in batch mode. After 5 days of culturing, the bacteria were inoculated into the CBR. Biofilm formation was allowed on polyurethane tubing for 4 days. The accumulation, thickness, morphological characteristics, and distribution of the constituent bacteria of the biofilms were examined by confocal laser scanning microscopy and scanning electron microscopy. The taxonomic diversity of the biofilms was evaluated by pyrosequencing.

Conclusions

Biofilm accumulation on the CBR model was 1.3×10^5 CFU/cm^2 after 4 days. Bacteria were aggregated on part of the surface. Bacteria constituting the biofilms included cocci and rods of short and medium lengths. The thickness of the biofilms after 4 days was 10–14 μm. In addition, 38 bacterial genera were detected in the CBR biofilm. In this study, we demonstrated the suitability and reproducibility of the CBR model for DUWL biofilm formation. The model provides a foundation for the development of bacterial control methods for DUWLs, an important area of dental research.

FEMS7-3170
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

SINGLE CELL GENOMIC STUDY OF CANDIDATUS ATRIBACTERIA JS1 LINEAGE PREDOMINANT IN MARINE SEIMENTS OF THE ROSS SEA, ANTARCTICA

Y.M. Lee[1], H. Kuin[1], K. Mincheol[1], H. Soon Gyu[1], S. Seung Chul[2]
[1]Korea Polar Research Institute, Division of Polar Life Sciences, Incheon, Republic of Korea
[2]Korea Polar Research Institute, Unit of Polar Genomics, Incheon, Republic of Korea

Backgrounds

Candidate phylum *Atribacteria* JS1 lineage is among the predominant members in anoxic subseafloor environments, especially in methane-rich sediments. However, the metabolic potential and biogeochemical role of this phylum have remained elusive due to the lack of axenic culture representatives.

Objectives

To understand the metabolic potential and ecological funtion of candidate phylum *Atribacteria* JS1 lineage, single cell genomic approach was applied.

Methods

From the marine sediment at 40 cmbsf of the Ross Sea with 38.9% portion of JS1, 18 single cell amplified genomes considered to be a single species and consistent with the dominant *Atribacteria* JS1 species in that environment were obtained.

Conclusions

The composite genome with the highest genome coverage (2.3Mb) encoded redundant ABC transpoters for amino acid, peptide, and saccharide, complete sets of enzymes in glycolysis and the Wood-Ljungdahl pathway for CO_2 fixation. *Atribacteria* JS1 in the Rose Sea was predicted to be homoacetogenic bacteria, which is capable of growing on H_2/CO_2 or CO_2, and have heterotrophic lifestyle by fermenting various carbon sources. The presence of the Wood-Ljungdahl pathway to run in reverse showed the possibility of *Atribacteria* JS1 as a syntrophic acetate-oxidizer with hydrogenotrophic methanogens which explains their predominance in anoxic methane-rich sediments. Genomic analysis of *Atribacteria* JS1 provided functional potential of this uncultivated but considered to be very important group in carbon cycling.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ENTEROCOCCUS FAECALIS IN SPANISH WILD AND MIGRATORY BIRDS: FROM POPULATION STRUCTURE TO ACCESSORY GENOME

R. León-Sampedro[1], E. Martins[2], R. del Campo[1], M. Rodríguez-Baños[1], A.P. Tedim[1], M. Pozuelo[1], L. Peixe[2], A. Freitas[2], C. Novais[2], V.F. Lanza[1], F. Baquero[1], T.M. Coque[1]
[1]Insituto Ramón y Cajal de Investigación Sanitaria, Molecular Microbiology, Madrid, Spain
[2]UCIBIO/REQUIMTE - University of Porto, Microbiology Laboratory, Porto, Portugal

Backgrounds

Enterococcus faecalis (*Efs*) is a gut commensal of mammals, reptiles, insects and birds, and one of the main human and animal pathogens able to acquire antibiotic resistance. Sequence information of this species is overrepresented by strains from humans and foodborne animals.

Objectives

To evaluate the role of *Efs* from wild-birds as reservoirs of antibiotic resistance and potential vector of AbR transmission.

Methods

Efs isolates from wild birds (n=100; 9 taxonomic bird orders, two Spanish Centers of Nature Conservation) were analyzed for clonal relationship (PFGE/MLST), and antibiotic susceptibility (CLSI). Virulence and antibiotic resistant genes and mobile genetic elements was inferred by PBRT-PCR, hybridization and sequencing. Comparative genomics (Illumina-HiSeq-2500) of 5 isolates from different bird species was performed to analyze core, accessory genome-(ACCNET) and plasmidome-(PLACNET). The core and accessory genome were compared with available Efs genomes in databases.

Conclusions

Eight major PFGE clusters comprising isolates (n=100) with 41 different ST (25 singletons) detected. Variable resistance to tetracycline (67%-*tet*(M)), chloramphenicol (42%) erythromycin (28%-*erm*(B)) and high-levels of streptomycin (26%), kanamycin (19%) and gentamicin (5%) were observed. Most *Efs* contain 0-3 plasmids (3-90kb) of different families [RepA_N (rep9), Inc18 ($rep1_{pRE25}$; $rep2_{pVEF1}$), Rep_trans-RCR ($rep7_{pS194\text{-}like}$; $rep17_{pRUM}$ and $rep14/orf1_{pEFNP1}$) and Rep3_small_theta ($rep18_{pEF418}$; rep_{pCIZ2}; $rep6_{pAMα1/pS86}$)]. Only MOB_C and MOB_P relaxases were detected. Although the core genome of the sequenced wild bird Efs clusters with ST16, ST55 and ST82 of human and animal origin, a host specific accessory genome (mobile genetic elements, transcriptional regulation and metabolism proteins) was identified. The results highlight the evolvability and networking of *Efs* in different hosts and environments.

FEMS7-0774
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ALTERATION IN GUT MICROBIOME BY DIETARY PROTEIN AND CARBOHYDRATE COMPOSITION IN OBESE VS LEAN DOGS

J. Li[1], C. Lauber[2], G. Czarnecki-Maulden[1], Y. Pan[1], S. Hannah[1]
[1]Nestle Purina PetCare Company, Basic Research, Saint Louis, USA
[2]Nestle Institute of Health Sciences, GI Health & Microbiome, Lausanne, Switzerland

Backgrounds

More than 50% of dogs in the United States are either overweight or obese. Microbial dysbiosis has been associated with metabolic disorders including obesity. High protein low carbohydrate (HPLC) diets have been known for weight management benefits, but their effects on the gut microbiome remains unknown.

Objectives

To evaluate the differential impacts of protein and carbohydrate ratio on the gut microbiome in obese vs. lean dogs.

Methods

Thirty-two Labrador Retrievers and 32 Beagles, half obese or overweight (mean body fat 40%) and half lean or normal (mean body fat 22%) with a mean ages of 5.7, were fed the common baseline diet (phase 1) for 4 weeks, followed by one of the intervention diets (phase 2) for 4 weeks. The HPLC diet contained 49.4% protein and 10.9% carbohydrate, while the low protein high carbohydrate (LPHC) diet had 25.5% protein and 38.8% carbohydrate. Fecal samples were collected at the end of each phase and were subject to 16S rRNA gene sequencing analysis.

Conclusions

Significant diet effects, mostly on the predominant phyla, *Bacteroidetes* and *Firmicutes*, were observed. The effect appears to be greater in obese dogs than in lean dogs, but independent of breed. The HPLC-fed dogs had decreased *Bacteroidetes* to *Firmicutes* ratios, and enriched microbial gene networks associated with weight maintenance, when compared with those on the high carbohydrate diet. The abundances of *C. hiranonis*, *C. perfringens*, and *R. gnavus* were higher in the HPLC group, while those of *B. uniformis* and *C. butyricum* were greater in the LPHC group.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

BDELLOVIBRIO PREDATION ON AEROBIC GRANULAR SLUDGE

R. Liébana[1], E. Szabó[1], F. Persson[1], O. Modin[1], M. Hermansson[2], W. Britt-Marie[1]
[1]Chalmers University of Technology, Civil and Environmental Engineering, Gothenburg, Sweden
[2]University of Gothenburg, Department of Chemistry and Molecular Biology, Gothenburg, Sweden

Backgrounds

Predation is one of the main causes of bacteria mortality, having a big influence on the microbial community structure and function. Despite its importance, microbial predation is poorly understood. Wastewater treatment bioreactors offer the opportunity to study basic aspects of microbial ecology, for instance predation, due to the well-defined environment. Predators, such as protists, bacteriophages and predatory bacteria, are considered to have direct impact on the microbial community in bioreactors and hence, on wastewater treatment.

Objectives

The aim was to study the prevalence and predation of *Bdellovibrio* sp. in aerobic granular sludge.

Methods

Cryosections of 9 weeks old granules, harvested from a sequencing batch reactor, were used for fluorescence in situ hybridization (FISH) targeting the *Bdellovibrio* genus (BDE525), ammonia-oxidizing bacteria (AOB; NEU654, Nse1472, Cluster6a192) and total cells (Syto 40). *Bdellovibrio* sp. prevalence was followed in the reactor biomass and the effluent using 16S rRNA gene sequence analysis on the Miseq Illumina platform.

Conclusions

Bdellovibrio sp. was not washed out from the reactors, which indicate that aerobic granules offer a niche to this predator. FISH revealed *Bdellovibrio* sp. actively predating inside the granules, preferentially on AOB, as seen by their localization. This results suggest that AOB, among other bacteria, were subjected to predation which might have an impact on the nitrification process in engineered and natural ecosystems.

PREVALENCE OF E. COLI O157:H7 GFP+ ON LEAFY VEGETABLES AS AFFECTED BY PLANT CULTIVAR

J. Lindén[1], T. Bengtsson[1], M. Mieli[2], R. Hartmann[1], L. Mogren[1], M.E. Karlsson[1], B.W. Alsanius[1]
[1]Swedish University of Agricultural Sciences SLU, Biosystems and Technology, Alnarp, Sweden
[2]IUT de Laval, Département Génie Biologique, Laval, France

Backgrounds

Outbreaks of foodborne illness due to consumption of leafy vegetables contaminated with human pathogens have increased during the past 20 years. Interest in maintaining a healthy diet is also increasing and since leafy vegetables are an essential part of a healthy diet the production increases. Several outbreaks have been associated with leafy vegetables contaminated with the harmful *Escherichia coli* O157:H7. Different investigations studied the fate of *E. coli* O157:H7 on the leaf surface and inside the leaf; however, used model crops and cultivars vary widely. Previous studies investigating the impact of the plant cultivar on different plants species have given varying results. We wanted to know if the plant species or the cultivar drives the fate of *E. coli* O157:H7 on leafy vegetables.

Objectives

The plant species selects upon the phyllosphere microbiota and the impact of cultivar of greenhouse grown baby leaf spinach, rocket and Swiss chard is similar.

Methods

A greenhouse experiment was conducted where *E. coli* O157:H7 *gfp*+ was inoculated onto the leaves. The phyllosphere associated bacteria were analysed with viable count, 16S rRNA gene sequencing of pure isolates and metagenomics.

Conclusions

Our results show that the analysed cultivars does not have a significant impact on the colonization of *E. coli* O157:H7 *gfp*+. We demonstrate the phylogenetic diversity of dominating culturable bacteria of the three plant species and three cultivars respectively and show that the phylogenetic diversity however, differ between the plant species and the plant cultivars.

MICROBIAL DEGRADATION OF AROMATIC FRACTION FROM DIESEL FUEL

M. Ljesević[1], *B. Kekez*[1], *S. Bulatović*[1], *M. Ilić*[2], *G. Gojgić-Cvijović*[3], *V. Beškoski*[1], *M.M. Vrvić*[1]
[1]*University of Belgrade- Faculty of Chemistry, Department of biochemistry, Belgrade, Serbia*
[2]*University of Belgrade- IChTM-Institute of Chemistry- Technology and Metallurgy, Department of Chemistry, Belgrade, Serbia*
[3]*University of Belgrade- IChTM- Institute of Chemistry- Technology and Metallurgy, Department of Chemistry, Belgrade, Serbia*

Backgrounds

Diesel fuel is a complex mixture of alkanes and aromatic compounds that can be harmful if released into the environment. Various microorganisms capable of petroleum degradation were isolated, however the most difficult task is the degradation of polycyclic aromatic hydrocarbons (PAHs). They are a large class of compounds that can be mutagenic and carcinogenic (1). Due to their high molecular masses and hydrophobicity, they adsorb to soil particles, which limits their bioavailability to microorganisms (2).

Objectives

Aim of this study was to separate aromatic fraction from diesel fuel and then to investigate the microbial biodegradation of aromatic fraction.

Methods

Aromatic fraction was separated from diesel fuel on silica gel column by elution with hexane and mixture of hexane:toluene, respectively (3). The bacterial strain *Rhodococcus sp*. RNP05, isolated from petroleum contaminated soil was inoculated into mineral medium where the only source of carbon was aromatic fraction. The remaining aromatic fraction was determined after 30 days by GCxGC/MS.

Conclusions

The aromatic fraction of diesel fuel consists mainly of aromatic hydrocarbons. The results showed the reduction of aromatic fraction concentration in samples after 30 days of degradation. From the GCxGC/MS chromatograms it can be seen that the naphthalens and biphenyls are almost completely removed.

CORRELATION BETWEEN VIRULENCE FACTORS AND QUORUM SENSING SIGNAL MOLECULES IN THREE MARINE VIBRIO PATHOGENS

M. Torres[1,2], J.C. Reina[1], P. Izquierdo[1], I. Llamas[1,2]
[1]University of Granada, Microbiology, Granada, Spain
[2]Institute of Biotechnology. Center for Biomedical Research, Microbiology, Granada, Spain

Backgrounds

The most common and serious bacterial pathogens that affect aquaculture belong to the *Vibrio* species and they are responsible for many diseases such as bleaching in corals and hemorrhagic septicemia (vibriosis) in fish and shellfish.

During recent years the virulence of different pathogenic bacteria has been associated with quorum sensing (QS), a sophisticated mechanism for coordinating gene expression by means of small signal molecules, such as *N*-acylhomoserine lactones (AHLs). In this study, we present the results of AHL inactivation in three aquaculture *Vibrio* pathogens and its correlation with the expression of some virulence factors.

Objectives

To evaluate to what extent the expression of some virulence factors is affected by AHL inactivation in three aquaculture pathogenic strains.

Methods

AHL deficient mutants of *V. mediterranei*, *V. coralliilyticus* and *V. owensii* were constructed by transferring plasmids that contain AHL lactonases and co-cultivation experiments of the three pathogenic species with AHL-degrading strains or QQ enzymes were carried out. The AHL extract in each case was analysed by using AHL biosensor strains. The effect of the AHL degradation upon some of the virulence factors produced by the *Vibrio* species was evaluated by different approaches.

Conclusions

This study shows the correlation between AHLs and the expression of some virulence factors in three aquaculture *Vibrio* pathogens. The information from this research contributes to the development of future new therapies based on AHL disruption, one of the most promising alternatives nowadays for fighting infectious diseases in aquaculture.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

LITTER DECOMPOSITION IN A WET TROPICAL FOREST: MULTI-TROPHIC IMPACTS ON CARBON TRANSFORMATION AND NUTRIENT MOBILIZATION

E. Lloret Sevilla[1], E.L. Brodie[1], Z. Hao[1], M. Bill[1], J.A. Ceja-Navarro[1], N.J. Bouskill[1]
[1]Lawrence Berkeley National Laboratory, Ecology De, Berkeley, USA

Backgrounds

Phosphorus (P) is an essential yet limiting element within highly weathered tropical forest soils. Leaf litter decomposition likely represents an import source of available P and may be regulated by plant-microbe-metazoan interactions but these mechanisms remain poorly defined leading to uncertainty in models of vegetation dynamics.

Objectives

We initiated a leaf litter decomposition experiment in a humid tropical forest in Luquillo (Puerto Rico) to determine the magnitude of P released from leaf litter decomposition and how this is impacted, by excluding different trophic levels (plant roots, micro and mesofauna, fungi, and bacteria).

Methods

To study decomposition of leaf litter from a dominant tree species (*Dacryodes excelsa*) we collected freshly fallen litter and constructed litter bags with varying mesh sizes to control access to different trophic groups. We deployed these litter bags across two sites with contrasting slopes and redox properties and sampled over 12 months. Bulk chemical analysis of litter C, N and P, together with infrared analysis of leaf chemistry was combined with measurements of biomass across trophic levels.

Conclusions

Preliminary results show lower decomposition rates where access to all trophic levels was possible, although N and P loss was higher. Where roots and fauna were excluded more rapid decomposition of lignocellulose was observed. Ongoing work will determine the microbial players in decomposition and how they are impacted by trophic interactions.

HORIZONTAL GENE TRANSFER OF ANTIBIOTIC RESISTANCE GENES IN BACTERIA ISOLATED FROM THE GUT OF THE MUMMICHOG FISH, FUNDULUS HETEROCLITUS

N. Lloyd[1], T. Barkay[2]
[1]Rutgers - The State University of New Jersey, Biochemistry and Microbiology, New Brunswick, USA
[2]Rutgers University, Biochemistry and Microbiology, New Brunswick, USA

Backgrounds

Microbial resistance to antibiotics is a serious public health concern. Antibiotic and metal resistance genes may be linked on mobile genetic elements leading to co-selection whereby resistance to antibiotics is enhanced by exposure to metals.

Objectives

The aim of this research is to investigate co-selection of mercury and antibiotic resistance in a contaminated environment.

Methods

We isolated multi drug resistant bacteria from the gut content of mummichog fish (*Fundulus heteroclitus*) that were collected from Berry's Creek, a legacy mercury contaminated site, and Great Bay, a relatively non-contaminated site in New Jersey, USA. The whole genomes of three strains were sequenced.

Conclusions

Gut isolates were resistant to several antibiotics and mercury and, significantly, mercury resistant strains were more likely to be resistant to 3 or more antibiotics than mercury sensitive isolates ($p < 0.001$). A pattern of co-resistance to ampicillin, chloramphenicol, and trimethoprim was common among isolates representing the *Vibrio*, *Aeromonas*, and *Shewanella* genera. Antibiotic resistance genes were found for all observed phenotypes. Genes encoding for the multi-antimicrobial extrusion (MATE) protein family of drug efflux pumps were found in the isolates. Additionally, the isolates' genomes included genes encoding horizontal gene transfer, such as type IV secretion systems, integrons, transposons, and putative conjugal transfer proteins. Together, the data suggest that a mobile antibiotic resistance gene pool may be created by virtue of a genetic linkage between resistance genes and those that facilitate horizontal gene transfer and microbial adaptation to life in contaminated environments.

TRANSCRIPTOMIC PROFILING OF A PLANT BENEFICIAL PHOTOTROPHIC BACTERIUM, RHODOPSEUDOMONAS PALUSTRIS PS3 IN RESPONSE TO CHINESE CABBAGE ROOT EXUDATES

K.J. Lo[1], *C.T. Liu*[1]
[1]*Institute of Biotechnology, Institute of Biotechnology, Taipei, Taiwan R.O.C.*

Backgrounds

Rhodopseudomonas palustris strain PS3 is a plant growth promotion rhizobacteria (PGPR) which was isolated from Taiwanese paddy soil. In our previous study, we found that strain PS3 exerted beneficial effects on plant growth by improving efficiency of applied fertilizer nutrients uptake. Moreover, PS3 also reduced the accumulation of nitrate in plant tissue.

Objectives

To explore the mechanisms of plant growth promotion of PS3 and interactions between this bacterium with host plant.

Methods

We performed comparative transcriptomic analyses of PS3 and an ineffective *R. palustris* strain YSC3.in response to root exudates.

Conclusions

Although the genomic backgrounds of PS3 and YSC3 resemble each other, the gene expressions of these two bacteria in response to root exudates were different. Total of 813 and 1,271 genes representing 16.9% and 25.9% of the PS3 and YSC3 transcriptome showed significantly altered expression levels after 24 hours treatment with root exudate. 410 genes (8.5%) and 839 (17.1%) of PS3 and YSC3 were up-regulated after incubation with root exudates for 24 hours, whereas 410 genes (8.5%) and 432 (8.8%) genes were down-regulated. In addition, we also found that several groups of the genes in PS3 which were significantly induced by the root exudates, such as those involved in amino acid metabolism, biofilm formation and flagellar biosynthesis. These results indicate that the interaction between PS3 and host plant plays a critical role in bacterial-stimulated growth promotion. We expect the new insights of this investigation will provide new insights into PGPR, and aid improve efficiency and stability in agricultural practices.

ORGANIC CARBON AND ORGANIC NITROGEN AT THE CROSSROADS OF FUNGI AND BACTERIA MUTUALISM

A. Lohberger[1,2], J. Spangenberg[3], Y. Ventura[1], N. Jeanneret[1], S. Bindschedler[1], E. Verrecchia[2], R. Bshary[4], P. Junier[1]
[1]Institute of Biology, Laboratory of Microbiology, 2000 Neuchâtel, Switzerland
[2]Institute of Earth Surface Dynamics, Laboratory of Biogeosciences, 1015 Lausanne, Switzerland
[3]Institute of Earth Surface Dynamics, Laboratory of Organic Geochemistry, 1015 Lausanne, Switzerland
[4]Institute of Biology, Laboratory of Eco-ethology, 2000 Neuchâtel, Switzerland

Backgrounds

Roles of organic carbon (Corg) and nitrogen (Norg) as stabilising factors of the interaction between the ectomycorrhizal and saprophytic fungal genus *Morchella* spp. and the soil model bacterium *Pseudomonas putida* were investigated. In *Morchella crassipes*, a complex mutualistic interaction coined bacterial farming, has been previously described. During this interaction three phases were identified: dispersal of bacteria on the fungal mycelium, rearing by the fungus, and harvesting of bacteria. So far, it has been shown that the bacterium benefits during dispersal and rearing, whereas the fungus benefits during harvesting. However, a direct benefit for the fungus during the first two phases remains unidentified.

Objectives

In this study, we further investigated a possible direct benefit for the fungus as a result of bacterial dispersal.

Methods

We tested bacteria moving on the fungal mycelium in a medium containing Corg and Norg, which led to an increase in proteolytic activity by the fungal partner. This increase in proteolytic activity was a general feature of several *Morchella* spp., but required the presence of living bacteria. Comparing the biomasses of both partners as a proxy to fitness, we showed that a truly mutualistic interaction only appears when Corg and Norg are provided in excess. When changing conditions to Corg excess, the fungus took advantage, whereas with Norg without excess Corg, the bacterial partner is favoured.

Conclusions

We conclude that the Corg/Norg ratio is one of the key nutritional factors to determine the outcome of interactions between soil fungi and bacteria.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

EXPLORATION OF NOVEL DEFENSE STRATEGIES OF BACTERIA USING BACTERIA-PHAGE ANTAGONISTIC COEVOLUTION

A. Lopatina[1], A. Millman[1], E. Abram[1], S. Silverman[1], S. Melamed[1], A. Leavitt[1], R. Sorek[1]
[1]Weizmann Institute of Science, Molecular Genetics, Rehovot, Israel

Backgrounds

Prokaryotes are faced with a constant threat of predation, and have developed a broad range of defense mechanisms against viruses. Recently it has become clear that the whole arsenal of microbial immune systems must be even more complex and diverse, therefore discovery of yet unexplored functional defense systems has attracted more and more attention over the last few years. Experimental approach provides advantages in detection of novel defense strategies, as the memory of host-predator interactions could be recorded in the genomes of bacteria as rearrangements at specific loci, and could be monitored during real-time evolutionary experiments.

Objectives

To discover novel defense strategies of bacteria using bacteria-phage coevolution experiments.

Methods

In this work we performed over 70 separate coevolution experiments with dozens of strains of *Bacillus* and *Thermus* and their phages. Each bacterial strain was infected with one of its phages in 500 µl of liquid media, allowing coevolution for seven days with serial daily transfers. Whole genome sequencing of bacterial and phage genomes was performed, followed by analysis of genome changes suspected as responsible for phage and bacterial survival during the multiple coevolution passages.

Conclusions

Different bacteria-phage growths dynamics were observed during co-incubation, indicating different defense strategies of bacteria. Mutations in phage receptors, lysogenisation and rearrangements in CRISPR arrays were among most common defense strategies of bacteria. In addition, multiple short fragment inversions were detected in the genome of *Thermus* strains after phage infection; further experiments are required to discover the mechanisms of these rearrangements.

UNCULTURED AND CANDIDATE LINEAGES IDENTIFIED AS VIABLE MICROORGANISMS IN THE DEEP TERRESTRIAL BIOSPHERE

M. Lopez-Fernandez[1], *D. Simone*[1], *E. Broman*[1], *X. Wu*[1], *S. Bertilsson*[2], *M. Dopson*[1]
[1]*Linnaeus University, Department of Biology and Environmental Science, Kalmar, Sweden*
[2]*Uppsala University,*
Department of Ecology and Genetics- Limnology and Science for Life Laboratory, Uppsala, Sweden

Backgrounds

The 'deep biosphere' is the largest 'bioreactor' on earth and is estimated to contain 2 to 19% of the total biomass. Nevertheless, due to the difficulty of obtaining samples, this milieu is one of the least understood ecosystems on the planet. Microorganisms inhabiting this biome strongly influence the global nutrient and energy cycles.

Objectives

An important question for deep biosphere microbiology is not only its diversity but also whether or not specific populations are viable or not. The Äspö Hard Rock Laboratory provides access to investigate the microbial life in the deep terrestrial subsurface.

Methods

Previous studies at the site revealed the presence of microbial anaerobes, putative H_2 oxidizers and NO_3^-, Fe^{3+}, SO_4^{2-}, and Mn^{2+} reducers along with acetogens and methanogens. The current work expands on these earlier findings to identify the viable (i.e. having an intact cellular membrane) and non-viable (i.e. having a compromised membrane) populations in three aquifers with different chemistries and depth below the surface. High throughput 16S rRNA gene sequencing of total and viable cells revealed significant differences between the subsets of the community and that the viable diversity decreased with temporal separation from the surface. The viable population was mainly related to uncultured candidate phyla such as *Parcubacteria* (OD1), *Gracilibacteria* (GN02), *Atribacteria* (OP9), *Katanobacteria* (WWE3), *Microgenomates* (OP11), Candidate TA06, and unclassified *Euryarchaeota*.

Conclusions

Our results emphasize the importance of unclassified and candidate phyla in the deep biosphere, while ongoing metatranscriptomics analysis will further dissect the metabolic capacities and functions of active microbial populations in this biome.

COMPARATIVE GENOMICS AND PHYLOGENOMICS OF THE GENUS SALINIVIBRIO

C. Lopez-Hermoso[1], R. Ruiz[1], A. Ventosa[1], C. Sanchez-Porro[1], K. Konstatinidis[2]
[1]Universidad de Sevilla, Microbiology and Parasitology, SEVILLA, Spain
[2]Georgia Tech, Building- Georgia Institute of Technology, Atlanta, USA

Backgrounds

Vibrio costicola was first described by Smith in 1938. This species was then transferred to the genus *Salinivibrio*, which today comprises four species, one of them with three subspecies. Salinivibrios are moderately halophilic bacteria isolated from salted meats, brines and hypersaline environments. Recently, next-generation sequencing (NGS) technology has allowed us to conduct whole genome scan of several members of this genus.

Objectives

The aim of this study was to sequence and to perform a comparative genomic study of 36 strains of the genus *Salinivibrio* including all the type strains of species and subspecies, as well as other representative new strains isolated from different solar salterns in Spain and Puerto Rico.

Methods

WGS was accomplished by using Illumina and PacBio technologies. After assembly, the main features of each *Salinivibrio* genome were studied, their taxonomic affiliation was confirmed by means of phylogenomic analyses and other *in silico* indexes, and the presence/absence of genes, abundance in saline and hypersaline environments and main metabolic pathways were analyzed.

Conclusions

The studied strains can be classified in five different specific lineages. It seems that representatives of *Salinivibrio* are not a predominant population in hypersaline environments despite they can be easily cultivated in artificial media. Genes related to motility, anaerobic respiration, ectoine synthase, choline dehydrogenase, betaine aldehyde dehydrogenase and bacterial type II secretion systems were significantly abundant in the studied genomes.

FEMS7-0739
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

OYSTERS AS RESERVOIRS FOR THE ZOONOTIC SEROVAR OF VIBRIO VULNIFICUS: ROLE OF VVP, VVHA AND RTXA1

C. Lopez-joven[1], C. Murciano[2], J. Perez-larruscain[3], E. Sanjuan[2], A. Llorens[2], C. Amaro[2]
[1]Faculty of Veterinary Sciences, Preventive Veterinary Medicine Institute, Valdivia, Chile
[2]Facultad de Ciencias Biológicas. Universidad de Valencia.,
Departamento de Microbiología y Ecología, Valencia, Spain
[3]Institut de Recerca i Tecnologia Agroalimentàries, IRTA-SCR, Sant Carles de la Ràpita, Spain

Backgrounds

Vibrio vulnificus is a heterogeneous aquatic bacterial species that comprises avirulent and virulent strains responsible for fatal sepsis either by raw seafood ingestion (primary sepsis), or wound infections (secondary sepsis). The species is subdivided into biotypes (Bt), being Bt1 and Bt2 distributed worldwide; Bt1 is the responsible for primary sepsis and Bt2 for fish-handling-associated secondary sepsis. Bt2 is also a zoonotic agent that causes outbreaks of primary sepsis in fish, and it never has been isolated from bivalves.

Objectives

The objective of this work has been to find out if oysters could also be a reservoir for Bt2.

Methods

To this end, we performed a series of colonization experiments in which oysters were infected or co-infected with selected strains of Bt 1 and 2, both of clinical origin, or with the wild-type strain and a derivative mutant (either in *vvp* [protease involved in chemotaxis], *vvhA* [that codifies an unknown hemolysin], or in *rtxA* [toxin involved in invasion, using two polymorphic variants of *rtx*A1; *rtx*$A1_{1,}$ specific for the most virulent Bt1 strains, and *rtx*$A1_3$, specific for Bt2 strains].

Conclusions

The global results suggest that oysters can act as a reservoir for the zoonotic biotype, being both *vvp* and *rtxA* involved in the process. These selected genes are essential for persistence in the oyster probably conferring a higher resistance to the bactericidal effect of the oysters' hemolymph.

FEMS7-1571
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

AN INTEGRATED APPROACH TO UNRAVEL BACTERIOMA OF INDUSTRIAL COMPOSTING

M.J. Lopez[1], *F. Suárez-Estrella*[1], *M.D.M. Jurado*[1], *J.A. López-González*[1], *J. Moreno*[1]
[1]*Universidad de Almería, Dpt. Biologia y Geologia, Almería, Spain*

Backgrounds

Composting is a self-heating process in which organic matter is biotransformed to rich humic-like matter by mesophilic and thermophilic microbial consortia. Most research on composting microbioma focuses on composting processes using specific raw material and technology, and the conclusions obtained are limited to them.

Objectives

The goal of this study was to perform a comprehensive investigation of the structure of the bacterioma in time-series samples of industrial composting of different raw materials while simultaneously evaluating the enzymes produced.

Methods

Samples were collected from 15 industrial composting facilities. Three facilities were sampled for each of five raw materials, namely, municipal solid waste, sewage sludge, vegetal wastes, alperujo (solid waste from olive oil processing) and food processing wastes. In each facility, six samples were collected at critical phases of composting. After DNA extraction the region V3-V4 was amplified. 16S rDNA gene amplicons were sequenced with the Illumina MiSeq platform. Microbial enzymes involved in metabolism of C, N and P were evaluated in samples after aqueous extraction.

Conclusions

The bacterial diversity and succession was strongly influenced by the different operating conditions and raw materials. The enzymes profile showed a pattern marked by a fluctuant hydrolytic activity during the early stages and a dominance of C over N and P metabolism at the maturation. This study enables an unprecedented detailed view and comparison of bacterial community structure, dynamics, and function in full-scale composting operation facilities.

This research has been funded by the Spanish “Ministerio de Economía y Competitividad” Project AGL2015-64512-R.

CHARACTERIZATION OF CULTURABLE BACTERIAL ENDOPHYTES ASSOCIATED WITH FLOATING MACROPHYTES

M. Saganome[1], A. Delgadillo[1], L. Lozano[1]
[1]Universidad de La Salle, Ciencias Básicas, Bogota, Colombia

Backgrounds

Floating aquatic plants have potential for nitrogen and phosphorus phytoremediation in eutrophic wetlands. Endophytic bacteria inhabit plant tissues without causing any visible negative effect. Endophytes can confer beneficial effects to their host, like tolerance to abiotic stresses and they may contribute to degradation of pollutants. However, there are a few reports on endophytic bacteria associated with floating macrophytes.

Objectives

The aim of this study was to characterize culturable endophytic bacteria isolated from two floating macrophytes (*Lemna sp.* and *Azolla sp*).

Methods

Lemna sp. and *Azolla* sp. were colected at eutrophic wetland in Bogota, Colombia. Endophytic bacteria were isolated from surface-sterilized plants and cultured in Nutrient Agar. Isolates were evaluated in heterotrophic ammonia oxidizers medium and nitrite denitrification medium and bacteria were identified using 16S rRNA gene.

Conclusions

68.8% of isolates were classified as aerobic heterotrophic ammonia oxidizers and aerobic nitrite denitrifiers. Endophytic strains isolated from *Azolla* sp. belonged to phylum Proteobacteria (71.4%), Actinobacteria (14.3%) and Bacteroidetes (14.3%). Strains isolated from *Lemna* sp. were classified into genus belonging to phylum Proteobacteria (67%) and Actinobacteria (33%). *Brevundimonas* was the only genus isolated from both macrophytes. Results suggest that these bacteria endophytes could be candidates for further studies examining their potential for nitrite and ammonium removal in contaminated wetlands.

TRANSCRIPTOME-SIP OF A HYPOXIC POLLUTANT-DEGRADING AQUIFER MICROBIOME

L. Bradford[1], G. Vestergaard[2], A. Táncsics[3], B. Zhu[1], T. Lueders[1]
[1]Helmholtz Zentrum München, Institute of Groundwater Ecology, Munich Neuherberg, Germany
[2]Helmholtz Zentrum München, Research Unit Comparative Microbioome Analysis, Munich Neuherberg, Germany
[3]Szent István University, Regional University Center of Excellence in Environmental Industry, Gödöllö, Hungary

Backgrounds

Stable isotope probing (SIP) of nucleic acids is a well-established approach in molecular ecology, with most RNA-SIP studies to date focusing on tracing functionally relevant populations in complex microbiota via ^{13}C-labeled 16S rRNA. However, the new mRNA-SIP approach opens the unique possibility to link specific transcripts in complex systems to the metabolism of a particular labelled substrate. This technique has the potential to provide access to a wealth of process-relevant gene expression, without the caveats of current non-target or probe-directed methods.

Objectives

Here, we successfully demonstrate the feasibility of total RNA-SIP for microaerophilic microcosms from BTEX-contaminated aquifer sediments exposed to ^{13}C-labeled toluene. We were specifically interested in the niche partitioning between aerobic and anaerobic catabolic capacities under transitory redox.

Methods

From the total RNA-seq reads (average 30 mio. NextSeq500 reads per sample), an average of 10^5 reads from each sample were identified as transcripts of functional genes (~1-2 %). Gene categories related to cell motility, secondary metabolite formation and xenobiotics degradation were amongst the most highly ^{13}C-labeled transcripts.

Conclusions

Marked ^{13}C-labeling of abundant catechol 2,3-dioxygenase (C2,3-DO) but not of C1,2-DO transcripts were in line with an hypothesis that the first could be especially important in nitrate-respiring, but oxygen-dependent catabolism of aromatics. Uncultured members of the *Rhodocyclaceae* (related to *Quatrionicoccus* spp.) were amongst the most highly abundant and ^{13}C-labelled in total rRNA. this pioneering demonstration of the applicability of transcriptome-SIP to a complex groundwater microbiome reveals the untapped potential of this new targeted approach in environmental transcriptomics.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

CHARACTERIZATION OF A NEWLY HALOPHILIC SALINICOCCUS SP. HMS ISOLATED FROM WADI AN NATRUN, EGYPT

M. Mabrouk[1], H. Al-kordy[1], S. Sabry[2]
[1]Faculty of Science- Damanhour University, Botany and Microbiology Department, Damanhour, Egypt
[2]Faculty of Science- Alexandria University, Botany and Microbiology Department, Alexandria, Egypt

Backgrounds

A wide diversity of organisms exists in soil. Well-adapted groups can be found in extreme environments.Hypersaline ecosystems show a considerably rich diversity of microbes and are biologically very productive. These environments are rich source for novel microbes to be discovered. The wide biotechnological application of these particular microbes is immense and need to be discovered.

Objectives

The aim of this study was to explore, identify a halophilic bacterium from Wadi An Natrun in Egypt and study its characteristics as a potent candidate in biotechnological applications.

Methods

Bacterial isolation

Morphological and physiological characterization

16SrDNA gene sequencing

Determination of extracellular hydrolytic enzymesactivity

Biopolymer and pigment detection

Conclusions

A newly isolated *Salinicoccus* sp. HMS from a soil sample of Wadi An Natrun was characterized.A mucoid, glistening, reddish-orange pigmented colonies on Horikoshi-I agar plates was identified as *Salinicoccus* sp. HMS by morphological, physiological and biochemical characterization and 16S rDNA sequencing. *S.*sp. HMS grew in presence of 0–25% (w/v) of NaCl and at pH 6–11, with optimum growth at 11.7% (w/v) NaCl and pH 9. *S.*sp. HMS participates in halite formation in Horikoshi-I broth supplemented with 2M, 11.7% (w/v) NaCl at pH 8. The bacterium was shown to produce a wide variety of extracellular hydrolytic enzymes including, inulinase, pectinase, amylase, lipase, mannanase, protease, cellulase, and xylanase. The strain was found to be capable to degrade phenol and chlorpyrifos. Moreover, the isolate due to its biopolymer, pigment and enzymes production under extreme condition displays potential biotechnological and bioremediation applications.

VIBRIO COMMUNITY PROFILING OF SEA URCHINS AND THE SURRONDING ENVIRONMENT

A. Machado[1,2], *A. Bordalo*[1,2]
[1]*ICBAS-UP - Institute of Biomedical Sciences Abel Salazar- University of Porto, Hidrobiology and Ecology Laboratory, Porto, Portugal*
[2]*CIIMAR/CIMAR - Centro Interdisciplinar de Investigação Marinha e Ambiental, Hidrobiology and Ecology Laboratory, Porto, Portugal*

Backgrounds

Sea urchin is a valuable seafood resource with growing demand because their gonads are considered a gourmet delicacy worldwide. Moreover, they represent an important source of bioactive substances with highly beneficial effects to human health, like polyunsaturated fatty acids and carotenoids. *Vibrio* genus has been associated to disease in sea urchin (wild and aquaculture), and to seafood outbreaks.

Objectives

The aim of this study was to assess the potential pathogenic risk associated with *Vibrio* sp. to both animal survival and fitness, and human consumers.

Methods

The structure and abundance of *Vibrio* sp. community in coastal water and sea urchins (*Paracentrotus lividus*) were evaluated by PCR-DGGE and MPN-PCR approaches. In addition, characterization of vibrio isolates, with special attention to genotypes associate with toxicity and antibiotic resistance, was performed.

Conclusions

Vibrio sp. were successfully detected in all samples, with abundance ranging from 2.46 to 10^4 in water, and up to 10^7 in sea urchin. Significant differences in community profiles between sea urchin-associated and seawater were observed, indicating that diverse and specific groups can thrive within the sea urchin. Of the V*ibrio* species isolated, *V. alginolyticus* clear predominated among the isolates. Nevertheless, *V. parahaemolyticus*, a known leading causative agent of acute gastroenteritis in humans, was detected in the sea urchin gonads in the warmer months (spring and summer). Our results highlight the need to better knowledge about *Vibrio* community dynamics to understand their pathogenic potential and/or environmental importance in the growing demand and culture of sea urchin, and associated food safety context.

IMPACT OF IRON AMENDMENT ON SOIL BACTERIAL ABUNDANCE AND DIVERSITY

A. Machado[1,2], R.B.R. Mesquita[1,3], J.F.C. Vieira[3], M. Rangel[4], A.O.S.S. Rangel[3], A.A. Bordalo[1,2]
[1]ICBAS-UP - Institute of Biomedical Sciences Abel Salazar- University of Porto, Hidrobiology and Ecology Laboratory, Porto, Portugal
[2]CIIMAR/CIMAR - Centro Interdisciplinar de Investigação Marinha e Ambiental, Hidrobiology and Ecology Laboratory, Porto, Portugal
[3]Universidade Católica Portuguesa- CBQF - Centro de Biotecnologia e Química Fina – Laboratório Associado- Escola Superior de Biotecnologia, ., Porto, Portugal
[4]REQUIMTE-UCIBIO- Instituto de Ciências Biomédicas de Abel Salazar- Universidade do Porto, ., Porto, Portugal

Backgrounds

According to the World Health Organization, two billion people suffer iron deficiency, and the consumption of iron-rich plants can be a way of tackle the problem. Iron has also a crucial role in plant nutrition being an essential element for plant growth, yet one-third of earth soil is iron deficient. The use of synthetic Fe(III)-chelates remains one of the most effective measures to solve this iron deficiency in plants, but their environmental impact must be mastered, since they are highly stable in soils. The search for efficient and sustainable Fe-chelates is, therefore, pressing.

Objectives

The aim of the study was to investigated the effect of iron complexes (synthetic Fe(III)-chelates), on soil bacterial dynamics to better understand their mode of action.

Methods

Soil pots with and without strawberry plants (*Fragaria* sp.), were exposed to different ferrous iron treatments (Fe(III) solution as weak complexes with hydroxide ions, FeEDDHA iron-chelate present in commercially fertilizers, and $Fe(dmpp)_3$ as new alternative iron-chelate). The abundance and diversity of the bacterial community was evaluated by PCR-DGGE and qPCR (*rpoB)* approaches.

Conclusions

No major differences were found in the abundance between soil treatments. Cluster analysis of DGGE profiles revealed that the presence of the plant by itself was not enough to cause a significant change in the bacterial composition. However, the microbial composition seems to shift as a response to Fe(III) amendment and bioavailability. These changes can underline a selection for bacteria that can use Fe(III) in its metabolism, or are more tolerant to its presence, that need to be understood

GENOMIC CHARACTERIZATION OF A FRUCTOPHILIC BEE SYMBIONT LACTOBACILLUS KUNKEEI REVEALS ITS NICHE-SPECIFIC ADAPTATION

S. Maeno[1], Y. Tanizawa[2], Y. Kanesaki[3], E. Kubota[3], H. Kumar[4], L. Dicks[5], J. Nakagawa[1], M. Arita[2], A. Endo[1]
[1]Tokyo University of Agriculture, Food and Cosmetic Science, Hokkaido, Japan
[2]National Institute of Genetics, Center for Information Biology, Shizuoka, Japan
[3]Tokyo University of Agriculture, Genome Research Center, Tokyo, Japan
[4]University of Turku, Functional Foods Forum, Turku, Finland
[5]Stellenbosch University, Microbiology, Stellenbosch, South Africa

Backgrounds

Lactobacillus kunkeei is sole obligate fructophilic lactic acid bacterium in the genus *Lactobacillus*, and its unique phenotypic characteristics, including a requirement of electron acceptors for glucose metabolism, are distinct the species from other lactobacilli but are similar to phylogenetically distant *Fructobacillus* spp.

Objectives

The genome sequences of *L. kunkeei* strains were used to study their adaptation to habitats, i.e. fructose-rich niches.

Methods

The genomes of 16 strains of *L. kunkeei* were characterized by comparative genomics against other lactobacilli (n=57) and *Fructobacillus* spp. (n=5). The species possessed significantly less CDSs in smaller genome when compared with other lactobacilli. Functional classification of the genes revealed that *L. kunkeei* had specifically reduced genes for carbohydrate transport and metabolism. The species also lacked most of the genes for respiration, although growth was enhanced in the presence of oxygen. These genomic characteristics were similar to those of *Fructobacillus* spp. The *adhE* gene of *L. kunkeei*, encoding a bifunctional alcohol dehydrogenase (ADH)/aldehyde dehydrogenase (ALDH) protein, lacked the part encoding the ADH domain, which is reported here for the first time in lactic acid bacteria. The deletion resulted in the lack of ADH activity, implying a requirement for electron acceptors in glucose assimilation.

Conclusions

These results clearly indicated that *L. kunkeei* had undergone a specific reductive evolution in order to adapt to fructose-rich environments. The reduction characteristics were similar to those of *Fructobacillus* spp., but distinct from other lactobacilli with small genomes. Fructose-richness thus induced an environment-specific gene reduction in phylogenetically distant microorganisms.

THE EXPRESSION PROFILE OF SECONDARY METABOLITES IN BIOFILMS OF B. AMYLOLIQUEFACIENS CECT 8237 BIOCONTROL STRAIN

M.C. Magno Pérez-Bryan[1], J. Hierrezuelo León[1], A. de Vicente Moreno[2], A. Pérez García[2], D.F. Romero Hinojosa[1]
[1]IHSM-UMA-CSIC. Departamento de Microbiología- Centro de Supercomputación y Bioinnovación- Universidad de Málaga., Microbiology, Málaga, Spain
[2]IHSM-UMA-CSIC. Departamento de Microbiología- Facultad de Ciencias- Universidad de Málaga., Microbiology, Málaga, Spain

Backgrounds

The contribution of *Bacillus amyloliquefaciens* CECT 8237 (UMAF6639) strain to the plant protection against bacterial and fungal pathogens is mainly based on: i) the production of antimicrobial compounds, ii) the plant-growth promotion capability and iii) the induction of systemic resistance in plant host.

In previous works, we demonstrated the relevant implication of the three families of lipopeptides in the biocontrol activity and biofilm formation on melon leaves. The analysis of the genome sequence revealed features previously identified in other *Bacillus* strains, such as genes related to biofilm formation, phytostimulation and induction of systemic resistance in the host plant, and novel genomic regions non-conserved within the *Bacillus* genus, and therefore with potential genes implicated in the biocontrol activity.

Objectives

Considering the relevance of biofilm formation and production of secondary metabolites in biocontrol, we analyzed the expression profile of several secondary metabolites produced by CECT 8237 in biofilm inducing conditions.

Methods

To do so, we optimized an *in situ* detection method based on MALDI-TOF analysis of secondary metabolites within the bacterial colony and in supernatants and pellicles of *B. amyloliquefaciens* biofilms.

Conclusions

We found a major accumulation of these secondary metabolites in the core and middle area of the colony and in the spent medium compared to pellicle.

Further studies will help elucidating the real implication of these molecules in the bacterial ecology or in its mechanisms of defence, against competitors, and/or offense, against pathogens and its possible relation with the niche they occupy.

This work was supported by grants from the Plan Nacional I+D+I (AGL-2012-31968) and Incentivos a Proyectos de Excelencia de la Junta de Andalucía (P10-AGR-57-97), both cofinanced by FEDER funds (EU). This work was also supported by grant from Koppert B.V. (8.06/60.4086) and European Research Council-Starting Grant BacBio ERC637971.

[4]Institut Charles VIOLLETTE ICV- E.A. 7394- Université d'Artois- Lens- France., 62300, Lens, France

Backgrounds

Vibriosis caused by *Vibrio spp* infection is one of the most prevalent diseases in the fishes and other aquaculture-reared organisms. Mortality prevention in aquaculture systems by setting-up of preventive or curative adequate treatments is, in part, closely associated with improved methods of pathogenic strains identification.

Objectives

The present study aimed using the MALDI-TOF-mass spectrometry for rapid identification of *Vibrio* species isolated from *Acartia tonsa* eggs issued from the copepod culture collection of the marine station of Wimereux located in the English Channel, northern coast of France.

Methods

From pure colonies grown on the nutrient agar, a sample preparation procedure was established and combined with a rapid and automated MALDI-TOF-MS measurement protocol, performed at least in triplicates. For the bacteria identification, the mass spectra were processed using BioTyper software (version 3.0; Bruker Daltonics) running with the BioTyper database version DB-5989, containing 5,989 reference MALDI-TOF- MS profiles (5,298 of bacteria, 626 of yeasts and 65 of filamentous fungi). Matching between experimental MALDI-TOF- MS profiles obtained from bacteria isolates and the reference MALDI-TOF- MS profiles is expressed by BioTyper according to a Log(Score) and an associated-color code (green, yellow and red). Some identified species were confirmed by DNA extraction, 16S rDNA PCR and sequencing.

Conclusions

The bacteria identification based on MALDI-TOF-MS allowed to fast, easy , cost-effective, and unambiguous identification of *V. anguillarum, V. pomeroyi, V. cyclitrophicus, V. alginolyticus, V. scoophthalmi, V. gigantis and V.changasii*. The more- time consuming bacteria identification method based on the 16S rDNA produced comparable results.

INSIGHTS INTO TEMPERATURE MODULATED COMMUNITY DYNAMICS OF AN ARSENIC RICH HIMALAYAN GEOTHERMAL SPRING

N.K. Mahato[1], A. Sharma[1], Y. Singh[1], R. Lal[1]
[1]University of Delhi, Department of Zoology, NEW DELHI, India

Backgrounds

Geothermal springs are natural extreme niches where ambient environmental conditions restrict the life only to prokaryotes. Community genomics analyses provide insights into diversity of extremophiles flourishing in these habitats along with their metabolic roles.

Objectives

Metagenomic survey of an arsenic rich Himalayan geothermal spring was performed to elucidate the diversity of microbial communities inhabiting bubbling water and their functional adaptations to withstand high temperature.

Methods

Samples of water were collected from two geothermal spring openings (>96 °C) located at Parvati Valley, Himachal Pradesh, India (32°01′34.8″N, 077°20′50.3″E). Illumina GAII technology was selected for sequencing the community DNA. Taxonomic status was assigned to quality filtered metagenomic raw reads using MetaPhlAn. Functional annotation was done using KAAS and MinPath server. Comparative account of environmental shotgun data from different habitats (bubbling water, sediment and microbial mat) of same geothermal spring was employed to explore habitat specific variations within the same ecosystem.

Conclusions

Diversity analyses revealed predominance of phyla namely, *Proteobacteria, Thermi, Actinobacteria, Crenarchaeota* and *Bacteroidetes* in the water samples. Functional analyses showed genetic enrichment of genes encoding for repair system and homologous recombination highlighting the environment-driven evolution of DNA repair system to withstand high temperature. Additionally, Metagenomic data of water samples was also used to reconstruct draft population genome of *Emticicia* sp. MM along with its four plasmids. Temperature plays a pivotal role in shaping bacterial community and their metabolic adaptations across different habitats of geothermal springs. We observed inter-habitat functional conservedness, however microbial diversity varies at different habitats within same environment.

CLADOSPORIUM AS AN IMPORTANT ALLERGIC FUNGUS ISOLATED FROM AN EDUCATIONAL AND THERAPEUTIC CENTER, BABOL, IRAN

S. Mahdaviomran Mahdavi Omran[1], F. Nazari[1], M. Hajiahmadi[2], M. Taghizadeh[3]
[1]Babol University of Medical Sciences, Dept. of Medical Parasitology and Mycology, Babol, Iran
[2]Babol University of Medical Sciences, Dept. of Biostatistics, Babol, Iran
[3]Mazandaran University of Medical Sciences, Dept. of Medical Parasitology and Mycology, Sari, Iran

Backgrounds

Fungi are the most important microbial agent to produce of allergy and asthma in the world. Hospitals have a key role in this disorder in hospitalized patients.

Objectives

According to this matter, the present study was performed for isolation and determination of *Cladosporium*, an allergenic fungus in some important wards of an educational and therapeutic center, Babol (Northern Iran).

Methods

The air sampling was performed actively using Anderson's equipment with Sabouraud dextrose agar plate complemented by chloramphenicol (Sc), in two times (morning and afternoon). Totally 63 plates (from 3 important wards) used for survey of *Cladosporium* spp. as an allergenic fungi in the air of an educational and therapeutic Hospital of Babol (Northern Iran). Plates were placed up to 2 weeks in the room temperature; then growth of colonies and the morphology of fungi were examined by light microscope.

Conclusions

In this study 963 colonies were related to *Cladosporium* spp. with 15.29 colony/plates (270.1 colonies/m^3). The most pollution was seen in Internal Care Unit (ICU), which 578 colonies (24.08 colonies/plates, or 425.55 colonies/m^3) were grown on plates. The best ward was the morning surgical room (0.75 colonies/plate or 13.25 colonies/m^3). The most colonies were observed in morning (566 colonies, 15.72 colonies/plates).
The result of this study showed, Cladosporium (an allergenic fungus) is as a prevalent fungus in this Hospital. According to this matter it is necessary to have a suitable planning for decreasing of *Cladosporium* in the air of Hospital.

INTERACTIONS BETWEEN PHOTOAUTOTROPHIC ORGANISMS AND BELOW-GROUND MICROORGANISMS IN DRYLAND ECOSYSTEMS

S. Maier[1], A. Tamm[1], D. Wu[1], J. Caesar[2], T. Hoffman[3], M. Grube[4], B. Weber[1]
[1]Max Planck Institute for Chemistry, Multiphase Chemistry, Mainz, Germany
[2]University of Applied Sciences, Department of Agriculture and Food Sciences, Neubrandenburg, Germany
[3]University of Cape Town, Department of Botany, Rondebosch, South Africa
[4]University of Graz, Institute of Plant Sciences, Graz, Austria

Backgrounds

Biological soil crusts (biocrusts) play a vital role in dryland regions that cover over 35% of the Earth´s land mass. They provide important ecosystem services such as protection against soil erosion and facilitation of seedling establishment of higher plants. Furthermore, their contribution to the carbon and nitrogen cycle is substantial at a global scale. Cryptogamic covers, including biocrusts, contribute ~7% to the annual carbon uptake by terrestrial vegetation and approximately 40% to the maximum annual terrestrial biological nitrogen fixation.

Objectives

The aim of this study is to test the hypothesis that the successional stage, characterized by a dominating photoautotrophic organism, modifies the local microhabitat and hence influences the composition and physiology of the microbial community.

Methods

We analysed the microbial composition of different successional stages of biocrusts using qPCR and 16S rRNA gene and fungal internal transcribed spacer region sequencing. In a second approach, we studied the physiological response of the different successional stages with regard to their CO_2 gas exchange and nitrogen cycling capabilities under varying environmental conditions.

Conclusions

The 16S and 18S rRNA gene copy numbers as well as alpha diversity values were highest in late successional biocrust stages. We observed that soil respiration rates of late successional biocrusts were approximately seven times higher than those of poorly developed biocrusts, and different successional stages showed distinct nitrogen gas emissions. These findings indicate that organisms within the biocrusts alter the local environment and thereby influence the composition of microbial communities.

BACTERIA, ARCHAEA AND FUNGI ARE STRONGLY INFLUENCED BY ABIOTIC FACTORS ALONG A 1600 KM ARIDITY GRADIENT

T. Makhalanyane[1]
[1]*University of Pretoria, Department of Genetics, Pretoria, South Africa*

Backgrounds

Climate change is a major threat to biodiversity and functionality across ecosystems globally, resulting in increased desertification. Arid regions, which are generally depauperate, with low vegetation cover and extremely oligotrophic soils are excellent models for understanding the impact of climate change on microbially-derived ecosystem function. However, little is known regarding how increases in aridity may influence the relationship between microbial diversity and ecosystem functionality; specifically, on the contributions of nutrient cycling by microbial guilds at varying aridity levels.

Objectives

Here we assess microbial communities along a west-east aridity gradient across South Africa (sub-humid, semi-arid and arid regions) to determine the environmental effects on microbial community structure and composition.

Methods

We used 16S rRNA gene and ITS sequencing, enzyme activity assays and statistical analysis.

Conclusions

We found significant differences in microbial community composition and structure across the three regions. The fungal class *Agariomycota,* bacterial class *Alphaproteobacteria* and archaeal class *Thaumarchaeota* were abundant across these regions. Soil chemistry had a significant effect in shaping the microbial community composition and structure across the aridity gradient. A high silt content (40 - 60%) was a major determinant of microbial communities, whereas total carbon determined fungal communities structure in sub-humid regions. In addition, β-glucosidase activity occurred within all samples in this region ranging from 60-150 $mmolh^{-1}g^{-1}$ and positively correlated with carbon content (0.4 correlation). In bacterial and archaeal communities, pH was determined to be the influencing factor in arid regions. In summary, abiotic factors influence bacterial, archaeal and fungal community dynamics along an aridity gradient across South Africa.

BEHAVIOR OF FUNGAL BIOFILMS USED FOR REMEDIATION EXPOSED TO LONG-TERM MICROBIAL STRESS

C. Novotny[1], H. Valkova[2], P. Slosarcikova[2], K. Svobodova[3], K. Malachova[2]
[1]Institute of Microbiology ASCR, Ecology, Prague 4, Czech Republic
[2]University of Ostrava, Department of Biology and Ecology, Ostrava, Czech Republic
[3]Institute of Microbiology ASCR, Laboratory of Environmental Biotechnology, Prague, Czech Republic

Backgrounds

Biofilms of ligninolytic fungi (LF)have potential for remediation of pollutants but their sustainability when competing with other microbes is not well understood.

Objectives

Behavior of mature and nascent biofilms of three LF exposed to long-term microbial stress was compared, extracellular enzyme activities, biodegradation capacity and structural changes of biofilms were measured.

Methods

Shallow-liquid LF cultures immobilized on polyamide were exposed to bacterial/yeast suspensions (10^6 CFU). Fungal growth, CFU, extracellular enzyme activities and degradation of anthraquinone- or azo dyes were determined. SEM and fluorescence microscopy monitored biofilm structure and viability. Activated sludge (AS) was profiled using DGGE analysis of 16SrDNA and EcoPlate assays.

Conclusions

Comparative study of three different LF documented that 90-d exposure of mature fungal biofilms to *Escherichia coli*, *Pseudomonas fluorescens* and *Bacillus licheniformis* bacteria and *Saccharomyces cerevisiae* and *Issatchenkia occidentalis* yeasts did not decrease the fungal degradation capacity. Minor effects of microbial stress on peroxidase and laccase levels were observed. Densely packed biofilms with abundant extracellular polysaccharide were formed even in the presence of competing microbes. Nascent fungal biofilms formed in the presence of *P. fluorescens* but not *B. licheniformis* or *E.coli* lacked high-degradative power. Spontaneous colonization of *P. ostreatus* biofilm by AS selected certain bacterial species as documented by different genotype and phenotype profile. A remarkable ability of mature LF biofilms to resist bacterial and yeast stress was demonstrated.

ISOLATION OF MICROORGANISMS FOR BIODEGRADATION OF POLYMER PLASTICS

K. Malachova[1], Z. Rybková[1], J. Malach[2], Č. Novotný[3]
[1]University of Ostrava, Faculty of Science- Biology and Ecology, Ostrava, Czech Republic
[2]University of Ostrava, Pedagogical Faculty, Ostrava, Czech Republic
[3]Institute of Microbiology ASCR, Laboratory of Environmental Biotechnology, Prague, Czech Republic

Backgrounds

Accumulation of recalcitrant plastic polymer waste is a serious environmental problem.

Objectives

Our objective was to isolate bacteria and fungi with a potential to efficiently degrade selected plastic polymers in liquid media cultures.

Methods

Standard enrichment isolation methods employing low-nutrient-concetration media were used to obtain monocolony isolates of bacterial and fungal organisms. Microorganisms were isolated from plastic wastes originating from a polymer production plant, composting sites, anaerobic sludge and soil samples. The ability to degrade plastic polymers was determined in aerobic liquid media at 24 or 28°C using virgin and pretreated [γ (200 KGy)+T (100°C)] LLDPE, LDPE and virgin PP, PS and PVC films during a 2-month degradation. The degradation was measured gravimetrically and with FTIR, TGA, GPC and SEM methods.

Conclusions

A total of 29 bacteria were isolated and identified by 16S rDNA eubacterial primer set. The bacterial community was dominated by *Bacillus* sp. A total of 16 filamentous fungi and 10 yeasts were also identified using 18S and ITS sequencing of SSU rDNA. One bacterial *Bacillus amyloliquefaciens* and three fungal *Trichoderma hamatum, Trichaptum abietinum, Byssochlamys nivea* strains were able to grow on the polymers and attack pretreated and virgin LLDPE and virgin LDPE and PVC. The most efficient strains were *Bacillus amyloliquefaciens* and *Trichoderma hamatum*.

MICROBIAL CONSORTIUM WITH DEGRADING, PHYTOPROTECTIVE AND GROWTH-PROMOTING PROPERTIES AS THE BASIS OF COMPLEX BIOPREPARATION FOR SOIL REMEDIATION AND PROMOTION OF CROP HARVESTS

M. Mandryk-Litvinkovich[1], *A. Muratova*[1], *T. Nosonova*[1], *E. Kolomiets*[1]
[1]*Institute of Microbiology - Belarus National Academy of Sciences,*
Laboratory of biological control agents, Minsk, Belarus

Backgrounds

The problem of agricultural land degradation has acquired top priority in latest decades. Anthropogenic activities resulted in soil destructuring, technogenic acidification, pollution with xenobiotics. Agrostress impairs processes in phytocenoses, reduces soil fertility and microbial populations. The most severe impact on soil depreciation is caused by intense pesticide application, abuse of doses of chemical supply leading to their uncontrolled build-up in the environment. A vital factor in alleviating adverse effects of exposure to herbicides is soil recovery utilizing microorganisms possessing a complex decomposing, phytoprotective and growth-stimulating action.

Objectives

The study was aimed at formulation of microbial consortium with elevated plant-protecting and growth-promoting potential capable to break down residual amounts of herbicides of sulfonylurea and imidazolinone series.

Methods

Various investigation methods were used: microbiological, biochemical, molecular-genetical.

Conclusions

An effective consortium comprising 3 native bacterial strains of genera *Bacillus*, *Herbaspirillum* and *Pseudomonas* showing high degrading, phytoprotective and growth-stimulating activities was composed. It is distinguished by the following characteristics:

-suppresses development of phytopathogens from genera *Fusarium, Botrytis, Pseudomonas, Xanthomonas* and contributes to restoration of agrobiocenoses*;*

-drops the level of residual herbicides of sulfonylurea and imidazolinone series in soil (decay extent of herbicides imazamox (50 MPC) and chlorimuron-ethyl (100 MPC) ranges from 45 to 82 % by 7 days;

-eliminates phytotoxic effect of residual herbicide amounts on plants, facilitating 1,2-1,5 times elongation of seedlings and increasing seed germination rate by 25-35%.

The obtained results evidence attractive prospects of introducing microbial constituents into complex biopreparation for soil bioremediation and recultivation.

BIODIVERSITY AND PRELIMINARY SCREENING OF ENDOPHYTIC FUNGI ASSOCIATED WITH INDIGENOUS MEDICINAL PLANT UMCKALOABA (PELARGONIUM SIDOIDES)

M.C. Manganyi[1], A. Kumar[1], C.C. Bezuidenhout[2], T. Regnier[3], C.N. Ateba[1]
[1]North West University, Biology, Mmabatho, South Africa
[2]North West University, Enviromental Sciences, Mmabatho, South Africa
[3]Tshwane University of Technology, Food and Biotechnology, Pretoria, South Africa

Backgrounds

Medicinal plants well-known to harbour diversity group of endophytic fungi possessing bioactive compounds. Endophytic fungi isolated from marine environments are known to produce secondary metabolites with broad spectrum biological properties including antimicrobial, anticancer, anti-inflammatory and antiviral activities. Despite the fact that the biodiversity of *Pelargonium sidoides* has been established using molecular analysis, this is the first study in which the endophytic fungal species isolated from this plant was assessed for microbial activity.

Objectives

i. isolate and establish the biodiversity of the fungi though phylogenetic assessments;
ii. determine the potential of endophytes in producing bioactive compounds;
iii. assess bioactive compounds with antimicrobial activity

Methods

A total of 133 endophytic fungi were successfully isolated from 50 plants of *Pelargonium sidoides.* The fungal isolates were classified into 32 genera using the internal transcribe spacer (ITS-1 and ITS-4) primers for DNA barcoding as well as translation elongation factor gene (TEF1 or EF1-α gene) for *Fusarium* identification. Identification of the investigating fungal isolates was conducted using morphological and/or molecular techniques. Preliminary screening was conducted by agar diffusion method using an environmental multiple antibiotic resistant *Escherichia coli* strain.

Conclusions

Large proportions (23%) of the isolates were *Penicillium* species while 12% were *Fusarium*. *Alternaria* and *Aspergillus* at 11% respectively representing the biodiversity. Preliminary screening produced growth inhibition zone diameter data of 11mm for *Aspergillus* sp., (KM458796.1), 5 mm for *Penicillium expansum* (LC015096.1), and 4 mm for *Aspergillus niger* (KP172477.1). These findings indicate that endophytic fungi associated with *Pelargonium sidoides* plants possessing bioactive compounds. Further characterisation of the bioactive compounds is being conducted.

GRADIENTS IN PROKARIOTIC COMMUNITY AND GEOCHEMISTRY IN AN ALPINE ROCK GLACIER ASSOCIATED POND

I. Mania[1], N. Colombo[2], M. Freppaz[1], M. Martin[1], R. Gorra[1], A. Anesio[3]
[1]University of Turin, DISAFA, Grugliasco To, Italy
[2]University of Turin, Earth Sciences, Torino, Italy
[3]University of Bristol, School of Geographical Sciences, Bristol, United Kingdom

Backgrounds

Rock glaciers (RGs) are geomorphological features widespread in high-elevation alpine environments, consisting of slow-flowing mixtures of rocks and ice, and are considered indicators of ice-rich permafrost presence. Due to their capability to influence waters passing through and originating from them, RGs have the potential to influence connected alpine water bodies, both in terms of water geochemistry and, as pointed out mainly in the last years, overall ecosystem ecology.

Objectives

In this study, we describe archaeal and bacterial communities in the sediments of an alpine RG-associated pond (Col d'Olen Rock Glacier, Valle d'Aosta, Italy), characterized by serpentinitic mineralogy.

Methods

Abundance and diversity of 16S rRNA genes have been assessed by qPCR and MiSeq Illumina sequencing, along a distance gradient from the RG front. We have also analysed the microbial community composition in relationship with different geochemical factors (DOC, TDN, pH, nitrogen forms, major anions and cations), focusing on the sediment-water interface as a major location for biogeochemical cycling and weathering processes.

Conclusions

While community composition shows a certain degree of variation across the gradient, as well as Na^+, Ca^{2+} and Mg^{2+} concentration, increasing with distance from the RG front, microbial abundance and several geochemical parameters (pH, DOC, TDN, NH_4^+ and Si) follow an apparently depth-based distribution pattern. Our results suggest that a complex net of environmental factors, such as water depth, in addition to the environmental gradient derived from icemelt waters, can have a significant impact on the distribution of the prokariotic community and geochemistry along the Col d'Olen Rock Glacier Pond.

JOINING THE TEAM: CO-OBLIGATE SYMBIONTS OF APHIDS EVOLVING FROM DISTANTLY RELATED BACTERIA

A. Manzano-Marín[1], A.L. Clamens[1], A. Coeur d'Acier[1], E. Jousselin[1]
[1]Institute National De La Recherche Agronomique INRA,
UMR1062 - Centre de Biologie pour la Gestion des Populations CBGP, Montferrier-sur-Lez, France

Backgrounds

Typically, aphids house the obligate nutritional bacterial symbiont *Buchnera* inside specialised cells called bacteriocytes. *Buchnera* supplies the aphid with essential amino acids and vitamins, thus insuring the correct development of its host. However, some *Buchnera* lineages have lost the ability to fulfil this role, either triggered or rescued by new and younger endosymbionts. One such case are the aphid species from the Lachninae subfamily, where an ancient loss of the riboflavin biosynthetic genes in the genome of *Buchnera* was accompanied by the acquisition of a co-obligate partner.

Objectives

However, co-obligate symbioses are not restricted to this subfamily, and examples of these have been previously reported mainly by microscopic studies. Thus, we sought to discover the identity of these secondary associates, as well as to determine their contribution to the symbiotic consortium.

Methods

Through whole genome sequencing, we have reconstructed the genomes of the co-obligate endosymbionts from several aphid species belonging to different subfamilies, mainly the Lachninae.

Conclusions

We have corroborated that these co-obligate symbionts indeed supplement essential metabolic auxotrophies found in *Buchnera*. Not surprisingly, they have evolved genomes with similar core metabolic capabilities. Also, we have determined that these co-symbionts have evolved from diverse facultative symbiotic taxa associated to aphids as well as free-living bacterial strains. These findings show that co-obligate symbiosis in aphids is more widespread than previously thought. This suggests a fragile mono-symbiotic association between the aphid host and its *Buchnera* symbiont, whose highly degenerated genome could undergo simple metabolic losses leading to a secondary symbiont establishing as a co-obligate one.

SOIL FORMATION ADJUSTS THE RHIZOSPHERE EFFECT IN STEERING THE BACTERIAL COMMUNITY ASSEMBLY ASSOCIATED TO A PIONEER PLANT

F. Mapelli[1], R. Marasco[2], M. Fusi[2], E. Rolli[1], S. Fodelianakis[2], D. Daffonchio[2], S. Borin[1]
[1]University of Milan, Department of Food- Environmental and Nutritional Sciences, Milan, Italy
[2]King Abdullah University of Science and Technology,
Biological and Environmental Sciences and Engineering Division, Thuwal, Saudi Arabia

Backgrounds

Plants drive the establishment of a specific root microbiome despite the influence exerted by the environment and host genotype. However, it is not clear to which extent plants growing under evolving environmental settings and soil developmental stages maintain the same ability. Chronosequences in polar moraines, representing environmental gradients characterized by increasing soil deglaciation times and different pedogenesis stages, are ideal environments to disentangle the contribution of the rhizosphere effect and the changing soil developmental stages to select the rhizosphere microbiome.

Objectives

We studied the rhizosphere of an autochthonous pioneer plant growing along a High Arctic glacier chronosequence to clarify if the rhizosphere bacterial community assembly is diversely modulated according to the pedogenesis stages.

Methods

16S rRNA Illumina sequencing and OTU co-abundance network analysis were applied to unravel the structure of bacterial communities inhabiting unvegetated and rhizosphere soils. Statistical analyses showed that soil physicochemical parameters and metabolomics traits, characterized by NMR-based analysis of soluble organics, were significantly correlated to microbiome structure in both soil types.

Conclusions

Plant-driven selection was demonstrated independently from the soil developmental stage. Besides a rhizosphere core microbiome, a variable fraction of adaptable bacteria, typical of each pedogenesis stage, was detected. We proved that physicochemical parameters highly relevant for soil formation and fertility drove the assembly of rhizosphere bacterial communities along the chronosequence. Moreover, OTU co-abundance network complexity changed along the chronosequence, showing a different role of the environmental settings in steering the rhizosphere bacterial community assembly, tuned by the soil developmental stage.

CHANGES IN MICROBIAL DIVERSITY DURING DIFFERENT BLOOM STAGES OF THE TOXIC DINOFLAGELLATE DINOPHYSIS ACUMINATA

I. MARIN[1], M. García-Portela[2], F. Rodriguez[2], B. Reguera[2], J.P. Abad[1]
[1]Universidad Autónoma de Madrid, Biología Molecular, Madrid, Spain
[2]Instituto Español de Oceanografía IEO, Centro Oceanográfico de Vigo, Vigo, Spain

Backgrounds

Dinophysis species of dinoflagellates are world-wide distributed and include photosynthetic organisms producers of lipophilic diarrethic toxins. One of the most frequently found is *D. acuminata*, a strict mixotroph containing plastids (kepto-plastids) that seem to come from the prey dinoflagellates feed on. Laboratory studies have shown that, one of *Dinophysis* preys is the ciliate *Myrionecta*, which itself prey on several cryptophytes.

Objectives

With the aim of determining whether *D, acuminata* can prey in nature on other organisms beside those studied in vitro, we have started a study based on metagenomics to determine the biological diversity, prokaryotic as well as eukaryotic, present along the development of an algal bloom of this species of dinoflagellate.

Methods

Sampling was made in three stages of an algal bloom at Bueu (Pontevedra, Spain) during the period Jan-Jun/2016, corresponding to a stage before the bloom, at the maximum density of dinoflagellate cells, and at the decay phase. Samples were sequentially filtered through polycarbonate 5 and 0.22 µm filters, and DNA extracted. Variable regions V3-V4 of 16S rDNA and 563-1132 of 18S rDNA were amplified by PCR using appropriate primers, and sequenced using MiSeq Illumina technology.

Conclusions

Preliminary bioinformatics analysis of the sequences obtained for 16S rDNA show that the major groups present in peak of the bloom were Alphaproteobacteria (37.3% of the sequences), Bacteroidetes (26.8%), Cyanobacteria (13.9%), Euryarcheota (9.2%), Gammaproteobacteria (7.7%) and Actinobacteria (2.6%). At this point a decrease of Alpha and Gammaproteobacteria and an increase of the other groups were observed from the point of no bloom.

SIGB AND AGRA REGULATION IN LISTERIA MONOCYTOGENES: EFFECT ON SURVIVAL IN SOIL/RHIZOSPHERE UNDER BIOTIC AND ABIOTIC CONDITIONS

C. Marinho[1,2], D. Garmyn[2], L. Gal[3], C. O'Byrne[1], P. Piveteau[2]
[1]National University of Ireland- Galway, Department of Microbiology, Galway, Ireland
[2]Univ. Bourgogne Franche-Comté, Agroecologie- INRA, Dijon, France
[3]AgroSup- Dijon, Agroecologie- INRA, Dijon, France

Backgrounds

Listeria monocytogenes is the agent of listeriosis, a life-threatening condition in at-risk people. Complex transmission routes between outdoor environments and the food chain result in foodstuff contamination. Sensing of environmental changes can trigger regulation of gene expression, allowing bacteria to adapt their physiology and survive. The Agr cell-cell communication system transcription regulator AgrA is triggered during several environmental conditions including soil, an important reservoir of *L. monocytogenes*. The RNA polymerase σ^B factor aids survival in several stress conditions and may be required for *L. monocytogenes* survival in the soil environment.

Objectives

This study aims to investigate the involvement of AgrA and σ^B in the regulatory network of *L. monocytogenes* during saprophytic life in soil and rhizosphere according to the background biotic environment.

Methods

A collection of in-frame deletion mutant strains (Δ*agrA*, Δσ^B and Δ*agrA*+Δσ^B) was constructed from parental *L. monocytogenes* EGD-e. Strains were inoculated into clay soil mesocosms at different water holding capacities and with or without background microbiota. Kinetics of strains survival was followed during incubation for 14 days. Growth was investigated in the rhizosphere of *Festuca arundinacea* plants *in vitro*. One-week kinetics of strains survival was performed during incubation into climatic chamber.

Conclusions

Depending on the incubation conditions, the fitness of the deletion mutants were affected. During its saprophytic life in soil habitat, *L. monocytogenes* have to cope with ever-changing environmental conditions and adapt in order to sustain life. Integration of various stimuli results in a coordinated response including communication and stress response systems through AgrA- and σ^B-mediated regulation.

Backgrounds

Vancomycin-resistant enterococci (VRE) have been detected in wild animals representing a public health concern. The red-legged partridge is a common game bird and its meat is consumed in several countries including Portugal.

Objectives

This study aims characterize *van*A-*Enterococcus faecium* isolates from Wild Red-Legged Partridges using MLST analysis.

Methods

Three hundred faecal samples of red-legged partridge (*Alectoris rufa)* from the North of Portugal were screened for VRE. Samples were cultured on Slanetz-Bartley agar supplemented with vancomycin (4 mg/L). Enterococcal isolates were tested for antibiotic resistance and virulence genes. Multilocus sequence typing (MLST) was performed to study the genotypic diversity of *van*A-containing VRE.

Conclusions

VRE was recovered from 6 out of the 300 samples corresponding to *E. faecium* species. High values of resistance were detected for vancomycin, erytromycin, ampicillin, tetracycline, teicoplanin, ciprofloxacin and kanamycin and low values for quinupristin-dalfopristin. The *van*A and *erm*(B) genes were detected in all isolates, as well as the *tet*(M) gene in all tetracycline isolates. All 6 isolates harbored the *esp* gene whereas *hyl* gene was detected in 5 isolates. MLST analysis grouped the isolates as ST448 (n=1), ST139 (n=1) and ST18 (n=4). Our findings show that the red-legged partridges could be a reservoir of antimicrobial resistance genes and may contribute to the dissemination and transference of the resistance genes to other animals and humans.

Department of Food and Environmental Sciences University of Helsinki, Helsinki, Finland
[4]KTH Royal Institute of Technology Science for Life Laboratory,
School of Biotechnology Division of Gene Technology, Stockholm, Sweden
[5]Marine Biological Section, University of Copenhagen, Helsingør, Denmark

Backgrounds

Marine bacteria are major drivers of biogeochemical nutrient cycles and energy fluxes, yet how they respond to environmental change is not well known. Metagenomic approaches allow examination of genetic responses of the entire microbial community to environmental changes. However, it still remains a major challenge to link molecular information directly to microbial biogeochemical process rates.

Objectives

Here, we investigate metagenomic responses in natural bacterioplankton communities to well-defined environmental stressors in the Baltic Sea, including increased river input, increased nutrient concentrations, and reduced oxygen.

Methods

Using a comparable metagenomics approach, we were able to identify changes in the microbial metagenomic blueprints after exposure to distinct environmental conditions, and to link these changes to biogeochemical process rates and microbial activity.

Conclusions

The results provide new knowledge for developing models of ecosystem structure and biogeochemical cycling in future climate change scenarios and advance our exploration of the potential use of marine microorganisms as markers of monitoring environmental conditions.

NEW MARINE GROUP III EURYARCHAEOTA, FROM DARK TO LIGHT

A.B. Martin Cuadrado[1], *J.M. Haro-Moreno*[2], *I. Garcia-Heredia*[1], *F. Rodriguez-Valera*[2]
[1]*Universidad de Alicante, Departamento de Fisiología- Genética y Microbiología, Alicante, Spain*
[2]*Universidad Miguel Hernández, Departamento de Producción Vegetal y Microbiología, Alicante, Spain*

Backgrounds

Marine Euryarchaeota remain among the least understood major components of marine microbial communities. Marine group II Euryarchaeota (MG-II) are more abundant in surface waters (4–20% of the total prokaryotic community), whereas marine group III Euryarchaeota (MG-III) are generally considered low-abundance members of deep mesopelagic and bathypelagic communities.

Objectives

Up to date, there are no cultivated representatives and little is known about their physiology and ecological role in the oceans. Therefore, to obtain representative genomic sequences will help in this sense.

Methods

Using genome assembly from direct metagenome reads and metagenomic fosmid clones, we have identified six novel MG-III genome sequence bins from the photic zone (Epi1–6) and two novel bins from deep-sea samples (Bathy1–2).

Conclusions

Photic-zone MG-III bins corresponded to novel groups with no similarity, and significantly lower GC-content when compared with previously described deep-MG-III genome bins. As found in many other epipelagic microorganisms, photic-zone MG-III bins contained numerous photolyase and rhodopsin genes, as well as genes for peptide and lipid uptake and degradation, suggesting a photoheterotrophic lifestyle. Phylogenetic analysis of these photolyases and rhodopsins as well as their genomic context suggests that these genes are of bacterial origin, supporting the hypothesis of an MG-III ancestor that lived in the dark ocean. Epipelagic MG-III occur sporadically and in relatively small proportions in marine plankton, representing only up to 0.6% of the total microbial community reads in metagenomes. Most low-GC bins were highly enriched at the deep chlorophyll maximum zones, with the exception of Epi1, which appeared evenly distributed throughout the photic zone worldwide.

DISENTANGLING MECHANISMS INVOLVED IN THE ADAPTATION OF MICROCYSTIS AERUGINOSA TO THE EXTREME SULPHUREOUS WATER FROM LOS BANOS DE LA HEDIONDA (S SPAIN)

E. Martín-Clemente[1], I.J. Melero-Jiménez[1], A. Reul[2], M. Hernández-López[3], E. Salvo[1], E. Bañares-España[1], M.J. García-Sánchez[1], A. Flores-Moya[1]
[1]Facultad de Ciencias- Universidad de Málaga, Biología Vegetal, Málaga, Spain
[2]Facultad de Ciencias- Universidad de Málaga, Ecología y Geología, Málaga, Spain
[3]Facultad de Ciencias- Universidad de Málaga, Química Analítica, Málaga, Spain

Backgrounds

Los Baños de la Hedionda (Málaga, S Spain) is a natural sulphureous spa where sulphide can reach a concentration of 150-200 µM. Although this ion has biocide properties, including inhibition of the photosynthetic process, a rich flora can be found in this extreme environment.

Objectives

To study the adaptation mechanisms allowing resistance of photosynthetic microorganisms to these sulphureous waters

Methods

For this purpose, a modified Luria–Delbrück fluctuation analysis was carried out. The adaptation to La Hedionda waters of three different strains of the cyanobacterium *Microcystis aeruginosa* (Kützing) Kützing (isolated from a non-sulphureous freshwater reservoir) was analyzed in order to find out if it was achieved by a physiological adaptation process (acclimation) or by the selection of rare spontaneous mutations (genetic adaptation).

Conclusions

Several resistant strains were obtained after 6 weeks of cultivation with La Hedionda waters. The fluctuation analysis showed that genetic adaptation was the phenomenon that allowed resistant *M. aeruginosa* cells from the three strains to survive, with similar mutation rates in the order of magnitude of 1 mutant resistant cell per 10^6-10^7 cell division^{-1}. It could be hypothesized that this cyanobacterium could adapt to sulphureous environment by the selection of favoured mutants.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

CHARACTERIZATION OF OSCILLATORIA SP. ISOLATED FROM EXTREME SULPHUREOUS WATER FROM LOS BANOS DE LA HEDIONDA (S SPAIN)

E. Martín-Clemente[1], I.J. Melero-Jiménez[1], A. Reul[2], M. Hernández-López[3], E. Bañares-España[1], A. Flores-Moya[1], M.J. García-Sánchez[1]
[1]Facultad de Ciencias- Universidad de Málaga, Biología Vegetal, Málaga, Spain
[2]Facultad de Ciencias- Universidad de Málaga, Ecología y Geología, Málaga, Spain
[3]Facultad de Ciencias- Universidad de Málaga, Química Analítica, Málaga, Spain

Backgrounds

Los Baños de la Hedionda (Málaga, S Spain) is a natural sulphureous spa (150-200 µM sulphide). Although this high sulphide levels can affect the photosynthetic process, there are numerous photosynthetic microorganisms inhabiting the spa. Among them, we isolated a strain of the cyanobacterium *Oscillatoria* sp., a genus well known by its tolerance to sulphide.

Objectives

Firstly, to analyze the photosynthetic characteristics and growth rate of the isolated strain, as well as the effect of the presence of sulphide in both processes. Secondly, to determine the limit of genetic adaptation of this strain to sulphide.

Methods

The resistance of the isolated strain to sulphide was studied by analyzing the effect of increasing sulphide levels (up to 1600 µM) on photosynthetic performance and growth. The limit of genetic adaptation was explored using an evolutionary experimental design named as ratchet protocol. This design allows discerning the maximum capacity of genetic adaptation of *Oscillatoria* sp. to the exposure of increasing doses of sulphide

Conclusions

The strain showed maximum growth rates at 200 µM sulphide although reduced rates can be found up to 800 µM sulphide. A significant increase in resistance was achieved in all derived populations during the ratchet experiment (surviving at sulphide concentrations higher than 2 mM). Moreover, they showed different evolutionary potential to adapt to sulphide, depending on historical contingency.

MICROCOSMS FOR EVALUATING MICROBIAL INDICATOR PERSISTENCE AND MOBILISATION IN FLUVIAL SEDIMENTS DURING RAINFALL EVENTS

J. Martín-Díaz[1], C. García-Aljaro[1], M. Pascual-Benito[1], W. Calero-Cáceres[1], B. Galofré[2], A.R. Blanch[1], F. Lucena[1]
[1]University of Barcelona, Department of Genetics- Microbiology and Statistics, Barcelona, Spain
[2]Aigües de Barcelona EMGCIA, -, Barcelona, Spain

Backgrounds

Climate change and demography evolution would probably increase the intensity and frequency of heat waves and extreme precipitations in several places in the Earth. The study of Mediterranean rivers, subjected to long dry periods, heavy rainfall events and punctual severe droughts could be useful to understand future climate scenarios. Riverbank sediment resuspension into the water column due to heavy rainfalls entails pathogen mobilisation that causes the water quality decline, with the consequent health risk for humans and animals and also the environment deterioration.

Objectives

The evaluation of indicator persistence (T_{90}) and mobilisation from sediments into the river water during the simulation of rainfalls events in 42-day-duration microcosms.

Methods

Considering the One Health concept, six microbial indicators were evaluated in microcosms simulating rainfall events naturally occurring in a Mediterranean river (NE Spain). Flow, turbidity and *E. coli* data from the river were used to set microcosms conditions. T_{90} in sediments were calculated and mobilisation patterns were studied.

Conclusions

T_{90} obtained in sediments were: sorbitol-fermenting *Bifidobacterium*, 4 days; qPCR-detected *E. coli*, 11 days; bacteriophages infecting *Bacteroides thetaiotaomicron* strain GA17, 36 days; culturable *E. coli*, somatic coliphages and spores of sulfite-reducing clostridia, more than 42 days. Different mobilisation patterns were found for bacteriophages and bacteria. Five out of the six indicators were still detected in sediments and water after 42 days, warning against the health risk of pathogen mobilisation into the water column. Valuable data were generated for enhance predictive models that evaluate the effects of climate change over surface waters quality.

METAL BIOREMEDIATION CAPACITY OF TETRAHYMENA THERMOPHILA ADAPTED STRAINS TO EXTREME METAL CONCENTRATIONS

P. De Francisco[1], J.C. Gutierrez[1], A. Martin-gonzalez[1]
[1]Universidad Complutense De Madrid, Microbiologia-III, Madrid, Spain

Backgrounds

Heavy metals are considered one of the most toxic and soil persistent pollutants. Due to several antropogenic activities, their environmental levels have increased in the last years and they can cause serious health problems. Physical-chemical techniques or phytoremediation try to remove metals from the environment but they are not so effective in many cases and new tools for metal bioremediation are required.

Objectives

The aim of this study was to analyze the metal bioremediation capacity of three metal-adapted strains from the ciliate *Tetrahymena thermophila.*

Methods

Metal adapted strains were obtained after exposing cells over time to increasing metal (Cd^{2+}, Cu^{2+} or Pb^{2+}) concentrations. They were characterized by TEM and fluorescence microscopy and their bioremediation capacity was studied by flow cytometry and ICP-AES.

Conclusions

The maximum tolerated concentrations (MTCs) of these metal-adapted strains were: 115 mM Cd^{2+} for Cd-adapted strain, 4 mM Cu^{2+} for Cu-adapted strain and 5.5 mM Pb^{2+} for Pb-adapted strain, being these values 2.5, 13 and 6-fold the LC_{50} of the control strain, respectively. Metal toxicity was analyzed by bioassays using control cultures after metal removing by adapted-strains and we observed a significant cell mortality reduction in all cases. Likewise, Pb-adapted strain removed about 95 or 99% of metal after only 24 or 48h exposures, respectively. In our opinion, these ciliate metal-adapted strains could be good cellular tools for metal bioremediation in both soil and aquatic ecosystems.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

ROLE OF COPPER IN PREDATION BY MYXOCOCCUS XANTHUS

G. Martínez Navajas[1], *J. Pérez*[1], *F.J. Marcos-Torres*[1], *A. Moraleda-Muñoz*[1], *J. Muñoz-Dorado*[1]
[1]*Facultad de Ciencias. Universidad de Granada., Microbiología, Granada, Spain*

Backgrounds

Predation is a strategy that is present in multiple living beings. Among the eukaryotes, some organisms are able to prey, such as the amoebas or the macrophages. These organisms use the oxidative stress generated by the presence of divalent metals, among others strategies, for lysing other microorganisms.

M. xanthus is a social bacterium able to prey on other microorganisms. In this bacterium 12 systems that are inducible by the presence of metals in the medium (mainly copper) have been identified. They participate in the oxidation and the extrusion of metallic cations to the exterior. However, these systems do not protect this bacteria from high metal concentrations, so they could have a different function as it could be participating in bacterial predation, in a similar way as the eukaryotic organisms do.

Objectives

For this reason, we have tried to determine whether these systems participate in bacterial predation.

Methods

We have constructed 12 strains harboring fusions between genes of each system and *lacZ*, and analyzed the expression of each system during predation of *M. xanthus* on *Sinorhizobium meliloti* on agar plates containing X-gal and different metal concentrations.

Conclusions

We have observed that some systems are induced in the interface between predator and prey, indicating that at least copper accumulates in this area. It remains to be elucidate whether metals are used as weapons by the predator or as a mechanism of defense by the prey.

This work has been supported by the Spanish Government (grant BFU2016-75425-P).

DIETS AND ENTEROCOCCI, A MURINE MODEL STUDY

M. Martínez-Cañamero[1], B. Sánchez[1], A. Cobo[1], M. Hidalgo[1], I. Prieto[1], N. Martínez[1], A. Gálvez[1]
[1]Universidad de Jaén, Ciencias de la Salud, Jaén, Spain

Backgrounds

The genus *Enterococcus,* part of the lactic acid bacteria (LAB), is of great importance in food because of its involvement both in fermentations and their deterioration. However, it is also an important nosocomial pathogen with strains with virulence traits and resistance to antibiotics.

Objectives

During our studies on the influence of different diets on the intestinal microbiota, we isolated several strain collections from mice faeces and detected a strain, framed in the species *E. faecalis*, of special interest in the host. We set out to further study this relation.

Methods

The enterococci were physiologically characterized, searched for virulence traits, bacteriocin production, as well as genotyped by Randomly Amplified Polymorphic DNA (RAPD). The strain of interest was used in an intervention study conducted on ten inoculated mice, compared to ten other mice treated with placebo. After three weeks, physiological variables were measured in mice as well as enterococci were isolated in stools, in order to know which animals had acquired our strain, as measured by RAPD. The strain was further studied by Multilocus Sequence Typing and, together with a second one isolated from faeces from mice that did not acquire the inoculum, it has been characterized at the proteomic level by two-dimensional SDS electrophoresis and by mass spectrometry.

Conclusions

Results will be shown in order to give a global picture about the presence of intestinal enterococci in a murine model, on how they are influenced by the diet of the host and, in their turn, how they affect their hosts.

FITNESS ANALYSIS OF TETRACYCLINE RESISTANT AND SENSITIVE SHIGELLA FLEXNERI IN THAMES RIVER WATER MICROCOSMS UNDER SUB-LETHAL CONCENTRATIONS OF TETRACYCLINE.

R. Maruzani[1], M. Marvarsi[1], A. Shah[1], V. Serafim[1]
[1]Middlesex University, Natural Sciences, London, United Kingdom

Backgrounds

It is becoming increasingly important to monitor how antibiotics influence fitness of microbial populations in the environment due to emergence of antibiotic resistance.

Objectives

We analyse the fitness of resistant and sensitive *S. flexneri* strains under tetracycline selection pressures in Thames River water environments.

Methods

Microcosms of Thames water from upstream, central London region and downstream inoculated with zero, lethal and sub-lethal concentrations of tetracycline were prepared. Approximately 10^4 CFU/mL isogenic pair of *Shigella flexneri* 1100 (resistant) and 1363 (sensitive) were added to each microcosm at a 1:1 ratio. Fitness was measured by comparing resistant and sensitive colonies after two days' exposure to selection pressure. PAH concentration and tetracycline degradation was determined using UPLC with fluorescence detection and HPLC with tandem mass spectrometric detection, respectively.

Conclusions

S. flexneri 1363 was found to significantly outcompete 1100 at sub-lethal and lethal concentrations of tetracycline in downstream microcosms, where PAH levels were highest. Upstream, *S. flexneri* 1100 outcompeted the sensitive strain in the same environment. The concentration of benzo(a)pyrene in upstream, London and downstream samples was found to be 0.24µg/mL, 1.35µg/mL and 30.79 µg/mL, respectively. Phenanthrene was detected at 1.10 mg/L, 20.51 mg/L and 140.90 mg/L in upstream, London and downstream sites respectively. Antibiotic degradation was observed in downstream lethal samples from 25 µg/mL to 10 µg/mL over 5 days.

Our results suggest PAHs in the environment may complex with tetracycline rendering it bio-unavailable. Resistance genes become a selective disadvantage where tetracycline is not bioavailable. Degradation of tetracycline may also contribute to selection of sensitive strains.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

MICROBORER COLONIZATION OF A SCLERACTINIAN CORAL HOLOBIONT, ACROSS ITS LIFE STAGES

A. Masse[1], A. Tribollet[2], I. Domart-Coulon[1], S. Golubic[3]
[1]Museum National d'Histoire Naturel, UMR7245, Paris, France
[2]Institut de Recherche pour le Développement, UMR7159, Paris, France
[3]Biological Science Center, Boston University, Boston, USA

Backgrounds

Although filamentous microborers are known as one of the major agents of carbonate dissolution in coral reefs, their diversity and dynamics of colonization in early life stages of reef-building scleractinian corals remains unexplored.

Objectives

Here, the microboring Ulvophyceae *Ostreobium* sp. was detected in the skeleton of the branching coral *Pocillopora damicornis* (type beta lineage), from the primary polyp to the budding juvenile colony and in adults.

Methods

Larvae of the *P. damicornis* were allowed to recruit and develop for 3 months on carbonate or non-carbonate substrates, both initially colonized by natural biofilms in aquarium settingsDiversity of *Ostreobium* in adult coral colonies was compared between three aquaria and two reefs sites. Morphological criteria were confirmed by phylogenetic analysis of *Ostreobium rbc*L chloroplastic marker, and distribution and abundance of microborers were quantified using thin sections.

Conclusions

Surprisingly our results show that 7 days old juveniles (primary polyp stage) were already colonized by microborers. Their abundance depended however on the nature of the settlement substrate and its degree of pre-colonization by microborers. The coral growth rate also affected the ability of microborers to reach the skeletal interface with tissue resulting in a ‘dilution effect’ of microboring filaments towards the apex of juveniles (1-3 months-old) and adult coral colonies. Altogether, 8 *rbc*L clades of *Ostreobium* were detected in the studied holobiont, with one dominant clade shared by all life stages, and also present in seawater, carbonate settlement substrates, and reef settings. These results suggest that in living corals the geography influences *Ostreobium* clade distribution and dominance.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

METSCHNIKOWIA PULCHERRIMA INFLUENCE ON FILAMENTOUS FUNGI METABOLISM.

J.J. Mateo Tolosa[1], *S. Maicas*[1], *R. Ferragut*[1], *Z. Raquel*[1]
[1]*Universitat de Valencia, Microbiología y Ecología, Valencia- Burjassot, Spain*

Backgrounds

Yeasts have the ability to survive in variable environmental conditions without the production of toxic compounds that could affect the human health. Moreover, yeasts can be produced in fermenters on cheap media and are able to survive in a wide range of environmental conditions. Competition with yeasts can dramatically inhibit the growth of fungi such as *Aspergillus, Botrytis, Penicilium* and *Alternaria* by affecting their secondary metabolism.

Objectives

The aim of this work was to determine de influence of *Metschnikowia pulcherrima* simultaneous growth with development of different interesting molds

Methods

M. pulcherrima yeasts were isolated from grapes surface and identified following both physiological and molecular methods. So, they were analysed by RFLP analysis of the 5.8S-ITS rDNA region and for sequence analysis of the D1/D2 domains of the 26S rDNA gene, PCR amplification was performed. Interactions between yeast and mold development were determined by simultaneous inoculation and growth on Malta Agar plates. Inhibition degrees were determined by using ImageJ software.

Conclusions

Once *M. pulcherrima* isolates were positively identified, all studied isolates have shown a high capability to inhibit mold growth and also to interfere their secondary metabolism. These results could open a new door in the field of biological control of fungal contamination, avoiding economical loses produces by this fact.

This work was supported by the project “Identification and biotechnological characterization of yeasts isolated from agrifood residues of the Valencian Community”, grant AICO-2016-079.

MOLECULAR ANALYSIS OF VANCOMYCIN – RESISTANT ENTEROCOCCUS ISOLATED FROM SURFACE AND GROUND WATER SAMPLES

D.P. Matlou[1], *A. Collins Njie*[2]
[1]*NORTH WEST UNIVERSITY, Department of Biological Sciences, MAFIKENG, South Africa*
[2]*North-West University- Mafikeng Campus, Department of Biological Sciences, Mmabatho, South Africa*

Backgrounds

Vancomycin Resistant *Enterococcus* (VRE) has been responsible for numerous outbreaks of serious infections in humans worldwide. *E. faecium* and *E. faecalis* are usually associated with Vancomycin resistance determinants thus cause hospital and community acquired infections in humans.

Objectives

The study was aimed at determining the antibiotic resistance and virulence profiles of VREs isolated from water samples.

Methods

Methods: A total of 170 water samples were collected and analysed. Eighty one potential isolates were screened for characteristics of *Enterococcus* species using preliminary biochemical tests, PCR assays and sequence analysis. The antimicrobial resistance profiles of isolates against 10 antibiotics were determined and a dendrogram was generated to access the relatedness of the isolates. Isolates were screened for the presence of antibiotic resistance and virulence genes by Multiplex PCR.

Results: A total of 56 isolates were confirmed as *Enterococcus* species. Large proportions (78.6%) of the isolates were resistant to Vancomycin. Forty four VREs isolates were detected phenotypically and 16% and 3.6% of the isolates possessed the *vanA* and *vanB* genes respectively. Large proportions of the isolates were resistant to multiple antibiotics and isolates with MAR phenotype VAN-NAL-STR-CHIL-AMP-OXYTET-GEN-NIT-SMX were resistant to eight antibiotics. Cluster analysis revealed two major clusters (Cluster 1 and Cluster 2). Sixteen (36.4%), 14 (27.3%), 3 (6.8%) and (4.5%) of the isolates possessed the *gel*, *asa*1, *hyl* and the *esp* virulence genes. None of the isolates possessed the *cylA* gene.**Conclusions**

Multiple antibiotic resistant enterococci that were also resistant to vancomycin and possessed virulence factors thus highlight the need for continuous monitoring.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

MICROBIAL MONITORING FOR THE IMPACT OF COMBINED SEWER OVERFLOW INTO URBAN WATERWAY IN JAPAN, AND ITS REMEDIAL EFFECTS BY BUILDING A STORMWATER STORAGE TUNNEL.

K. Matsui[1]
[1]*Kindai University, Department of Civil and Environmental Engineering, Higashiosaka, Japan*

Backgrounds

A combined sewer system collects domestic sewage and rainwater into one pipe. However, the volume of wastewater exceeds the capacity of sewer pipe during heavy rainfall events. When this occurs, untreated sewage discharges directly into rivers as combined sewer overflow (CSO).

Objectives

To evaluate the effectiveness of newly commissioned stormwater storage tunnel, we explore the impact of CSO on the water quality of an urban waterway running through thickly populated Osaka-city, Japan.

Methods

We characterized the bacterial community of the Higashiyokobori-gawa waterway using next-generation DNA sequencing (Illumina Miseq). We examined bacterial 16S rRNA gene amplicons during rainfall periods.

Conclusions

When rainfall exceeded 4 mm/h at our experimental site on the waterway, the bacterial populations in the river water exhibited transient changes attributable to the CSO. The bacterial populations in the waterway differed greatly from those in sewage, suggesting that the CSO had been diluted with bulk rainwater prior to discharge into the river. After a newly constructed stormwater storage tunnel (i.e. underground storage capacity) was commissioned, we found no changes in the bacterial community in river water even when rainfall exceeded 8 mm/h. This reveals that the CSO was a key factor for the bacterial community changes. The result also indicates that the storage tunnel effectively prevented CSO discharge into the waterway. We suggest that bacterial community composition analysis is useful when monitoring water quality.

VIBRIO CHOLERAE HMGA-MEDIATED PYOMELANIZATION CONFERS RESISTANCE TO PREDATION BY ACANTHAMOEBA CASTELLANII

D. McDougald[1], P. Noorian[2], Z. Chen[3], S. Kjelleberg[4], M. Wilkins[3], S. Sun[1]
[1]University of Technology Sydney, ithree Institute, Sydney, Australia
[2]University of New South Wales, School of Biotechnology and Bimolecular Science, Sydney, Australia
[3]University of New South Wales,
Systems Biology Initiative- School of Biotechnology and Biomolecular Sciences, Sydney, Australia
[4]Nanyang Technological University, Singapore Centre for Environmental Life Sciences Engineering, Singapore, Singapore

Backgrounds

Predation by heterotrophic protists is one of the main biological factors constraining bacterial growth in aquatic environments, and thus has led to the evolution of a number of defence mechanisms that protect the bacteria from predation. These mechanisms may also function as virulence factors in infection of animal and human hosts, thus leading to a pathogenic lifestyle

Objectives

In order to identify the genes expressed by *V. cholerae* during predation by *Acanthamoeba castellanii,* whole transcriptome shotgun sequencing was performed.

Methods

Analysis of the transcriptome of grazed *V. cholerae* biofilms revealed that 197 transcripts were differentially regulated when compared to the non-grazed control. Differentially regulated transcripts included transcripts involved in biosynthetic and metabolic pathways, flagellar assembly and biosynthesis, iron transport, outer membrane proteins, and transcriptional and translational regulators.

Conclusions

The transcripts of genes involved in tyrosine metabolism were down-regulated in the grazed population, which indicates that the tyrosine metabolic regulon (VC1344-1347) may have a role in the response of *V. cholerae* biofilms to *A. castellanii* predation. Indeed, a pigmented mutant, disrupted in VC1345 (*hmgA*), was more grazing resistant to amoebae than the wild type. The increased grazing resistance was due to increased production of pyomelanin and thus reactive oxygen species.

MICROBIAL AND PHYSICAL-CHEMICAL CHARACTERIZATION OF NATURAL WATER RESOURCES FROM COASTAL AND ANDEAN REGIONS IN ECUADOR

D. Vinueza[1], J. Carrera[1], L. Mejia Castaneda[1], V. Ochoa Herrera[2], A.G. Pazmiño[2], A. Machado[1]
[1]Universidad San Francisco de Quito, Institute of Microbiology, Cumbayá, Ecuador
[2]Universidad San Francisco de Quito, Colegio de Ciencias e Ingeniería, Cumbayá, Ecuador

Backgrounds

One of the major worldwide health problems is the contamination of drinking water sources with toxic compounds and pathogenic bacteria. Some pathotypes of *Escherichia coli*, *Campylobacter*, *Legionella*, *Shigella* and *Salmonella* spp are causing global serious health problems.

Objectives

This study aims to analyze the quality of natural water resources in urban areas in Ecuador based on microbial and physical-chemical parameters, in order to compare the Costal and Andean regions and evaluate possible correlations between these parameters.

Methods

Escherichia coli and total coliforms quantification was conducted through growth media and PCR analysis for each of the aforementioned genera and *E. coli* pathotypes in triplicate samples from six different rivers. Meanwhile, environmental parameters in surface waters such as pH, conductivity, dissolved oxygen, chemical oxygen demand (COD), and total suspended solids (TSS) were determined following standard protocols.

Conclusions

Escherichia coli and total Coliforms counts showed the highest indices in samples from Guayllabamba, Machangara and Zamora rivers (Andean Region). Although samples from the Costal Region (Guayas, Chone and Esmeraldas rivers) showed lower numbers of *E. coli* and total Coliforms, both regions evidenced the presence of the same *E. coli* pathotypes (EIEC, EPEC and EAEC). On the other hand, the presence of *Shigella*, *Salmonella* and *Campylobacter* spp. was not detected, while *Legionella*was found in all samples. In the case of Guayas and Zamora rivers, TSS and COD values exceeded the maximum permissible limits from Ecuadorian legislation. Finally, a positive correlation was found between the COD concentration and the presence of *E. coli* and Coliforms.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

AN EVOLUTIONARY APPROACH TO DETECT THE MAXIMUM POTENTIAL ADAPTATION OF MICROCYSTIS AERUGINOSA TO SALINITY

I.J. Melero Jiménez[1], E. Martín-Clemente[1], M.J. García-Sánchez[1], A. Flores-Moya[1], E. Bañares-España[1]
[1]Facultad de Ciencias- Universidad de Málaga, Departamento de Biología Vegetal, Málaga, Spain

Backgrounds

Salinity is increasing in many inland waters, on a world-wide scale, due to agricultural practices, droughts, or rise in sea level. In order to understand the effects of increased salinity on freshwater ecosystems, the cosmopolitan toxic cyanobacterium *Microcystis aeruginosa* (Kützing) Kützing was selected as a model. It is known that this species that this species cannot proliferate in salinity >10-15 $g \cdot L^{-1}$ but the limit of the adaptation to salinity remains to be investigated.

Objectives

To detect the maximum genetic adaptation capacity of three strains of *M. aeruginosa* (isolated from a freshwater reservoir with salinity <0.025 $g \cdot L^{-1}$, i.e. without previous "evolution salinity history") to the exposure of increased salinity.

Methods

An experimental evolutionary approach (ratchet experiment) was used. In order to analyze the differential evolutionary potential of three *M. aeruginosa* strains, two ratchet experiments were performed based on "soft" or "intense" exponentially increased salinity.

Conclusions

Acclimation (supported by the gene expression already present in the ancestral populations) was similar in the three strains in both ratchets experiments ("soft" and "intense"). A significant enhancement in resistance, supported by the selection of new genetic variants arising by mutations (genetic adaptation), was achieved in all derived populations in both ratchet experiments, and in the three strains. However, the results showed that the dynamics and the limit of genetic adaptation depend on previous adaptation history (historical contingency).

TEMPORAL VARIABILITY OF OSCILLATORIA SP. IN EXTREME ENVIRONMENT: A SULFIDE-RICH SPRING OUTFLOW

A. Reul[1], E. Martín-Clemente[2], I.J. Melero Jiménez[2], M. Hernández-López[3], F.J. Toro[2], E. Bañares-España[2], A. Flores-Moya[2], M.J. García-Sánchez[2]
[1]Facultad de Ciencias- Universidad de Málaga, Departamento de Ecología y Geología, Málaga, Spain
[2]Facultad de Ciencias- Universidad de Málaga, Departamento de Biología Vegetal, Málaga, Spain
[3]Facultad de Ciencias- Universidad de Málaga, Departamento de Química analítica, Málaga, Spain

Backgrounds

The Hedionda Spa (Andalucía, southern Spain) is a sulfide-rich spring outflow, but despite the inhibitory effect of sulfide on photosynthesis, a phytoplankton community inhabits this extreme environment.

Objectives

To analize the phytoplanktonic groups present in La Hedionda Spa along an annual cycle, and to study the possible correlation between sulphide concentration and the presence of different groups.

Methods

A monthly and weekly sampling was started on March 2016. Samples were analyzed with a fluorospectrometer to detect the presence of different groups. A FlowCAM analysis of photoplankton was carried out at 5-100 µm ESD to determine biovolume and abundance. Water samples were analized to determine sulphide concentration.

Conclusions

Sulphide concentrations varied from 0.8 to 219.4 µM, while chlorophyll *a* ranged between 0.4 and 11.7 ug l^{-1}. Cyanobacteria is the predominant phytoplanktonic group, accounting for 50-90% of total chlorophyll. *Oscillatoria* sp. is the predominant cyanobacteria in terms of abundance (0.55-65.6 filamemts·ml^{-1}) and biovolume ($9 \cdot 10^5$-$3 \cdot 10^8$ μm^3 ml^{-1}). A positive correlation was found between sulphide concentration and *Oscillatoria* sp. abundance, but not between sulphide and total chlorophyll *a* concentration. The positive correlation could be due to (i) dilution of both sulphide and *Oscillatoria* sp. abundance by runoff, or (ii) to a physiological advantage of *Oscillatoria* sp. under elevate sulphide, which has been confirmed in laboratory experiments. However, high sulphide might also reduce *Oscillatoria* sp. growth rate, but the absence of potential predator or competitor provides *Oscilatoria* sp. an advantage in the environment not detectable in laboratory approaches.

CULTURABLE DIVERSITY OF HALOPHILIC ARCHAEA ISOLATED FROM HYPERSALINE ENVIRONMENTS IN NORTHEASTERN ALGERIA

T. Menasria[1,2], L. Benammar[2], A. Ayachi[2], H. Hacène[3], M. Monteoliva-Sánchez[1], M. Aguiler[1]
[1]Faculty of Pharmacy, Department of Microbiology- University of Granada s/n 18071-, Granada, Spain
[2]Faculty of Natural and Life Sciences,
Department of Microbiology and Biochemistry- University of Batna 2- 05078, Batna, Algeria
[3]Faculty of Biological Sciences,
Departement of Cellular and Molecular Biology- University of Sciences and Technology Houari Boum ediene USTHB, Algiers, Algeria

Backgrounds

Algeria includes a multitude of wetlands with rare typology and ecology in the world, where 50 sites are classified as Ramsar sites of international importance. However, very original, diverse and typical extreme environments including saline lakes, salterns, saline and hypersaline soils in the steppes and Sahara, which owns 80% of the country land area, still be little studied for assessing their biological resources especially in term microbial diversities.

Objectives

Our research work deals with the issue of halophilic microbial diversity in a representative arid and desertic areas (hot hyper-lands) of South and Eastern Algeria. Thus, to establish a model of knowledge of the halophilic Archaeal communities in salt lakes (Chott and Sebkha)

Methods

In this study, the diversity of halophilic archaea from different chotts and sebkha (dry salt lakes and salt flat) in northeastern Algeria, was investigated using media supplemented with different salt concentration (15, 20, 25 and 30%) based on recognized halophilic techniques followed by preliminary identification analyzes and determination of some biological activities (hydrolytic enzyme, antibacterial activities). More than 70 halophilic archaea were isolated and preliminary polyphasic study with different conventional phenotypic tests (physiological, morphological and cultural) associated with 16S rRNA genes and phylogenetic analysis were done for the typing of the isolates.

Conclusions

Thus, the biodiversity found was considered wide in these environments, and sequencing of the 16S rRNA genes and phylogenetic analysis allowed the identification of possible novel species from different Archaeal genera such as Haloferax, Haloarcula, Halogeometricum, Natrinema and Natrialba,

FEMS7-2885
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

PHYLOGENETIC DIVERSITY OF RARE HALOPHILIC ACTINOMYCETES ISOLATED FROM SALINE SOILS IN NORTH-EASTERN ALGERIA

T. Menasria[1,2], L. Benammar[2], A. Ayachi[2], H. Hacène[3], M. Monteoliva-Sánchez[1], M. Aguilera[1]
[1]Faculty of Pharmacy- University of Granada, Department of Microbiology, Granada, Spain
[2]Faculty of Natural and Life Sciences- University of Batna 2,
Department of Microbiology and Biochemistry, Batna, Algeria
[3]University of Sciences and Technology HouariBoumediene,
Departement of Cellular and Molecular Biology, Algiers, Algeria

Backgrounds

Hypersaline environments present extreme conditions for life, however they are present in many regions throughout the world. In Algeria, there are several hypersaline sites with rare and unique typology without characterization or very scarce microbial investigation. Therefore, the archaeal and bacterial diversity including actinomycetes of these extreme saline environment remains poorly understood. Moreover, due to the antibiotic resistance global health problem, a renewed interest in the searching and development of new products with interesting biological activity is being actively pursued.

Objectives

To identify the Actinomycetes microbiota present in these extreme and unexplored environments. They could be targeted as new sources of structurally diverse natural products with new significant biological activity and potential biopharmaceutical applications

Methods

In this study, isolation of halophilic actinomycetes from different chotts and sebkha in northeastern Algeria, was investigated using media supplemented with different salt concentration based on recognized halophilic culture techniques followed by preliminary identification and determination of somebiological activities (hydrolytic enzymes, antibacterial activities). A total of 23 halophilic actinonmycetes isolates were recovered from different selected Algerian soils sampling. Sequencing and analysis of 16S rRNAgenes from representative isolates displayed the presence of members affiliated to rare actinobacterial genera: *Nocardiopsis and Actinonpolyspora.*

Conclusions

To the best of our knowledge, this study constitutes the first characterization of rare actinomycete diversity on salterns and hypersaline soils located in the eastern region of Algeria. Appropriate identification of rare actinomycetes species retrieved from the Algerian saltern soil samples will contribute to laid a platform to search for novel biotechnologically significant bioactive substances.

[2]*ICBAS/UP - Institute for the Biomedical Sciences Abel Salazar/ University of Porto, ICBAS, Porto, Portugal*
[3]*Faculty of Sciences of University of Porto, Porto, Portugal*

Backgrounds

Oil spills from anthropogenic sources pose a serious threat to coastal ecosystems, requiring prompt mitigation measures. There is thus a need for the development of cleaner and more efficient remediation techniques. Bioremediation has proven to be an eco-friendly and promising remediation technique, especially when using autochthonous microorganisms.

Objectives

In this line, we aimed to develop consortia of autochthonous bacterial strains, capable of degrading petroleum hydrocarbons, which could be used for the bioremediation of oil spills.

Methods

Thus, two different consortia were prepared, each constituted by a mixture of 5 bacterial strains previously isolated from a sandy beach (Cabo do Mundo) in the NW Portuguese coast, cultivated in Bushnell – Haas broth (BH) in the presence of two different sources of carbon (crude oil or sodium acetate).

Then, microcosm experiments were performed in flasks containing beach sediment, BH and crude oil, for 15 days, under three different conditions: natural attenuation, biostimulation (through the addition of nutrients) and bioaugmentation (through the addition of the previous consortia) combined with biostimulation. Samples were taken at the beginning and end of the experiment to assess hydrocarbon degrading microorganisms through an adapted most probable number method. Analysis of total hydrocarbons by FT/IR, to evaluate their degradation along time, was also carried out.

Conclusions

This study provides an insight of the natural community capacity to degrade hydrocarbons and its possible future application in bioremediation techniques. In this way, it is possible to act locally and ecologically facing an eventual oil spill incident.

Acknowledgments - project NORTE-01-0145-FEDER-000035 (ERDF) and ICBAS (UP).

OVEREXPRESSION OF ISIB FLAVODOXIN IN BURKHOLDERIA XENOVORANS CONTRIBUTES TO ENHANCED TOLERANCE TO HYDROGEN PEROXIDE AND AROMATIC DEGRADATION

V. Mendez[1], *A. Moyano*[2], *A. Smania*[2], *M. Seeger*[1]
[1]*Laboratorio de Microbiología Molecular y Biotecnología Ambiental, Departamento de Química & Centro de Biotecnología, Universidad Técnica Federico Santa María, Valparaíso, Chile*
[2]*Centro de Investigaciones en Química Biológica de Córdoba (CIQUIBIC), CONICET, Departamento de Química Biológica, Facultad de Ciencias Químicas, Universidad Nacional de Córdoba, Córdoba, Argentina*

Backgrounds

Long-chain flavodoxins (Flds), electron carrier flavoproteins that contain a flavin mononucleotide as prosthetic group, play a key protective role against reactive oxygen species (ROS) in diverse microorganisms. Flds, largely isofunctional with the electron carrier ferredoxins, are sensitive to ROS and its overexpression has been shown to confer increased tolerance to stress in plants and bacteria. However, Flds are restricted to specific prokaryotes and oceanic algae.

Objectives

To study the effects of flavodoxin IsiB from *Anabaena variabilis* overexpression in the model aromatic compounds-degrading strain *Burkholderia xenovorans* LB400 under oxidative stress conditions

Methods

In this study, we overexpressed flavodoxin IsiB from the cyanobacterium *Anabaena variabilis* in *Burkholderia xenovorans* LB400, a model aromatic compounds-degrader bacterium. We analyzed the effects of flavodoxin IsiB in bacterial survival and ROS formation upon hydrogen peroxide exposure. Growth on aromatic compounds by recombinant cells was also studied, a condition that leads to oxidative stress.

Conclusions

Cyanobacterial IsiB conferred increased tolerance to hydrogen peroxide and decreased ROS formation upon exposure for 1 h (10 and 20 mM). Moreover, IsiB contributed to bacterial survival after 10 mM hydrogen peroxide exposure for 1 h. Growth of recombinant *B. xenovorans* cells on aromatic compounds was also tested. Interestingly, turbidity of IsiB-overexpressing cells was higher when using 3- and 4-hydroxyphenylacetate as sole carbon sources in minimal media. Flavodoxin IsiB contributed in an enhanced response to oxidative stress and degradation of aromatic compounds in *B. xenovorans*.

SPATIO-TEMPORAL DYNAMICS OF THE MICROBIAL COMMUNITIES IN GYPSUM-RICH EXTREME ENVIRONMENTS (MONEGROS DESERT, SPAIN)

M. Menendez Serra[1], X. Triadó-Margarit[1], C. Castañeda[2], J. Herrero-Isern[3], E. O Casamayor[1]
[1]Centre for Advanced Studies of Blanes CEAB- Spanish Research Council CSIC, Ecología Continental, Blanes, Spain
[2]Estación Experimental de Aula Dei- Spanish Research Council CSIC, Soil Management and Global Change, Zaragoza, Spain
[3]Estación Experimental de Aula Dei- Spanish Research Council CSIC, Irrigation- Agronomy and Environment, Zaragoza, Spain

Backgrounds

The Monegros desert contains one of the largest sets of aquatic and soil saline environments in Europe forming a unique landscape of great scientific and ecological value. The uniqueness of these saline and gypsum-rich environments has been documented in geologic, hydrologic, mineralogic and edaphic studies providing habitats for rare and threatened plants and animals. A large number of endemisms have been reported mainly of invertebrates, vascular plants, lichens and bryophites. The genetic identity, novelty and temporal dynamics of the microbial component remains poorly studied.

Objectives

To describe the composition and distribution of microbial communities in saline environments of the Monegros desert and Gallocanta lagoon and the underlying patterns behind microbial community colonization, assembly and diversity.

Methods

The Monegros Desert is located within the semi-arid Central Ebro Basin (41°42′N, 0°20′W), and includes an endorheic area (c. 400 km2) with 149 scattered saline depressions. The basins are excavated on gypsum-rich bedrock and range in size from < 2 to 239 ha. Gallocanta is a large endorheic rain-fed shallow lagoon (14.4 km2, 50 cm deep) located in a plateau 1000 m a.s.l. in the Iberian Mountain system (40°58′N 1°29′W). DNA was extracted from soil and water samples along a temporal survey, and PCR amplicons were analysed by high-throughput sequencing Illumina and cloning and sequencing techniques.

Conclusions

The microbial genetic diversity was broad and with remarkable novelty with recurrent presence of bacteria initially isolated from polar marine habitats, and new groups of Archaea. Microbial eukaryotes were substantially different from protists and fungi previously reported from marine or freshwater. The great scientific and ecological value found for macroorganisms can be extended to the idiosyncratic microorganisms inhabiting such unique habitat in Europe.

Backgrounds

Antibiotic resistant bacteria and antibiotic resistance genes (ARGs) are major human-health threats, widely distributed in the environment. Quantitative PCR (qPCR) is a standard approach to detect and quantify ARGs in environmental compartments. However, the comparison of gene quantification reported by different laboratories is challenging since data are predominantly obtained under non-harmonized conditions, using different qPCR protocols.

Objectives

The aim of this study was to develop and calibrate standardized qPCR procedures for quantification of key ARGs, analyzing the same samples with common protocols and distinct equipment, reagents batches and operators.

Methods

Treated wastewater from three European countries were processed immediately after collection and transported to the laboratory for total DNA extraction. DNA extracts from each sample were pooled and aliquots were distributed by five partners involved in the calibration procedure. The genes 16S rRNA, *vanA*, bla_{TEM}, *qnrS*, *sul1*, $bla_{CTXM-32}$ and *intI*1 were analyzed using harmonized qPCR protocols and the constructed pNORM1 plasmid, which contains fragments of the seven targeted genes, was used for generating standard curves.

Conclusions

The 16S rRNA gene was the most abundant, followed by *sul1*, *intI*1, *qnrS* and bla_{TEM}. Quantifications made by different partners were reproducible and inter-laboratory variation was < 20%. The notorious exception was for the *qnrS* gene, and therefore protocol improvement is recommended. The genes $bla_{CTXM-32}$ and *vanA* were below the limit of quantification in most or all of the samples analyzed. The inter-laboratory calibration is an adequate approach to reliably assess ARG abundance and environmental contamination in different environments and geographic locations.

[3]Hasselt University, Centre for Environmental Sciences CMK, Hasselt, Belgium
[4]Université de Pau et des Pays de l'Adour, Equipe Environnement et Microbiologie EEM, Pau, France
[5]University of Oviedo, Department of Exploitation and Mining Prospecting, Mieres, Spain

Backgrounds

Asturias (NW Spain), is characterized by the existence of a significant number of degraded areas from the dismantling of chemical industry. These anthropogenic activities have generated waste with high metal(loid)s content, among them arsenic is one of the most hazardous element. A representative example of a large-scale contaminated site is *Nitrastur*, which is a highly-contaminated abandoned fertilizer industry. *Betula celtiberica* is a deciduous tree, pseudometallophyte, and fast-growing high biomass plant colonizing the study area.

Objectives

The potential of indigenous arsenic-tolerant bacteria to enhance arsenic-phytoremediation using as accumulator plant the autochthonous *Betula celtiberica* was addressed.

Methods

Analysis of the whole rhizosphere and endophytic bacterial communities, the cultivable species and subsequent bioaugmentation experiments.

Conclusions

Betula celtiberica's microbiome was dominated by taxa related to *Flavobacterium, Burkholderiales* and *Pseudomonas*. A total of 54 cultivable rhizobacteria and 41 root endophytes, mainly affiliated to the phyla *Proteobacteria*, *Bacteroidetes*, *Firmicutes* and *Actinobacteria* were isolated and characterized with ability to promote plant growth and to mitigate heavy metal stress. Seven bacterial isolates were selected and tested for *in vitro* arsenic plant-accumulation and four of them were finally tested in a field-scale study. The exposure to arsenic *in vitro* caused an increase in content of total non-protein thiol compounds in roots, suggesting a detoxification mechanism through phytochelatins complexation. In the field, an endophytic bacterial consortium enhanced As-accumulation in leaves and roots, whereas the rhizosphere isolate *Ensifer adhaerens* strain 91R mainly promoted plant growth. Field experimentation showed that additional factors, arsenic content and pH of soil, influenced the plant arsenic uptake.

FEMS7-1278
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

BACTERIAL, ARCHAEAL, AND EUKARYOTIC DIVERSITY ACROSS ECOLOGICAL NICHES IN LOS RUELDOS ACID MINE DRAINAGE

V. Mesa[1], C. Méndez-García[2], R. González-Gil[3], J.L. R. Gallego[4], J. Sánchez[1], A.I. Peláez[1]
[1]University of Oviedo, Department of Functional Biology, Oviedo, Spain
[2]University of Illinois, Carl R. Woese Institute for Genomic Biology, Urbana, USA
[3]University of Oviedo, Department of Organisms and Systems Biology, Oviedo, Spain
[4]University of Oviedo, Department of Exploitation and Mining Prospecting, Oviedo, Spain

Backgrounds

Acid mine drainages are characterized by their low pH and the dissolved toxic metallic species. Los Rueldos, an abandoned mercury mine has originated an environment typical of acid drainage, where a very specific set of geochemical conditions act as key in the development of a unique microbial community.

Objectives

We surveyed the microbial diversity in all domains of life in different niches (acid water, sediments, and biofilms), and predicted bacterial function based on community composition.

Methods

The analysis was addressed through phylogenetic analysis based on 18S rRNA gene and large-scale parallel pyrosequencing of 16S and 18S.

Conclusions

Sediment samples contained higher proportions of soil bacteria (AD3, Acidobacteria), Crenarchaeota, and Methanomassiliicoccaceae archaea. Subaerial biofilm at the interface rock/acid water and biofilm at the interface sediment/water samples, were enriched in iron oxidizers (genus *Leptospirillum*), Acidithiobacillales, Betaproteobacteria, and Thermoplasmata archaea. Water samples were enriched in Cyanobacteria and Thermoplasmata archaea at 3-98% of the sunlight influence, while Betaproteobacteria, Thermoplasmata, and Micrarchaea dominated in acid water collected in total darkness. Stalactites hanging from the Fe-rich ceiling samples were dominated by the neutrophilic iron oxidizer *Gallionella* and lineages absent in the rest of micro-habitats (Chlorobi, Chloroflexi). Eukaryotes were detected in biofilms and outdoors water samples, and belonged mainly to clades SAR (Alveolata and Stramenopiles), and Opisthokonta (Fungi). Acidic biofilm with uppermost oxic and hypoxic biofilms displayed higher proportions of ciliates (Gonostomum, Oxytricha), whereas outside water samples were enriched in fungi (*Paramicrosporidium* and microbial Helotiales). Predicted function through bacterial community composition suggested adaptive evolutive convergence of function in heterogeneous communities.

AGROBACTERIUM FABRUM HYDROXYCINNAMIC ACIDS DEGRADATION REGULATION: OPTIMIZATION FOR CONTRASTING LIFESTYLES?

T. MEYER[1], S. RENOUD[1], I. KERZAON[1], A. VIGOUROUX[2], V. GAILLARD[1], S. MORERA[2], L. VIAL[1], C. LAVIRE[1]
[1]UMR Ecologie Microbienne- CNRS- INRA- VetAgroSup- UCBL- Université de Lyon, Biology, Villeurbanne, France
[2]Institute for Integrative Biology of the Cell I2BC- CNRS CEA University Paris-Sud, Biophysics- Biochemistry and Structural Biology, Gif-sur-Yvette, France

Backgrounds

Hydroxycinnamic acids (HCA) are plant compounds, precursor of lignin synthesis and moreover toxic for certain bacteria. However, in *Agrobacterium fabrum* strains, HCA are degraded and used as carbon sources thanks to a species specific genes cluster, absent from the other *Agrobacterium* species. This degradation pathway and its genomic organization are original and contains both the genes involved in the degradation process and their putative regulator (*hcaR*), a MarR family regulator (Campillo et al., 2014, Lassalle et al., 2011). Regulation allows to optimize the cell response and to narrow the fitness expression cost in changing environments. *A. fabrum* HCA degradation species specific genes have been proposed to be selected by natural selection for their importance in plant-bacteria interaction. However, *Agrobacterium* has two different lifestyles both in interaction with plant: either commensal living in plant rhizosphere, or pathogenic by creating its own ecological niche after plant cells transformation leading to tumor formation (crown gall disease).

Objectives

The aim is to investigate the molecular and ecological role of *A. fabrum* HcaR in the two contrasting lifestyles of the bacteria.

Methods

We studied the HcaR regulation by molecular approaches (deletion mutant, transcriptional fusion, gel-shift assays). The implication of HcaR in bacterial fitness *in planta* was studied by gene expression and competition assays.

Conclusions

We described the HcaR regulation of HCA degradation genes and demonstrated that it is an important phenomenon for *A. fabrum* interaction with plants. Contrasting results of the fitness cost associated to HcaR deletion were observed for the two lifestyles of *Agrobacterium*.

[3]Faculty of Food Technology and Biotechnology, Department of Biochemical Engineering, Zagreb, Croatia
[4]Faculty of Food Technology and Biotechnology, Department of Process Engineering, Zagreb, Croatia
[5]Ruđer Bošković Institute, Division of Materials Chemistry, Zagreb, Croatia

Backgrounds

Effluents from antibiotic manufacturing are recognised as the most important contributors to aquatic pollution with antibiotics which could have negative impact on biological balance of natural environments and could also facilitate the development and dissemination of antibiotic resistance.

Objectives

The objective of this study was to characterize effluents from a local pharmaceutical industry manufacturing the macrolide antibiotic azithromycin with respect to its antibiotic content, ecotoxicity and diversity of macrolide-resistance genes.

Methods

The effluents were collected on two occasions in 2016, in winter and in spring. LC-MS analysis of effluents showed high concentrations of azithromycin, N-desmethyl azithromycin and dehydrated erythromycin (in the range of mg/L). Ecotoxicity tests showed high toxicity of effluents to diverse freshwater organisms (algae, *Daphnia* and zebrafish embryos). Culturing showed that effluents contained high frequency of azithromycin-resistant bacteria (> 70%). Functional metagenomics identified two main macrolide resistance mechanisms which include antibiotic efflux and inactivation. Some macrolide resistance genes are flanked by mobile genetic elements such as IS elements suggesting that they are candidates for dissemination to other bacteria in the environment, including pathogens.

Conclusions

Using a wide array of analyses we have demonstrated that discharges of local pharmaceutical industry may pose a significant ecological and public health concern due to their high toxicity to aquatic biota and the potential to promote global spread of antibiotic resistance.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

USE OF SUBSTRATES AND ENZYMATIC ACTIVITIES BY THE AQUATIC MICROBIAL ASSEMBLAGES OF ENDORHEIC LAKES ALONG A SALINITY GRADIENT

J. Miralles[1], A. Camacho[1], A. Picazo[1], C. Rochera[1], A. Camacho[1]
[1]Institut Cavanilles de Biodiversitat i Biologia Evolutiva, Limnologia, Paterna, Spain

Backgrounds

Salinity is a paramount environmental variable shaping the microbial communities thriving in aquatic environments and their phenotypic characteristics.

Objectives

In this work, we aim to assess the community-level physiological profile (CLPP) and the enzymatic activities of the aquatic microbial community of 17 endorheic lakes located in La Mancha Húmeda Biosphere Reserve (Central Spain), showing an increasing salinity gradient among them and also through time.

Methods

The assessment was performed by using the Biolog EcoPlate system, which is especially designed for the analysis of the CLPP in soils and waters. We additionally measured two enzymatic activities (phosphatase and celobiase).

Conclusions

As a general pattern, salinity increases resulted in lower consumption but also in the use of a narrow variety of substrates. Our results also show a pattern of specialization on the CLPP with increasing salinity. Lakes with low salinity show a very similar pattern of substrate use, but with low consumption of each substrate. Contrarily the most saline lakes show a high consumption of just a few substrates, and this specialization grows towards the warmest periods, as do enzymatic activities.

ISOLATION AND CHARACTERIZATION OF CYANOTROPHIC AND ARSENIC OXIDIZING BACTERIUM PSEUDOMONAS SP. P6115

C. Hernández Rodríguez[1], *A. Miranda Carrazco*[1], *L. Villa Tanaca*[1]
[1]*Instituto Politécnico Nacional, Microbiología, Mexico City, Mexico*

Backgrounds

Mine wastes are man-made environments with high concentrations of heavy metals and cyanide but low concentration of organic matter, and inorganic and organic sources of combined nitrogen. Some pioneer bacteria can colonize and grow in mine wastes with several selection pressures and nutritional limitations.

Objectives

Identify and characterize of a cyanotrophic bacterium able to degrade cyanide and oxidize arsenic from mine wastes as a potential candidate for biological treatment of cyanide mine tailings.

Methods

A bacterium was isolated from waste tailings with high concentration of cyanide and it was identified as *Pseudomonas* sp. P6115 by phylogenetic analysis of 16S rRNA, *gyrB, rpoB* and *rpoD* genes. Also, the strain was tested to cyanide degradation and arsenic oxidation by in vitro physiological and molecular assays.

Conclusions

The growth kinetics of the strain in media with cyanide as a sole nitrogen source was associated to cyanide removal. Also, ferricyanide, a component of wastewater, was used as a sole nitrogen source. The strains tolerated arsenite and arsenate, and exhibited capacity to oxidize arsenite. *Pseudomonas* sp. P6115 can be proposed as candidate for the biological treatment of cyanide and arsenic in mine wastes.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

A PILOT CORRELATION STUDY: HOW GENETIC VARIATION REGULATES WITHIN-POPULATION DIFFERENCES IN THE GUT MICROBIOTA OF GIANT PANDA?

S. Mishra[1], J. Tang[1], Y. Li[1]
[1]SICHUAN AGRICULTURAL UNIVERSITY,
Farm Animal Genetic Resources Exploration and Innovation Key Laboratory of Sichuan Province, CHENGDU, China

Backgrounds

For an enigmatic species like the bamboo-eating giant panda, which still retains a carnivore-like short gastrointestinal tract, it becomes extremely significant to examine its gut microbiota diversity for its health status and future survival. Gut microbiota composition and diversity vary within and among populations and several factors have been reported to play important roles in shaping the gut microbiota at different taxonomic scales. Therefore, to understand variations in gut microbial communities, we must determine how processes regulating microbial community assembly (colonization, persistence) differ among hosts and affect microbiota composition.

Objectives

Hence, we examine the correlation of structural composition of gut microbiota with genetic diversity in wild giant pandas.

Methods

Eighty fecal samples of wild giant pandas were collected from Wolong National Nature Reserve, China. Further, we investigated the structural profile of the giant panda gut microbiome comprehensively based on pyrosequencing of V4-V5 region of 16S rDNA and assessed genetic diversity using primers for Cyt-b gene and D-loop region of mitochondrial DNA.

Conclusions

The bacterial composition in the wild giant pandas was primarily dominated by *Proteobacteria*, *Bacteroidetes*, and *Firmicutes* (contributing 60.49%, 21.85% and 14.95%, respectively). We also found within-population differences in the gut microbiota of Wolong pandas. Furthermore, we attempted to correlate within-population differences in gut microbiota with genetic variation in pandas. Here we discuss the first attempt to identify and partition colonization and sorting process in a gut microbiota metapopulation of the wild giant panda with large sample-size. This study would help in developing effective future conservation plans.

USING MICROBIAL SOURCE TRACKING MARKERS TO PREDICT OCCURRENCE OF WATERBORNE PATHOGENS IN URBAN AND AGRICULTURAL WATERSHED

M. Molina[1]
[1]*US Environmental Protection Agency, ORD, Athens, USA*

Backgrounds

Runoff from agricultural fields and urban landscapes may carry a variety of microbial contaminants that compromises water quality and increases the possibility of human exposure to pathogenic microorganisms.

Objectives

The objective of this study was to predict occurrence of waterborne pathogens using measurements of fecal indicator bacteria (FIB), microbial source tracking (MST) markers and environmental parameters to support development of risk assessment models and gain better understanding of pathogen behavior in mixed use watersheds.

Methods

Collection of stream water and sediment samples was conducted from November 2012 to December 2013 in an agricultural watershed in N.E. Georgia, USA and from November 2015 through December 2016 in an urban watershed (Atlanta, Georgia). *E. coli, Enterococcus sp., Salmonella (invA)*, *Shiga toxin* producing pathogens (*Stx2*), and MST markers were measured in over 25 locations across both watersheds. Decision tree analysis was used to determine independent variables describing the occurrence of waterborne pathogens.

Conclusions

Salmonella, and Stx2 were detected in 76.2%, and 61.1% of water samples and in 51.1%, and 43.3% of sediment samples, respectively. Water *E. coli* concentration, temperature, DO, pH and ruminant-associated marker concentration predicted presence of pathogens in agricultural watersheds. In the urban watershed, temperature, conductivity, and D.O predicted the presence of *Salmonella.* Culturable *E. coli* and the human associated marker were poor *Salmonella* predictors, suggesting that *Salmonella* may be originating from non-human sources. This study shows the utility of integrating microbial water quality measurements with MST markers to predict pathogen occurrences in streams impacted by mixed land uses.

ANTARCTIC FUNGI DIVERSITY WITH BIOTECHNOLOGICAL APPLICATIONS

L. Monserrate-Maggi[1], M. Ratti-Torres[1], J. Vargas-Peréz[1], L. Serrano-Mena[1], I. Valderrama[1], J. Cevallos-Cevallos[1]
[1]Escuela Superior Politécnica del Litoral, Centro de Investigaciones Biotecnológicas del Ecuador, Guayaquil, Ecuador

Backgrounds

The study of microbial community was much advanced by recent introduction of Next Generation Sequencing (NGS) technologies, this has allowed to understand structures and relationships with biotic and abiotic factors of microbial community in extreme environments, in addition to the different uses in biotechnology.

Objectives

This study focused on the molecular identification and bioprospecting of cultured, and non-cultured fungal community from Antartic soils.

Methods

The samples were processed by molecular techniques including 454 pyrosequencing. Isolates were identified by PCR amplification and ITS1, 5.8S, and ITS2 region sequencing. Bioinformatic analyzes were performed using the Quantitative Insights Into Microbial Ecology software and compared to the UNITE version 7 database. Wealth and Shannon were calculated using pyrosequencing data. Yeast bioprospecting was performed by incubating each isolate at 20 ° C on mineral media enriched with urea, casein / gluten, starch, or fat to test for ureases, peptidases, amylases, or lipases respectively. Fermentation of sugars was tested using sucrose, fructose, glucose, maltose, lactose, and glycerol.

Conclusions

The presence of fungi in Antarctica is mainly due to their role in the primary decomposition of organic material, besides genres that increase in abundance at lower temperatures. This research combining fungal isolation with 454 pyrosequencing emphasizes the importance of the use of molecular methods of detection to obtain a more accurate description of diversity, although there are other sequencing technologies that are used today. The diversity of fungal genera in the Antarctic is still low relative knowledge. Finally, fermentation of *Candida* showing potential application in the production of beer.

MICROBIOLOGICAL VARIABLES AS SOIL QUALITY INDICATORS: EVALUATION OF AEROBIC TREATED MANURE APPLICATION IN AGRICULTURAL SOILS

A. Montanez[1], S. Vico[1], L. Nuñez[1], C. Silva[1], N. Rigamonti[1]
[1]Facultad de Ciencias, Montevideo, Montevideo, Uruguay

Backgrounds

Soil microbial properties related to the biodiversity and biocycles of soil nutrients, are indicators of soil quality, but there is still no consensus as to how they should be used.

Objectives

In this study we evaluated the impact of aerobic treated manure application on soil microbiological characteristics, with the aim of identify a minimal microbiological data set to monitor early changes in soil quality

Methods

The biofertilizer utilized in the experiment was obtained through *in situ* aerobic treatment of livestock manure. Two field sites were used, with high and low input application and soil samples were with and without application of biofertilizer. Soils pH, water content and rate of N mineralization were determined. Different microbial activities were measured: carbon soil microbial biomass; soil biodiversity, including the metabolic profile of soil microbial organism and number of cultivable mesophilic aerobic bacteria, fungi and actinomyces; soil enzyme activity; soil physical properties, related to glomalin concentration in soil; soil fertility, includes functional microbial groups with the ability to supply directly or indirectly essential plant nutrient and. soil suppressive capacity.

Conclusions

Results showed that biofertilizer application had the potential to increase functional diversity in soil microbial communities and soil microbial biomass. Actinomyces, soil suppressive capacity, glomalin and enzyme activity were strongly correlated. However it is important to make greater efforts to understand the behavior of a broad group of soil biological properties and how they relate to each other in particular areas and situations to contribute to generate information for more globally applicable evaluation of soil quality.

THOUGH INHABITANTS OF THE INTERNATIONAL SPACE STATION

M. Mora[1], A. Perras[1], L. Wink[1], T. Alekhova[2], R. Krause[1], C. Moissl-Eichinger[1,3]
[1]Medical University of Graz, Internal Medicine, Graz, Austria
[2]Moscow State University, Department for Microbiology, Moscow, Russia
[3]BioTechMed, -, Graz, Austria

Backgrounds

An important part of planning future long-term space flight missions (e.g. to Mars) is the development of strategies to safely manage the indoor microbiome of spacecraft, which represent completely isolated habitats. Since microorganisms pose a potential hazard for crew and spacecraft material, it is critical to assess microbial population dynamics and also to detect eventually developing resistances within the microbiota of such special closed systems. The best model system to date to investigate the microbiome of a confined habitat with constant human occupation in space is the International Space Station (ISS).

Objectives

To contribute to the big picture of the ISS indoor microbiome in addition to already existing data, we analysed 8-12 years old dust samples from Russian ISS modules with a focus on extremotolerent bacteria and archaea.

Methods

We assessed the cultivable microbiota of these desiccated samples via a broad range of cultivation assays and analysed their extremotolerant potential. Additionally, we assessed the microbial community of these samples via Next Generation Sequencing (NGS).

Conclusions

Besides confirming the presence of a broad variety of microorganisms onboard the ISS, of which many are equipped with a profound resistance capacity gainst clinically relevant antibiotics and other parameters, we were able to prove the presence of archaeal signatures on board the ISS. Elucidating the microbial population dynamics of the ISS and other similarly confined habitats can not only be used for spaceflight purposes but also help understanding possible risks in confined habitats on Earth, as e.g. industrial clean-rooms or confined hospital wards.

MICROBIAL COMMUNITY EVOLUTION IN ORGANIC FRACTION OF MUNICIPAL SOLID WASTE BY ANAEROBIC DIGESTION

S. Morandi[1], P. Cremonesi[2], T. Silvetti[1], C. Cortimiglia[2], M. Decimo[1], E. Casaletta[3], B. Castiglioni[2], M. Brasca[1]
[1]Institute of Sciences of Food Production ISPA-CNR, Italian National Research Council CNR, Milan, Italy
[2]Institute of Agricultural Biology and Biotechnology IBBA-CNR,
Italian National Research Council CNR, Lodi, Italy
[3]Austep SpA, Austep SpA, Milan, Italy

Backgrounds

The organic matter originated from the household waste treatment facilities has potential agronomic properties as fertilizer and soil amendment. On the other hands, digestate products could contain pathogens or otherwise harmful microorganisms such as aerobic and anaerobic spore-forming bacteria.

Objectives

This work aimed to investigate in different process plants the bacterial population of organic fraction of municipal solid waste (OFMSW) at the beginning and at the end of the digestion process using both conventional culture approach and metagenomics by Next Generation Sequencing (NGS). To deeply characterize the population of spore-forming bacteria in digestates, aerobic/anaerobic spore-forming bacteria were isolated.

Methods

Six biowaste samples of OFMSW and the corresponding digestates were analyzed for total viable count, *E. coli*, coliforms, enterococci, aerobic/anaerobic spore forming bacteria, yeasts and moulds. Spore-forming bacteria were isolated and identified by 16S rRNA sequencing. For metagenomics analysis, the bacterial DNA was extracted using a commercial kit and 16S rRNA gene amplicons on V3-V4 region analyzed by Miseq (Illumina).

Conclusions

Output digestates showed a good hygienic quality and lower counts of bacteria than OFMSW samples. Most abundant spore-forming bacteria belonged to *Bacillus aerophilus*, *B. amyloliquefaciens*, *B. cereus*, *B. licheniformis*, *B. safensis*, *B. subtilis* and *Clostridium sporogenes* species. The bacterial community of OFMSWs was dominated by *Firmicutes*, *Proteobacteria* and *Bacteriodetes*, while the output digestates revealed higher presence of *Synergistetes*, *Thermotogae* and *Euryarcheota*. The study provides new insights into microbiota evolution of OFMSW digestate and potential spores that can contaminate soils and crops when digestate is used as fertilizer

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

COMPARISON OF TWO DIFFERENT PRIMER SETS AND AMPLIFICATION CONDITIONS USED IN AN 18S RRNA AMPLICON-BASED METAGENOMICS STUDY

L. Moreno-Mesonero[1], Y. Moreno[1], I. Amorós[1], M.A. Ferrús[2], J.L. Alonso[1]
[1]Instituto Universitario de Ingeniería del Agua y Medio Ambiente- IIAMA, Universitat Politècnica de València, Valencia, Spain
[2]Departamento de Biotecnología, Universitat Politècnica de València, Valencia, Spain

Backgrounds

Currently, molecular techniques are the most promising methods for the sensitive, accurate, and simultaneous detection of protozoan parasites. Among these, 18S rRNA amplicon-based metagenomics could be a powerful tool to investigate the presence of pathogenic protozoa all together in the environment.

Objectives

In this study, two different sets of designed primers, able to amplify simultaneously most of the protozoan organisms, were tested in a mock sample, sequenced by 18S rRNA metagenomics and analysed by an optimized bioinformatics pipeline.

Methods

The first set of primers was EUKAF 5´-GCCGCGGTAATTCCAGCTC-3´ and EUKA21R 5´-CYTTCGYYCTTGATTRA-3' and the second one was F18S-G: 5'-CGGCGGTAATTCCAGCTC-3' and R18S-G: 5'-TCYAAGAATTTCACCTCT-3'. An *in silico* PCR was conducted on SILVA databases allowing 2 mismatches (https://www.arb-silva.de/search/testprime/) for both sets of primers. Different enhancing agents for PCR, such as BSA, DMSO, glycerol, betaine or acetaine were tested, with the normally used PCR mix in order to improve Giardia spp. DNA amplication. Two polymerase systems, Accuprime G+C and KAPA HiFi with G+C buffer, were also tested. A mock sample containing *Cryptosporidium hominis*, *Giardia intestinalis*, *Cryptosporidium parvum*, *Entamoeba histolytica*, *Toxoplasma gondii* and *Blastocystis hominis* was amplified with both sets of primers using G+C KAPA HiFi buffer, sequenced in an Illumina MiSeq system and analysed in QIIME™.

Conclusions

The amplicon sequencing with the first primers and the use of the KAPA HiFi system with G+C buffer allowed the recovered of all the sequences from the mock, and although the second primers did not detect *Giardia* spp., they allowed a better identification of the rest of microoorganisms.

PSEUDOMONAS FLUORESCENS SBW25 USES N-OCTANOYL-L-HOMOSERINE LACTONE AS A QUORUM SENSING MOLECULE.

O. Moshynets[1], S. Rogalsky[2], D. Irodov[1], S. Karakhim[3], S. Tarnavsky[4], M. Kharhota[5], G. Volynets[4], A. Spiers[6]
[1]Institute of Molecular Biology and Genetics- National Academy of Sciences of Ukraine, Cell Regulatory Mechanisms, Kiev, Ukraine
[2]Institute of Bioorganic Chemistry and Petrochemistry- National Academy of Sciences of Ukraine, Laboratory of Modification of Polymers, Kiev, Ukraine
[3]Palladin Institute of Biochemistry- National Academy of Sciences of Ukraine, Biochemistry of Muscle, Kiev, Ukraine
[4]Institute of Molecular Biology and Genetics- National Academy of Sciences of Ukraine, Medical Chemistry, Kiev, Ukraine
[5]Zabolotny Institute of Microbiology and Virology- National Academy of Sciences of Ukraine, Antibiotics, Kiev, Ukraine
[6]Abertay University, School of Science- Engineering and Technology, Dundee, United Kingdom

Backgrounds

Pseudomonas fluorescens SBW25 is a soil and plant-associated bacteria which form cellulose-based biofilms at the air-liquid interface of static microcosms. Robust biofilms are associated with mutations in diguanylate cyclases resulting in the induction of the cellulose synthase complex. However, it remains unclear whether biofilm formation, maturation and detachment involve quorum sensing (QS) regulation as is commonly observed for other pseudomonads.

Objectives

Objectives were assess a possible role of QS in *Pf.* SBW25.

Methods

Bioinformatics, cultivation assays, GC-MS and CLSM were used.

Conclusions

Our bioinformatics analysis of the *Pf.*SBW25 genome revealed a number of QS genes such as AHL synthase-like protein of HdtS family, LuxR-family proteins, and orthologues of the TpbA/TpbB system which control biofilm formation in *P. aeruginosa* PA01. In preliminary work we found that N-dodecanoyl-L-homoserine lactone (C12-HSL) influenced *Pf.*SBW25 biofilm structure, repressing cellulose production and increasing biofilm thickness. We were able to detect the presence of N-octanoyl-L-homoserine (C8-HSL) in *Pf.*SBW25 cultures grown in King's B medium by GC/MS, but could not detect it in PSM minimal medium cultures where less well-developed biofilms were also formed. The QS inhibitor azithromycin able to repress AHL production and biofilm formation in *Pa.*PA01 also repressed *Pf.*SBW25 biofilm formation without effecting growth, adding further evidence that AHL plays some sort of role in biofilm formation by SBW25. Our task for future work is to reveal the specific effects of C8-HSL in biofilm-forming and planktonic cultures, and to determine how QS and c-di-GMP regulation combine to regulate *Pf.*SBW25 biofilm formation in experimental microcosms and in natural environments.

DETECTION OF BIOCONTROL RELATED GENES AND THE EFFECT OF VOLATILE COMPOUNDS OF PSEUDOMONAS ISOLATES ON THE MOBILITY OF XANTHOMONAS AXONOPODIS PV PHASEOLI

A. moura[1], M. Sangiogo[1], I. Souza-Junior[1], J. Pelegrineli[1], R. Moccellin[1]
[1]Universidade Federal de Pelotas, Fitossanidade, Pelotas, Brazil

Backgrounds

Pseudomonas spp. are widely recognized as biocontrol agents of diseases of different plant species. One of the main mechanisms of biocontrol of these bacteria is antibiosis, given the diversity of antimicrobial compounds produced by this group.

Objectives

The aim of this study was to detect genes related to the production of antimicrobial compounds and the influence of volatile compounds produced by biocontrollers on the motility of *Xanthomonas axonopodis* pv. *phaseoli* (XAP).

Methods

PCR was performed with primers specific for the genes *phlD* (2,4-diacetylphloroglucinol), *phzCD* (phenazine-1-carboxylic acid), *prn* (pyrrolnitrin), *plt* (pyoluteorin), *pupA* (pseudobactins), *gacA* (cyanide production), *hcnBC* (hydrogen cyanide), for the isolates DFs513 (*Pseudomonas veronii*), DFs831 (*P. fluorescens*) and DFs842 (*P. fluorescens*), previously selected for the control of XAP. In addition, an experiment was performed to evaluate the effect of volatile compounds on XAP motility.

Conclusions

The *phlD*, *phzCD* and *prn* genes were detected in the isolates DFs831 and DFs842, whereas the *phlD* gene was detected in all three isolates. In the PCR for the *gacA*, *plt* and *pupA* genes, none of the reactions were positive for the isolates in study. The isolates DFs831 and DFs842 reduced significantly XAP motility (25% and 40%, respectively). Thus, isolates DFs831 and DFs842 have a greater diversity of genes related to the production of antimicrobial compounds, and are still able to reduce the motility of XAP through the volatile compounds produced.

FEMS7-2823
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

TEMPERATURE IMPACTS THE BACTERIAL MOTILITY OF BIOCONTROLLERS SELECTED TO CONTROL DISEASES OF COMMON BEANS

A. moura[1], J. Fasolin[1], I. Souza-Junior[1], M. Sangiogo[1], R. Moccellin[1]
[1]Universidade Federal de Pelotas, Fitossanidade, Pelotas, Brazil

Backgrounds

The success of plant diseases biocontrol is dependent of the performance of the antagonistic microorganisms and the environment conditions where they are inserted. Currently the impact of climate changes on the behavior of microorganisms has been in foccus, since the increase of the ambient temperature can influence the microorganisms survival.

Objectives

In order to evaluate an influence of different temperatures on the ability of preselected biocontrollers bacteria in common bean crop, the present study evaluated in vitro swarming motility.

Methods

The experiment was conducted in a completely randomized design with five replicates. The isolates DFs93 and DFs769 (*Bacillus cereus*), DFs348 (*Bacillus* sp.), DFs513 (*Pseudomonas veronii*); DFs831 and DFs842 (*P. fluorescens*), DFs843 and DFs912 (*Rhodococcus fasciens*) were incubated at different temperatures: 17, 22, 27, 32 and 37 °C. The bacteria were grown in LB agar (0.6%) grown in BOD under different temperatures for 24 hours. The evaluation was done measuring the bacterial colony diameters.

Conclusions

Higher temperatures provided higher colony diameters for most of the isolates, except for DFs513. The bacteria of *Bacillus* genus showed higher motility at temperatures of 32 and 37 °C. For *Pseudomonas* and *Rhodococcus* genus, the best temperature was 32 °C. The DFs513 isolate had higher motility at 17 °C, although without differing from 22, 27 and 32 °C. The results suggest that the increase in temperature may increase the spread and future colonization capacity of these bacteria.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

UNDERSTANDING THE IMPACT OF PRODUCTION ANIMALS ON THE DISSEMINATION OF MCR-1

G. Moyano[1], J.F. Delgado-Blas[1], A. Hoefer[1], N. Montero[1], B. Gonzalez-Zorn[1]
[1]Complutense University of Madrid, Animal Health, Madrid, Spain

Backgrounds

During the last decade, colistin has been catagorized as one of the last resort agents to treat multidrugresistant bacteria. Contrary to its application in humans, colistin has been a widely used antibiotic in animal production. The discovery of the first mobilizable colistin resistance gene (*mcr-1*) greatly concerns the scientific community, especially with regards to animal production. Here we present the preliminary results of the EFFORT project pertaining to the prevalence of *mcr-1* throughout animal production.

Objectives

The main objective of this work is to study the prevalence of *mcr-1* in pig, poultry and turkey farms.

Methods

A total of 60 farms within the inclusion criteria were selected in Spain: 20 pig farms, 20 poultry farms and 20 turkey farms. At each location 25 individual faecal samples were taken and 10 *E. coli* per farm were independently isolated from different samples. The presence of the *mcr-1* gene was determined by PCR and the XbaI-PFGE profiles of the *mcr-1* positive strains were compared.

Conclusions

The high prevalence of *mcr-1* was detected not only in single epidemic clones but also in unrelated clones. This suggests that the dissemination of *mcr-1* is simultaneously caused by horizontal and vertical gene transfer. The presence of an identical clone in pig and poultry farms demonstrates the capacity of different *mcr-1* bearing clones to adapt to new hosts. These results show that production animals act as a reservoir for *mcr-1* and underline the importance of fighting antimicrobial resistance with a one health approach.

THE PROTEOMIC RESPONSE OF PSEUDOMONAS PUTIDA KT2440 DURING POLYHYDROXYALKANOATES SYNTHESIS

J. Mozejko-Ciesielska[1], *A. Mostek*[2]
[1]*University of Warmia and Mazury in Olsztyn, Department of Microbiology, Olsztyn, Poland*
[2]*Institute of Animal Reproduction and Food Research, Department of Gametes and Embryo Biology, Olsztyn, Poland*

Backgrounds

Polyhydroxyalkanoates (PHAs) are bacterial polyesters that are accumulated as discrete granules and used as a storage material for carbon and reducing equivalents. Generally, PHAs are synthesised when a carbon source is present in excess and an essential nutrient such as nitrogen, phosphate or oxygen is available in limited concentrations. In spite of the potential of PHAs, their introduction to the world-wide market is currently limited due to their increased production cost compared to their synthetic alternatives. The PHAs synthesis process could be improved by a better understanding of how the metabolic networks that are responsible for mcl-PHAs synthesis respond to culture conditions and the type of substrate.

Objectives

The main aim of this study is to determine the influence of nutrients limitation on the global changes in the protein expression profile during PHAs synthesis by *Pseudomonas putida* KT2440.

Methods

Bioreactor experiments were conducted to determine the effect of different substrates and culture conditions on cell growth, PHAs content and proteome profile. PHAs were isolated and purified to determine their composition by gas chromatography. Two-dimensional polyacrylamide gel electrophoresis was applied to investigate the differences in the protein profile during biosynthesis process.

Conclusions

The obtained results enabled to identify proteins that are involved in the regulatory mechanisms of PHAs synthesis. The proteome analysis provided the information about the molecular basis of the physiological phenomena driving the PHAs accumulation inside bacterial cells that occur under various growth conditions. The study is a good starting point to gain insight into the PHAs accumulation machinery.

SPECIES-SORTING AND MASS-TRANSFER PARADIGMS CONTROL MANAGED NATURAL METACOMMUNITIES

S. Günther[1], K. Faust[2], S. Müller[1]
[1]Helmholtz Centre for Environmental Research, Environmental Microbiology, Leipzig, Germany
[2]KU Leuven-, VIB Center for the Biology of Disease, Leuven, Belgium

Backgrounds

In a circular economy wastewater treatment plants (WWTP) do not only purify water but produce biogas or/and recover phosphorus. These tasks are performed by microbial communities at different reactor localities in a WWTP.

Objectives

To avoid frequent reactor failures ecological theories were tested to better understand and, as a result, control wastewater metacommunities.

Methods

A complex microbial system consisting of six different interconnected localities was thoroughly investigated at full-scale for over a year. The metacommunity concept originating from macro-ecology was used to uncover mechanisms of community assembly by observing microbial interrelationships in and between the different localities via correlation and network analysis. The individual-based observation approach was applied using high-throughput microbial community cytometry in addition to next generation sequencing.

Conclusions

We found robust α-diversity values for each of the six localities and high β-diversity values despite directed connectivity between localities, classifying for endpoint assembly of organisms in each locality. Endpoint characteristics were based on subcommunities with high cell numbers whereas those with lower cell numbers were involved in dispersal. Perturbation caused abiotic parameters to alter local community assembly with especially the rare cells announcing community restructuration processes. The mass-effect paradigm as part of the metacommunity concept was identified by an increase in inter-locality biotic correlations under perturbation which, however, did not unbalance the predominant species-sorting paradigm in the studied full-scale metacommunity.
Data as generated in this study might contribute to the development of individual based models for controlling managed multi-species natural systems in future (Environment. Microbiol. 2017 online).

HIGH-RESOLUTION FLOW CYTOMETRY TO DETERMINE MICROBIOTA DYNAMIC COLITIS-ASSOCIATED CHANGES IN MOUSE FECES

J. Zimmermann[1,2], T. Hübschmann[3], H.D. Chang[2], S. Müller[3]
[1]University of Bern, Department of Clinical Research Gastroenterology, Bern, Switzerland
[2]German Rheumatism Research Center Berlin DRFZ, Cell Biology Group, Berlin, Germany
[3]Helmholtz Centre for Environmental Research, Environmental Microbiology, Leipzig, Germany

Backgrounds

The mammalian gut is colonized by a myriad of microbes referred to as the commensal microbiota. These bacteria are not only important for nutrient metabolism but also for the development and homeostasis of the immune system. Pathological changes in the composition of the microbiota, known as dysbiosis, are suggested to contribute to an array of diseases including inflammatory bowel disease, arthritis, encephalitis, and cancer.

Objectives

The profiling of the commensal microbiota by 16s rDNA or metagenome sequencing has become the current standard in the field, but it is time and labor intensive. Flow cytometry offers unique options to analyze the heterogeneity of the intestinal microbiota. We tested this cytometric approach for the profiling of the microbiota from healthy and colitic mice.

Methods

We introduce a method based on single cell light scattering and DNA content to analyze the heterogeneity and dynamic changes of the intestinal microbiota in the murine model of T-cell transfer-induced colitis.

Conclusions

We could demonstrate that overall microbial diversity decreases and that changes in the composition of the fecal microbiota in colitis coincide with weight loss and diarrhea. This analysis resolves up to 80 different populations per fecal microbiota. Subpopulations are phylogenetically homogeneous and their frequencies change dramatically when monitored in the course of murine T-cell transfer-induced colitis. High-resolution flow cytometry of the microbiota provides a fast and inexpensive tool for the analysis of the microbiota and offers the unique opportunity to isolate defined bacterial subpopulations for further molecular and functional analysis (European J Immunol 2016, 46: 1300-1303).

CYANIDE PRODUCTION BY PREY BACTERIA PROTECTS THEM AGAINST PREDATION BY BDELLOVIBRIO BACTERIOVORUS

W. Mun[1], H. Kwon[1], H. Im[1], S.Y. Choi[1], A.K. Monnappa[1], R.J. Mitchell[1]
[1]Ulsan National Institute of Science and Technology UNIST, Life science, Ulsan, Republic of Korea

Backgrounds

Bdellovibrio bacteriovorus is obligate predatory bacterium which is prey upon numerous gram-negative bacteria and ubiquitous in terrestrial and aquatic environments

Objectives

Co-existence of prey and predator is wide spread among bacterial feeding microorganisms include *B. bacteriovorus.* Predation by *B. bacteriovorus* gives impact on structure of bacterial communities and many bacteria have evolved defense mechanism against predation. In this study, we show that extracellular secondary metabolite produced by the soil bacterium *Chromobacterium piscinae* functions as a defense strategy against predatory bacteria

Methods

We found that *C. piscinae* is not predated by *B. bacteriovorus* when cultivated in Dilute Nutrient Broth (DNB). However, *C. piscinae* can be predated on within a nutrient-free buffer, HEPES. We examined that spent-DNB media of *C. piscinae* significantly delays predation of *E. coli* MG1655 by *B. bacteriovorus*. We identified that hydrogen cyanide (HCN) is major inhibitory metabolite of *C. piscinae* spent-media by removing cyanide with purging and scavenging with Vitamin B12a. The concentration of cyanide of DNB spent-media is about 110uM, we examined that it show same level of inhibitory effect with KCN 110uM solution.

Conclusions

The results suggest that bacterial secondary metabolites, hydrogen cyanide, responsible for the inhibition of *B. bacteriovorus* predation and thus likely contribute to protect prey against predation.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

MOLECULAR IDENTIFICATION OF CYANOBACTERIA IN A RESERVOIRS TRAIN LOCATED IN THE DEPARTMENT OF ANTIOQUIA, COLOMBIA

L.M. Múnera[1], N.J. Pino[1], G.A. Peñuela[1]
[1]University of Antioquia, GDCON Research Group- School of Microbiology, Medellin, Colombia

Backgrounds

Cyanobacteria are photosynthetic microorganisms that has been linked mainly to eutrophic waters. The excessive load of nutrients received by bodies of water has generated a considerable and worrisome increase of blooms around the world. These blooms are related with problems of public interest as toxicity, alteration of the food chain and its functionality, deoxygenation of the water column, reduction of biodiversity, among others.

Objectives

The objective of this study was to evaluate the relationship between the presence of cyanobacteria and the physicochemical variables: pH, temperature, TA, TP, DO, DOC, TOC, NTK, NO_3 and dissolved iron measured in three reservoirs located between 2.300 and 900 meters above sea level.

Methods

Sampling was carried out in the study reservoirs during the months of November of 2015, February, April and June of 2016. Within each reservoir, three sampling points were chosen: tributary entrance with higher flow, central area of the reservoir and exit close to catchment. The collected samples were evaluated for *in situ* and *ex situ* physicochemical parameters according to the procedures described by APHA, 2012.

Cyanobacterial samples were collected using a phytoplankton mesh. DNA extraction and amplification of the 16s rRNA gene using specific cyano-primers were performed. The PCR products were separated by DGGE, statistically analyzed using GelCompar® II program, bands were excised, purified and sent to sequencing. The edited sequences were analyzed on GenBank using BLAST.

Conclusions

This study concludes that the meteorological conditions and economic activities surrounding the reservoirs analyzed have a strong relation with the presence of cyanobacteria identified

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part II

MECHANISMS OF BACTERIAL CONVERSION AND DEGRADATION OF PHARMA POLLUTANTS FROM NONSTEROIDAL ANTI-INFLAMMATORY DRUGS

I. Ivshina[1], E. Tyumina[2], E. Vikhareva[3]
[1]Institute of Ecology and Genetics of Microorganisms UB RAS,
Laboratory of Alkanotrophic Microorganisms, Perm, Russia
[2]Perm State National Research University, Microbiology and Immunology, Perm, Russia
[3]Perm State Pharmaceutical Academy, Analytical Chemistry, Perm, Russia

Backgrounds

Bacterial degradation of pharma pollutants from non-steroidal anti-inflammatory drugs (NSAIDs, particularly diclofenac) is an effective method for their removal from contaminated environments by biocatalytic processes.

Objectives

1. To demonstrate the use of *Rhodococcus* to degrade diclofenac, the leading pollutant from NSAID group detected in the environment. 2. To study the interaction mechanisms of rhodococci and the pharma pollutant. 3. To investigate the major metabolic pathways for bacterial conversion of diclofenac, to identify metabolites, and to analyze several diclofenac-degrading enzymes.

Methods

The work was performed using the bioresources of IEGM Collection of Alkanotrophic Microorganisms (WDCM # 768, www.iegmcol). Chromatographic and mass-spectral methods were employed to detect diclofenac and its metabolites. A combined scanning system of an atomic force microscope and a confocal laser scanning microscope was used to study the specific features of actinobacterial interactions with the anthropogenic exotoxicant. Physiology of key bio-oxidizers was investigated by high-resolution respirometry.

Conclusions

For the first time the ability of *Rhodococcus* to efficiently biodegrade diclofenac in the presence of *n*-hexadecane was demonstrated. Using laboratory microcosms and model soil systems, novel basic data contributing to the in-depth insight into the processes occurring with pharma pollutants, the so-called “emerging contaminants”, in the environment were obtained.The developed heterogeneous biocatalysts based on *Rhodococcus* immobilized on solid carriers will be employed to design efficient biotechnologies for removal of pharma pollutants from waste water, and ecologically safe technologies for pharmaceutical waste detoxification and disposal.

The research was supported by the UB RAS Integrated Program and the Russian Foundation for Basic Research.

THE PHYLOGENETIC CORE OF THE HUMAN PAN-MICROBIOME

D. Aguirre de Cárcer[1]
[1]*Unidad de Genética, Ciencias, Madrid, Spain*

Backgrounds

Whether or not there is a 'core' gut microbiome, consisting of bacterial groups common to all healthy humans, remains an open question with important scientific and medical implications. Unfortunately, the strong variability in gut microbiome composition persistently observed across individuals has so far hindered efforts towards its detection.

Objectives

The present study analyzes the human gut core pan-microbiome in terms of 16S rRNA OTUs present in all individuals, where such OTUs have been produced dynamically over a range of phylogenetic depths, as opposed to using an arbitrary fixed threshold which represents the dominant practice in the field.

Methods

This approach was applied in the meta-analysis of three large and comprehensive datasets (totaling 2,243 individuals; > 150M sequences).

Conclusions

The results show that the human gut pan-microbiome contains a preeminent compositional phylogenetic core, defined in terms of discrete units of varying depth along the bacterial phylogeny, whose members are present in all individuals studied.

This result provides a new conceptual framework with great potential for advancing our understanding of the ecosystem. In addition to providing a novel perspective on (i.e.) the study of community assembly, the results obtained in this study should guide the selection of more meaningful combinations of bacterial species (or genomes) in many frequent *in vivo*, *in vitro*, or *in silico* experimental scenarios. Furthermore, the results should be used as a revised list of "most wanted" bacteria to guide future genome sequencing and isolation efforts, significantly as it also includes information on the biologically meaningful breadth of the targeted group's pan-genome.

ECOLOGICAL INTERPLAYS IN THE TRANSITION TO MULTICELLULARITY

B. Baselga Cervera[1], *M. Travisano*[2]
[1]*Universidad Complutense de Madrid, Animal Production, MAdrid, Spain*
[2]*University of Minnesota, College of Biological Sciences, st. Paul, USA*

Backgrounds

Throughout the history of life, the evolution from single-celled to pluricellular organisms emerged, somehow serendipity, more than 20 times under separate scenarios. This mayor evolutionary transition constituted a source of novelty that reshaped the Earth's biodiversity and ecology. Notwithstanding recent discoveries both experimentally and in the fossil record, the underling processes and mechanisms of multicellularity arise are poorly understood.

Objectives

The complex interplays between organisms and their environments, lead to multiple interactions, features and properties. Thus, ecological conditions might have played a significant role during the transition to multicellularity and it persistence. Here, we examined the implications of different environmental conditions, related with resources availability, in the origin of multicellularity from an ecological perspective.

Methods

By means of experimental evolution and capitalizing the advantages of using the model organisms *Saccharomyces cerevisiae*, we have performed two different 2x2 factors experiments based on the original experiment of Ratcliff et al. (2012). Each experiment presented two types of environmental conditions: YPD rich media and Minimal media, and two types of treatment; no selection and settling selection, starting from differentness ancestral populations: a unicellular *S. cerevisiae* strain (Y55) and an evolved multicellular strain, snowflake yeast strain.

Conclusions

The evolution from unicellular to multicellular phenotypes took place in minimal media under setting selection, however we found different phenotypic distributions among replicates. The recently evolved snowflake yeast phenotype strain did not return to its ancestral unicellular phenotype in any of the environmental conditions. Ecological differences can lead to different results in the evolution of multicellularity.

COMPARISON OF METHODOLOGIES USED IN THE ANALYSIS OF ESCHERICHIA COLI IN TREATED SEWAGE SLUDGES

A. Lopez[1], M. Benito[1], J. Gomez[2], R. Mosteo[1], A.M. Lasheras[2], P. Goñi[3]
[1]Water Quality &Treatment Research Group-Institute of Environmental Science, Chemical Engineering and Environmental Technologies, Zaragoza, Spain
[2]NILSA, NILSA, Pamplona, Spain
[3]Parasitology- Self-care&Environmental Health Research Group, Preventive Medicine and Public Health, Zaragoza, Spain

Backgrounds

In wastewater treatment plants the microorganisms tend to concentrate in the sludge line and the control of pathogens has become an important issue on sludge management. There are current regulations for the disposal of biosolids for agricultural applications in USA and Europe being *Escherichia coli* considered a microbial indicator of sludge quality.

Objectives

The objective of this study is to compare different techniques based on standard analytical methodologies and using various culture media in the analysis of *E.coli* in two treated sludge samples (SM9221E, ISO72351:2005, SM9222D, SM9215B/C/D, UNE-EN-ISO16649-1/2/3). Specifically, membrane filtration (0.45µm), spread plate, pour plate and multiple tubes techniques were used.

Methods

Sludge samples used in the study came from a real wastewater treatment plant situated in Navarra(Spain). Raw sludge was treated in anaerobic digesters at 35°C/15days (mesophilic digestion) or at 55°C/10days (thermophilic digestion). Samples treated thermophilically presented lower microbial concentration than samples treated mesophilically. Assays were done in triplicate.

Conclusions

The results were different in function of the bacteria concentration in the sludge. When the *E.coli* concentration in treated sludge sample was≥10^3UFC/g there were not remarkable differences in terms of sensibility in the compared techniques and spread plate technique presented the results with the highest accuracy. On the other hand, when the *E.coli* concentration in treated sludge sample was≤10^3UFC/g, membrane filtration technique presented highest sensibility to quantify the bacteria in the majority of the culture media considered; the other techniques used show high uncertainty and low accuracy. The obtained results indicate that current regulations should be updated and similar criteria established.

PRESENCE OF POTENTIALLY PATHOGENIC PROTOZOA IN URBAN WASTEWATER TREATMENT PLANTS: RISKS OF REUSE

M. Benito[1,2], D. LaPlante[1], E. Rubio[1], A. López[2], N. Miguel[2], J. Gomez[3], A.M. Lasheras[3], M.P. Ormad[2], M.P. Goñi[1]
[1]University of Zaragoza, Parasitology- Self-Care and Environmental Health PSEH- DGA-FSE B124. Microbiology- Preventive Medicine and Public Health., Zaragoza, Spain
[2]University of Zaragoza, Water Quality and Treatment DGA-FSE T33: Environmental Sciences Institute of the University of Zaragoza . Chemical Engineering and Environmental Technologies, Zaragoza, Spain
[3]Navarra de Infraestructuras Locales S.A., I+D, Pamplona, Spain

Backgrounds

Reutilization of effluents and sludge from wastewater treatment plants(WWTP) provides a new application for this voluminous residue. However, the presence of potentially pathogenic protozoa may present a risk to public health. Current normative regulates the presence of *E. coli*, nematode eggs, *Legionella* spp., and *Salmonella* spp. Nevertheless, there are no references for protozoa, even though the use of traditional indicators does not predict their presence.

Objectives

The aim of this work is to study the presence of potentially pathogenic parasites and protozoa in water and sludge from WWTP with different treatments and evaluate the risk associated with their reutilization.

Methods

Five different WWTP located in the Ebro River basin(Spain) were studied. The presence of *Cryptosporidium* spp., *Giardia duodenalis*, and *Entamoeba* spp. was analysed using conventional methods and molecular biology techniques for genus and genotype identification. Free living amoebas(FLA) were cultivated and genetically identified. The presence of Amoeba Resistant Bacteria(ARB) inside FLA was also analysed.

Conclusions

Entamoeba was detected in all effluents, followed by *Cryptosporidium*(40%) and *Giardia*(20%). In sludge, *Cryptosporidium* was positive by PCR in all WWTP, *Entamoeba* spp. in 75%. *Giardia* was not detected. Forty-one FLA were isolated, 32 from water and 9 from sludge. Six FLA were indentified as *Naegleria* spp., 2 as *Vermamoeba* spp. and 13 as *Acanthamoeba* spp. ARB were detected in 27 of the FLA isolated, including *Legionella* spp. and *Mycobacterium* spp.

Persistance of potentially pathogenic protozoa has been observed in effluents and sludge, suggesting that more intensive treatments, than those currently employed, are needed in case of agricultural reuse.

CONSISTENT DYNAMICS AND COMMUNITY ASSEMBLY PATTERNS DIRECTLY ARISING FROM THERMODYNAMIC THEORY OF MICROBIAL GROWTH

H. Delattre[1]
[1]*IRSTEA, HBAN, antony, France*

Backgrounds

Microbial communities are key engines that drive earth biogeochemical cycles. Developing models able to capture and predict their dynamics and community assembly patterns is therefore of outmost importance for the study of global earth ecological equilibria and the development of innovative microbial biotechnology processes. However, ecosystem models today exhibit only limited abilities in predicting microbial dynamics and require the calibration of multiple population specific empirical equations.

Objectives

In order to build more generic models, there is a need to more thoroughly capture the fundamental drivers of microbial growth and to mathematically express how they contribute to the emergence of the many community assembly patterns observed in nature.

Methods

We simulate the dynamics of microbial functional communities using a kinetic model of microbial growth based on statistical physics (Desmond-Le Quéméner & Bouchez, 2014). We show how the theory coupled to simple mass and energy balance calculations offer a parsimonious explanation for many well-known microbial community assembly patterns along redox gradients.

Conclusions

Strikingly, considering only these simple physical assumptions, we show that consistent microbial dynamics, successions and functional community assembly patterns can be obtained, without population-specific parameter calibration, for systems ranging from pure cultures to communities of multiple populations.

EVALUATION OF METAGENOMIC METHODS FOR THE STUDY OF THE GUT MYCOBIOME

A. Frau[1], B. Campbell[1], A. Darby[2], J. Kenny[3], N. Hall[4], J. Anson[5], C. Probert[1]
[1]University of Liverpool, Institute of Translational Medicine- Cellular and Molecular Physiology, Liverpool, United Kingdom
[2]University of Liverpool, Institute of Integrative Biology- Functional and Comparative Genomics, Liverpool, United Kingdom
[3]University of Liverpool, Institute of Integrative Biology- Centre for Genomic Research, Liverpool, United Kingdom
[4]Earlham Institute, -, Norwich, United Kingdom
[5]Royal Liverpool University Hospital NHS, Infection and Immunity, Liverpool, United Kingdom

Backgrounds

Metagenomics has revolutionized the study of the gut microbiome but most methods are tailored for bacteria.

Objectives

The mycobiome likely plays a key role in intestinal diseases and hence metagenomic methods need to be adapted to study this. Here, we evaluated two DNA extraction methods and 5 primer sets.

Methods

Genomic DNA was extracted from seven characterised fungal cultures (*C. albicans*, *C. tropicalis*, *C. neoformans*, *M. furfur*, *S. cerevisiae*, *A. fumigatus* and *P. crysogenum*) using either the PSP Spin Stool DNA kit (Stratec), with and without extra bead-beating (6 min, 0.1 and 0.5 mm zirconia beads), or the QIAamp Fast DNA Stool Mini Kit (QIAGEN), and compared using 18S rRNA qPCR. Subsequently, stool was spiked with cells and spores from the same species and gDNA extracted (as above). DNA from spiked stool samples and a mock community were amplified and sequenced. Five primer sets were tested (18S rRNA, ITS1, ITS2-2X and 28S rRNA) for HiSeq Illumina sequencing.

Conclusions

Results: 1) the extra bead-beating did not increase the extraction; 2) the Stratec Kit extracted more gDNA from *C. albicans* VS *A. fumigatus* (Cp=29.1 SD=0.52 and Cp=31.9 SD=0.51), the reverse occurred with QIAGEN kit (Cp=34.3 SD=0.74 and Cp=26.6 SD=0.06); 3) on stool DNA similar amounts of 18S rRNA copies/ng of DNA were observed with both kits. Sequencing data are being currently evaluated: this will show how extraction methods and primer sets influence analysis of the mycobiome. In conclusion, the method of DNA extraction and primer design influence results and interpretations of the mycobiome.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

CONTRIBUTION OF THE PSEUDOMONAS FLUORESCENS MFE01 TYPE VI SECRETION SYSTEM TO BIOFILM FORMATION

M. Gallique[1], *V. Decoin*[1], *C. Barbey*[1], *A. Merieau*[1]
[1]*Laboratoire de Microbiologie Signaux et Microenvironnement EA 4312, Université de Rouen- Normandy University, EVREUX, France*

Backgrounds

To persist in an ecological niche, bacteria have developed several strategies to enable them to resist in the environment. One of these mechanisms, able to struggle with other bacterial species, is the Type VI Secretion System (T6SS). This allows bacteria to inject toxins directly into prey cell cytoplasm. A mucoid environmental isolate of *Pseudomonas fluorescens,* the MFE01 strain, has antibacterial activity carried by T6SS [1]. Indeed, MFE01 can immobilise prey cells through the action of the Hcp1 protein of the T6SS [2]. Currently, genomic analysis reveals only one T6SS core component cluster and three orphan *hcp* genes (named *hcp1*, *hcp2* and *hcp3)*.

Objectives

Aims of this study are to assign a role to each Hcp proteins (Hcp1, Hcp2 and Hcp3) in biofilm maturation and competition against prey strains during co-inoculation in biofilm condition.

Methods

Biofilms were grown on a glass surface, for 48 h at 28°C, under a flow of LB medium and observed by confocal laser scanning microscopy. Prey cells bearing pSMC2.1 *gfp*, encoding green fluorescent protein, were co-cultured alone or with MFE01 or derivatives, in a 1:5 ratio.

Conclusions

Mutations of *hcp1*, *hcp2* and *hcp3* did not reduce *P. fluorescens* MFE01 biofilm formation [3], but the three Hcp proteins were required for the completion of biofilm maturation. Moreover, a mutant with a disruption of one of the unique core component genes, MFE01Δ*tssC*, was unable to produce its own biofilm or to inhibit prey cells biofilm formation.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

HOW DO MARINE BACTERIA INTERACT WITH THE AMOEBA ACANTHAMOEBA CASTELLANII ?

R. Guillonneau[1], *C. Baraquet*[1], *M. Molmeret*[1]
[1]*Université de Toulon, MAPIEM EA 4323, La Garde, France*

Backgrounds

Amoebae are common in soils, freshwater and marine ecosystems. They are suspected to have an important role in most microbial ecosystems, especially in biofilm. However the interaction between these protozoa and marine bacteria is poorly investigated

Objectives

The aim of this work is first to study interactions between different marine bacteria and the axenical amoeba *Acanthamoeba castellanii* in order to identify different behavioural patterns. The second objective is to understand if, in this context, the bacterial biofilms could provide any sort of advantage against this predator.

Methods

Bacteria-specific antibodies were used during the co-culture experiments for confocal laser scanning microscopy observations while amoebas were labelled with DAPI. Transmission electronic microscopy was also used to visualize intracellular localisation of bacteria.

Conclusions

These marine bacteria presented different profiles of interaction with *Acanthamoeba castellanii.* They appeared to be localized in different intracellular compartments or to behave in a singular manner. For instance, *Persicivirga mediterranea* (TC4) was located in the amoeba nucleus, which could at least in part protects the bacteria from phagolysosomal digestion. *Shewanella sp.* (TC11) appears to be within suspected expelled fecal balls after its interaction with the amoeba. The objective was to identify the different bacterial behaviour within the host cell, and to understand if these behaviours could trigger specific outcomes when the protozoa is added to monospecific and multispecies biofilms. This is one of the first study comparing different isolated marine bacterial species in presence of the amoeba *A. castellanii*.

EFFECT OF CUSO4 AND ZN2SO4 ON TRANSFER OF ANTIBIOTIC RESISTANCE GENES PROFILES FROM ENVIRONMENTAL BACTERIA TO ESCHERICHIA COLI

C.J. Guzman Otazo[1], V. Iniguez[2], J. Larsson[3], Å. Sjöling[1]
[1]Karolinska Institutet, Microbiology- Tumor and Cell Biology MTC, Stockholm, Sweden
[2]Universidad Mayor de San Andres UMSA, Institute of Molecular Biology and Biotechnology, La Paz, Bolivia
[3]University of Gothenburg, Department of Infectious Diseases- Institute of Biomedicine, Gothenburg, Sweden

Backgrounds

The increase of antibiotic resistance genes (ARG) in pathogenic bacteria is considered one of the biggest threats for human health worldwide. Environmental compartments might be important reservoirs of antibiotic resistance genes (ARGs) and where transfer and spread of environmental ARGs to human-associated bacteria needs to be studied. The presence of metals in the environment has been associated with selection of antibiotic resistance in bacteria by means of cross and co-resistance mechanisms.

Objectives

In this study, we evaluated the impact of addition of two different metal salts: $CuSO_4$ and Zn_2SO_4 on lab mating experiments using environmental bacteria as donors and the lab *Escherichia coli* strain CV601 as recipient.

Methods

Donors were obtained from two different sampling points in the highly polluted Choqueyapu River in La Paz, Bolivia and prepared for mating conditions without any prior culture, thereby including also the non-cultivable bacterial fraction. Two different concentrations of metal salts (0,5M and 1M) were evaluated for its effects on Transfer Frequency (TF) using Sulfamethoxazol 150 ug/ml supplemented plates as transconjugants selection media.

Conclusions

Our results showed that the there is no significantly increase in Transfer Frequency (TF) after 3 hours of mating in media with metals salts versus control LB media. Different antibiotic resistance patterns will be analyzed by Kirby-Bauer Disk Susceptibility Test in the > 300 transconjugants recovered from the mating experiments in order to identify the potential association between co-selection of metals and the type of antibiotic resistance pattern transferred.

THE MICROBIAL ECOSYSTEM OF THE GREENLAND ICE SHEET SURFACE

C.S. Jacobsen[1], K. Cameron[2], S. Marek[3]
[1]Aarhus University, Environmental Sciences, Roskilde, Denmark
[2]Geological Survey of Denmark and Greenland, Department of Geochemistry, Copenhagen, Denmark
[3]Charles University, Department of Ecology, Pragh, Czech Republic

Backgrounds

The surface of the Greenland ice sheet (GrIS) harbors a simple yet unique microbial ecosystem. The biological active margin of the ice sheet is more than 200 000 km^2, can be up to ~100km wide, and has tended to increase in area each year within recent history. This ecosystem contains microbial communities that are important for biogeochemical processes and surface melt and that are likely important for the injection of biota and nutrients into downstream environments.

Objectives

Our research suggests that the GrIS surface receives a “baseline” cell supply via deposition of atmospheric waters, and that wind-borne dust deposited on the ice sheet likely contains additional cells and may provide limiting nutrients for microbial growth. Ablation areas with high dust concentrations and longer melt seasons are therefore expected to contain higher numbers of active microbes compared to the accumulation area.

Methods

Geochemical anlysis, qPCR and amplicon seqiencing.

Conclusions

Within the ablation area, significant differences exist between the bulk and potentially active bacterial communities collected at the margin and the interior of the GrIS, with a higher total abundance but lower proportion of active bacteria at the margin. Higher microbial activity in the interior compared to the margin is also supported by productivity measurements. Nitrate had no significant effect on the abundance and community structure, which suggests that this system is not nitrate limited. In terms of diversity, we do not find a core, uniform bacterial community across the biologically active area of the GrIS; instead, km-scale variations between the microbial communities exist.

AUTOREGULATED BIOTOPE SUPPORTED BY SYMBIOTIC SYSTEMS RECOGNIZING POLYVALENT POLYMERIC GLYCOCONJUGATES

M. Lakhtin[1], V. Lakhtin[1], S. Afanasiev[1], A. Bajrakova[1], V. Aleshkin[1]
[1]Medical Biotechnology, G.N.Gabrichevsky Institute of Epidemiology and Microbiology, Moscow, Russia

Background
Microbial communities participate in biotope healthy status.
Objectives
The objective was to develop one more strategy of supporting healthy human biotope.
Methods
Probiotic systems recognizing glycoconjugate patterns **(**PSRGP) of human probiotic bacteria; intestinal and urogenital microbial clinical strains were used. Microbes were grown in standard media and conditions in the absence or presence of PSRGP.
Conclusions
1. *Features of* PSRGP. PSRGP are localized, organized and act as cell layer mosaic surface and secreted truncated/ modified and assembled systems imitating pro/syn/symbiotics. Molecular-cellular PSRGP are represented by synergistically cofunctioning probiotic microorganisms (autoregulated probiotic pool of strains producing bifidobacterial and lactobacillar lectins, their complexes, protective glycosyl hydrolases and oxydoreductases). PSRGP function as major and minor soluble and surface signals directed against virulent factors. PSRGP reveal features of metabolomebiotics, net switchers, quorum sensing molecules, cross-talking cells. PSRGP reveal synergistic cascade antipathogen (antifungal, antistaphylococcal) effects towards ranging targets. **2.** *Biotope communications. L.acidophilus* and *L.casei* selected strains limit fungal growth of *C.albicans, C.tropicalis, C.krusei* or *C.albicans+A.niger* as well as influence subspecies microecological niches distribution within group of increased infection risk (*C.albicans* and *C.tropicalis*). *L.acidophilus* and *L.casei* PSRGP include leader strains which interrupt communications between *Candida* species pools or within *C.albicans* continuous massive. PSRGP participate in on duty elimination of changeable potentially dysbiotic lactobacillar strains. On the other hand, biotope *Candida* pools contain leader strains which interrupt communications between probiotic (*Lactobacillus*) species. **3.** *Strategy of supporting biotope*: screening probiotic and potentially pathogenic leader strains; delivery of synbiotic PSRGP; elimination of antibiotics-sensitive potentially pathogenic leader strains. **4.** Conception of biotope multilevel-healthy net-knot multitaxonomic microbiocenose is proposed.

DISINFECTION BYPRODUCT-INDUCED TRANSFORMATION OF COLLOIDAL ANTIBIOTIC RESISTANCE GENES (ARGS) IN NATURALLY COMPETENT BACTERIA

D. Mantilla[1]
[1]*King Abdullah University of Science & Technology KAUST, BESE, Thuwal Jeddah, Saudi Arabia*

Backgrounds

Disinfection of the treated wastewater leads to the formation of disinfection byproducts (DBPs), which are genotoxic agents formed due to the reaction of chlorine with naturally occurring organic matter. The genotoxicity of these compounds rely on their ability to cause double-strand breaks in DNA of viable cells. In prokaryotes, double-strand breaks are repaired by diverse mechanisms including homologous recombination mediated by RecA. This protein is also involved in other cellular processes such as the integration of DNA into the bacterial genome, which constitutes a critical step in the mechanism of natural transformation. In addition, reclaimed wastewater has shown to carry high abundances of antibiotic resistance genes (ARGs), which could be partially found as extracellular DNA in the colloidal fraction of such treated effluents. Due to the presence of extracellular ARGs and the central role of RecA in DNA repair and transformation, we hypothesize that DBP-mediated DNA damage may enhance foreign DNA integration in naturally competent bacteria.

Objectives

The objective of this project is to evaluate whether exposure to DBPs might increase the fixation of ARGs using *Acinetobacter baylyi* as a model, a naturally competent and environmentally ubiquitous microorganism.

Methods

To evaluate transformation rates, a reporter strain of *A. baylyi* that expresses a green fluorescent protein and spectinomycin resistance as a result of a transformation event was used. Transformation rates were initially evaluated in cell cultures exposed 0, 75, 150 and 200 uM of bromoacetic acid (BAA), a known mutagen and regulated DBP.

Conclusions

Transformation rates of the donor DNA increased at the higher BAA concentrations following a dose response curve. Besides spectinomycin resistance, transformants were further confirmed by PCR to ensure the presence of the donor DNA.

MICROBIAL METAGENOMIC AND METATAXONOMIC STUDY OF BILIARY SAMPLES IN PATIENTS WITH CHOLEOLITHIASIS AND A CONTROL GROUP

N. Molinero[1], I. Gutierrez-Diaz[2], C. Milani[3], M. Mangifesta[3], C.M. García-Bernardo[4], A. Cabrera[5], J.I. Rodríguez[5], S. Gonzalez[6], M. Ventura[3], A. Margolles[1], S. Delgado[1]
[1]IPLA-CSIC, Microbiology and Biochemistry of Dairy Products, Villaviciosa, Spain
[2]University of Oviedo, Functional Biotogy, Oviedo, Spain
[3]University of Parma, Life Sciences, Parma, Italy
[4]HUCA, Cirugía General, Oviedo, Spain
[5]Hospital de Cabueñes, Servicio de Cirugía General y del Aparato Digestivo, Gijón, Spain
[6]University of Oviedo, Functional Biology, Oviedo, Spain

Backgrounds

In recent years, the relationship between cholesterol, bile salt metabolism, intestinal microbiota and its potential implication in health is been elucidated. However, the composition and role of the biliary microbiota remains obscure. The characterization of the human bile microbiota as a whole has been hampered by difficulties in accessing biological samples and the lack of adequate methodologies to assess molecular studies.

Objectives

The aim of this work was to generate new knowledge of human bile microbial profiles, functions and activities in patients with choleolithiasis vs healthy individuals, and identify possible dysbiosis associated with this pathology.

Methods

To characterize the biliary microbiome of patients with cholelithiasis and healthy subjects we collected bile samples from 15 gallstone patients and a comparable control group. We performed with Illumina technology high throughput sequencing of 16S rDNA amplicons, together with whole metagenome shotgun of selected bile samples.

Conclusions

A high diversity was present in the biliary microecosystem, with main fila represented: *Firmicutes*, *Bacteriodetes*, *Actinobacteria* y *Proteobacteria*. Significant differences in the relative abundance of different taxa present in the bile of both groups were found. Sequences belonging to the family *Propionibacteriaceae* were more abundant in bile samples from healthy subjects, meanwhile in patients with choleolithiasis members of the families *Bacteroidaceae, Prevotellaceae* y *Veillonellaceae* were more frequently detected.

Sequencing of total DNA from bile of three healthy subjects and functional analysis allowed us to observe that the main COG functions and categories were similar to that describe in the human intestinal microbiome.

FEMS7-1428
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

ISOLATION AND CHARACTERIZATION OF AN ALKANES-DEGRADING PSEUDOMONAS AERUGINOSA FROM GULF OF MEXICO

L.F. Muriel-Millan[1], J. Rodríguez-Mejía[1], D. Xahonero-Canavesi[1], W. Escobedo-Hinojosa[1], A. Estradas-Romero[1], H. Sánchez-Texis[1], L. Pardo-López[1]
[1]Institute of Biotechnology-UNAM, Gulf of México Research Consortium CIGoM, Cuernavaca, Mexico

Backgrounds

Oil spills have severely affected different marine ecosystems due to its high persistence in the environment. Alkanes represent an important fraction of total hydrocarbons that conform the crude oil and its biodegradation is a challenge for different microorganisms due to their low solubility and reactivity. Nevertheless, some bacteria have the metabolism to synthesize surfactants that permit the alkane solubilization and their posterior degradation.

Objectives

The aim of this study was to characterize the hydrocarbon-degrading capacity of a strain isolated from Gulf of México.

Methods

Initially, a bacterial consortium from water column (55 meters of depth) was isolated from Gulf of México in mineral medium with a mix of oil crude and kerosene as carbon and energy source. From this consortium, a strain named B9MF-1 was isolated and phylogenetic analysis of 16S rRNA sequence showed that this strain is closely related to *Pseudomonas aeruginosa* species. B9MF-1 strain was able to grow in mineral medium using hexadecane (C16) or eicosane (C20) as sole carbon source. Microbial Adherence To Hydrocarbon (MATH) assays showed that, cells previously adapted in medium with hexadecane, had a cell surface hydrophobicity of 70%, while in presence of glucose, the strain exhibited a hydrophobicity of 37%. Analysis of the cell culture supernatants by thin-layer chromatography, revealed the presence of aminolipids and glycolipids in cultures added with hexadecane but not in those added with glucose.

Conclusions

These results indicate that cell surface properties and synthesis of glycolipids and aminolipids are associated to the capacity of *P. aeruginosa* B9MF-1 strain to degrade aliphatic hydrocarbons.

EXAMINING THE INFLUENCE OF MODE OF DELIVERY ON THE GUT MICROBIOTA COMPOSITION IN ADULTHOOD

A.B. Murphy[1,2,3], P.J. Kennedy[2,4], J.F. Cryan[2,5], R.P. Ross[1,2], P.W. O'Toole[2,3], T.G. Dinan[2,4], C. Stanton[1,2]
[1]Teagasc Food Research Centre, Food Biosciences Department, Cork, Ireland
[2]University College Cork, APC Microbiome Institute, Cork, Ireland
[3]University College Cork, Microbiology Department, Cork, Ireland
[4]University College Cork, Department of Psychiatry, Cork, Ireland
[5]University College Cork, Department of Anatomy & Neuroscience, Cork, Ireland

Backgrounds

Colonisation of the infant gut early in life has an important role in directing development of the immune system, nervous system and brain. It is well established that birth by Caesarean (C)-section disrupts the normal colonisation of the infant gut due to the lack of contact between the new-born and maternal vaginal and intestinal microbes. Indeed, there is accumulating evidence that C-section delivery can have many long lasting health effects including the development of immune and metabolic disorders.

Objectives

The objective of this study was to examine the long term impact of mode of delivery on the gut microbiota composition of young adults.

Methods

The effects of C-section birth were investigated by examining the gut microbiota of a cohort of male adults aged between 18 and 24, either born vaginally (N=36) or by C-section (N=31). Participants did not differ in age, body mass index (BMI) or units of alcohol consumed per week. Data were also collected on general gut health, diet and physical activity. The gut microbiota of both groups was profiled using 16S rRNA gene amplicon sequencing.

Conclusions

The microbiota of C-section and vaginally-born subjects showed similar pair-wise relative abundances at phylum level with Firmicutes and Bacteroidetes dominating. This was reflected at family and genus levels with few significant differences present between participants. Additionally, diversity levels were not influenced by mode of delivery. These findings indicate that the gut microbiota disturbances due to C-section which occur during infancy do not persist to adulthood.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

COMPLEX MICROBIAL PREPARATION FOR REMEDIATION OF SOIL MICROBIAL CENOSES AND PROMOTION OF CROP PRODUCTIVITY

T. Nasonava[1], M. Mandryk-Litvinkovich[1], L. Kartyzhova[2], Z. Aleschenkova[2], E. Kolomiets[1]
[1]Institute of Microbiology - Belarus National Academy of Sciences,
Laboratory of Biological Control Agents, Minsk, Belarus
[2]Institute of Microbiology - Belarus National Academy of Sciences,
Laboratory of interactions between soil microorganisms and higher plants, Minsk, Belarus

Backgrounds

Analysis of contemporary state of agricultural production, evaluation of dynamics of land qualitative parameters highlight the tendency of falling soil fertility and aggravation of general ecological situation in agroindustrial sector. Intensive mechanical and chemical treatment of arable fields, inadequate supply of organic nutrients coupled to erosion processes lead to irreversible loss of soil bioorganic potential. As a result the structure of microbial associations undergoes changes affecting steady-state of soil ecosystem, its ability to sustain fertility and productivity. One of the ways to decrease pressure on biocenoses is formulation and use in agrotechnologies of effective biopreparations derived from living microbial cultures.

Objectives

The study was aimed at composing microbial preparation for restitution of soil microbial cenosis and increase of crop harvests.

Methods

Microbiological, biochemical, molecular-genetical methods were engaged in this research.

Conclusions

Based on 5 bacterial strains representing genera *Bacillus*, *Pseudomonas*, *Brevibacillus*, a complex microbial preparation displaying a number of valuable properties was developed:

- it suppresses development of pathogenic microbiota and ensures recovery of agrobiocenoses;
- accelerates degradation of plant residues in soil;
- mobilizes insoluble phosphorus compounds;
- enriches soil with biological nitrogen;
- upgrades soil fertility;
- raises productivity of cultivars by 10-20%.

Application of microbial preparation allows to replace supply of chemical and mineral fertilizers, to increase crop harvests and to yield eco-friendly products at minimal costs.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

ISOLATION AND IDENTIFICATION OF GAMM RRADIATION RESISTANT BACTERIA FROM LOUT DESERT OF IRAN

A. nasrollahi omran[1], M. Mohseni[2], J. Abbaszadeh[1]
[1]Faculty of biology Sciences- Islamic Azad University of Tonekabon Branch- Tonekabon- Iran, Department of Microbiolgy, Tonekabon, Iran
[2]Department of Molecular and Cell Biology- University of Mazandaran- Babolsar- Iran, Department of Molecular and Cell Biology- University of Mazandaran- Babolsar- Iran, babolsar, Iran

Backgrounds

Members of genus Deinococcus are able to live in extreme conditions such as arid deserts, under ionizing radiations, ROS (reactive oxygen species) molecules and other oxidative stress inducing chemicals.

Objectives

Aim of this study is to investigate microorganisms that live in surface soil of desert where is exposed to high temperatures at days and low temperature at nights, also desiccation and rehydration. The Lout desert of Iran isknown for its high surface temperature that is named as the hottest surface place on earth. Both ionizing radiation and desiccationmay cause damage on genome

Methods

Two native ionizing radiation-resistant bacteria were isolated and identified from a soil sample collected from extreme conditions of the Lout desert in IranSoil sample was irradiated in order to eliminate sensitive bacteria then cultured in onetenth-strength tryptic soy broth medium. Bacterial suspension used for radiation treatment. Morphological and physiological characterization and phylogenetic studies based on 16S rRNA gene sequence were used for identification.

Conclusions

The cells were rod shape, non-motile, non-spore forming and gram positive. The 16S rRNA gene sequence showed 99.5 % of similarity to Deinococcus ficus. Phylogenetic dendrogram demonstrated that the isolates branched with D. xibeiensis, D. ficus and D. mumbaiensis. Phylogenetic analysis showed the relationship between LD4 and LD5 isolates and other Deinococcus species.Both isolates were resistant to>15 kGy of gamma radiation and >600 J m^{-2} of UV radiation. This is the first report on radiation resistant bacteria belonging to genus Deinococcus isolated from the Lout desert of Iran.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

EVATUATION OF DRUG SUSCEPTIBILITY OF ANTIFUNGAL DRUGS AGAINST ASPERGILLUS SPECIES ISOLATED FROM ICU OF HOSPITALS AT INVITRO

A. nasrollahi omran[1]
[1]*Faculty of biology sciences- Tonekabon Branch -Islamic Azad University- Tonekabon -Iran-, Department of Microbiology, tonekabon, Iran*

Backgrounds

Invasive aspergillosis is a disease that could threaten the patients having immune system defects which causing nosocomial fungal infections and high mortality in them.There are some resons including delayed diagnosis, lack of appropriate curing, and exsisting the various diseases and neutropenia which lead to the high mortality rate of patients with aspergillosis, especially in paiteients of intensive care units (ICUs).

Objectives

The aim of this study was to assess the sensitivity of the antifungal drug on Aspergillus sp. isolated from the hospital

Methods

After collecting 160 plates containing SDA medium from the air of hospital's ICU and incubating, the suspected fungal colonies grown on macroscopic and microscopic morphology were approximately detected. DNA extraction and molecule identification were performed using sequencing method with specific primers. Ultimately the species identification was fulfilled using microdilution method and drug susceptibility tested for existing drugs using CLSIM38A2 guidance for isolates in 96 microplates

Conclusions

According to a study of 40 plates suspected to *Aspergillus*, containing 11 definitive colonies after sequencing, 5 cases were *A. flavus*, 3 cases *A. sydowii*, 1 case *A. fumigatus* and 2 cases were confirmed as *A. Oryzae*. Regarding to susceptibility test, *A. sydowii* and *A. fumigatus* were sensitive to Amphotericin and Voriconazole and were sensitive to Itraconazole. *A. sydowii* was resistant to Caspofungin while *A.* fumigatus was sensitive to the drug. Also *A. flavus* was sensitive to all study drugs.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

FABRICATING RECHARGABLE N-HALAMINE NANOPARTICLES FOR ANTIFOULING APPLICATIONS

M. natan[1]
[1]*bar ilan university, life sciences, ramat gan, Israel*

Backgrounds

Biofilm formation is a serious problem in medical and industrial settings due to the increased resistance of these communities to killing compared to free-living bacteria. This has prompted the search for agents that can inhibit both bacterial growth and biofilm formation. In this study, N-halamine rechargeable nanoparticles (NPs) were synthesized by co-polymerization of the monomer methacrylamide and the cross-linker monomer N,N-methylenebisacrylamide, and were subsequently loaded with Cl^+, using bleach. The chlorinated NPs demonstrated remarkable stability and durability to organic reagents and to repetitive bacterial loading cycles. The antibacterial mechanism of the P(MAA-MBAA)-Cl NPs involved generation of reactive oxygen species (ROS) only upon exposure to organic media, but not upon suspension in water, revealing that the mode of action is target-specific. Further, a unique and specific interaction of the chlorinated NPs with *Staphylococcus aureus* bacteria but not with human cells was discovered, whereby these microorganisms were all specifically targeted and marked for destruction. Finally, in collaboration with Netafim Ltd. irrigation drippers containing the P(MAA-MBAA)-Cl were incubated in the field and were shown to prevent fouling on them for 5 months compared with the control, hence providing the drippers with 'self-cleaning' and 'self-sterilizing' properties. Further, the NPs offer recharging to the surface, thus providing long-lasting protection that does not exist in the products available today. In summary, our findings underscore the potential of developing sustainable P(MAA-MBAA)-Cl NPs-based devices for inhibiting bacterial colonization and growth.

Objectives

synthesize rechargable n-halamine nanoparticles

Methods

synthesizing nanoparticles by co polymerization process

Conclusions

n-halamine nanoparticles were synthesized to carry halogens and proved to be effectvie against microorganisms

FEMS7-1239
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

AMENDMENT WITH HIGH DOSES OF AEROBIC AND ANAEROBIC BIOSOLIDS PRODUCED LONG-TERM CHANGES IN THE METABOLIC PROFILE AND THE BACTERIAL COMPOSITION OF A CROP SOIL

F. Navarro-García[1], I. Nadal-Rocamora[1], C. Gondim-Porto[1], L. Platero[1]
[1]Dept. Microbiología II- School of Pharmacy- Universidad Complutense de Madrid, Microbiología II, Madrid, Spain

Backgrounds

The use of biosolids as amendments is a frequent way to increase the fertility in crop soils as well as to give added value to a residue whose amount is raising every year due to national regulations. However, the effect of these compounds at high rates needs to be assessed more deeply in order to determine the long term modifications in the soil microbiota that could hamper the normal function of crop soils under Mediterranean climate.

Objectives

To evaluate the effect of two types of high doses of biosolids on the bacterial population composition and their metabolic profiles of a crop soil in a 2-year experiment.

Methods

Crop soils amended with 160 $Tm \cdot ha^{-1}$ of an aerobic and an anaerobic biosolid were analyzed every four months for two years. The metabolic profiles of microbial populations (CLPPs) were obtained using the Microresp© system. The composition of bacterial populations was determined by pyrosequencing 98 16S rDNA libraries. Sequences were prepared and taxonomically asigned using Mothur, VAMPS and Greengenes. This work has been financed by projects CGL2006-13915/CLI and MMA022/PC08/3-04.2.

Conclusions

The proportion of *Proteobacteria*, *Firmicutes*, *Bacteroidetes*, *Gemmatimonadetes* and *Verrucomicrobia* phyla increased, while *Acidobacteria*, *Cyanobacteria* and *Planctomycetes* phyla decreased upon treatment, producing the anaerobic biosolid a largest number of microbial changes that allowed us to define a set of relevant microbial markers. Nevertheless, the effect of amendment on CLPPs was similar, a result that could be explained by a functional redundancy of bacterial populations. Several microbial groups were statistically related with the metabolism of some chemical compounds.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

AQUATIC FUNGI AND THEIR SURFACE COUNTERPARTS IN THE HAINICH CRITICAL ZONE EXPLORATORY

A. Nawaz[1,2], *F. Buscot*[1,3], *T. Wubet*[1,3]
[1]*Helmholtz Centre for Environmental Research, Department of Soil Ecology, Halle Saale, Germany*
[2]*University of Leipzig, Department of Biology II, Leipzig, Germany*
[3]*German Centre for Integrative Biodiversity Research, iDiv, Leipzig, Germany*

Backgrounds

Subsurface groundwater aquifers are primarily recharged by infiltration of surface water, which brings down not only dissolved organic matter but also the surface microbial communities into the subsurface. Aboveground surface conditions like vegetation cover and landuse management types have profound impact on the belowground fungal community structures and compositions. Whereas the effects of these surface conditions on subsurface fungal communities beyond the rooting zone in fresh water aquifers at different depths are largely unknown

Objectives

Objective of this study were to:
- investigate the fungal community structures in two subsurface groundwater aquifers and their surface recharge areas
- find the dominant functional groups in surface and subsurface
- find the core fungal microbiome of surface and subsurface and their shared taxa

Methods

Soil and water samples were analyzed by using DNA based high-throughput sequencing of fungal internal transcribed spacer (ITS) rDNA gene to compare the fungal community structure and composition in two habitats.

Conclusions

Our results indicated that the fungal OTUs belonging to phylum Basidiomycota and Ascomycota dominate the aquifers. The core fungal microbiome of surface and subsurface samples indicates the high similarities between two habitats reflecting that surface conditions have impact on the subsurface fungal communities. Specifically the presence of different functional groups and, in particular plant and cattle pathogens that are not typical of subsurface habitats, further strengthened that their potential transport of fungi between surface and subsurface. In addition to this, we also find fungal taxa specific to the subsurface samples only and that points to a groundwater specific fungal microbiome.

FEMS7-0655
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

BIODEGRADATION OF CHLORPYRIFOS BY MICROBES ISOLATED FROM RICE PADDY FIELDS: EFFECT OF BIOSTIMULATION AND IMPACT OF MIXED MICROBIAL CONSORTIA

T. Nayak[1], *T.K. Adhya*[1], *M. Suar*[1], *V. Raina*[1]
[1]*KIIT University, KIIT School of Biotechnology, Bhubaneswar, India*

Backgrounds

Chlorpyriphos (CP) is a broad-spectrum organophosphorous pesticides (OP) majorly used for pest (termites, beetles) control in agri-crops like rice, maize, soyabean, cauliflower etc in many countries. Extensive use of this compounds result in their accumulation in agricultural soil, water source and affecting insects and humans by inhibiting acetylcholinesterase in the nervous system. Degradation of CP results in the formation of a compound TCP (3,5,6-trichloro-2-pyridinol) classified as mobile, toxic also has antimicrobial property.

Objectives

Present investigation showed (a) bacterial strains isolated and screened for their degradation ability from agricultural soil amended with CP and (b) study the effect of biostimulation on CP degradation using mixed microbial consortia.

Methods

Resting cell assay for Chlorpyrifos degradation in liquid media followed by HPLC analysis and biostimulation using carrier material for Chlorpyrifos degradation.

Conclusions

Strains *Ochrobactrum* CPD-03, *Microbacterium* CPD-20 and *Bacillus* CPD-33 were identified based on 16s rRNA approach. Effect of biostimulation on the CP degradation in stimulated (addition of nutrients) and non-stimulated conditions were performed resulting 88% CP degradation in stimulated condition and 66% degradation in non-stimulated condition respectively. This showed CP degradation under stimulated condition has provided nutritional environment for CP degradation. Corncob acted as a good carrier material for CPD-03 viability resulted enhanced CP degradation. It was also found that, the consortia MC-1 had shown better degradation efficiency in liquid media (80% degradation efficiency in 24 hours) and in presence of carrier material (58-60% degradation efficiency in 10 days). This can be potential for *in situ* bioremediation of contaminated soil ecosystem.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

MICROBIAL COMMUNITIES CHARACTERISTICS DURING TWO-YEAR GROWTH OF BIOFUEL CROP MISCANTHUS X GIGANTEUS ON THE MILITARY CONTAMINATED SOIL

D. Nebeská[1], V. Pidlisnyuk[1], J. Trögl[1], L. Seidlová[1], P. Veronesi-Dáňová[1], P. Kuráň[1], L. Erickson[2], L. Davis[3]
[1]Jan Evangelista Purkyně University in Ústí nad Labem - Faculty of the Environmen, Department of technical sciences, Ústí nad Labem, Czech Republic
[2]Kansas State University, Department of chemical engineering, Manhattan, USA
[3]Kansas State University, Department of biochemistry & molecular biophysics, Manhattan, USA

Backgrounds

Phytoremediation of contaminated soils using second generation biofuel crops is a promising way to restore soil functions together with biomass production.

Objectives

Perennial grass *Miscanthus x gigantheus* was tested for cleaning metal (Ti, Fe, Mn, Zn, Sr, Zr) contaminated soil from post-military site in Sliač, Slovakia in two year pot experiment. Soil microbial community characteristics in rhizosphere and bulk soil were assessed by determination of phospholipid fatty acids (PLFA), respiration and activities of enzymes representing C, N, P, S cycles.

Methods

PLFA were determined according to ISO 29843-2. Enzyme activities were determined by direct incubation of soil with artificial enzyme substrates.

Conclusions

Microbial characteristics of polluted soil were lower in comparison to other agricultural soils. Significantly lower value of *cy/pre* PLFA stress indicator in rhizosphere soil compared to bulk soil and year-over-year comparison of activities of phosphatases, arylsulphatases, oxidases and soil respiration indicate gradual positive effect of *Miscanthus x giganteus* roots to soil microorganism.

POLYPHASIC CHARACTERIZATION OF METHANOTROPHIC COMMUNITIES ENRICHED FROM ACIDIC SOILS

N.L. Nguyen[1], W.J. Yu[1], H.Y. Yang[1], J.H. Gwak[1], S.K. Rhee[1]
[1]Chungbuk National University, Department of Microbiology, Cheongju, Republic of Korea

Backgrounds

Acidic soil covers approximately 30% soils of the world and acidification is accelerated in agricultural soils. However, little is known about methane-oxidizing bacteria in acidic soil environments.

Objectives

We investigated the methanotrophic communities enriched from acidic soils using the sequencing batch reactor at pH 4 and isolated the acidophilic methanotrophs from enrichment culture.

Methods

Illumina sequencing for 16S rRNA gene analysis indicates that the families *Methylocystaceae* (15.3%), *Xanthomonadaceae* (10.0%), *Acidobacteriaceae* (8.7%), *Rhodocyclaceae* (5.0%), *Crenothrichaceae* (4.6%) and *Beijerinckiaceae* (0.7%) were major members in the methanotrophic communities. The family *Methylocytaceae*, *Crenothrichaceae* and *Beijerinckiaceae* might be key members involved in methane oxidation in acidic soils. The floating culture and extinction culture techniques were performed to isolate the key methanotrophic strains from the enrichment culture. Two isolates belonging to the genus *Methylovirgula* of the familiy *Beijerinckiaceae* and the genus *Methylobacter* of the family *Methylococcaceae* were obtained from the enrichment cultures.

Conclusions

Our findings suggest that various methanotrophs in diverse phylogenetic clades are involved in methane oxidation in acidic soils. Metagenomic sequencing for reconstruction of genome and their metabolic pathways of the dominant members in the acidic methanotrophic enrichments is on-going to get insight on the methane oxidation in acidic soils.

REAL TIME ANALYSIS OF THE INTERACTION OF ISOLATED INTESTINAL MICROBIOTA AND SUPERNATANTS FROM DIFFERENT HUMAN POPULATION GROUPS WITH A COLON ADENOCARCINOMA CELL LINE

A.M. Nogacka[1], E. Gómez[1], G. Solís[2], M. Suárez[2], N. Fernández[3], A. Suárez[4], C. Martínez-Faedo[5], P. Ruas-Madiedo[1], N. Salazar[1], C. G. de los Reyes-Gavilán[1], M. Gueimonde[1]
[1]IPLA-CSIC, Microbiology and Biochemistry of Diary Products, Villaviciosa-Asturias, Spain
[2]Hospital Universitario Central de Asturias- SESPA, Pediatrics Service, Oviedo, Spain
[3]Hospital de Cabueñes, Pediatrics Service, Gijón, Spain
[4]Hospital Universitario Central de Asturias, Gastroenterology, Oviedo, Spain
[5]Hospital Universitario Central de Asturias, Endocrinology, Oviedo, Spain

Backgrounds

The gut microbiota constitutes a complex ecosystem that changes through the lifespan. Our understanding on the functional characterisitcs of the microbiota is mainly based on *in vitro* models that focus in the analysis of the interaction between the host and specific bacterial strains. Therefore, the development of simple and economically affordable study models, which take into account the complexity and functionality of the intestinal microbiota is required.

Objectives

The ability of an *in vitro* model, based on the real-time monitoring of the HT29 colon adenocarcinoma cell line, was evaluated to asses its ability to detect differences in the functionality of faecal supernatants (FS) and isolated faecal microbiotas (M) from different human population groups: obese (n = 9), healthy normal weight adults (n = 7) and ulcerative colitis patients (n = 5). A group of infants (n = 20), divided in full-term infants (2 days of age, n = 10) and preterm infants of the same age (n = 10) were also studied.

Methods

The composition of the M was characterized by 16S rRNA gene sequencing. The quantification of short chain fatty acids was also determined by gas chromatography in the FS. Moreover, the effect of M and FS was monitored in real time, using RT-Cell Analyzer technology on the proliferation and confluence phases of the HT29 cell line.

Conclusions

The microbiota-host interaction *in vitro* model developed allowed to detect differences in the functionality of the microbiotas of different population groups. This *in vitro* model shows potentiality for the characterization of the functionality of complex microbiotas and the resulting effect of modulating them by probiotics, prebiotics or other functional components of diet.

FEMS7-1243
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

ACTIVITY OF BACTERIAL ENDOPHYTES ASSOCIATED WITH RICE UNDER ALUMINIUM TOXICITY

F. Nongkhlaw[1], *D. Thakuria*[1]
[1]*College of PG Studies - Central Agricultural University, NRM, Shillong, India*

Backgrounds

The decline in rice (*Oryza sativa* L.) production is responsible for enormous economic loss world-wide. The production of rice in the North-eastern part of India is limited by aluminium toxicity. Endophytes are microbes that reside inside tissue of healthy plants without causing damage. Endophytes have several beneficial effects on their host plants, including growth promoting activity, modulation of plant metabolism and phytohormone signalling. Endophytes play a vital role by synthesizing a wide range of bioactive metabolites that leads to adaptation to environmental stresses.

Objectives

This study involves the use of endophytic bacteria associated with *Oryza sativa* L. for agricultural applications and to ensure improved crop performance under contaminated soil conditions, such as Al toxicity. The study includes an investigation on the bioactive potential of bacterial endophytes under stressed environment.

Methods

Molecular characterization of bacterial endophytic communities living inside rice tissue grown in tissue culture at increasing concentration of aluminium (50-500 ppm Al). Screening of phytochemical compounds produced by endophytes associated with tissue cultured rice at increasing concentration of aluminium using gas chromatography-mass spectroscopy (GC-MS).

Conclusions

Rice tissue culture was successful in growing rice at increasing concentration of aluminium. Different bacterial populations were detected in culturable medium. The associated endophytes were observed to enhance the growth of rice under Al toxicity.

FEMS7-0098
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

LACCASE ACTIVITY CHANGE IN CRYPHONECTRIA HIPOVIRUS 1-INFECTED CRYPHONECTRIA PARASITICA IS INFLUENCED BY CULTURE CONDITIONS, FUNGAL ISOLATE AND VIRUS STRAIN

L. Nuskern[1], M. Tkalec[2], M. Gačar[1], M. Ježić[1], M. Ćurković-Perica[1]
[1]University of Zagreb- Faculty of Science, Department of Microbiology, Zagreb, Croatia
[2]University of Zagreb- Faculty of Science, Department of Botany, Zagreb, Croatia

Backgrounds

In chestnut blight fungus *Cryphonectria parasitica,* laccase, a polyphenol oxidase, is thought to be involved in pathogenesis towards chestnut due to its ability to degrade lignin, which is intensively synthetized by chestnut trees as a defensive reaction. Infection with virus *Cryphonectria hypovirus 1* (CHV1), a hyperparasite of *C. parasitica*, has been shown to reduce laccase activity of infected fungus, reducing its virulence towards chestnut. Thus far the research has been done on only limited number of fungal isolates and virus strains.

Objectives

Our aim was to determine the effect of local CHV1 strains on laccase activity in different Croatian *C. parasitica* isolates, which could have important implications in choosing the optimal virus strain for human aided biocontrol of chestnut blight.

Methods

Three CHV1 strains were transferred to three Croatian isolates of *C. parasitica* by hyphal anastomosis. The cultures were grown on potato dextrose agar and broth, and laccase activity was assayed with 2,2'-azino-bis(3-etilbenzotiazoline-6-sulphonic acid) as a substrate. For cultures grown on solid medium total laccase activity was measured, and for cultures grown in liquid medium extra- and intracellular laccase activity was measured.

Conclusions

When grown on solid medium, total laccase activity of CHV1-infected fungal isolates increased compared to control, virus-free isolates. In liquid medium extracellular laccase activity either increased or decreased, depending on fungal isolate, while the intensity of the change depended on the virus strain. Intracellular laccase activity of isolates grown in liquid medium showed almost no responsiveness to CHV1 infection. Thus we conclude that *C. parasitica* laccase activity depends on more parameters than just the CHV1 infection.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

16S RRNA SEQUENCING OF THE VAGINAL MICROBIOME IN BACTERIAL VAGINOSIS AND AEROBIC VAGINITIS

E. Oerlemans[1], S. Wuyts[1], S. Wittouck[1], I. Claes[1], G. Donders[2], S. Lebeer[1]
[1]UAntwerpen, Bioscience engineering, Antwerp, Belgium
[2]University Hospital of Antwerp, Gynaecology and Obstetrics, Antwerp, Belgium

Backgrounds

In most women, the healthy vaginal microbial community is characterized by a low complexity and often a dominance of *Lactobacillus* species, which exert an apparent protective role. In some medical conditions, these lactobacilli disappear. Bacterial vaginosis (BV) is recognized as an overgrowth of mainly anaerobic bacteria such as *Gardnerella vaginalis*, *Prevotella spp.*, *Atopobium vaginae* and *Mobiluncus* species. In contrast, aerobic vaginitis (AV) is less known, but culture and microscopy suggest an increased presence of more aerobic bacteria such as *Streptococcus agalactiae*, *Staphylococcus aureus*, *Escherichia coli* and Enterococci. Moreover, AV is mostly associated with an increased inflammatory response. Currently, AV is often misdiagnosed as BV, which might act as a confounding factor for studies investigating the microbiome in BV.

Objectives

Microbiome profiles of both AV and BV will be useful to gain more insight into these conditions, and help clinicians in the search for proper treatments.

Methods

We characterized the vaginal microbiome of 51 women, including subjects with a normal *Lactobacillus*-dominated microbiota (NL) and patients suffering from AV or BV. DNA was isolated from cervicovaginal lavage fluid, and used for *16S rRNA* amplicon sequencing of the V4 region using Illumina Miseq. The obtained data was analysed using the dada2 bioinformatic pipeline.

Conclusions

Our results indicate a more diverse community in BV as compared to the NL and AV group. Additionally, a unique *Gardnerella* ribosomal sequence variant was almost solely found in the BV samples. Contrary to the culture data, we found heterogeneous communities in the AV group, with mainly anaerobic species.

FEMS7-3159
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

EXOCYCLIC DNA METHYLTRANSFERASES FROM MARINE ALPHABACTERIA

H.M. Oh[1], J. Kim[1], K.K. Kwon[2]
[1]Marine Genomics Lab, Marine Bio-Convergence, Busan, Republic of Korea
[2]Korean Institute of Ocean Science and Technology, Marine Biotechnology Research Division, Ansan, Republic of Korea

Backgrounds

DNA methylation is involved in a diversity of processes in bacteria, including maintenance of genome integrity and regulation of gene expression. CcrM, the DNA methyltransferase conserved in Alphaproteobacterial species, has N6-Adenine or N4-cytosine methyltransferase activities using S-adenosyl methionine as a co-substrate. Using PacBioRSII genomic data, methylation patterns were observed and summarized for a exocyclic DNA methylases of potential CpG and GpC methylation.

Objectives

Single molecule real-time sequencing method (SMRT) is a tool for genomic analysis as well as a methods to monitor bacterial DNA methylome. Here we report two distinct exocyclic DNA methyltransferase genes from two alphaproteobacteria strain from marine environments.

Methods

Using PacBioRS II sequencing, methylation patterns of *Celeribacter marinus* IMCC12053 and *Novosphingobium pentaromativorans* US6-1 were compared using Gibbs motif sampler program. Both strains have been observed to change adenosine of 5'-GANTC-3' as N6-methyladenosine, and N4-cytosine of 5'-CpG-3' (IMCC12053) and 5'-GpC-3' (US6-1) as N4-methylcytosine. Using phylogenetic analysis exocylic DNA methyltransferases from both of the species were chosen for cloning.

Conclusions

In this study cloned exocyclic DNA methylases are presented, and the potential use of novel type of CpG and GpC methylases in molecular biology and epigenetics.

FEMS7-3160
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

COMPLETE GENOME ANALYSIS OF FLAVOBACTERIALES BACTERIUM STRAIN UJ101

H.M. Oh[1], J. Kim[1], K.K. Kwon[2]
[1]Marine Genomics Lab, Marine Bio-Convergence, Busan, Republic of Korea
[2]Korea Institute of Ocean Science & Technology, Marine Biotechnology Research Division, Ansan, Republic of Korea

Backgrounds

Flavobacteriales bacterium strain UJ101was isolated from a xanthid crab shell collected from East Sea of Korea. Here we report the complete genome sequence of strain UJ101 for the study of metabolic interaction between UJ101 and its host organism.

Objectives

Completed genome of strain UJ101 was compaired to other Flavobacteriales genomes for further analysis.

Methods

Single molecule real-time technology (PacBio RSII) was used for the single circular chromosome that is 3,074,209 base pairs in length and the GC content was 30.74%. The genome of UJ101 contains 2,698 ORFs with 46 tRNAs and 9 rRNAs genes. Genomic data were processed by the EzCG comparative genomic pipeline by www.chunlab.com with some customizations.

Conclusions

According to the annotated list of genes Embden–Meyerhof and pentose phosphate pathway is well conserved, but key enzymes of Entner-Douddoroff pathway were impared. TCA and glyoxylate cycle were conserved while carbon fixation and one carbon metabolism were mostly lacking except formaldehyde dehydrogenase. UJ101 encodes degradation enzyme including 8 glycosyl transferases, 3 amylases, and 8 peptidases. Biosynthetic enzymes for canonical amino acids were all conserved. Alcohol and/or organic acid fermentation could not be expected. Genomes from Flavobacteriales and related groups were chosen for comparative genomic analysis. Strain UJ101 was compared with bacterial genomes isolated from other marine animals (3 strains from invertebrate and 5 strains from fishes). Other related genomes from the same genera were included although they were isolated from seawater and marine sediments. UJ101 is deficient in biotin metabolism, which was also observed between marine fish dwelling isolates and seawater genomes in this study.

PREVALENCE OF SALMONELLA AND CAMPYLOBACTER IN CAPTIVE CROWS (CORVUS CORONE AND C. MACRORHYNCHOS) IN THE NORTHEASTERN JAPAN

M. Okamura[1], H. Sano[1], K. Sakata[1], M. Kaneko[1], J. Shindo[2], H. Shirafuji[3], D.L. Hu[1]
[1]Kitasato Univ. School of Veterinary Medicine, Laboratory of Zoonoses, Towada, Japan
[2]Kitasato Univ. School of Veterinary Medicine, Laboratory of Wildlife Sciences, Towada, Japan
[3]Kyusyu Research Station National Institute of Animal Health,
Subtropical Disease Control Unit Division of Transboundary Animal Diseases, Kagoshima, Japan

Backgrounds

Salmonella and *Campylobacter* cause human foodborne enteritis via consumption of raw/undercooked contaminated poultry meat and products worldwide to date. Broiler flocks are primarily contaminated with the bacteria. The pre-harvest control measures include the avoidance of transmission of the bacteria from environmental reservoirs to broiler flocks. Although the reservoirs have not clearly been identified, the roles of wildlife in the contamination of broilers are suggested recently.

Objectives

In the current study, we investigated the prevalence of *Salmonella* and *Campylobacter* in free-living crows to estimate the potential risk in contamination of broiler flocks with *Salmonella* and *Campylobacter*.

Methods

A total of 123 crows were captured between October 2012 and April 2014 in the box traps, and cloacal swabs were sampled for isolation of *Salmonella* and *Campylobacter*. Relatedness or diversity among the isolates were analyzed by pulsed field gel electrophoresis (PFGE).

Conclusions

Salmonella serovers Bredeney and Derby were isolated from only 11 of 123 crows (8.9%), which are not common in broiler chickens. *Campylobacter* spp. were isolated from all of 89 crows tested (100%) of which *C. jejuni* was the most prevalent (85 crows). PFGE patterns showed the vast diversity in *C. jejuni* isolates from crows and only possible relatedness to the broiler isolates epidemiologically. These results suggest the potential risk of transmission of *Salmonella* and *C. jejuni* from crows to broilers is limited.

COMPREHENSIVE ANALYSIS OF THE FECAL MICROBIOTA OF HEALTHY JAPANESE ADULTS REVEALS A NEW BACTERIAL LINEAGE ASSOCIATED WITH HIGHLY FREQUENT BOWEL MOVEMENTS AND A LEAN BODY-TYPE

K. OKI[1], M. Toyama[2], T. Banno[2], O. Chonan[1], Y. Benno[2], K. Watanabe[1]
[1]Yakult Honsha, Central Institute, Kunitachi Tokyo, Japan
[2]RIKEN Innovation Center, Benno Laboratory, Wako Saitama, Japan

Backgrounds

In Japan, a variety of traditional dietary habits and daily routines have developed in many regions. The effects of these behaviors, and the regional differences in the composition of the gut microbiota, are yet to be sufficiently studied.

Objectives

We aimed at characterizing the Japanese gut microbiota and identifying the factors shaping its composition.

Methods

We collected fecal samples from 516 healthy Japanese adults (325 females, 191 males; age, 21–88) residing in various regions of Japan and conducted 16S metagenomics analyses. Each participant also completed a 94-question lifestyle questionnaire.

Conclusions

Clustering analysis based on the fecal bacterial family composition showed that two enterotype-like clusters were observed in the males, but not the females, suggesting that the composition of the fecal microbiota has a gender-specific component. However, subjects' region of residence and gender were not strongly correlated with the general composition of the fecal microbiota.
The bacterial compositions were then compared with lifestyle questionnaire scores. The abundances of *Christensenellaceae*, *Mogibacteriaceae* and *Rikenellaceae* were negatively correlated ($P < 0.001$) with bowel movement frequency. Furthermore, the abundance of these bacterial families was significantly ($P < 0.01$ or 0.05) higher in lean subjects (BMI < 25) than in obese subjects (BMI > 30). The abundances of these families were positively correlated with each other and comprised a correlative network with 14 other bacterial families. These results implied that the abundances of *Christensenellaceae*, *Mogibacteriaceae* and *Rikenellaceae* contributed subject's highly frequent bowel movements and a lean body-type together with those of some other bacterial components comprising correlative network with them.

SPATIAL DISTRIBUTION AND DIVERSITY OF BACTERIAL ASSEMBLAGES IN THE LAURENTIAN GREAT LAKES: COMPARISONS BETWEEN LAKES MICHIGAN, ERIE AND HURON

O. Olapade[1]
[1]*Albion College, Biology & the Center for Sustainability & the Environment, Albion, USA*

Backgrounds

The Laurentian Great Lakes, including Lakes Superior, Michigan, Huron, Erie and Ontario, located in the eastern part of North America are considered the largest of freshwater lakes in the world. However, the diversity and distribution of indigenous microbial assemblages within these vast bodies of freshwater systems remains largely unexplored.

Objectives

To qualitatively and quantitatively delineate the microbial structure and community composition in these vast body of freshwater systems

Methods

Combinations of high-throughput sequencing of the 16S rRNA genes and fluorescent *in situ* hybridization (FISH) approaches were utilized to quantitatively characterize the occurrence, diversity and distribution of bacterioplankton assemblages in six different sites located along the coastal regions of Lakes Michigan, Huron and Erie.

Conclusions

Phylogenetic examination showed a diverse bacterial community belonging to eleven different taxonomic groups. Pyrosequencing results revealed that the majority of the sequences were clustered into four main groups i.e. *Proteobacteria, Bacteriodetes* and *Cyanobacteria*; while fluorescent *in situ* hybridization also showed the numerical dominance of members of the *GammaProteobacteria* and the *Cytopahaga-Flavobacteria-Bacteroidetes* (CFB) cluster in the six lake sites examined. Overall, the assemblages were shown to be quite similar in distribution among the lake sites examined, comprising of heterotrophic populations, except for the Sandusky Bay site in Lake Erie that was mostly autotrophic, with more than 50% of the population comprised by members of the Cyanobacteria. This further indicate that combinations of factors, including water chemistry, various anthropogenic disturbances and lake morphometric characteristics, are probably continuously influencing the community structure and diversity of the lake's bacterial assemblages.

DIVERSITY OF MOBILOME PRESENT IN TIETE RIVER

L.R. Olchanheski[1], L. Rada[1], E.G. Silva[1], S. Ichiwaki[1], F.L. Melo[1], W.L. Araújo[1]
[1]Biomedical Sciences Institute, Microbiology Department, São Paulo, Brazil

Backgrounds

Tiete river is the most important river in São Paulo State, and now a days is consider one of the most polluted river in the country. A factor that confer resistance and evolutionary advantages of determined organisms is the horizontal gene transfer (HGT). These advantages keep some organisms even in unfavorable conditions.

Objectives

For these reasons, the aim of this work were access the cover of genes with capacity of horizontal gene transfer in Tiete River.

Methods

Four sites were choose, based to their water quality index (very poor, fair, good and excellent). Metagenomic Shotgun sequencing of water samples were perform using Illumina HiSeq 2000™ platform. The assembly were perform using IDBA-UD. Transposase genes were finding by IsSaga2, and the genes nearby were annotated using the Metagenomics Rapid Annotation Server (MG-RAST).

Conclusions

The results revealed a distribution pattern of antibiotics resistance genes. In the site of very poor quality water, there were a prevalence of *sul*2 gene, which confer resistance to sulfonamide specifically. In contrast, in the good site the gene *sme*B (an efflux bomb) were prevalent. The results based only in the genes near insertion sequence, there is a prevalence of genes related to resistance to antibiotics and toxic compounds, mainly efflux bomb. Tiete River is a polluted river, receiving daily dumping of domestic and industrial sewage. These conditions keep some advantages to bacteria that contains the genes of antibiotic resistance.

Others genes can growth the fitness of bacteria in and impacted environmental, for this reason another genes near insertion sequence will be related with physical-chemical parameters and analyze if there is a distribution pattern of the genes that condition the bacteria fitness.

EFFECTS OF LONG-TERM STARVATION ON VIBRIO HARVEYI MEMBRANE SUBPROTEOME DURING ITS PERMANENCE IN SEAWATER

M. Orruño[1], C. Parada[2], Z. Bravo[2], E. Ogayar[2], I. Larrañaga[2], V. Kaberdin[3], I. Arana[2]
[1]Faculty of Pharmacy - University of the Basque Country UPV/EHU, Immunology- Microbiology and Parasitology, Vitoria-Gasteiz, Spain
[2]Faculty of Science and Technology - University of the Basque Country UPV/EHU, Immunology- Microbiology and Parasitology, Leioa, Spain
[3]Faculty of Science and Technology - University of the Basque Country UP/EHU / IKERBASQUE- Ba sque Foundation for Science, Immunology- Microbiology and Parasitology, Leioa, Spain

Backgrounds

The behavior of *Vibrio harveyi,* pathogen for a wide range of marine animals, in environments is conditioned, among others, by temperature, salinity or nutrient scarcity.

Objectives

To evaluate the physiological and proteomic changes that take place during *V. harveyi* survival in seawater, especially those associated with the long-term survival.

Methods

V. harveyi populations were maintained for 230 days in sterile natural seawater at 20°C. The total and active cells were regularly monitored via epifluorescence microscopy, while the culturable bacteria were determined by the spread plate method in Marine Agar. Additionally, samples were collected for extraction of membrane proteins and their subsequent identification and quantification via mass spectrometry.

Conclusions

Nutrient-limited conditions led to the loss of *V. harveyi* culturability and its entry into the viable but nonculturable (VBNC) state after 14-15 days. The membrane subproteome composition also underwent changes during the survival process. Although the level of many proteins remained nearly the same after 3 weeks of starvation (initial phase), there was a fast disappearance of proteins involved in chemotaxis. The depletion of these non-essential proteins could prevent unnecessary waste of energy required for survival. In contrast to the initial phase, the long-term survival process (230 days) led to more profound changes in the membrane subproteome. While several proteins with structural and bioenergetics functions became undetected, a number of transport-related proteins increased their abundance.
Thus, in response to suboptimal conditions, *V. harveyi* triggered an adaptation process which included its entry into the VBNC state and the membrane subproteome reorganization.

EFFECT OF HABITAT DISTURBANCES ON THE POPULATION DYNAMICS OF ALLOCHTHON LISTERIA MONOCYTOGENES IN SOIL

A.R. Ortiz Camargo[1], A. SPOR[2], S. GABA[3], D. Garmyn[4], L. Gal[5], P. Piveteau[4]
[1]UNIV. BOURGOGNE-FRANCHE-COMTE- UFR SANTE, Agroecologie, DIJON, France
[2]INRA, INRA UMR1347 Agroecologie, Dijon, France
[3]INRA, INRA UMR1347, Dijon, France
[4]UNIV. BOURGOGNE-FRANCHE-COMTE, INRA UMR1347 Agroecologie, Dijon, France
[5]AgroSup, INRA UMR1347 Agroecologie, Dijon, France

Backgrounds

Soil is in many cases the first stage in the routes of transmission of foodborne pathogens to plant, farm animals, foodstuff and humans as final consumers. Soil is a complex, heterogeneous environment which shelters many organisms such as allochthon bacteria. The persistence of these organisms depends on abiotic factors (temperature, humidity, texture, chemistry) and on biotic interactions, for example competition with native microflora.

Objectives

In this study, we used the foodborne pathogen *Listeria monocytogenes* as model system to investigate how disturbances affect habitat invasion by allochthon organisms.

Methods

Two soils with contrasting abiotic and microbiome characteristics were used. Inoculated soil microcosms were submitted to two cycles of temperature shifts (either increase to 42°C or freezing at -20°C) separated by 20 days of incubation at 20°C. Control microcosms were kept at 20°C. In order to investigate the impact of the indigenous microbiota, similar experiments were run in γ-irradiated, sterilized soil microcosms. Cultivable *L. monocytogenes* were evaluated by plate counts throughout the 40 days incubation. Additionally, soil samples were taken at the start of the experiment and after 20 and 40 days for DNA extraction and subsequent 16SrDNA diversity analysis. Variations of diversity were assessed in non-inoculated microcosms to evaluate the influence of *L. monocytogenes* invasion on the native soil microbiota.

Conclusions

While growth was observed in sterilized soil, the population of *L. monocytogenes* decreased in the other experimental conditions. Results showed that the fate of allochthon *L. monocytogenes* depended on the disturbance regimen. Higher survival was observed in when soil underwent cycles of freezing

ENVIRONMENTAL AND GEOGRAPHIC PATTERNS SHAPING MICROBIAL COMMUNITIES IN HIGH MOUNTAIN LAKES (PYRENEES, SPAIN)

R. Ortiz-Álvarez[1], J. Catalán[2], L. Camarero[1], X. Triadó-Margarit[1], E. O. Casamayor[1]
[1]Center for Advanced Studies of Blanes CSIC, Continental Ecology, Blanes, Spain
[2]CREAF- Campus UAB- Edifici C- E-08193, CREAF, Cerdanyola del Vallès, Spain

Backgrounds

The lacustrine district in the Pyrenees shows unique characteristics for the study of microbial communities and their distributions in a spatial context. The Pyrenees mountain system is limited by the Cantabrian Sea to the west and the Mediterranean Sea to the east, and its limnological network has evolved since the onset of the last interglacial period. Nowadays, the lacustrine landscape shows very heterogeneous environmental conditions.

Objectives

Understanding the distribution of microbial community types within this region will hint at the general underlying patterns behind community colonization, assembly and diversity.

Methods

We took samples from the lake outlet of ~300 lakes during summer 2011, and applied tag-sequencing of 16S and 18S rRNA genes to disclose bacterial, archaeal and microbial eukaryotes populations identity and community structure.

Conclusions

We fully characterized microbial diversity within this region unveiling a huge degree of novelty and important trophic players within the lake dynamics. Bacteria seem to be assembled by a complex combination of geographic factors and environmental sources of colonization, with a sub-regional structuration. In turn, microbial eukaryotic communities showed strong influence of nutrient content (NO^{3-}, TP and DOC) and especially of water pH, in addition to a geographical signature. Our results indicate that bacterial and microbial eukaryotic communities seem to be distributed and shaped by different chemical and geographic factors.

PRIMARY SUCCESSION PATTERNS IN MICROBIAL COMMUNITIES ACROSS A WIDE RANGE OF ENVIRONMENTS

R. Ortiz-Álvarez[1], N. Fierer[2], A. de los Ríos[3], E. O. Casamayor[1], A. Barberán[2]
[1]Center for Advanced Studies of Blanes CSIC, Continental Ecology, Blanes, Spain
[2]CIRES- University of Colorado-Boulder, Ecology and Evolutionary Biology, Boulder, USA
[3]National museum of natural sciences- CSIC, Biogeochemistry and microbial ecology, Madrid, Spain

Backgrounds

Ecologists have studied primary succession, the changes that occur in biological communities from initial colonization of an environment, for decades. Most of this work focused on primary succession in plant communities and has established the basis for much of what we currently know about community assembly patterns. Because of their prevalence and importance in ecosystems, there are an increasing number of studies focusing on microbial community dynamics along the primary succession process.

Objectives

Here we aimed to determine whether consistent changes in the diversity, community composition, and functional traits of bacteria over the course of primary succession exist.

Methods

We conducted a meta-analysis of bacterial primary succession samples occurring across a range of distinct habitats including infant gut, plant surfaces, soil chronosequences and water associated communities.

Conclusions

Despite each habitat harbored distinct bacterial communities, we found common patterns, such as the trend of community taxonomic and functional alpha diversity to increase along the succession process. In addition, communities and their functional potential become less variable (lower beta diversity) in the latest successional stages. Finally, consistent shifts in both the rRNA operon copy number and the high efficient phosphate assimilation process (Pst system) were observed, while other functional traits had more ambiguous responses. Overall, these results indicate that successional regularities can be predicted by the underlying general rules of microbial primary succession.

A NOVEL PSYCHROTOLERANT METHANOTROPHS OF THE GENUS METHYLOVULUM: ECOPHYSIOLOGY AND INSIGHT INTO GENOMIC FEATURES

I. Oshkin[1], *S. Dedysh*[1]
[1]*Winogradsky Institute of Microbiology, Microbiology, Moscow, Russia*

Backgrounds

Methanotrophs represent a unique group of microorganisms attenuating methane fluxes to the atmosphere. The knowledge on methanotrophs that inhabit low-temperature environments remains limited. This study was focused on two strains of *Methylovulum*-like methanotrophs (Sph1^T and OZ2), which were obtained from two different permanently cold environments and described as a novel species, *Methylovulum psychrotolerans* sp. nov.

Objectives

We aimed to investigate ecophysiology and get insights into genomic features of these bacteria.

Methods

The linear decrease of methane over time in incubations at 5-15 % of methane was used to estimate maximum methane oxidation rates (Vmax). The draft genome sequence of strain Sph1^T was generated using Illumina technology.

Conclusions

Strains grew at 2–32 ^{o}C. Although their optimal growth occurred at 20–25 ^{o}C, they grew very well at lower temperatures, down to 4 ^{o}C. Vmax was in the range of 0.54-1.02×10^{-6} and 0.37-0.39×10^{-6} nmol CH_4 h^{-1} per cell at 10 ^{o}C and 4 ^{o}C, respectively. The total estimated genome size is 5.1 Mb, with an average G+C content of 50.8%. A single rRNA operon, 41 tRNAs, and 4873 predicted protein-coding genes were identified. The genome contains *pmoCAB* operon for pMMO, while sMMO-coding genes are absent. Both *mxa* and *xox* clusters of PQQ-linked dehydrogenases were found. Genes involved in H_4MTP and H_4folate-linked C1 transfer, formate oxidation and dinitrogen fixation were also identified. Complete sets of genes for the function of the RuMP, CBB, TCA, Entner-Doudoroff pathways are present. Thus, analysis of Sph1^T genome confirmed the presence of major genes for methane oxidation and key metabolic pathways.

BIOPROSPECTING OF METHANOGENIC ARCHAEA IN ARCTIC AND ANTARCTIC PERMAFROST

V. Oshurkova[1], V. Shcherbakova[1], E. Rivkina[2]
[1]G.K. Skryabin Institute of Biochemistry and Physiology of Microorganisms, All-Russian Collection of Microorganisms VKM, Pushchino, Russia
[2]Institute of Physicochemical and Biological Problems in Soil Sciences, laboratory of cryosol, Pushchino, Russia

Backgrounds

Permafrost represents natural deposit of ancient microorganisms which survive at permanently subzero temperatures much longer (over geological epochs) than at any known habitats. Recently some methanogenic archaea were isolated from Arctic permafrost and metagenomic data for six permafrost samples were obtained.

Objectives

The objectives of this work were to investigate the diversity of methanogenic archaea in Arctic permafrost of different origin using metagenomic data, to provide the research of methanogenic population in Antarctic microcosms and to isolate psychroactive methanogenic archaea.

Methods

Based on studied metagenomic data we used different substrates and conditions for stimulation of methanogenesis in numerous enrichments and provided experiment of long-term cultivation of pshychroactive methane-producing microbial community from Arctic permafrost. To monitor the species dynamics in the continuous enrichment thermal gel gradient electrophoresis (TGGE) was used.

Conclusions

The results showed the presence of psychrotolerant representatives of Methanospirillum, Methanosarcina and Methanosphaerula genera in enrichments from some Arctic samples and Antarctic microcosms.

The work was supported by Russian Foundation of Basic Research (grant # 15-04-08612).

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

QUORUM SENSING IN DENTAL PLAQUE: A PARADIGM REVISITED

A. Otero-Casal[1], A. Muras[1], C. Mayer[1], M. Romero[1], N. Mallo[1], J.M. Suarez-Quintanilla[2], P. Otero Casal[2], J.M. Pose-Rodríguez[2]
[1]Faculty of Biology- CIBUS- Universidade de Santiago de Compostela, Department of Microbiology and Parasitology, Santiago de Compostela, Spain
[2]Faculty of Medicine and Dentistry- Universidade de Santiago de Compostela, Department of Surgery and specialized Medical Surgery, Santiago de Compostela, Spain

Backgrounds

Although Quorum sensing (QS) plays a central role in bacterial biofilm formation, its role in dental plaque formation remains unclear. So far the Autoinducer-2 (AI-2) and the peptides produced by oral streptococci are the only QS signals described in pure cultures of oral pathogens, while acyl-Homoserine Lactones (AHLs) have not been reported so far.

Objectives

The detection of AHLs in oral samples to a better understanding of the role of these type of QS molecules in dental plaque formation and in development of bacteria-associated oral pathologies.

Methods

A total of 34 samples of dental plaque from healthy donors and patients presenting different oral pathologies were obtained with a dental explorer, introduced in vials with 500 µL of acidified PBS and extracted with ethyl-acetate. Detection and quantification of AHLs was performed using HPLC-MS. Six extracted teeth were processed and analyzed in the same way.

Conclusions

A wide variety of AHLs was found in both, dental plaque and extracted teeth being C8-HSL the most common signal presents in large amounts in almost all samples. The presence of AHLs in dental plaque and extracted teeth indicate that the QS network in the oral cavity may be much more complex than the accepted paradigm. Although the presence of C8-HSL was not related to the clinical profile of the donors, a different pattern of AHLs was found associated to different pathology profiles. The association of certain AHLs with specific pathologies main ignite new research lines in the field and and opens new treatment possibilities.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

NEW BIODEGRADATION TESTS FOR CHEMICAL COMPOUNDS AT LOW ENVIRONMENTAL RELEVANT CONCENTRATIONS

B. Ozel Duygan[1], J. van der Meer[1]
[1]Faculty of Biology and Medicine, Department of Fundamental Microbiology, Lausanne, Switzerland

Backgrounds

Assessment of the biodegradation potential of microbial communities is important to judge the environmental fate of polluting substances. Existing biodegradation tests based on oxygen consumption or CO_2 evolution from added substrate are typically carried out at relatively high substrate concentrations (e.g. 20 mgC L^{-1}). However, pollutant concentrations at this level may cause toxicity to microbes and underestimate the potential for biodegradation. Also, since pollutant concentrations in the environment are often much lower, their biodegradation kinetics may be over-estimated from tests at higher concentrations.

Objectives

We aim to develop tests that enable to measure compound biodegradation at concentrations between 0.1-10 mgC L^{-1}.

Methods

The overall methodological concept of our test is based on sensitive measurements of (prokaryotic) community size increase by flow cytometry at the expense of the added compound. We conducted our experiments with aquatic microbial communities from Lake Geneva at initial cell densities of 1E4, 1E5 and 1E6 cells mL^{-1} incubated for up to 7 days. As readily biodegradable substances we tested benzoate, 1-octanol, anthraquinone and phenol, compared to methyl jasmonate, precyclemone B and myrcene.

Conclusions

Community growth up to approximately 1E7 cells mL^{-1} was observed at substrate concentrations of 1-10 mgC L^{-1}. The lowest measurable community size increase was observed for 0.1 mgC L^{-1}. Benzoate, 1-octanol and phenol indeed supported rapid community growth, in contrast to anthraquinone. For benzoate we observed cell aggregation, which complicates community size measurements. Reported conversion coefficients range between 0.02 and 0.2 pgC per cell, with which we obtain up to 60% biomass yield from added compound.

FEMS7-0954
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

USING BOTH LACCASE AND LIGNIN PEROXIDASE ENZYMES FOR PULP BLEACHING

A. Ozer[1], S. Canakci[1], A.O. Beldüz[2]
[1]Karadeniz Technical University, Department of Biology, Trabzon, Turkey
[2]Karadeniz Technical University, Departmant of Biology, Trabzon, Turkey

Backgrounds

Background: Lignin is a heterogeneous polymer that constitutes 30% of woody plant cell walls. Microorganisms that degrade lignin are fungi, actinomycetes and bacteria. Environmental concerns and increasingly stringent emissions standards have led the pulp and paper industry to devise improved treatment technologies. Bleaching with the the enzymes may be very efficient, and can be used under industrial conditions.

Objectives

Objectives: In the light of the current knowledge, the present study focused on the improvement of effictive and synergistic use of laccase and lignin peroxidase biocatalysts on pulp biobleaching. The XOQP TCF sequence was developed as the best pretreatment approach for the biobleaching of pine and eucalyptus kraft pulps .

Methods

Methods: All bleaching experiments were carried out in polyethylene bags by examining different bleaching sequence. The TCF bleaching sequence performed in this study was “XOQP”. X refers to the enzymatic treatment with laccase and lignin peroxidase, O illustrates the oxygen delignification stage, Q represents the chelation treatment, P exemplifies the bleaching with hydrogen peroxide. Washed and oven-dried Kraft pulp was filled into dry polyethylene bags and pretreated with xylanase and lignin peroxidase under optimized experimental conditions. Then, the pulp was subjected to the bleaching sequence for downstream analyses.

Conclusions

Conclusion: The consecutively use of laccase and lignin peroxidase has pulp bleaching effects more higher than the individual enzymes. The usage of the laccase and lignin peroxidase produced from domestic source can reduce external-source dependency, release of harmful chemicals into the environment, processing cost, and improve the biobleaching-based paper quality produced.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

THE PHYLOGENETIC DIVERISTY OF CEFTRIAXONE-RESISTANT ISOLATES IN SOIL, DIVERSITY OF THEIR EXTENDED-SPECTRUM B-LACTAMASE (ESBL) GENES, AND THEIR CAPACITY FOR MULTI-DRUG RESISTANCE

E. Pagaling[1], *J. Gatica*[2], *K. Yang*[3], *E. Cytryn*[2], *T. Yan*[3]
[1]*The James Hutton Institute, Ecological Sciences, Aberdeen, United Kingdom*
[2]*Agriculture Research Organisation, Water and Environmental Sciences, Bet-Dagan, Israel*
[3]*The University of Hawaii at Manoa, The Department of Civil and Environmental Engineering, Honolulu, USA*

Backgrounds

The third-generation cephalosporins have been useful in treating infections by Gram negative bacteria as they exhibit wide antimicrobial activity. However, in recent years, increasing levels of resistance have been observed in clinical isolates. Since the soil microbiome is considered to be a natural reservoir of antibiotic resistance genes, soil microbes could potentially pose a risk to public health. However, few studies have reported the presence of extended-spectrum β-lactamase (ESBL) genes in undisturbed soils.

Objectives

1. To determine the phylogenetic diversity of ceftriaxone-resistant soil isolates.
2. To determine the diversity of ESBL genes in ceftriaxone-resistant soil isolates.
3. To determine the extent of multi-drug resistance in ceftriaxone-resistant soil isolates.

Methods

Six undisturbed (non-agricultural or human-impacted) and physiocochemically diverse soils were collected from Hawaii (USA) and Israel. Ceftriaxone-resistant soil isolates were obtained either by irrigation of soil microcosms with clinically relevant concentrations of ceftriaxone, or by creating soil slurries amended with ceftriaxone. The identity of the isolates was determined by sequencing their 16S rRNA genes. To determine their multi-drug resistance, the microdilution method was used to find the minimum inhibitory concentrations (MIC) against 13 other antibiotics as well as ceftriaxone. The isolates were screened for three common ESBL genes by multiplex PCR.

Conclusions

Ceftriaxone-resistance was conferred by a diverse group of microorganisms (within the *Proteobacteria*, *Actinobacteria*, *Firmicutes* and *Bacteroides*). Higher levels of ceftriaxone-resistance correlated with higher levels of multi-drug resistance. Three distinct ESBL genes were detected in nine genera, suggesting its ubiquitous presence and/or horizontal gene transfer in soil microbiomes.

ANALYSIS OF 2-(2-HYDROXYLPHENYL)-THIAZOLE-4-CARBALDEHYDE PRODUCTION VIA THE AMBABCDE GENE CLUSTER AND ITS RELATIONSHIP WITH P. AERUGINOSA QUORUM SENSING

A.C. Paiva[1], *F. Matthew*[2], *M. Alexander*[3], *P. Williams*[1]
[1]*The University of Nottingham, School of Life Sciences, Nottingham, United Kingdom*
[2]*Centre for Biomolecular Sciences, School of Life Sciences, Nottingham, United Kingdom*
[3]*The University of Nottingham, School of Pharmacy, Nottingham, United Kingdom*

Backgrounds

Pseudomonas aeruginosa is able to colonize several hosts by producing a variety of virulence factors and secondary metabolites. One of these is the anti-metabolite, L-2-amino-4-methoxy-trans-3-butenoic acid (AMB). AMB biosynthesis is directed by the gene products of the five-gene cluster *ambABCDE*. Recently, these genes have been associated with quorum sensing (QS) in *P. aeruginosa* by directing the biosynthesis of another putative QS molecule, 2-(2-hydroxylphenyl)-thiazole-4-carbaldehyde (IQS). IQS was reported to activate the *rhl* and *pqs* QS systems in an *ambB* mutant, where pyocyanin production was restored under phosphate-limited conditions.

Objectives

Look at IQS production in *amb* mutants compared to the wild type. Analyse the expression of ambA and *ambB* genes under different phosphate conditions. Evaluate how pyocyanin production is affected in these mutants. Understand how this cluster is involved in swarming motility and biofilm development, as *P. aeruginosa* QS is also involved.

Methods

IQS production was measured by LCMS. Transcriptional fusions of *ambA* and *ambB* were created and the expression of these genes was tested in several *amb* and QS mutants, under different phosphate conditions and 200uM IQS. *phzA1* and *phzA2* transcriptional reporter fusions were constructed and the expression and production of pyocyanin was analysed. Lastly, motility and biofilm assays were performed.

Conclusions

Production of IQS and expression of *ambA* and *ambB* was unaltered in *amb* mutants in all conditions tested. Similar occurred in pyocyanin analysis. Moreover, no motility and biofilm defects were noticed. The relationship of the *ambABCDE* genes with IQS production and of the putative IQS signal molecule to QS is therefore unclear.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

VERTICAL AND SEASONAL DISTRIBUTION OF FUNCTIONAL NITROGEN GENES IN A HIGH-ALTITUDE WARM-MONOMICTIC TROPICAL LAKE

S. Pajares[1], M. Merino-ibarra[1], J. Alcocer[2]
[1]Institute of Marine Sciences and Limnology- UNAM, Ecology and Aquatic Biodiversity, Mexico City, Mexico
[2]FES Iztacala- UNAM, Proyecto de Investigación en Limnología Tropical, Mexico City, Mexico

Backgrounds

The N cycle is highly dependent on microbial processes. Distribution of these communities is one of the most important factors in the variation in N cycling in different aquatic ecosystems. However, little is known about the N transformations and their communities throughout the water column in monomictic tropical lakes.

Objectives

We explored vertical and seasonal patterns of the genetic potential for ammonium oxidation (*amoA*), anammox (*hzo*), DNRA (*nrfA*), and denitrification (*nirS, nirK*) through qPCR to assess the importance of the major N-cycling pathways and their relationships with the main limnological variables in Lake Alchichica (a monomictic tropical lake at Central Mexican Plateau).

Methods

Ten depths were sampled during late stratification (November 2015) and mixing (February 2016) periods, covering the epilimnion, metalimnion (oxycline), and hypolimnion layers.

Conclusions

Thermal and oxygen stratification shaped the distribution of functional N genes in this lake. These genes also varied in relation to nutrient conditions and underwent temporal changes throughout the water column. The *amoA* genes were more abundant during the stratification, mainly at the oxycline layer. Denitrifying genes showed strong variations during this period, with highest gene copy numbers at the oxycline and hypolimnion layers. The *hzo* gene was only detected during stratification at the oxycline and hypolimnium layers. Anoxic conditions were characterized by a relative increase in abundance of the *nrfA* gene, which was positively correlated with NH_4^+ concentration. Our findings highlight the importance of oxygen as one of the main factors influencing the genetic potential for N transformations along the water column in monomictic tropical lakes.

BACTERIAL COMMUNITY DIVERSITY OF ARTIFICIALLY SUNKEN WOODS IN THE ANTARCTICA SHED LIGHT ON DEEP SEA LARGE ORGANIC FALLS MICROBIAL BIOGEOGRAPHY

C. Palacios[1], M. Zbinden[2], A.G. Glover[3], T.G. Dahlgren[4], M.L. McCormick[5], C.R. Smith[6]
[1]Université de Perpignan Via Domitia- CEFREM-, CNRS- CEFREM- UMR 5110- F-66860, Perpignan, France
[2]Sorbonne Universités- Univ Paris 06- UMR CNRS MNHN 7208 BOREA, Equipe Adaptation aux Milieux Extrêmes, Paris, France
[3]Life Sciences Department- - London- UK, Natural History Museum, London, United Kingdom
[4]Uni Research- Bergen- Norway, University of Gothenburg- Gothenburg- Sweden, Bergen, Norway
[5]Hamilton College, Clinton, NY, USA
[6]University of Hawaii at Manoa, Honolulu, HI, USA

Backgrounds

Sunken wood falls are vegetal deposits resulting from uprooting during storms and carried by rivers to the oceans. During their journey, this debris becomes waterlogged and, when water occupies more volume than air, this woody material sinks to the ocean floor. Wood falls constitute, with kelp and animal remains, especially whale carcasses, large deposits of organic matter in the deep sea, which are thought to have played a major role in the evolution of chemoautotrophically supported communities at the ocean floor.

Objectives

The purpose of our work was to improve our knowledge on how microbial communities living in wood-fall environments evolve and disperse, what has not yet been fully investigated.

Methods

Wood parcels were artificially submerged during one year in the virtually devoid of wood Southern Ocean (Antarctica). We performed electron microscopy and targeted metagenomic analyses to compare microbes mediating wood degradation and microbial diversity in Antarctic sunken wood with those in other ocean waters where wood falls are naturally present.

Conclusions

Photonic and transmission electron microscopy showed that Antarctic microorganisms were able to degrade wood, with patterns of degradation varying according to wood type, as observed in other oceans. Microbial diversities in wood submerged in anaerobic vs. aerobic sediments differed. Nevertheless, microbial communities in Antarctic sunken wood were phylogenetically similar to those from woods immersed for short time periods in other oceans. Our results demonstrate a high dispersal rate and similar evolutionary origin of microorganisms able to colonize organic falls in the deep-sea ocean floor.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

SHIFTING OF BACTERIAL COMMUNITIES IN MEDITERRANEAN WATERCOURSES WITH GEOGRAPHICAL LOCATION, HYDROLOGICAL REGIMES AND ANTHROPOGENIC FORCING, PARTICULARLY DURING MULTICONTAMINATION PHENOMENA

B. Reoyo-prats[1,2], D. Aubert[1,2], O. Verneau[1,2,3], C. Palacios[1,2]
[1]Université de Perpignan Via Domitia, CEFREM UMR5110, F-66860 Perpignan, France
[2]CNRS, CEFREM UMR5110, F-66860 Perpignan, France
[3]University for Environmental Sciences and Management, North-West University, ZA-2520 Potchefstroom, South Africa

Backgrounds

Mediterranean contrasted climate influences river dynamics and therefore the concentration of micropollutants encountered in freshwaters. In a previous study, we have demonstrated that multipollution phenomena occur during heavy rainfall events. Indeed, during dry periods, contaminants get concentrated in rivers watersheds, while at storm events contaminants get remobilized from soils and sediments or come with combined sewer overflows. Thus, Mediterranean rivers are good natural models to study the impact of pollutants mixtures on ecosystems. Moreover, microorganisms are capable of responding very rapidly to variations in the environment, adapting to them, being therefore potential indicators of pollution stress.

Objectives

In this study, we aimed at understanding how bacterial community' diversity changes with variations in pollutants concentrations in river and littoral waters, particularly during recurrent Mediterranean multipollution phenomena.

Methods

A total of 34 samplings were conducted on a typically Mediterranean coastal watercourse, the Têt River, from upstream to downstream, in a complete drought-flood-drought hydrological cycle along 2013-2014. A high frequency monitoring during the flood (13 samplings) at the most impacted station was also performed. Among physic-chemical parameters measurements, up to 350 contaminants have been analyzed including fecal indicators, nutrients, metals, pharmaceuticals and pesticides. A targeted metagenomics analysis was conducted to study bacterial communities.

Conclusions

Multipollution phenomena had a major impact on bacterial communities, among other changes we observed an increment of the opportunistic phylum Proteobacteria during the flood. In addition, beta diversity varies with seasons and stations, but a remarkable change was observed at the multipollution peak during heavy rain periods.

CHANGES IN ARCHAEAL COMMUNITY STRUCTURE DIVERSITY ALONG WITH VARIATIONS IN POLLUTANTS CONCENTRATIONS IN A TYPICAL MEDITERRANEAN COASTAL RIVER

B. Reoyo-prats[1,2], J. Ezagouri-larra[1,2], C. Palacios[1,2]
[1]Université de Perpignan Via Domitia, CEFREM UMR5110, F-66860 Perpignan, France
[2]CNRS, CEFREM UMR5110, F-66860 Perpignan, France

Backgrounds

Assessing the environmental impact of anthropogenic contaminants in aquatic environments represents a fundamental issue. Micropollutants concentrations in watercourses depend on numerous factors such as land use and rainfall events. Particularly relevant are the contrasting hydrodynamic regimes of droughts and floods at Mediterranean coastal rivers. We have shown that typical heavy rainfalls in these regions are at the origin of multipollution phenomena. In this context, microorganisms attached to suspended solids need a better consideration as markers of aquatic ecosystems reactivity to pollutants because these biofilms are the first to interact with contaminants, degrading or transforming them.

Objectives

In this study, we focused on the impact of contaminants changes on the structural diversity of archaeal biofilms associated to the Têt River, a major coastal watercourse in the South-East of France.

Methods

Water quality measurements, including the analyses of more than 300 micropollutant molecules, were performed from upstream to foreshore waters for a total of 34 samples, in a complete drought-flood-drought hydrological cycle along 2013-2014. A high frequency sampling during the flood (13 samples) at the most impacted station of the Têt River was also carried out. The diversity of archaeal communities attached to suspended matter in these samples was studied using targeted metagenomics analysis on the 16S rRNA gene.

Conclusions

Archaeal communities were composed of two main phyla, Thaumarchaeota and Euryarchaeota. Variations in phylogenetic composition within these phyla were observed among drought versus heavy rainfalls samples. Moreover, an archaeal taxonomic diversification could be directly linked to changes in pollutants levels during heavy rainfalls.

EFFECT OF FOUR DIFFERENT WASTEWATER TREATMENTS IN THE REDUCTION OF ANTIBIOTIC RESISTANCE GENES

R. Pallarés-Vega[1,2], L. Hernández-Leal[3], H. Schmitt[4], D.G. Weissbrodt[2], M.C. van Loosdrecht[2]
[1]Wetsus, Microbiology, Leeuwarden, The Netherlands
[2]Delft University of Technology, Biotechnology, Delft, The Netherlands
[3]Wetsus, Source Separation Sanitation., Leeuwarden, The Netherlands
[4]University of Utrecht., Veterinary Medicine, Utrecht, The Netherlands

Backgrounds

Antibiotic Resistance (AR) is considered a public health threat. Despite it is known to be ubiquitous in nature, there is a great concern of increasing the environmental resistome by spreading anthropogenic Antibiotic Resistance Bacteria (ARB) and Genes (ARGs) into the environment. Wastewater treatment plants (WWTPs) treat fecal residues and are suspected as one of putative hotspots of breed and spread of AR from human sources into aquatic ecosystems. Special attention is brought on their biological process (BP) in which genetic exchange might occur among incoming and indigenous bacterial community.

Objectives

The kind of sludge, the retention time and/or the addition of chemicals might make a difference in the AR removal rate. In order to assess the AR removal efficiency of different treatments, we studied three selected WWTPs harbouring four diverse BP: Two Conventional Activated Sludge (different Phosphorus removal), and a third plant harbouring a paralel treatment (i) AB system and (ii) Nereda.

Methods

Water line samples (24h flow proportional composite) and sludge line samples (grab samples) were collected monthly from all the stages of each WWTPs. Quantification of a panel of 9 relevant ARGs namely *ctxM*, *tetM*, *qnrS*, *sul1*, *sul2*, *mecA*, *ermB*, *vanA and intl1* was conducted by means of qPCR.

Conclusions

Preliminary results showed a high prevalence (10^5-10^6 gene copies/ml) of all the genes in the raw influent except for *mecA* and *vanA*. After treatment, 3logs of reduction were achieved, although some genes as *sul1* remained 10 fold more prevalent. Further data analyses are needed to conclude the differences between the treatments.

ORGANIC ACID PRODUCTION BY FUNGI: COMPARISON ON VARIOUS MEDIA AND EFFECT OF THE INTERACTION WITH BACTERIA

F. Palmieri[1], S. Bindschedler[1], P. Junier[1]
[1]Institute of Biology, Laboratory of Microbiology, Neuchâtel, Switzerland

Backgrounds

In fungi, low molecular weight organic acids (LMWOA) production can have important roles in processes as diverse as pathogenesis, competition, mineral weathering or lignocellulose degradation. More recently, LMWOA have been identified as being involved in the interaction between fungi and bacteria. This is particularly true in the case of oxalic acid, especially in soils. Several factors can influence LMWOA production. One of those is the availability of divalent cations. They trigger LMWOA production either as enzymatic co-factors or as a detoxification mechanism.

Objectives

The aim of this study is to evaluate the production of LMWOA in fungi on different media, in the presence of divalent cations (i.e. Mn^{2+} or Ca^{2+}), as well as bacteria. In this way the effect of cations and interactive bacteria in LMWOA production can be assessed.

Methods

LMWOA production in selected fungi will be confirmed by using various culture media and subsequent acid detection and quantification. Co-cultures of fungi and soil bacteria that interact with fungi will then be performed. LMWOA production will also be assessed chemically and the production of mineral complexes in the presence of divalent cations will be measured with optical microscopy or SEM.

Conclusions

Half of the fungal strains initially screened produced large amounts of organic acids in all media tested. With this study, we can gain new insights concerning the factors influencing LMWOA metabolism in fungi and the effect of those metabolites in the interaction with bacteria.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

EFFECT OF TRICHODERMA BREVICOMPACTUM AND DROUGHT ON STRESS RELATED GENES OF TOMATO PLANTS

D. Panković[1], G. Racić[1], I. Vukelić[1], N. Ćurčić[1], L. Prokić[2]
[1]Educons University, Faculty of ecological agriculture, Sremska Kamenica, Serbia
[2]University of Belgrade, Faculty of agriculture, Zemun, Serbia

Backgrounds

Trichoderma brevicompactum belongs to the *Brevicompactum* clade and it is known for the production of trichothecene-type mycotoxins,phytotoxins and inhibitors of protein synthesis in mammalian cells. Investigations on the effect of *T. brevicompactum* on plants are limited, as compared to those of the other species such as *T. viride* and *T. harzianum*. Moreover, the cross-talk between signaling pathways involved in *Trichoderma* mediated plant response to drought, as the most frequent abiotic stress, is still not clear.

Objectives

The expression of several stress related genes: markers of salicylic acid (SA) signaling pathway, jasmonic acid (JA) pathway and abscisic acid (ABA) related,in tomato root and leaves was examined in response to *T.brevicompactum* treatment only, or in combination with drought stress.

Methods

Tomato plants (Lycopersicon esculentum Mill. cv. Ailsa Craig) were used in this study. *T. brevicompactum* SZMC 22661 suspension was added to the root zone. Effect of *Trichoderma* treatment, on both drought stressed and control plants on the expression of stress related genes in tomato was examined by quantitative reverse transcription real-time polymerase reaction (qRT-PCR).

Conclusions

Analysis of gene expression in tomato leaves and roots, in response to both investigated stress factors- drought and the application of *T. brevicompactum* SZMC 22661, indicates that different signaling pathways are activated in the leaves and roots. Results indicated that SA, JA and ABA signaling pathways are involved in reaction to both introduced stresses. The mutual effect of investigated stresses leads to the modification of gene expression in comparison to the reaction to the single stress.

SELECTIVE NEXT GENERATION SEQUENCING-BASED AUDITING OF PROBLEMATIC MICROBIAL GROUPS IN WATER

A. Paparini[1], E. Lee[1], M. Khurana[1], A. Whiteley[2], P. Monis[3], A. Bath[4], C. Gordon[4], U. Ryan[1]
[1]Murdoch University, Vector- and Water-
Borne Pathogen Research Group School of Veterinary and Life Sciences, Murdoch WA, Australia
[2]The University of Western Australia, School of Earth and Environment, Crawley WA, Australia
[3]South Australian Water Corporation, Australian Water Quality Centre, Adelaide SA, Australia
[4]Water Corporation of WA, Drinking Water Quality Branch, Leederville WA, Australia

Backgrounds

Next generation sequencing (NGS) has rapidly become an invaluable tool for the detection, identification and relative quantification of environmental microorganisms. Universal PCR primers targeting the 16rRNA gene are typically used to perform high-throughput biodiversity assessments. Ideally, this approach is unselective and, by amplifying all taxa with equal efficiency, it aims at collecting genetic– and quantitative–information from all species present in the microbial community.

Objectives

Here, we present two new NGS-compatible primer sets, which are designed to specifically target only potentially problematic microbial groups, during water quality studies.

Methods

The primers were designed from an alignment of 6,513 cyanobacteria 16S rDNA sequences, and NGS was performed by Ion Torrent PGM. Bacterial cultures and heterogeneous types of environmental waters were tested.

Conclusions

Compared to universal primers, in silico and experimental analyses demonstrated that the new primers showed increased specificity for Cyanobacteria and Proteobacteria, allowing increased sensitivity for the detection, identification and relative quantification of toxic bloom-forming microalgae, microbial water quality bioindicators and common pathogens. Significantly, Cyanobacterial and Proteobacterial sequences accounted for ~95% of all sequences obtained within NGS runs (when compared to ~50% with standard universal NGS primers), providing higher sensitivity and greater phylogenetic resolution of key microbial groups affecting water quality. The increased selectivity of the new primers allow parallel sequencing of more samples through reduced sequence retrieval levels required to detect target groups, potentially reducing NGS costs by 50% but still guaranteeing optimal coverage and species discrimination.

COPPER NANOPARTICLES IN SOIL: EFFECT ON MICROBIAL COMMUNITIES AND ATRAZINE DEGRADATION

J. Parada[1], O. Rubilar[2], N. Millahueque[1], M. Martinez[3], G. Tortella[4]
[1]Universidad de La Frontera, Departamento de Ingenieria Quimica, Temuco, Chile
[2]Universidad de La Frontera, Departamento de Ingeniería Quimica, Temuco, Chile
[3]Universidad de Concepción, Departamento de Microbiología, Concepción, Chile
[4]Universidad de La Frontera, Departamento de Ingenieria Química, Temuco, Chile

Backgrounds

Copper nanoparticles (Nano-Cu) have been included on many products due to the antimicrobial effect of copper. However, the potential impact of Nano-Cu on the environment and the possible co-existence with pesticides in soil has not been studied.

Objectives

Therefore, the aim of this study was to evaluate the effect of Nano-Cu combined with atrazine (ATZ) on the soil ability to degrade this pesticide and the consequent impact on soil microbial communities.

Methods

The main activities that were carried out were to pollute soil (Andisol) with increasing concentrations of commercial Nano-Cu (500 and 1500 mg kg^{-1}) and ATZ at field dose (3 mg kg^{-1}). ATZ residual was measured by HPLC to evaluate the ATZ degradation capacity at different time intervals (0, 10, 20 and 30 days). Changes on the structural diversity of soil microbial communities were observed by PCR-Denaturing Gradient Gel Electrophoresis (DGGE), with universal primers (16S and 18S rDNA for bacteria and fungae, respectively). The abiotic impact in soil was evaluated through adsorption-desorption experiments. Copper sulfate ($CuSO_4$) was used as control.

Conclusions

The results showed that Nano-Cu (1500 mg kg^{-1}) affected significantly the ability to degrade atrazine (10-fold reduced after 30 days), and this effect was major than $CuSO_4$. It was also observed a major adsorption of ATZ as the Nano-Cu concentration increased. DGGE patterns demonstrated that microbial community structure remained relatively stable in time when compared to controls. In conclusion, our results demonstrated that Nano-Cu in soil have a negative impact on atrazine degradation capacity potentially related to physical-chemical processes in soil.

ENDOPHYTIC HERBASPIRILLUM SP. AND BURKHOLDERIA TROPICA ISOLATES PROMOTE ALUMINIUM TOLERANCE IN SUGARCANE SEDDLINGS

E. Labanca[1], A.P.D. Silveira[1], E. Kuramae[2], S.A.L. Andrade[3], C.L. Mazzolani[1]
[1]Agronomic Institute, Center of Soil and Environmental Resources, Campinas, Brazil
[2]Netherlands Institute of Ecology NIOO-KNAW, Department of Microbial Ecology, Wageningen, The Netherlands
[3]University of Campinas, Institute of Biology, Campinas, Brazil

Backgrounds

Plant-growth promoting bacteria (PGPB) are known for their ability to increase plant biomass and to improve plant fitness, especially under adverse conditions. Aluminium (Al) induces several disorders in plants such as plasmatic membrane changes, nucleic acids damage, reative oxigen species production and negative impact on nutrient uptake and transport. On the other hand, plants reduce these negative effects by increasing the activity of antioxidant enzymes and the content of proline and phenolics compounds.

Objectives

Two bacteria species (*Burkholderia tropica* and *Herbaspirillum* sp.), isolated from sugarcane roots with PGPB properties were tested in order to evaluate their potencial to enhance the crop capability to cope with Al stress.

Methods

In this study, the two bacteria were inoculated in sugarcane plantlets grown in a soil with high Al content for 32 days.The bacteria-plant interaction resulted in: (1) Increase of the activities of superoxide dismutase, ascorbate peroxidase and peroxidase in roots; (2) High concentration of Al in the shoots; (3) Increment of proline and aromatic amino acids in the leaves; (4) Increase of plant biomass and water content.

Conclusions

Al transport to the shoots, associated with the higher activity of the antioxidant enzymes in the roots, probably alleviated the Al damage to the roots. The increment of aromatic amino acids points to an enhancement in the shikimate pathway, route related to the biosynthesis of several defense compounds. The results suggest that these bacteria species induced sugarcane acclimatation to the Al stress.

DETECTION AND DIVERSITY OF THE NITRITE OXIDOREDUCTASE ALPHA SUBUNIT (NXRA) GENE OF NITROSPINA IN MARINE SEDIMENTS

S.J. Park[1], K. Hyeon-Woo[1], F. Hirotsugu[2]
[1]Jeju National University, Department of Biology, Jeju, Republic of Korea
[2]Waseda University, Department of Life Science and Medical Bioscience, Tokyo, Japan

Backgrounds

Nitrite-oxidizing bacteria (NOB) are chemolithoautotrophs that catalyze the oxidation of nitrite to nitrate, which is the second step of aerobic nitrification. In marine ecosystems, *Nitrospina* is assumed to be a major contributor to nitrification. To date, two strains of *Nitrospina* have been isolated from marine environments.

Objectives

Despite their ecological relevance, their ecophysiology and environmental distribution are understudied owing to fastidious cultivation techniques and the lack of a sufficient functional gene marker. To estimate the abundance, diversity, and distribution of *Nitrospina* in various marine sediments, we used *nxrA*, which encodes the alpha subunit of nitrite oxidoreductase, as a functional and phylogenetic marker.

Methods

In this study, we explored and compared *Nitrospina* diversity in six marine sediments, including samples from both polar regions, using pyrosequencing.

Conclusions

We observed that *Nitrospina* diversity in polar sediments was significantly lower than that of non-polar samples. Moreover, *nxrA*-like sequences revealed an unexpected diversity of *Nitrospina*, with approximately 41,000 different sequences based on a 95% similarity cut-off from six marine sediments. We detected *nxrA* gene copy numbers of up to 3.57×10^4 per gram of marine sediment sample. The results of this study provide insight into the distribution and diversity of *Nitrospina*, which is fundamentally important for understanding their contribution to the nitrogen cycle in marine sediments.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

DUAL-ACTION OF AEROBIC NON-UREOLYTIC AND ANAEROBIC DENITRIFYING LYSINIBACILLUS SP. YS11 FOR CALCIUM CARBONATE PRECIPITATION

Y.S. Lee[1], H.J. Kim[1], W. Park[1]
[1]Korea University, Environmental Sciecne and Ecological Engineering, Seoul, Republic of Korea

Backgrounds

Microbially induced calcium carbonate precipitation (CCP) occurs through different metabolic pathways. Although CCP through ureolysis has been widely considered in environmental engineering fields, urea utilization might cause environmental problems due to production of ammonia and nitrate

Objectives

In this study, several non-ureolytic CCP bacteria that induced alkali pH were isolated from rhizosphere of *Miscanthus sacchariflorus* near artificial stream and their non-ureolytic mechanisms for CCP was investigated

Methods

CCP using phase-contrast microscopy and ion-selective electrode was observed. Only *Lysinibacillus* sp. YS11 has shown dual-action for CCP: aerobic non-ureolytic and anaerobic denitrification. Energy dispersive X-ray spectrometry mapping confirmed the presence of calcium carbonate. Field emission scanning electron microscopy analysis indicated morphologically distinct minerals formation under those conditions.

Conclusions

Resistance in alkali pH and high salt concentrations and spore formation of strain YS11 advocate potential applicability in self-healing concrete. Successive monitoring of growth, pH, and calcium ion using CFU counting, pH meter and ion-selective electrode suggested that strain YS11 was able to induce alkaline condition up to pH 9 and utilize 96% of free Ca^{2+}. It is first to report dual-action of bacteria for CCP under aerobic and anaerobic conditions.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

DEHALOGENIMONAS-DRIVEN 1,2-DICHLOROPROPANE-DEGRADING CONSORTIUM: ESTABLISHMENT AND COMMUNITY ASSESSMENT

E. Parlade[1], S.H. Mortan[2], M. Llirós[1], L. Martín-González[2], G. Caminal[3], E. Marco-Urrea[2], N. Gaju[1], M. Martínez-Alonso[1]
[1]Universitat Autònoma de Barcelona, Department of Genetics and Microbiology, Bellaterra, Spain
[2]Universitat Autònoma de Barcelona,
Department of Chemical Biological and Environmental Engineering, Bellaterra, Spain
[3]Institut de Química Avançada de Catalunya IQAC-CSIC, -, Barcelona, Spain

Backgrounds

Organochlorides are among the main pollutants in aquifers, especially those close to historically contaminated sites, representing a health risk for consumers depending on groundwater supply.

Objectives

The aim of this study is to describe the consolidation process of an anaerobic bacterial consortium with great bioremediation potential due to its metabolic capabilities to transform 1,2-dichloropropane (1,2-DCP) to propene.

Methods

Bacterial community composition and 1,2-DCP degradation rates were determined at three different stages during consortia development using three different molecular techniques (i.e., DGGE, clone libraries, and Illumina sequencing) and gas chromatography, respectively. The abundance of *Dehalogenimonas,* the genus responsible of DCP degradation, was assessed through real-time qPCR along the 19 months of activity.

Conclusions

The consortium in the final stage was clearly dominated by *Dehalogenimonas* and *Azonexus* genera, while other accompanying microorganisms such as *Desulfovibrio*, *Geobacter* or *Sphaerochaeta* exhibited modest concentrations. Enrichment of *Dehalogenimonas* genus was further demonstrated by specific 16S rRNA gene qPCR and ultimately lead to overall higher degradation rates. Our results confirmed a specialized community development in the consortia with potential to maintain the dechlorinating activity in the natural environment. Most of the abundant genera detected are known to supply either essential factors or growth enhancers useful to the organohalide-respiring bacteria. In parallel, comparison among molecular techniques revealed that dominant genera were detected in all tested methodologies and low-abundant sequences remained undervalued in DGGE and clone library approaches.

DEVELOPMENT AND VALIDATION OF A NEW PHYLOGENETIC DNA-MICROARRAY SPECIFIC FOR THE ORAL MICROBIOTA

C. Parolin[1], B. Giordani[1], R.A. Ñahui Palomino[1], E. Biagi[1], M. Severgnini[2], C. Consolandi[2], G. Caredda[2], S. Storelli[3], L. Strohmenger[3], B. Vitali[1]
[1]University of Bologna, Department of Pharmacy and Biotechnology, Bologna, Italy
[2]National Research Council, Institute of Biomedical Technologies, Segrate- Milan, Italy
[3]University of Milan,
Department of Biomedical Surgical and Dental Sciences- ASST Santi Paolo e Carlo, Milan, Italy

Backgrounds

The oral cavity contains hundreds of different microbial species, and their quali-quantitative characterization is crucial for an exhaustive comprehension of the oral ecology. The study of the human oral microbiota and the modifications of the microbial composition that occur during the most common odontoiatric pathologies, such as dental caries, periodontitis and perimplantitis, is of great interest.

Objectives

The objective of the present study was to develop a phylogenetic DNA-microarray, named OralArray, to quickly and reliably characterize the most representative bacterial groups that colonize different sites of the oral cavity in healthy and pathological conditions.

Methods

The OralArray was based on the Ligation Detection Reaction technology associated to Universal Arrays, and includes 22 probe sets targeted to bacteria belonging to the phyla *Firmicutes*, *Proteobacteria*, *Actinobacteria*, *Bacteroidetes*, *Fusobacteria* and *Spirochaete.* The OralArray was tested and validated on different types of oral samples (saliva, lingual plaque, supragingival plaque and healing cap), collected from 10 healthy subjects.

Conclusions

The phylogenetic microarray is characterized by high specificity, high sensitivity (down to 1 ng of PCR product) and a reproducibility of 97.7%. The OralArray was able to detect the microbial signature of different types of oral samples. Our results established the presence of an oral microbial signature specific for each subject, rather than for sample type. Moreover, the molecular tool was employed to evaluate the efficacy of a disinfectant treatment on the healing caps before their usage. The OralArray is thus suitable to study the microbiota associated with various oral sites and to monitor changes arising from therapeutic treatments.

THE VAGINAL MICROBIOME OF HEALTHY, BACTERIAL VAGINOSIS AND CHLAMYDIA TRACHOMATIS-INFECTED WOMEN

C. Parolin[1], C. Foschi[2], L. Laghi[3], B. Giordani[1], V. Gaspari[4], A. D'Antuono[4], R. Cevenini[2], A. Marangoni[2], B. Vitali[1]
[1]University of Bologna, Department of Pharmacy and Biotechnology, Bologna, Italy
[2]University of Bologna,
Department of Experimental Diagnostic and Specialty Medicine- section of Microbiology, Bologna, Italy
[3]University of Bologna, Department of Agro-Food Science and Technology- Centre of Foodomics, Cesena, Italy
[4]University of Bologna,
Department of Experimental Diagnostic and Specialty Medicine- section of Dermatology, Bologna, Italy

Backgrounds

The vaginal microbiota of healthy women is generally dominated by *Lactobacillus* spp., which are known to protect the female genital tract from microbial dysbiosis and pathogen overgrowth. Alterations of the vaginal microbiota composition are found in bacterial vaginosis (BV). Lactobacilli have also been hypothesized to protect women from sexually transmitted diseases, including *Chlamydia trachomatis* (CT) infection, which represents the most common bacterial sexually transmitted infection worldwide. Both BV and CT infection can lead to severe sequelae and complications, including preterm labor and delivery, and tubal infertility.

Objectives

The aim of this study is to analyse the composition of the endogenous microbiota and the metabolic profiles of the vaginal niche in three different conditions: healthy, BV and CT infection.

Methods

Vaginal swabs were obtained from 66 women, belonging to three groups (healthy, BV and CT-infected women). The microbial composition of the samples was determined by using a microarray-based tool (VaginArray) targeting the most representative bacterial groups of the vaginal ecosystem, together with a quantitative real-time PCR for *Gardnerella vaginalis.* The metabolic profiles of the vaginal specimens were assessed by ^{1}H-NMR.

Conclusions

From our results the microbial signature of BV-affected women is clearly different from that found in healthy subjects, CT-infected women are characterized by a microbiota similar to the healthy condition. The metabolomics approach evidenced that BV-samples are characterized by significant variations in organic acids, aminoacids, short chain fatty acids concentrations. CT-infected women metabolome resembles that of healthy subjects, nevertheless significant variations in biogenic amines content were underlined.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

COPPER NANOPARTICLES INTERFERE THE TRANSFERENCE, BY CONJUGATION, OF A PLASMID BETWEEN CUPRIAVIDUS PINATUBONENSIS JPM134 AND PSEUDOMONAS PUTIDA KT2440.

M. Martínez[1], *G. Tortella*[2]
[1]*Universidad de Concepción, Microbiología, Concepción, Chile*
[2]*Universidad de la Frontera, Ingeniería Química, Temuco, Chile*

Backgrounds

In the last decade, engineered nanoparticles (NPs) are being increasingly used in diverse products. Antimicrobial properties of metallic NPs, such as copper (CuNps), have been reported in numerous studies. The toxicity mechanism is generated by the contact of NPs with microbial membranes, causing its disruption, oxidation of its proteins or interruption of energy transduction. Some soil bacteria possess plasmids carrying genes that allow the biodegradation of toxic compounds and they are frequently transferred by conjugation to other bacteria present in soil. In this context, the presence of CuNps could negatively affect the cell-cell contact necessary for this process.

Objectives

The aim of this study was to determine the effect of CuNps on the transference by conjugation of plasmid pJP4, containing genes necessary to degrade 2,4-dichlorophenoxyacetic acid, from *Cupriavidus pinatubonensis* JPM134 to *Pseudomonas putida* KT2440.

Methods

A 9:1 donor: receptor mixture was incubated during 2 h in R2A broth at 30ºC in the presence of CuNps (40-60nm), in a series of subinhibitory concentrations (0, 10, 20, 50, 100, 200 µg ml^{-1}). Transconjugants were selected on R2A agar containing chloramphenicol (40 µg ml^{-1}) and gentamicin (15 µg ml^{-1}). The transference of pJP4 was confirmed by PCR of the *tfd*B gene.

Conclusions

Results indicated that the presence of >50 µg ml^{-1} CuNps caused a significant reduction of conjugation frequency (*c.a*. 90%), from $4{,}4x10^{-6}$ to $5x10^{-5}$ UFC ml^{-1}. Therefore, CuNps may interfere with the transference of plasmids containing genes allowing the biorremediación of toxic compounds, reducing the biodegradative potential of microbial soil communities.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

THE ECOLOGICAL DYNAMICS OF BACTERIAL PRODUCTION OF CADAVERIC SEMIOCHEMICAL MOLECULES DURING MAMMALIAN CARCASS DECOMPOSITION IN SITU

J. Pascual[1], C. von Hoermann[2], A.M. Rottler-Hoermann[2], O. Nevo[2], A. Geppert[1], J. Sikorski[1], K.J. Huber[1], S. Steiger[2], M. Ayasse[2], J. Overmann[1]
[1]DSMZ, Microbial Ecology and Diversity Research, Braunschweig, Germany
[2]Institute of Evolutionary Ecology and Conservation Genomics- University of Ulm, Evolutionary Ecology and Conservation Genomics, Ulm, Germany

Backgrounds

The temporal dynamics of taxonomic and functional shifts of epinecrotic bacteria – major drivers of the decomposition of dead mammalian tissue – are only weakly explored.

Objectives

The main goal of the present study is to identify the systematic temporal changes in bacterial composition and function during the first stages of carcass decomposition. The characteristics of this process may drive other key players of carcass decomposition such as scavenger insects.

Methods

Carcass decomposition was monitored using still-born piglets incubated in different forest ecosystems for 96 hours. High-throughput Illumina 16S rRNA sequencing (bacterial community composition) was combined with gas chromatography-mass spectrometry of individual cadaveric volatiles produced by microbial degradation. The data were analyzed using mono- and multivariate statistics.

Conclusions

The taxonomic composition of epinecrotic bacteria changes over time while simultaneously alpha-diversity increases and beta-diversity decreases, suggesting deterministic and not stochastic processes. The cadaveric volatile compound composition changes similarly, suggesting a significant impact of the bacterial community. The synthesis of acetic acid, indole and phenol could be linked to the activity of *Enterobacteriaceae*, *Tissierellaceae* and *Xanthomonadaceae*, respectively. Based on identified volatiles (acetic acid, indole and phenol) which attract insects, we additionally hypothesize that temporal recruitment of macroscopic scavengers is also driven by bacterial function. This is the first report that attributes the *in situ* synthesis of cadaveric volatile organic compounds to particular types of epinecrotic microorganisms, and thus provides the basis for future further chemical ecology and forensic studies.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

RHIZOSPHERE MICROBIAL COMMUNITY ASSEMBLY IN RESPONSE TO DIFFERENT NUTRIENT INPUTS

F. Paula[1], E. Tatti[1], C. Thorn[1], F. Abram[1], J. Wilson[2], V. O'Flaherty[1]
[1]National University of Ireland- Galway, Microbiology, Galway, Ireland
[2]Monaghan Mushrooms, Research and Development department, Tyholland, Ireland

Backgrounds

The rhizosphere is a highly complex environment in which an array of ecological interactions between plant and microbes takes place. It represents a hotspot supporting microbial communities whose composition may differ from adjacent bulk soil, where nutrients are often limited. Despite the indications that changes in these communities may have implications in plant productivity, it is still unclear how their composition, diversity and turnover are affected by nutrient inputs.

Objectives

We aimed to evaluate how organic *versus* inorganic amendments impacted prokaryotic and fungal community assembly in *Lolium multiflorum* rhizosphere.

Methods

In a soil trial, stabilised spent mushroom compost was applied as sole source of NPK and microbial communities compared to soil treated with mineral fertilizer. Rhizosphere and bulk soil fractions were collected for 14 weeks and the composition of the community was assessed by barcode sequencing targeting the regions flanked by the primers 515F-806R (prokaryote) and ITS3F-ITS4R (fungi). Metaproteomics analysis was carried out to investigate changes in functional diversity.

Conclusions

Microbial community composition was significantly different among treatments, as revealed by taxonomic and functional data. Clear community turnover was observed with time. Increasing diversity was observed in both prokaryotic and fungal communities at later stages of plant development. Moreover, high microbial diversity, but not richness, was associated with high plant productivity. Finally, distinctions between bulk and root associated communities were less evident under organic treatment, in comparison to mineral. This suggests that the large inputs of organic matter may minimize differences in nutrient availability between the two soil fractions.

IDENTIFYING THE SPREAD OF RESISTANT E. COLI ISOLATES IN HOSPITAL AND COMMUNITY SEWAGE AND THEIR RECEIVING SEWAGE TREATMENT PLANT

E. Paulshus[1], K. O'Sullivan[1], I. Kuhn[2], P. Colque-Navarro[2], R. Möllby[2], H. Sørum[1]
[1]Norwegian University of Life Sciences, Department of Food Safety and Infection Biology, Oslo, Norway
[2]Karolinska Institutet, Department of Microbiology- Tumor and Cell Biology, Stockholm, Sweden

Backgrounds

Antibiotic resistance (AR) is a continuingly increasing threat to global health. Certain antibiotic resistant bacteria (ARBs) have previously been found in hospital and urban sewage before the same clones appear among clinical isolates, probably reflecting a low prevalence in the population. Thus, analysis of bacteria in sewage, especially from hospitals, might facilitate an indicator and early warning system for ARBs.

Objectives

We try to identify major sewage outlets with regard to ARBs before high-risk outlets reach the main sewage system. The results will be used to establish proper handling of drug resistant bacteria at certain hot-spots in the sewage system. This may be cost-effective compared to handling all sewage in the major sewage plant with respect to reducing the level of drug resistant bacteria.

Methods

Samples were collected monthly for 18 months from hospital (HS) and community sewage (CS), and from a sewage treatment plant (STP). *E. coli* were selectively cultivated (CHROMagar Orientation, 44°C) and their phenotypic relatedness and AR patterns analyzed using the *PhenePlate-AREB system*.

Conclusions

A total of 7221 *E. coli* isolates have been analyzed so far. Elevated resistance in HS compared to CS was observed towards several antibiotics. HS showed the highest overall resistance to the tested antibiotics (Multiple Antibiotic Resistance (MAR) index = 0.16), followed by CS (MAR = 0.15), whereas the resistance level in STP was lower than in HS and CS for all antibiotics tested (MAR=0.09). This indicates a dilution effect of the ARBs before they reach the STP.

PATHOGENIC E. COLI: NEW INSIGHTS INTO THE REGULATION AND INHIBITION OF BACTERIAL AGGREGATION/BIOFILM FORMATION

J. Paxman[1], A. Lo[2], S. Panjikar[3], T. Wang[1], C. Darmanin[4], M. Schembri[2], B. Heras[1]
[1]La Trobe Institute for Molecular Science, Biochemistry and Genetics, Melbourne, Australia
[2]The University of Queensland, Australian Infectious Diseases Research Centre, Brisbane, Australia
[3]Australian Synchrotron, Macromolecular Crystallography, Clayton, Australia
[4]La Trobe University, ARC Centre of Excellence in Advanced Molecular Imaging, Melbourne, Australia

Backgrounds

The self-associating autotransporters (SAATs) are a group of glycosylated proteins from widespread *E. coli* pathogens that are transported to the cell surface by the type V secretion pathway. These virulence factors have central roles in bacterial aggregation and biofilm formation, which are important attributes for colonisation and persistence, which is extremely relevant to the areas of bacterial pathogenesis, nonsocomial infections and food sanitation. We recently elucidated the mechanism by which the SAAT Antigen43 from uropathogenic *E. coli* (UPEC) promotes bacterial aggregation/biofilm formation, by means of self-association between neighbouring cells[1].

Objectives

We sought to determine if all SAATs shared a common mechanism for facilitating bacterial aggregation/biofilm formation, if this function was regulated and if it could be inhibited.

Methods

The SAAT TibA from enterotoxigenic *E. coli* (ETEC) was known to be glycosylated by the TibC glycosyltransferase. We determined the crystal structures of the glycosylated and unglycosylated forms of TibA and used this to inform further biophysical and phenotypic studies. We found that TibA self-associates similarly to that of Antigen43 to facilitate bacterial aggregation/biofilm formation, but with a more extensive interface. Glycosylation by TibC was found to physically block TibA self-association to reduce bacterial aggregation/biofilm formation. We are now developing specific inhibitors for SAAT mediated aggregation/biofilm formation and have determined the first Antigen43-inhibitor crystal structure.

Conclusions

In summary, we have used our 3 new autotransporter crystal structures to inform the mechanism of SAAT mediated bacterial aggregation/biofilm formation, to elucidate how glycosylation regulates SAAT function and to develop a strategy to block these virulence processes.

PHYTOPLANKTON IDENTIFICATION WITH CHEMOTAXONOMIC BIOMARKERS: IN COMBINATION THEY MAY DO BETTER

E. Peltomaa[1], M. Tossavainen[1], S. Taipale[2]
[1]University of Helsinki, Environmental Sciences, Lahti, Finland
[2]University of Jyväskylä, Biological and Environmental Science, Jyväskylä, Finland

Backgrounds

The composition of phytoplankton community is important when defining aquatic production, since phytoplankton synthesize many taxon-specific biomolecules, which consumers cannot synthesize *de novo*. Chemotaxonomic biomarkers are needed for monitoring phytoplankton communities and the nutritional quality of seston for upper trophic levels.

Objectives

Whereas the fatty acid and pigment profiles of phytoplankton are known to be mainly taxon-specific, sterols have not been successfully established as chemotaxonomic biomarkers. Neither have all these three been used concomitantly for the characterization of phytoplankton communities in nature. Here we studied the suitability of the combination of fatty acids, sterols and carotenoids as chemotaxonomic markers using multivariate statistics.

Methods

Our analysis included 40 phytoplankton strains from 10 classes isolated from freshwater lakes. The fatty acid and sterol analysis were conducted with GC-MS, whereas carotenoids were analyzed with HPLC.

Conclusions

We were able to detect altogether 47 fatty acids, 29 sterols and 13 carotenoids in our samples. As expected, fatty acids and carotenoids differed on class-level, but sterol composition was more heterogeneous within class and did not improve the class-level separation. However, sterols provided additional information on the abundance of specific genera within a class. GC-MS analysis could not separate cyanobacteria from algae due to their high variation in fatty acid composition and the absence of sterols, but when adding carotenoids to PCA, cyanobacteria clustered better together than when using only fatty acids and sterols. We conclude that the accuracy of phytoplankton identification can be significantly improved by combining these three groups of chemotaxonomic biomarkers

CITRUS MICROBIOMES: THE UNTAPPED DIVERSITY AS A SOURCE TO MINE FOR BENEFICIAL MICROBES

R. Penyalver[1], M.A. Forner-Giner[2], L.F.W. Roesch[3]
[1]Instituto Valenciano De Investigaciones Agrarias Ivia, Centro De Proteccion Vegetal Y Biotecnologia, Moncada, Spain
[2]Instituto Valenciano De Investigaciones Agrarias Ivia, Centro De Citricultura Y Produccion Vegetal, Moncada, Spain
[3]Universidade Federal Do Pampa Unipampa, Cip-biotech, Sao Gabriel, Brazil

Backgrounds

Citrus are the most cultivated fruit crop worldwide. Commercial citrus trees are grafted plants, where rootstocks are the hub of the most importantly horticultural and pathological traits. Mutualistic microbes present in root-associated communities (rhizospheric plant microbiome) have a great impact on host physiology and health, then providing a potential source of a variety of benefits for their host.

Objectives

The present study was devoted to stablish (i) the structure, variation and assembly of the rhizospheric citrus microbiome of two rootstock genotypes; and (ii) a prevalent "core-citrus" microbiome, as well as, to identify "genotype-specific" members.

Methods

Exploring citrus microbiota for beneficial microbes is the first step to develop future biotechnological applications for citrus industry. However, to carry it out successfully, it is crucial to capture as much as possible bacterial diversity. Therefore, metagenomic approaches are used to uncover the broad diversity of plant-associated communities. Previous studies on rhizospheric citrus microbiota were done elsewhere, but as far as we know, this is the first study of citrus microbiomes based on deep sequencing of 16S rRNA gene amplicon libraries (metataxonomics). Here, we present a detail characterization of the ectorhizosphere-associated microbiome of two agronomically-distint citrus rootstock genotypes grown in one soil for over 20 years.

Conclusions

We not found a significant genotype-dependent fine-tune of bacterial communities, since any citrus rootstock genotype selected an specific bacterial community. Nevertheless, some differentially abundant "operational taxonomic unit" OTUs were found in higher proportions in one genotype, suggesting that this citrus rootstock genotype has higher affinity for certain bacteria. We identifed a prevalent "core-citrus" microbime comprisig 544 OTUs as highy citrus-adpated bacterial members selected by the host. In summary, the untapped diversity of rhizospheric citrus microbiomes has provided a potential source to mine for plant beneficial microbes.

CELL BOUND PROTEINS P40 AND P75 ARE MULTIFUNCTIONAL MURAMINIDASES TYPICALLY FOUND IN THE LACTOBACILLUS CASEI/PARACASEI/RHAMNOSUS TAXON

G. Abitayeva[1], S. Sosa Carrillo[2], A. Mencher Beltran[3], N. Navarro Lleo[3], J.M. Coll[3], C. Bäuerl[3], G. Perez Martinez[3]
[1]L.N. Gumilyov Eurasian National University, Department of Natural Sciences, Astana, Kazakhstan
[2]Center for Research and Interdisciplinarity CRI, Center for Research and Interdisciplinarity, Paris, France
[3]Instituto de Agroquímica y Tecnología de Alimentos CSIC, Food Biotechnology, Paterna, Spain

Backgrounds

Lactobacillus casei proteins p40 and p75 (CmuA and CmuB) belong to a large family of cell wall proteins that contain a carboxy(C)-terminal CHAP or NLPC/P60 domain and with a variety of biological functions related to the nature of their amino(NH)-terminal domain. In Firmicutes they are frequently found secreted in the medium or bound to the cell wall with autolysin/muraminidase activity.

Objectives

The aim of this work was to study the Phylogeny and dissemination of this family of proteins and their likely (eco)physiological role.

Methods

Initially, PCR for specific conserved regions in their genes and western blot assays with polyclonal antibodies against their non-conserved NH-terminus regions of p40 and p75 showed that their presence is very specific of the taxon *L. casei/paracasei/rhamnosus*. Under laboratory conditions, these proteins had been found attached to the cell wall and also secreted in the culture medium. Using the mentioned antibodies, their presence was also detected in fermented milk commercial products that contained probiotic strains of *L.casei*. In order to partially explain their mode of action from the outer side of the cell wall, his-tag purified soluble proteins were used to complement satisfactorily p40 and p75 deficient mutants, and they also showed a significant cell lysis activity on different Firmicutes like, *Staphylococcus aureus, Enterococcus faecalis* and *Listeria monocytogenes*.

Conclusions

Results indicate p40 and p75 are found only in *L.casei/paracasei/rhamnosus* taxon and these secreted proteins can mediate the correct conformation of the cell wall, their presence in the extracellular medium may result in a competitive advantage.

THE SPERMOSPHERE EFFECT: BUILDING UP PLANT MICROBIOME ASSEMBLY

J.E. Pérez-Jaramillo[1], V.J. Carrión[1], M. de Hollander[1], R. Mendes[2], J.M. Raaijmakers[1]
[1]Netherlands Institute of Ecology NIOO-KNAW, Microbial Ecology, Wageningen, The Netherlands
[2]Embrapa Environment, Laboratory of Environmental Microbiology, Jaguariúna, Brazil

Backgrounds

Plants have a significant influence on the diversity and activity of soil microbial communities. During imbibition and germination, plant seeds release chemically diverse exudates thereby promoting microbial activity in the zone surrounding the seed, also referred to as the spermosphere. To date, little is known about the diversity and activities of microbial communities in the spermosphere and how this short-lived plant developmental stage affects microbiome assembly.

Objectives

Here, we deciphered the magnitude of the spermosphere effect for two different food crops, i.e. tomato and bean. More specifically, we investigated if a plant genotype-dependent influence is discernible in the spermosphere and to what extent the spermosphere microbiome relates to the rhizosphere microbiome.

Methods

We selected wild and modern accessions of tomato and common bean for which strong differences in the rhizosphere microbiome were found in previous studies.

Conclusions

Community profiling of the spermosphere revealed a decrease of α-diversity of all crop accessions as compared to the bulk soil. Similarly, a significant difference in the β-diversity was observed between bean accessions and bulk soil. Bacteroidetes, Firmicutes and Proteobacteria were the bacterial phyla that consistently responded to the seed germination and were significantly more abundant in the spermosphere. Albeit small, significant differences in the β-diversity were detected between wild and modern crop accessions, suggesting a plant genotype-dependent effect already at this early developmental stage. If and how seed exudates are the main driver of the differences in spermosphere communities between the wild and modern crop accessions is currently under investigation.

BACTERIAL COMMUNITIES AMPLICON PROFILES MODELLING BY MARKOV CLUSTERING AND NEURAL NETWORKS. DEFINING REFERENCE ANNOTATION SIGNATURES

D. Pérez-Villarroya[1], *A. Moya*[2,3,4], *G. D'Auria*[1,3]
[1]*FISABIO-Public Health, Sequencing and Bioinformatics Service, Valencia, Spain*
[2]*FISABIO-Public Health, Genomics and Health Area, Valencia, Spain*
[3]*Centro de Investigación en Red en Epidemiología y Salud Pública, CIBEResp, Madrid, Spain*
[4]*Institut Cavanilles de Biodiversitat i Biologia Evolutiva ICBiBE- Universitat de València, Evolutionary Genetics Unit, Valencia, Spain*

Backgrounds

Association studies between taxonomy contingency tables and related metadata describing the origins or the state of the samples, are commonly carried out inferring statistical models. This process is usually carried out in a closed framework where only subject samples are statistically described in terms of case vs controls, physiological conditions, environmental/metabolic differences, etc.. While more and more amplicon surveys as well as metagenomic datasets are made available from almost all known environments, multiple sample comparisons methods and platforms become a hot issue to resume and categorize datasets towards biological comprehension.

Objectives

We can use already published and/or new datasets to create annotation profile models by the mean of supervised machine learning techniques. Thus, we can then classify new samples on the basis of the proper annotation signatures.

Methods

In this work we employed unsupervised Markov cluster algorithm (mcl) to enrich authors provided metadata with formal samples categories. Neural networks (NNt) supervised machine learning techniques are then used to generate models from 16S taxonomy distributions suitable for further *de-novo* samples classification.

Conclusions

We found that using samples metadata coupled with mcl algorithm to define formal categories improve the NNt modeling showing higher sensitivity and specificity to classify samples. The combination of mcl and NNt is a powerful approach to create databases of profile-models for further classification of new samples enriched with new profiles when the issued sample is not recognized.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

CHARACTERIZATION OF BACTERIA ISOLATED FROM PROPOLIS

E. Casalone[1], F. Vitali[1], R. Alberti[1], I. Petrocelli[1], B. Perito[1]
[1]University of Florence, Department of Biology, Sesto Fiorentino Florence, Italy

Backgrounds

Propolis, an ancient natural remedy with antimicrobial and other therapeutic properties, is a resinous material derived by worker bees from the leaf buds and exudates of numerous trees. Bees used it to cover hive walls, seal openings and embalm invader insects, then contributing to the hive hygiene. Despite many studies recently done on microbiota of the hive system, especially of adult bee gut, very little is known about microbiota of propolis and its contribution to the hive health.

Objectives

First objective is to verify the presence of viable bacteria into propolis and identify them; secondly we want to investigate if bacteria would play any role in therapeutic properties of propolis. Here we report a preliminary study on the isolation and characterization of bacteria from propolis collected from the apiary of our Department.

Methods

We set up a method for recovering prokaryotic cells from propolis and isolated them by standard microbiological procedures. Isolated microorganisms were classified on the basis of colony and cellular morphology. Morphotypes were tested for their growth and antimicrobial properties, and identified by 16S rDNA analysis.

Conclusions

By analysing different samples of propolis we obtained up to 10^3 CFU/gram of propolis. Nineteen different bacterial morphotypes were recognized. Representatives for each morphotype differ in their spectrum of antimicrobial activity against Gram positive and Gram negative bacteria, and fungi, and in their ability to grow on aqueous extract of propolis as the only carbon source. Isolates identification is in progress.

BACTERIAL PROLIFERATION AS AN ADAPTIVE STRATEGY UNDER STARVATION

O. Petrova[1], V. Gorshkov[1,2], A. Daminova[1], M. Ageeva[3], I. Sergeeva[4], E. Kovtunov[1], N. Gogoleva[1], Y. Gogolev[1,2]
[1]Kazan Institute of Biochemistry and Biophysics - RAS, Laboratory of Molecular Biology, Kazan, Russia
[2]Kazan Federal University, Biochemistry and Biotechnology, Kazan, Russia
[3]Kazan Institute of Biochemistry and Biophysics - RAS, Laboratory of Microscopy, Kazan, Russia
[4]Kazan Federal University, Genetics, Kazan, Russia

Backgrounds

To adapt to adverse conditions, bacteria stop their growth to divert resources in order to promote survival. The adaptive reactions are known to be controlled at the population level in cell density-dependent manner. Herewith, the way of bacterial adaptation at low population densities remained unknown.

Objectives

We attempted to clarify if bacteria are able to adapt to stress conditions at low population densities and if so, to characterize the specific features of such kind of adaptation.

Methods

Various wild type and mutant gram-negative and gram-positive bacteria were subjected to carbon (or nitrogen) starvation at high (10^6-10^9, above quorum level) and low (10^1-10^5, below quorum level) population densities and the resultant model cultures were monitored by means of CFU and genome copy counting, electron microscopy, gene expression analysis and assessed for their resistance to various stress factors (cross-protection effect).

Conclusions

Bacteria are able to adapt to starvation at low population density; herewith, the initial part of stress response is related to cell proliferation until the population density reaches 1 million cells/ml – the value at which intercellular communication as well as stringent response was induced. Herewith, the cells acquired specific morphology different from that of the cells starved at high density. As a result of adaptation, cells that starved at low density same as those starved at high density acquired cross-protected phenotype, e.g. became resistant to multiple stressors. Thus, depending on population density bacteria realize alternative adaptive strategies that enable their survival under stress conditions. This study was supported by RSF (15-14-10022).

NOVEL ACETOBACTERIUM MALICUM STRAIN CAPABLE OF USING METALLIC IRON AS SOLE ELECTRON DONOR

J. Philips[1], E. Monballyu[1], S. Georg[1], K. Rabaey[1], J.B.A. Arends[1]
[1]Ghent University, Center for Microbial Ecology and Technology CMET, Ghent, Belgium

Backgrounds

Some microorganisms are capable of using metallic iron as electron donor. These strains cause severe corrosion to metallic structures, but can also have interesting biotechnological applications. Microbial electrosynthesis (MES) is an innovative technology to convert electrical power into biofuels. MES depends on homoacetogens capable of deriving electrons from a cathode to reduce carbon dioxide to acetate. Both metallic iron and a cathode are solid state electron donors, therefore, the use of metallic iron as electron donor for enrichments and isolations seems a promising strategy to obtain novel strains for microbial electrosynthesis.

Objectives

The goal of the presented work was to isolate acetogenic strains using metallic iron as electron donor from environmental rust samples.

Methods

The rust layer of metallic garbage present in a local river was scraped off and used to set up enrichments. Metallic iron particles were added as sole electron donor and methanogenic growth was inhibited. Isolation was performed using agar plates containing iron powder.

Conclusions

Most isolates were strongly related (99%) to *Acetobacterium malicum*. The new strain produces acetate 50 faster times (electron equivalent base) compared to hydrogen evolution due to abiotic corrosion. Consequently, this strain must have a mechanism for direct electron uptake or to enhance abiotic hydrogen evolution. Insights into the electron uptake mechanisms, as well as its capacity for microbial electrosynthesis will be presented. The study of this novel *Acetobacterium malicum* strain leads to new insights into biocorrosion and extracellular electron uptake mechanisms that can contribute to the improvement of microbial electrosynthesis.

ENHANCED MICROBIAL GROWTH AND METABOLISM IN PRESENCE OF SUSPENDED MINERAL PARTICULATES AND PROPOSED MECHANISMS

F. Picardal[1], *T. An*[1]
[1]*Indiana University, School of Public and Environmental Affairs, Bloomington, USA*

Backgrounds

Microbial interactions with fine inorganic particles in heterogeneous environmental systems can positively or negatively affect microbial growth and metabolism.

Objectives

We systematically examined mechanisms to explain observed microbial growth enhancement by particles.

Methods

We investigated the effects of hydrous ferric oxide (HFO) and Min-U-Sil 5, a high-purity silica, on *Acidovorax* sp. 2AN growth in batch cultures.

Conclusions

These micron- and submicron-sized particles stimulated growth and substrate utilization of strain 2AN in both oxic and anoxic cultures, although inhibition was initially observed with HFO. When grown anaerobically on acetate and nitrate in the presence of 1 mM HFO, final protein concentrations were 24.6% higher with HFO, compared to cultures lacking HFO, although 2AN is not an Fe(III)-reducer. Compared to non-amended controls, anaerobic growth in the presence of Min-U-Sil 5 was more rapid and 16% more protein was produced at the end of the experiment. Under aerobic conditions, protein concentrations were 15% and 13% higher in cultures with Min-U-Sil 5 and HFO, respectively, than in controls lacking particulates. Strain 2AN also formed more pili when grown with Min-U-Sil 5 than in its absence. Growth enhancement did not result from particulates serving as an electron acceptor, nutrient source, or pH buffer. Enhanced growth and metabolism was also not due to surface-charge-associated changes in proton motive force and increased ATP generation. The stimulatory effect may be the result of greater microbial access to sorbed substrates or a more generalized effect on gene expression, as evidenced by increased pili formation during particulate-cell association.

[4]Syndial S.p.A, Environmental Business Services,
Piazza M. Boldrini- 1 – 20097 S. Donato Milanese- Milan, Italy

Backgrounds

Bacterial communities associated with contaminated sites represent a great opportunity for environmental bioremediation considering that bacteria are able to use a wide number of chemical compounds as a source of carbon and energy. The use of an integrated approach based on different methodologies to gather more information about site-specific potential for bioremediation is gaining a wider acceptance from public authorities.

Objectives

The main objective of our work was to define quantitative indicators to assess the intrinsic degradation potential of a Monochloroebenzene (MCB)-contaminated aquifer by the use of a “toolbox” based on isotopic and molecular biology analyses.

Methods

Microcosms with groundwater collected from a MCB-contaminated site were set up under aerobic and anaerobic conditions to simulate both natural attenuation and biostimulated degradation processes. Enrichment factors for ^{13}C were determined by Compound Specific Isotope Analysis (CSIA). High-throughput sequencing (Illumina) and Ion Torrent analysis and quantitative PCR were performed to gain insights on the structure of the microbial community and to identify functional biomarkers.

Conclusions

MCB was completely depleted upon addition of nutrients, in both the conditions. Concerning aerobic biodegradation, CSIA results confirmed negligible C isotope fractionation under oxidative conditions. The gene *tod*, coding for toluene dioxygenase and *Pseudomonas* genus were identified as molecular and taxonomic marker, respectively. Moreover, preliminary results indicate that the anaerobic degradation of MCB is not linked to *Dehalobacter* or *Dehalococcoides* driven reductive dechlorination. On-going experiments suggest that the involved genes share considerable sequence homology with genes present on the plasmid pBHB of *Comamonas sp.*

FLUORESCENCE REPORTER GENE PLATFORM APPLICABLE FOR THE DETECTION AND QUANTIFICATION OF HORIZONTAL GENE TRANSFER IN ANOXIC ENVIRONMENTS

R. Pinilla[1], *S. Sørensen*[1], *L. Riber*[1]
[1]*University of Copenhagen, Biology Microbiology Section, København, Denmark*

Backgrounds

The study of horizontal gene transfer (HGT) in microbial communities has been revolutionised by advances in cultivation-independent methods based on fluorescence reporter-gene technologies. However, the use of fluorescent markers like green fluorescent protein (GFP) and mCherry is limited by environmental constraints that affect the correct maturation of their fluorophores, such as oxygen availability and pH levels. Few studies have focused on elucidating their impact, and the sheer amount of distinct protein variants requires each system to be examined in an individual fashion. The wealth of ecologically and clinically relevant oxygen-deprived micro-habitats in which bacteria thrive, calls for the urgent development of suitable tools that permit their study.

Objectives

Development of an aerobic fluorescence recovery method for mCherry and GFPmut3, as well as characterisation of the impact the pH has on their fluorescence intensities. Validation of the dual-labelling system for the study of HGT in anoxic milieus.

Methods

The time-course fluorescent recovery of mCherry and GFPmut3 *in vivo*, as well as the effect of the extracellular pH on fluorescence was monitored through flow cytometry. The applicability of the findings was validated in anaerobic filter mating experiments.

Conclusions

The findings present a solution to an intrinsic problem that has long hampered the utilisation of this system to study HGT in environments devoid of oxygen, highlight its pH limitations, and provide the experimental tools that will help broaden its horizon of application to other fields.

FEMS7-0466
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

METAVIR-ALP: ALPINE LAKES BENTHIC VIRAL COMMUNITY STRUCTURE AND DIVERSITY: A METAGENOMIC AND ECOLOGICAL APPROACH. A PILOT STUDY.

F. Pinto[1], N. Salmaso[2], N. Segata[1]
[1]University of Trento, CIBIO, Trento, Italy
[2]Fondazione Edmund Mach, Sustainable ecosystems & bioresources, San Michele all' Adige, Italy

Backgrounds

After three decades since the first virus-like particles (VLP) were observed, the viral role in aquatic ecosystems is becoming clearer. By impacting bacterial communities, viruses influence evolutionary dynamics, mineralisation processes, energy transfer across trophic levels and greenhouse gas emission. Nonetheless, virus in freshwater systems are yet a neglected component.

Objectives

The MetaVir-Alp project proposes a multidisciplinary approach combining metagenomics, microbiology, and advanced computation to characterise the genetic diversity, structure and function of viral and bacterial communities in lakes sediment and water. Several Alpine lakes will be investigated along an altitudinal gradient that mimics a natural temperature gradient.

Methods

In this pilot investigation, we reported the taxonomic, genotypic and functional diversity of the viral and bacterial community within one Alpine lake. We established a well-defined protocol for sample collection and preparation in order to get the best yield of the extracted viral genetic material from sediments. Water at three depths and different aliquots of sediments were collected at Caldonazzo Lake and processed separately. Bacterial and viral DNA were subjected to Illumina HiSeq 2000.

Conclusions

Results provided novel insights into the viral and bacterial genetic diversity of freshwater ecosystems. We also observed substantial variability of the community structure and diversity along the vertical environmental gradient, in the water column and sediments. This pilot study was crucial for the development of the MetaVir-Alp project where microbial diversity will be investigated over a temporal and altitudinal dimension to appraise the potential influence of anthropogenic impacts and global warming on Alpine lakes.

DIVERSITY OF FUNGAL COMMUNITIES IN DEAD LOGS: EFFECTS OF FOREST STRUCTURE AND SUBSTRATE QUALITY IN FOUR UNMANAGED ITALIAN FORESTS

S. Pioli[1], A. Bani[1], L. Borruso[1], L. Brusetti[1], R. Tognetti[2]
[1]Free University of Bolzano, Faculty of Science and Technology, Bolzano, Italy
[2]Università del Molise, Biosciences and Territory, Pesche, Italy

Backgrounds

Wood-inhabiting fungi are considered the major decomposers of organic matter in forest environments playing a crucial role for the maintenance of critical ecosystem processes. Despite their importance, very few studies have investigated wood-inhabiting fungi with molecular techniques, especially in Southern Europe.

Objectives

In our study, substrate quality along with stand structural attributes and ecological parameters were used to disentangle the relationships between habitat characteristics and fungal community structure.

Methods

Along the Italian peninsula, we collected dead wood samples from four forest reserves that differed in species composition, management history and successional stage. The fungal community was investigated through fingerprinting analysis while wood physical properties and stand features were assessed in the field. In addition, lignin, carbon and nitrogen content were analysed for each sampled wood.

Conclusions

Our results revealed an influence of stand structural characteristics in differentiating the fungal communities across the reserves, in particular, in relation to dead wood volume and living trees species diversity. Moreover, the mean annual temperatures exerted a major role compared to other climatic variables (i.e. precipitation), while only C:N ratios, decay stage and wood diameter resulted significantly correlated with the overall community structure regarding wood characteristics. We conclude that forest structural and compositional heterogeneity have strong effect on communities of decomposer fungi, suggesting that the promotion and conservation of complex ecosystems, with different tree species and great dead wood availability, is essential for the preservation of fungal diversity and forest functioning.

ECOLOGY OF LISTERIA MONOCYTOGENES IN SOIL: EFFECT OF THE BIOTIC ENVIRONMENT ON SURVIVAL AND TRANSCRIPTOME RESHAPING.

L. Gal[1], A. Ortiz Camargo[2], D. Garmyn[3], P. Piveteau[4]
[1]AgroSup Dijon, INRA UMR1347 Agroécologie, Dijon, France
[2]Univ. Bourgogne Franche Comté, INRA UMR1347 Agroécologie, Dijon, Colombia
[3]Univ. Bourgogne Franche Comté, INRA UMR1347 Agroécologie, Dijon, France
[4]Univ. Bourgogne Franche Comté, INRA UMR1347 Agroécologie, France, France

Backgrounds

Listeria monocytogenes is a bacterium found in many habitats such as soil, plants, animals, foodstuff and food processing facilities. Circulation between habitats is a source of its transmission to food and eventually to the consumer. Contaminated foodstuff is indeed the vector of listeriosis, a life-threatening disease mainly to immunocompromised people and pregnant women. One of the intriguing facets of *Listeria monocytogenes* is its ability to adapt its physiology to complex, heterogeneous habitats. With its complex chemistry, texture, dense microbiota and overall biotic fraction, soil is a nice example of such heterogeneous habitat. Persistence in many habitats suggests that *L. monocytogenes* is able to integrate a range of environmental cues in the circuitry of regulation of transcription.

Objectives

This study aimed at assessing in one hand extrinsic factors that shape the fate of *L. monocytogenes* in soil, and in the other hand the response of *L. monocytogenes* to the biotic environment found in soil.

Methods

The response of *L. monocytogenes* EGD-e to the biotic fraction of soil was investigated in irradiated and untreated microcosms through a combination of transcriptomic approaches and population dynamics.

Conclusions

The fate of *L. monocytogenes* is dependent on both abiotic and biotic characteristics and the latter have a major impact on the dynamics of the populations of *L. monocytogenes* in soil. Major transcriptome reshaping was observed where *L. monocytogenes* recruits its repertoire of transporters and specific pathways to access and utilise the available substrates. The biotic environment further affects transcriptome and triggers further regulation.

CHOLESTEROL CONVERSION INTO COPROSTANOL BY BACTERIAL STRAINS ISOLATED FROM THE HUMAN GUT MICROBIOTA CAN MODIFY HOST CHOLESTEROL METABOLISM

A. Potiron[1], A. Kriaa[1,2], S. Boudebbouze[1], A. Bruneau[1], M. Lhomme[3], P. Lesnik[3], E. Maguin[1], P. Gérard[1], M. Rhimi[1]
[1]INRA-Institut National de la Recherche Agronomique, MICALIS, Jouy en Josas, France
[2]LBPPE, Centre de Biotechnologie, Sfax, Tunisia
[3]INSERM, UMR S939, Paris, France

Backgrounds

Cholesterol level management is a keystone to limit cardiovascular diseases. Gut microbiota has emerged as a new target to modulate host metabolism including cholesterolemia. In fact, the transformation of cholesterol into coprostanol by intestinal microorganisms was reported almost one century ago. Interestingly, human feces analyses revealed two sub-populations: i) high-converters –HC– subjects showing a complete or almost complete conversion of cholesterol to coprostanol and ii) low-converters –LC– individuals showing no or low conversion level. We confirmed this distribution on a human cohort. However, the impact of this gut bacterial metabolism on blood cholesterol remains unclear. Only one cholesterol-converting bacterial strain has been isolated from human feces.

Objectives

Our objective was to isolate new coprostanol-producing bacteria and to evaluate *in vivo* their potential impact on cholesterolemia.

Methods

We isolated 27 new cholesterol-converting bacteria from HC feces using different cholesterol-supplemented culture media. Five bacteria were selected on their coprostanol production features, growth rate and biomass production. Two were retained for their abilities: i) to colonize germ-free mice gastro-intestinal tract and ii) to produce coprostanol *in vivo*. Germ-free mice associated with these bacterial strains will receive a cholesterol-enriched diet for 10 weeks. Cholesterolemia and *in vivo* production of coprostanol will be followed as well as expression of genes involved in cholesterol metabolism and inflammation.

Conclusions

We expect that these bacterial strains may limit the increase in cholesterolemia thanks to cholesterol-to-coprostanol conversion in the gut.

BIODEGRADATION AND DETOXIFICATION OF NICOSULFURON HERBICIDE BY NEW ISOLATE OF PSEUDOMONAS SP. IN A CONTAMINATED AGRICULTURE SOIL

A.A. Pourbabaee[1], *A. Solymani*[1], *H. Alizadeh*[2]
[1]*University College of Agriculture and Natural Resources- University of Tehran, Soil Science, Karaj, Iran*
[2]*University College of Agriculture and Natural Resources- University of Tehran, Department of Agronomy and Plant Breeding, Karaj, Iran*

Backgrounds

Nicosulfuron, a selective systemic herbicide from the sulfonylurea group, is used as post emergence for controlling weeds in corn fields.

Objectives

To being toxicity due to inhibitory effect on acetolactate synthetase enzyme, persistence of the herbicide residues in soil, and its adverse effects of the herbicide, this research were aimed to study the biodegradation and detoxification of it by bacterial isolates.

Methods

In this study, ten bacterial strains from the soil treated with herbicide during several years were isolated and screened on mineral base medium. Among ten isolated assayed for detoxification activity, the strain B9 was the most effective isolate and was chosen as the superior strain. Based on 16S rRNA sequence analysis and phenotypic characteristics, the isolate B9 was closely (96%) related to *Pseudomonas aeruginosa* BWH05. The effect of the herbicide on some biological traits in soil was measured. These traits were increased in less time in soil treated with herbicide as compared to non-inoculated soil.

Conclusions

Results of obtained from assay of nicosulfuron concentration in liquid medium by HPLC analysis showed that B9 isolate could reduce nicosulfuron concentration up to 61% and 90% for 5 and 30 days respectively at 30˚C . The results of experiments Petri dish and greenhouse bioassay of treated herbicide by B9 isolate on *Lepidium sativum* showed that this strain was able to detoxify and significantly reduced the inhibition effect of the herbicide. Therefore, this isolate can be used for removal of herbicide residues in contaminated soils.

REMEDIATION OF PHENANTHRENE FROM A SALT- AFFECTED SOIL IN MICROCOSM SYSTEM BY CONSORTIUM OF HALOTOLERANT BACTERIA

A.A. Pourbabaee[1], *N. Hashemi*[1], *M. Farahbakhsh*[1], *G. Bagheri marandi*[1]
[1]*University College of Agriculture and Natural Resources- University of Tehran, Soil Science, Karaj, Iran*

Backgrounds

Salinity is one of the major problems for bioremediation of petroleum-contaminated soils around of refineries Iran. Although in recent years many PAH biodegradation studies have been done but the major of reports are in aquatic system and or non-saline soils. So an acceptable process for remediation of salt-affected soil contaminated to PAHs is need.

Objectives

The aim of this study was to evaluate the performance of few native strains of halotolerant bacteria able to degrade phenanthrene (as model of PAH), in a saline soil in a microcosm system under aeration.

Methods

To conduct this study, the activity of bacteria in the form of quaternary in 24 flask containing 50 grams of salt-affected soil (by the electrical conductivity of 30) and phenanthrene at a concentration of 500 ppm under two conditions aeration and without aeration at 80 % moisture holding capacity and in 28 °C incubation for 90 days was investigated. The bacteria used in this research were: *Halobacillus debanensis* QSH1, *Bacillus hewajnpoensis* QSH3, *Acidovorax delafieldii* QSH12 and *Bacillus rhizosphera* QSH14, which recently isolated from saline soil and has been demonstrated phenanthrene degradability in mineral aquatic medium. Analysis of treatments has been done with measuring respiratory rate, dehydrogenase activity and HPLC of soil which extracted in N-hexane.

Conclusions

The results of the experiments indicated that consortium of 4 halotolerant bacteria used in this study, more than 90% of phenanthrene after 15 days under aerated conditions has been removed.

DUAL RNA-SEQ UNEARTHED THE UNSUCCESSFUL RESPONSE OF A PHYTOPATHOGENIC OOMYCETE TO THE ANTAGONISTIC STRATEGIES IMPLEMENTED BY THE BIOCONTROL BACTERIUM LYSOBACTER CAPSICI AZ78

G. Puopolo[1], *S. Tomada*[1], *P. Sonego*[1], *M. Moretto*[1], *K. Engelen*[1], *I. Pertot*[1], *M. Perazzolli*[1]
[1]*Fondazione Edmund Mach, Research and Innovation Centre, San Michele all'Adige, Italy*

Backgrounds

The establishment of plant diseases also depends on the outcome of the complex microbial interactions occurring between pathogenic microorganisms and their antagonists residing in the rhizosphere.

Objectives

The molecular mechanisms activated in the interaction between the beneficial rhizobacterium *Lysobacter capsici* AZ78 and the soilborne phytopathogenic oomycete *Phytophthora infestans* were finely dissected using a dual transcriptomic approach.

Methods

Simultaneous transcriptional changes of both *L. capsici* AZ78 and *P. infestans* occurring after 6 and 24 h of interaction were analysed. The transcriptional profiling of *L. capsici* AZ78 was mainly characterized by the up-regulation of genes involved in the biogenesis of type 4 pilus and lytic enzymes (cellulases, glucanases and proteases)involved in the host colonization and the subsequent attack of *P. infestans* cell wall, respectively. The activation of detoxification processes allowed *L. capsici* AZ78 to overcome the defence activity of *P. infestans*. Moreover, genes deputed to the antibiotic biosynthesis were up-regulated in *L. capsici* AZ78 resulting in the up-regulation of genes involved in programmed cell death in *P. infestans*. The consequences of the activation of these processes resulted in the overall down-regulation of primary metabolic pathways in *P. infestans*, such as carbohydrate, nucleic acids and protein metabolisms.

Conclusions

The dual transcriptional analysis revealed that the antagonistic activity of *L. capsici* AZ78 is based on transcriptional activation of motility, attachment, lytic and antibiotic processes. On the other hand, the activation of programmed cell death in *P. infestans* could explain its inability to actively respond to *L. capsici* AZ78 attacks.

SPATIAL AND TEMPORAL DYNAMICS OF ANTIBIOTIC RESISTANCE GENES IN THE URBAN WATER CYCLE

M. Quintela-Baluja[1], *D. Graham*[1]
[1]*Newcastle University, Environmental Engineering, Newcastle Upon Tyne, United Kingdom*

Backgrounds

Antibiotic **r**esistance (AR) is an evolutionary response in bacteria to antibiotics, which has become a serious worldwide public health concern with **A**ntibiotic **R**esistance **G**enes **(ARGs)** now considered by many as emerging pollutants. However, researchers have been focused on identifying and understanding the most important antimicrobial resistance mechanism in clinical settings. Although this data is useful in patient treatment, these knowledge is not able to wholly explain the spread of clinical relevant ARGs on a global scale.

Objectives

Our project studied the ARGs dynamics through the Urban Water Cycle, improving understanding of the main genetic transitions at different compartments.

Methods

High-throughput quantitative PCR targeting 285 ARGs, 8 transposases, and 16S ribosomal RNA gene was used in samples collected at different seasons, and different catchments of the UWC (Clinical, Domestic, wastewater treatment plant, and river). The microbial community was obtained by amplification of the 16S rRNA on the Ion Torrent PGM. Additionally, a specific set of primers and probes were designed to study the integron gene cassette rearrangement.

Conclusions

Our results suggest a spatial and temporal dynamic of the ARGs not only in their abundance, but also in the number of antibiotic resistance mechanisms. Additionally, we postulate that the clinical integron 1 is behind the genetic transition of ARGs in the UWC due to: i) its high dynamic (specially in the activated sludge), ii) its high relative abundance, iii) its function as a carrier of ARGs, and iv) its presence at different bacterial species (plasmid DNA or in chromosomal DNA)

CHROMIUM REDUCTION CAPABILITY BY NATIVE FUNGI ISOLATED FROM BIOSOLIDS OF A WASTEWATER TREATMENT PLANT

L.F. Quiroz Salazar[1], V.A. Castañeda-monsalve[1], O. Ruiz-Villadiego[1], O.I. Montoya-Campuzano[1]
[1]Universidad Nacional de Colombia, Science, Medellín, Colombia

Backgrounds

Heavy metals are contaminants commonly found in the environment and Chromium is one of the top twenty environmental contaminants. Chromium has five valence states but the most toxic form is the one with valence VI (Cr6+), while the less toxic form has valence III (Cr3+). For instance it would be useful to transform chromium to its reduced form (Cr3+), but the anthropogenic activities increase chromium concentration in soil and water sources.

In order to reduce this contaminant, researchers have developed some physicochemical techniques but these have shown low efficiency and may promote formation of harmful substances.

Biological techniques like bioremediation have demonstrated to be an efficient way and environmental friendly. These techniques involve the use of native microorganisms isolated from contaminated sources and test their ability to reduce heavy metals.**Objectives**

The aim of the project was to isolate native fungi capable to reduce chrome in high concentration.

Methods

During this study 15 fungi were isolated from samples of biosolids; in addition 9 were isolated from the air. Microorganisms were cultured in PDA media with addition of a known concentration of hexavalent chromium. The minimal inhibitory concentration was determined, and the reduction ability was tested in ME broth with hexavalent chromium at 800 ppm, 100 rpm and room temperature; one sample each 24 h was taken, hexavalent chromium was measured by spectrophotometry using the diphenilcarbazide method and total chromium by atomic emission.

Conclusions

The obtained isolates from polluted environmental samples showed a notable chromo-reductase activity. An unreported chromo-tolerant specie was found.

TOLERANCE OF INDIGENOUS TRICHODERMA STRAINS TO INCREASED CONCENTRATIONS OF METALS

G. Racić[1], I. Vukelić[1], M. Lazovic[2], L. Jovanovic[1], L. Nešić[3], M. Vrvić[4], D. Panković[1]
[1]Educons University, Faculty of ecological agriculture, Sremska Kamenica, Serbia
[2]A BIO TECH LAB, A BIO TECH LAB, Sremska Kamenica, Serbia
[3]University of Novi Sad, Faculty of Agriculture, Novi Sad, Serbia
[4]University of Belgrade, Faculty of Chemistry, Belgrade, Serbia

Backgrounds

Fungi belonging to the *Trichoderma* genus are known for a wide range of beneficial properties which are the basis of their application in different branches of biotechnology. Bioremediation is ecologically friendly method that is used to alleviate heavy metal pollution of the environment. Indigenous microorganisms are considered as most suitable for successful bioremediation for the particular site and metal. Thus, this study was performed with previously identified indigenous *Trichoderma* isolates.

Objectives

The aim of this study was to determine diethylene triamine pentaacetate (DTPA)-extractable metal content from different soil types in Vojvodina region and compare it with total metal content. Based on the calculated ratio of extractable/total metal content, sites where anthropogenic origin of metals were defined. Indigenous *Trichoderma* isolates from the selected sites where used for *in vitro* tolerance test to cooper and nickel.

Methods

The concentrations of extractable metals in the soil samples were determined by inductively coupled plasma-optima emission spectrometry (ICP-OES), Thermo iCAP 6500 Duo System. The metal tolerance test was performed by measuring the diameter of fungal colonies on plates containing Ni(II) and Cu(II) amended potato dextrose (PDA) medium at final concentrations of 0.5, 1, 2 and 4 ppm, and comparing the diameter with colonies on control PDA plates.

Conclusions

The ratio of DTPA-extractable in total metal content was the highest for Cu and Ni in the examined soil samples, indicating that contamination with these metals is of anthropogenic origin. Strains that showed best tolerance to the examined concentrations are proposed to be tested as potential bioremediation agents.

THE CLEANUP OF A RIVER: MICROBIAL TAXONOMIC AND FUNCTIONAL FEATURES INVOLVED IN THE TIETE RIVER SELF-PURIFICATION REVEALED BY METAGENOMICS

L.R.M. Rada[1], E.G. Silva[1], S. Ichiwaki[1], L.R. Olchanheski[1], W.L. Araújo[1]
[1]Institute of Biomedical Sciences, Microbiology, Sao Paulo, Brazil

Backgrounds

Tietê River in Brazil is the most important river in São Paulo State and also one of the most polluted rivers of the country. Interestingly, even with the daily dumping of domestic and industrial sewage, it doesn't remain polluted. Upon leaving the city of São Paulo the river begins a self-purification process and, at its mouth, water can be considered pristine.

Objectives

What's the role of the microorganisms in the self-purification process? How the environmental conditions affect it? To unveil these questions, four contrasting sites along the river were chosen for metagenomic analyses to characterize the taxonomic and functional diversity of microorganisms, and try to understand their role in the river self-purification process.

Methods

Metagenomic Shotgun sequencing of water samples was performed using Illumina HiSeq™ platform. Unassembled DNA sequences were annotated using the Metagenomics Rapid Annotation Server (MG-RAST) and statistical analyses were performed using the Statistical Analysis of Metagenomic Profiles (STAMP) software package.

Conclusions

Clear differences were found in taxonomic and functional profiles between the sampling sites, mainly related to the water quality. Prevalence of *Gamma* and *Betaproteobacteria* as well as genes involved in anaerobic organic matter degradation was observed in the contaminated sites. In non-polluted sites, genes related to iron acquisition and photosynthesis were predominant, along with high abundance of *Cyanobacteria*.
Our results suggest an important influence of local environmental features in the microbial community structure. Also our data showed that, in different sites of the river, self-purifying mechanisms are mostly related to microbial metabolic processes, mainly associated to organic matter degradation.

MICROBIAL COMMUNITIES IN THE NESTS OF BORNEO'S 'EXPLODING ANTS' COLOBOPSIS CYLINDRICA COMPLEX

M.J. Rahimi[1], C. Pretzer[1], M. Fischer[2], A. Kopchinskiy[1], A. Laciny[3], M. Grujic[1], K. Abu Salim[4], L. Lim[5], C.M. Chan[5], A. Parich[2], R. Schuhmacher[2], H. Zettel[3], I.S. Druzhinina[1]
[1]Vienna University of Technology,
Institute of Chemical Engineering- Research Area Biotechnology and Microbiology, Vienna, Austria
[2]University of Natural Resources and Life Sciences BOKU,
Department of Agrobiotechnology- Center for Analytical Chemistry, Tulln, Austria
[3]Natural History Museum Vienna, Zoological Department, Vienna, Austria
[4]Universiti Brunei Darussalam, Environmental and Life Sciences, Bandar Seri Begawan, Brunei
[5]Universiti Brunei Darussalam, Chemistry Programme, Bandar Seri Begawan, Brunei

Backgrounds

Cavity nesting 'exploding ants' in the *Colobopsis cylindrica* species complex ('COCY', Hymenoptera: Formicidae) possess hypertrophied mandibular gland (MG) reservoirs containing a diversity of chemical compounds. Most evolutionary advanced COCY ants use these products in suicidal defense of territory (autothysis), but many species have no such behavior. Interestingly some substances detected in MG have been described as antimicrobials in particular with fungicidal activity. This indicates that COCY MG products either play a role in nest hygiene and/or are involved in a yet unknown ant-microbe interaction.

Objectives

In this study, we focused on the microbial diversity in natural nests of the two evolutionary, phenotypically and ecologically well distinct COCY species: YG and BBQ, respectively.

Methods

Conclusions

Nests of suicidal YG in dead branches of *Shorea johorensis* were colonized by generalist hypocrealean fungi such as *Trichoderma* spp. and *Xenoacremomiun* sp. with the minor occurrence of *Penicillium* spp., Mucoromycotina and Saccharomycetales fungi. The microbiome of BBQ ants that rarely exhibit autothysis, was drastically different as it was dominated by a novel dimorphic melanised 'black yeast' fungus from Pleosporales that grew in its yeasty form only inside the nest but not *in vitro*. The fungus was slowly growing and had remarkable antifungal potential. The bacterial diversity in nests of both species has been assessed by Illumina sequencing and consists of species with potential to fix atmospheric nitrogen. The results of the microbe-microbe interaction assays and the effect of COCY chemistry on isolated microorganisms will be discussed in light of possible roles of hypertrophied MG reservoirs in these ants.

STUDYING THE EFFECTS OF ANAEROBIC BACTERIA IN CORROSION OF COOLING TOWER IN SANANDAJ AND BISTOON POWER PLANTS

B. Rahimian Zarif[1], *A. molasharifi*[1]
[1]*Department of biology- Sanandaj branch- Islamic Azad University- Sanandaj- Iran, biology, Sanandaj, Iran*

Backgrounds

In the age of technology ahead Power generation has a special strategic importance. Given that a few microns organisms have the capability to disrupt power generation, Identify these organisms in the industry has particular importance. Due to the structure of the cooling tower And the possibility of biofilm formation and the anaerobic area and aerotolerant properties of also some anaerobic bacteria (SRB), And their ability to corrosion of metals, these bacteria are the most damaging bacteria in the industry.

Objectives

In this study, anaerobic bacteria that influenced on cooling tower's corrosion were identified in Sanandaj and bistoon power plants

Methods

these bacteria were identified based on the reaction products with a medium composition. After anaerobic sampling and transferring, Samples were cultured in postgateB, And in anaerobic jars were incubated for 21 days. After 5 repetitions with an interval of one month. Thus in positive sample the black precipitate (hydrogen sulfide) from the reaction between medium and bacterial products was observed

Conclusions

The result of this reaction in Sanandaj power plant cooling towers for reasons such as structure and water supply were negative. While this reaction in a cooling tower Bistoon for reasons such as openness of water cycle and water supply have led to positive results. According to the results, with comprehensive study of environmental conditions and structure of the cooling towers, large losses can be avoided

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

WORMS AND BACTERIA: TOOL TO UNRAVEL HOST-MICROBIOTA INTERACTIONS

N. Rai[1], *P.E. Olsson*[1], *J. Jass*[1]
[1]*Örebro University, The Life Science Centre- School of Science and Technology, Örebro, Sweden*

Backgrounds

The host-microbiota plays an important role in facilitating digestion, providing nutrients and energy as well as in human diseases. However it is difficult to establish whether changes in microbiota are the cause or effect of their associated pathologies. Recent studies have shown that the gut microbiota impacts all aspects of host's life including development, metabolism, immunity and behaviour. The use of the mouse model offers a solution but the complexity and cost limits the use of this mammalian model. *Caenorhabditis elegans* is an excellent model for studying processes in a whole organism including energy metabolism, immunity, ageing and other signalling pathways. It is therefore possible to use these worms to understand how the microbiota affect the host physiology. The bacterial diet largely influences the stress response, metabolism and lifespan of the *C. elegans.* Despite the potential importance, the microbiome of this model organism is largely unknown. Hence exploring the microbiota of *C. elegans* and studying the contribution of the environment and food source would improve our understanding of the role of microbes in host physiology.

Objectives

Our study aims to establish the implications of different pathogenic and lab strains of *Escherichia coli* on *C. elegans* associated gut microbiota.

Methods

Viability, lifespan and gene expression analysis will be used to explore the role different bacteria and environmental contaminants on *C. elegans* physiology

Conclusions

Our results show that the type of bacterial diet impacts the development of *C. elegans*, and this may be due to perturbation of the gut microbiota of the worms.

Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

BIOFILM FORMATION AND COLONIZATION OF PLANT TISSUES BY A PLANT-BENEFICIAL STRAIN PSEUDOMONAS DONGHUENSIS P482

M. Rajewska[1], *S. Jafra*[1]
[1]*University of Gdansk,*
Department of Biotechnology- Intercollegiate Faculty of Biotechnology- UG & MUG, Gdańsk, Poland

Backgrounds

Biofilm is the most frequently encountered form of bacterial growth in many ecosystems. Bacteria interact with various surfaces, forming complex, multicellular communities ensuring survival in specific environmental conditions. Numerous research is conducted to elucidate the relationship between the ability of bacteria to colonize biotic and abiotic surfaces. In some cases, a correlation between biofilm development and adhesion of bacteria to plant tissues (e.g. root surface) is observed. The *Pseudomonas donghuensis* P482 strain is a little-known isolate from tomato rhizosphere, exhibiting antimicrobial activity towards bacterial and fungal plant pathogens. Earlier studies demonstrated that P482 efficiently colonizes the plant rhizosphere, however, the mechanism underlying this phenomenon has not been solved up to date.

Objectives

The objective of the ongoing research is to identify and analyze factors (genetic and environmental) involved in the ability of P482 strain to form biofilm on abiotic surfaces and to colonize plant tissues.

Methods

The P482 strain and its knock-out mutants were analyzed for their ability to move on synthetic media. Biofilm formation on abiotic surfaces (polystyrene and glass) was assessed in varying conditions by crystal violet staining and fluorescence confocal microscopy. Colonization of plant tissues was analyzed in an *in vitro* culture system on maize seedlings.

Conclusions

The obtained preliminary results suggest possible correlation between the ability to form biofilm on abiotic surfaces and colonization of plant tissues by the P482 strain. Moreover, the strain exhibits variability of biofilm formation depending on the environmental conditions. Further studies on biofilm formation and plant root colonization are under way.

RHIZOSPHERIC BACTERIAL COMMUNITIES ASSOCIATED TO GOLDEN SAGUARO (NEOBUXBAUMIA POLYLOPHA), GROWING IN SEMI-DESERTIC AREAS IN CENTRAL MEXICO, AS ASSESED BY CULTURING AND DEEP SEQUENCING TECHNIQUES

H. Ramirez Saad[1], M.L. Daniel[2], D.L.T.H. María Eugenia[1], M.A. Francisco[3], A.G. Félix[4]
[1]Universidad Autonoma Metropolitana-Xochimilco, Sistemas Biologicos, Mexico City, Mexico
[2]Universidad Autonoma Metropolitana-Xochimilco, Maestría en Ciencias Agropecuarias, Mexico City, Mexico
[3]Estación Experimental El Zaidin-CSIC, Ecología de la Rizosfera, Granada, Spain
[4]Universidad Autonoma Metropolitana-Lerma, Ciencias Ambientales, Lerma de Villada, Mexico

Backgrounds

Semiarid areas in Queretaro State, Mexico represent the southernmost extension of the Chihuahuan Desert. This area has been nominated as natural reserve because of its unique plant biodiversity constituted mainly by xerophytes, with exceptional occurrence of rare and endemic species. This natural diversity is being threatened by human activities; however, plant spoliation is probably the main hazard to various cacti species. Management and propagation of cactus plants normally do not consider the microbial community associated to their roots, which probably are related to plant important processes. Introduction of nursery-propagated cacti into natural environments is often hampered by low survival rates, this could be due to a lack of specific bacteria associated to the roots of forestation individuals.

Objectives

To assess by a NGS approach, structure and composition of rhizosphere bacterial communities of golden saguaro considering as possible sources of variation: plant origin and plant size.

Methods

N.polylopha individuals growing in 2 natural stands and in a nursery were selected, and sampled according to 2 size ranges: small (<1m tall), medium (1-6m tall). Rhizospheric samples were collected and used for metagenomic DNA extraction and further massive sequencing on an Illumina platform.

Conclusions

Variation sources have little effect on the rhizospheric bacterial community composition at Family and Class level. Differences in structure and composition were found at Genus level, however, the proportion of unclassified sequences was greatly increased in all samples.

FEMS7-0117
Environmental Microbiology/Microbial Ecology /Microbial Communities - Part III

CELL DIVISION BY LONGITUDINAL SCISSION IN THE INSECT ENDOSYMBIONT SPIROPLASMA POULSONII

E. Ramond[1], C. Maclachlan[2], S. Clerc-Rosset[2], G.W. Knott[2], B. Lemaitre[1]
[1]EPFL, Global Health Institute, Lausanne, Switzerland
[2]EPFL, Interdisciplinary Center for Electron Microscopy CIME, Lausanne, Switzerland

Backgrounds

Most bacteria rely on binary fission, which implies length growth followed by transversal division. So far, examples of bacteria with a Y-shape longitudinal scission remain scarce.

Objectives

Spiroplasma poulsonii is a natural endosymbiont of *Drosophila. It persists in the hemolymph (insect blood) of females and is vertically transmitted (from mother to offsprings). Spiroplasma has a distinctive helical morphology and belongs to the class of Mollicutes, a group of bacteria devoid of cell wall.* Here, we investigated the mechanism of *Spiroplasma poulsonii* division.

Methods

We used scanning and transmission electron microscopies, and immunogold staining to analyze *S. poulsonii* cell division. *S. poulsonii were collected from freshly hemolymph sample of Drosophila.*

Conclusions
